Another point in favor of the silica-based reversed-phase column was the shorter run time for running of unknown samples. Our observed retention times of netilmicin were approximately 5.0 and 15 minutes for the silica-based and polymeric column, respectively. Applying the formula for the total run time from Reference 2 ( 3 times the retention time of netilmicin), we obtain a total run time of 45 minutes for the polymeric column and 15 minutes for the silicabased column.

## Optimization of Integrated Amperometric Detection

As discussed in the Introduction, the two original references $(1,2)$ specify neither the size of the working electrode nor the geometry of the cell gasket. There are two available gasket-electrode combinations for the detector type utilized in Reference 1: Gasket A with a $3-\mathrm{mm}$ Au electrode and gasket B with a $1.4-\mathrm{mm}$ Au electrode (see Experimental). For the two available electrode-gasket combinations, we compared the peak heights of the major peak in the chromatograms of the $0.97 \mathrm{mg} / \mathrm{mL}$ STBE solution under otherwise identical conditions (identical eluent composition and flow rate, identical post-column hydroxide concentration and flow rate, silica-based column, and Table $1 b$ waveform). The peak height of the major peak (netilmicin, retention time approximately 5 min .) observed with the $3-\mathrm{mm}$ electrode was approximately 1.9 times higher than that obtained with the $1.4-\mathrm{mm}$ electrode.

It should be noted that the waveform of Reference 1 ( Ta ble $1 a$ ) is essentially a so-called triple-potential waveform recommended for the detection of another aminoglycoside in 1991 (4). The relatively long period of high positive potentials of that waveform was observed to cause a slow dissolution of the working electrode material, making the surface of that electrode recede below the level of its plastic housing. That in turn led to a gradual decrease of detection signal. Frequently, it was difficult to obtain comparable results between two or more electrodes due to a different degree of electrode recession. This observation prompted the development and introduction of a so-called quadruple-potential waveform that minimizes the problem of electrode corrosion by employing post-detection electrode cleaning at a negative instead of a positive potential (5). A detailed discussion of practical considerations for the use of the two types of waveform is offered in Reference 6.

The quadruple potential waveform was optimized for the detection of carbohydrates but not for the detection of aminoglycosides such as netilmicin. Keeping the cleaning ( -2.0 and +0.6 V ) potentials of the quadruple waveform un-
changed, the authors experimented with several different values for the detection and re-equilibration potentials for netilmicin, also making adjustments of the duration of the detection and re-equilibration intervals. The waveform that was found to give a maximum response for netilmicin is presented in Table $1 b$. Comparing the detection response obtained with the Table la and Table $1 b$ waveforms under otherwise identical conditions ( $25 \mu \mathrm{~L}$ of $10 \mu \mathrm{~g} / \mathrm{mL}$ netilmicin, identical eluent composition and flow rate, identical post-column hydroxide concentration and flow rate, silicabased reversed-phase column, and $3-\mathrm{mm}$ Au electrode with gasket A), we observed a 10 times higher signal with the newer of the two waveforms.

## Summary of Optimization Results

The silica-based reversed-phase column made possible shorter run times than did the polymeric reversed-phase column. Detection sensitivity also improved on the silica-based column due to the improvement of the signal-to-noise ratio. Comparing two different commercially available Au elec-trode-gasket combinations, we observed superior results with the Au electrode having a diameter of 3 mm and the gasket of matching geometry.
A new type of waveform, originally optimized for carbohydrates, was shown to significantly improve the sensitivity of netilmicin detection after only a minor adjustment of potentials and timing periods.

## APPLICATION

The optimized separation and detection method was applied to an analysis of a real pharmaceutical netilmicin sample. Unlike the sample of Reference 1, the netilmicin sample available to us contained only three instead of five unknown impurities in addition to $N^{\prime}$-ethylgaramine and sisomicin. The number of unknown impurity peaks was the same for both the polymeric and silica-based columns. Peaks 7 and 8 of Figure 2 in Reference 1 were missing in all chromatograms of our netilmicin sample.
The chromatographic results obtained with the silicabased column are shown in the overlay of six injections presented in Figure 2. Actual levels of impurities relative to the main ingredient netilmicin are shown in Table 3. The examined substance is thus in full compliance with the requirements and limits of Reference 2. The last column of Table 3 shows the $\%$ RSD value calculated from six repeat injections for each of the impurities. All of the RSD values are less than $5 \%$.

Fig. 2. Chromatograms of six repeat injections of a solution containing $0.97 \mathrm{mg} / \mathrm{mL}$ of a pharmaceutical netilmicin formulation. Injection volume: $25 \mu \mathrm{~L}$. Column: silica-based reversed-phase. Peak identities: S: unretained impurities, $1: 1-N$-ethylgaramine, 2 : sisomicin, 3 : unknown impurity 1,4 : netilmicin, 5 : unknown impurity 2,6 : unknown impurity 3 . See text for additional details.

## EXPERIMENTAL CONSIDERATIONS

A relatively large body of scientific literature (1,2, and 716) contains an in-depth discussion of method validation for various antibiotics following the relevant regulatory guidelines (17). This allows us to limit our discussion of relevant parameters to those that are important in the context of the optimization of netilmicin assays discussed in this report.

## Chromatographic System

Stainless steel surfaces are known to contaminate chromatographic eluents with trace concentrations of metals. Although such contamination remains invisible in UV and visible detection, it causes spurious peaks, fluctuating background levels, and electrode poisoning in amperometric detection. In a system for netilmicin assays such as the one discussed here, inertness of surfaces (PEEK, titanium, Teflon, etc.) exposed to the eluent is beneficial. Although the inertness of the liquid-swept surfaces between the main pump and the separation column outlet is merely recommended, the inertness of the fluid path for post-column addition of hydroxide is essential.

At present, a pressurized vessel is the most frequent mode of delivery of post-column sodium hydroxide. If complete automation of a system is required, attempts are made to substitute the pressurized pump with a more suitable one that is capable of becoming a part of an automated system. Accumulated experience shows single-piston pumps to be unsuitable for additions of purely aqueous fluids (such as 0.5 M NaOH ) into a stream of a chromatographic mobile phase containing a certain percentage of an organic solvent (such as the eluent of Reference 1). Large oscillations of baseline are observed if a single-piston pump is employed for post-column hydroxide addition in a system utilizing integrated amperometric detection. On the other hand, dual-
piston pumps employed for post-column addition do not cause any comparable problems under the same conditions (18).

Integrated amperometric detection with gold working electrodes is sensitive to the oxygen content in eluents. Dissolved oxygen can cause large negative peaks at one or more retention time intervals of a chromatogram. For this reason, optimization of a waveform always includes an attempt to minimize the effects caused by oxygen. This can be achieved to a varying degree depending on the actual eluent composition and the presence of on-line eluent degassing inside the main chromatographic pump. For that reason, most of the widely used waveforms (4-6) work best if used in a system that includes an on-line eluent degasser.

## Integrated Amperometric Detection

A description of an amperometric method that does not include electrode size and flow path geometry (gasket thickness, along with width and length of the cutout defining the flow path) is incomplete. It is not possible to reproduce a method knowing only the material of the working electrode and not its dimension. Even if the electrode dimension is given but the gasket geometry remains unknown, it is still impossible or very difficult to achieve comparable results.

Fluctuations of possible results with several commercially available electrode-gasket combinations are illustrated in Table 4. Applying a mathematical model (equation 5 in Reference 19), one uses gasket thickness, flow path
width, and electrode lengths as parameters in calculations of coulombic efficiency. Coulombic efficiency is a fraction (\%) of an electroactive compound that actually reacts at the working electrode during its passage through the detection cell. With everything else being equal, chromatographic peak heights will follow the same relationship as their corresponding coulombic efficiencies. Normalized coulombic efficiencies are included in the last column for easier comparison. All calculations were made for the same total volume flow rate of $1.3 \mathrm{~mL} / \mathrm{min}$. utilized by the technique under discussion. The linear flow rate differences are caused by differences in flow path cross sections defined by gasket thickness and the cutout width.

From all combinations in Table 4, the 3-mm cell used with a $125-\mu \mathrm{m}$ thick gasket delivers the highest peaks. The smaller electrode ( 1.4 mm ) available for the same cell in combination with a $50-\mu \mathrm{m}$ gasket produces peak heights that are lower by a factor of 1.5 . Note that the actual comparison for the same two sets of conditions confirmed a lower peak height for the $1.4-\mathrm{mm}$ electrode and $50-\mu \mathrm{m}$ gasket by a factor of 1.9 (see Optimization of Integrated Amperometric Detection above). This represents a good validation of the mathematical model used to generate the theoretical data in Table 4.
It should be noted that for the relatively few electrodegasket combinations listed in Table 4, possible peak height results may differ by more than a factor of 10 .

In conclusion, electrode size and gasket geometry must be included in all reports dealing with amperometric detection.

## Reference Electrode Care and Monitoring

Actual potentials applied to the working electrode are only as correct as the actual potential of the reference electrode relative to the hydrogen electrode. It is not uncommon for the potential of silver-silver chloride reference electrodes to increase by 60 mV or more when those electrodes are exposed to alkaline pH as, for example, in the method under discussion. In the worst case, lack of monitoring of reference electrode potential may cause passivation or corrosion of the gold working electrode. It is possible that the perceived "lack of stability" (1) of the electrochemical detection is at least partly caused by too infrequent or missing monitoring of reference electrode potentials by the majority
of users. The monitoring of reference electrodes can be easily accomplished by measuring the potential of an alkalineexposed electrode vs. another electrode that was never exposed to alkaline pH (stored in 3 M KCl ). For the monitoring measurement, both electrodes are immersed in the same 0.1 M KCl solution and connected to the leads of a suitable voltmeter. The authors recommend replacing any reference electrode exhibiting more than 30 mV of shift by a new or reconditioned reference electrode. Reference electrodes that have not been allowed to drift by more than approximately 30 mV can always be restored by several weeks of soaking in a solution containing 0.1 M HCl and 3 M KCl .

# Manufacturers' Market Containers and Closures Study II: Proposed Revisions to $\langle 671\rangle$ Containers-Permeation 

C. Jeanne Taborsky*, USP Consultant and Upendra Mehta, SETCO

#### Abstract

This article is the second in a series intended to provide meaningful data to aid in the establishment of specifications and functional test procedures for container-closure systems for solid oral dosage forms. The containerclosure systems tested in this study are in common use, and the laboratory that conducted the study is an FDA-registered facility that commonly conducts these studies. Several different closure, innerseal, and liner configurations are used to package drug products. In a departure from the previous study, the container-closure system in the present series consists of a bottle with an innerseal, liner, and screw closure. The innerseal is designed to be removed and discarded once the container is opened.

## INTRODUCTION

The functional/performance requirements and standards for $U S P-N F$ "tight" and "well-closed" are being reevaluated. The $U S P-N F$ contains standards for pharmaceutical bottles and for prescription vials, but $\langle 671\rangle$ ContainersPermeation standards do not apply to manufacturers' con-tainer-closure systems. In many cases, the smallest con-tainer-closure configuration for a solid oral dosage form is designed for dispensing or for consumer use and is provided with a child-resistant closure. At the present time, the manufacturer's unopened multiple-unit package is exempt from the $U S P$ general chapter $\langle 671\rangle$ test. In the past, only the moisture permeation data for the manufacturer's unopened market container was considered by FDA as part of the approval process for a drug application. The permeation of this container-closure system under actual conditions of use by the consumer was ignored. FDA has started to question manufacturers about the permeation data for the container once the innerseal is removed. This issue has been of concern to USP as well.

## BACKGROUND

Since the 1970s, USP general chapters $\langle 661\rangle$ Containers and $\langle 671\rangle$ Containers-Permeation have provided standards for container-closure systems (1, 2). When USP general chapter $\langle 671\rangle$ was originally written, no limits were provided for manufacturers' containers. FDA was to determine the standards for containers used by commercial manufacturers and packagers after USP published this section. FDA has been applying the $U S P$ general chapter $\langle 671\rangle$ standards to the containers in which drug companies package their drugs. FDA also has implemented a policy that if certain market containers meet $U S P-N F$ standards and the con-

[^189]tainer-closure system provides the same degree of protection, then the firm can change from one system to another and report the change in an annual report (3).

The $U S P-N F$ limits and tests should provide a standard for manufacturers' containers that would support FDA policy. Based on the information at hand, USP attempted to implement standards for market containers (4). On 4 May 2000, SETCO wrote to USP to comment on the revisions to USP general chapter $\langle 671\rangle$ as published in the First Supplement to USP 24-NF 19. After careful consideration, USP decided to withdraw the standard until additional information could be provided (5).

The section reads as follows:
$\ldots$ and containers utilized by manufacturers or distributors for products that are repackaged by the dispenser prior to distribution or sale . . . For multiple-unit containers used by manufacturers or distributors where the products are repackaged prior to distribution or sale, the containers so tested are tight containers if not more than 1 of the test containers exceeds 10 $\mathrm{mg} /$ day $/ \mathrm{L}$ in moisture permeability and none exceeds $25 \mathrm{mg} /$ day/L.
This wording states that manufacturers' market containers (not for dispensing) must meet $10 \mathrm{mg} / \mathrm{day} / \mathrm{L}$ to be "tight" containers if sold to a pharmacist for dispensing. Manufacturers' containers not meeting $10 \mathrm{mg} /$ day $/ \mathrm{L}$ would be in violation of this chapter. This section also states that if the container manufacturer or distributor packages in a container to be used for dispensing, this section does not apply.

The proposed revisions to this chapter should be written in the spirit of the law and regulations and incorporate less ambiguous language. Specifications should be based upon data from testing conducted on approved commercial container systems. USP recently published data on the test results multiple for a range of bottle sizes using alternate liners, closure designs, and closures manufactured with multiple sources of polypropylene (6). The data demonstrated that the closure size, design, and particularly the liner
had an effect on the permeation, but the use of polypropylene from alternative manufacturers to mold the closures had an insignificant impact.

The comments received on the proposal to test with and without innerseals in place were predictable (7, 8). For drug companies not yet asked to provide this data to FDA, the ultimate fear is that firms will be requested to conduct additional stability studies. It is also a given that removing the foil innerseal can yield greater variability in test data, but the same conditions exist when a consumer removes the seal. To some extent this can be corrected by adding a tab to the innerseal to make it easier to remove. This configuration already exists on food commodities, and makes it easier to remove the seal and leaves less foil on the bottle.

The liner and innerseal play an important role in protecting the product from moisture. Industry rushed to add foil innerseals when the ICH stability guidance mandated humidity requirements in room temperature stability studies (9). Practitioners did not consider protection of the drug product once the seal was broken. However, it is not the intention of these articles to support the need for additional stability studies but rather to demonstrate the need for permeation studies and reliable standards for protection of the drug once the container has been opened.

Some new drug applications and abbreviated new drug applications were approved for solid oral drugs that were packaged in containers that used a pressure-sensitive tack seal with a compressible liner. Because stability was demonstrated in these containers, the firms did not change to foil
induction seals. Some drug companies and repackagers have continued to use these liners and pressure-sensitive seals.
In order to establish meaningful specifications, it is important to consider these seals and liners as well as others currently approved for use with these dosage forms. In assisting USP and responding to the request for information, the following data are provided.

## PROCEDURE

To conduct this study, USP general chapter $\langle 661\rangle$ Containers testing was first performed on bottles (see Test Methods below). USP general chapter $\langle 671\rangle$ ContainersPermeation as modified was then used to test the bottles with the seal in place. Then the seals were removed, the bottles were opened and closed 30 times, and then they were retested. For this study, commercial pressure-sensitive innerseals were used. The tests reported here include the following variables:

- The same bottles, closures, and closure liners,
- One bottle size, and
- Testing before and after innerseals were removed.

All the materials used in these studies have been approved by CDER for use in packaging solid oral dosage forms. They all have market history and Drug Master Files that have been reviewed by CDER and have been found to be satisfactory.

## RESULTS

As provided in Figure 1 and Table 2, the testing of the bottles was first conducted according to USP general chapter $\langle 661\rangle$ as written without closures. The results are well within the limits of $10 \mathrm{mg} / \mathrm{day} / \mathrm{L}$. In the middle column are the test results for the bottles with the pressure-sensitive seal, liner, and child-resistant closure, which would represent the permeation expected for the unopened packaged product. Using this configuration, certain solid oral dosage forms have been tested and demonstrated to be stable for 24 months.

## CONCLUSIONS

The limits and requirements placed on manufacturers' and distributors' containers should be scientifically justified, and the limits should be consistent with and independent of the person packaging the drug. The standards with the associated expiration dates, discard dates, or beyond-use dates should be based on the protection afforded by the materials and the requirements provided by the manufacturer or listed in the $U S P-N F$ monograph. USP should establish limits for "well-closed" containers for drugs that do not require "tight" containers.

The manufacturer's multiple-unit container-closure system should be tested as marketed and as it appears in actual conditions of use in the hands of the consumer. If the market container employs an innerseal, the container should be tested for the two-week period as marketed with the innerseal in place, without opening and closing 30 times. The container should then be retested with the innerseal removed and the container opened and closed 30 times. Pharmacy prescription vials and consumer containers should continue to be closed and opened 30 times. The standards for containers under actual conditions for use in the hands of the consumer should be the same for the market container (with the seal removed) and the prescription vial. For the purpose of this article the limit proposed for "tight" market container permeation is $20 \mathrm{mg} /$ day/L.

Many prescription vials and containers do meet the standard of $20 \mathrm{mg} /$ day $/ \mathrm{L}$. It would seem logical that the acceptability for use of a particular container for a moisturesensitive drug should be based on the permeation and the storage time; shorter storage times should be allowed for more permeable containers. It may also be appropriate to consider some new class of protection between that of "tight" and "well-closed."

The following points are provided for consideration:

1. The commercial market container-closure system from which the product is removed and repackaged for dispensing usually holds the product for a short period of time. If the product is dispensed in the market container, there is no limit for permeation in the $U S P-N F$ or imposed by FDA. The prescription vial into which it is repackaged uses a beyond-use date of up to one year and permeation rates of 100 to $2000 \mathrm{mg} / \mathrm{day} / \mathrm{L}$. The rates for unit dose are uncontrolled at this time. The be-yond-use time periods are under review.
2. There are no market container provisions for "wellclosed containers" for drugs that do not require "tight" containers.
3. When tablets and capsules are repackaged, the repackager can use a container-closure system tested using USP standards and determined to be equivalent to those of the manufacturer, and the repackager can use the same expiration period as the manufacturer. In some cases, the repackager can enter into an agreement with the manufacturer to obtain container-closure and stability information. Alternatively, the repackager can conduct its own testing of containers and product, and assign an expiration date based upon these studies.
4. Manufacturers can use testing in USP general chapter $\langle 661\rangle$ and $U S P$ general chapter $\langle 671\rangle$ on container-closure systems to provide acceptability data to FDA in support of their proposed systems. These tests also can be used to support changes to alternative systems. The containers so tested should be equivalent to or better than those on which stability studies have been based in order to use the same expiration period.

## TEST METHOD: MULTIPLE-UNIT CONTAINERS FOR CAPSULES AND TABLETS

## Phase 1

## Desiccant

Place a quantity of 4- to 8-mesh, anhydrous calcium chloride in a shallow container, taking care to exclude any fine powder; then dry at $110^{\circ}$ for 1 hour and cool in a desiccator.

## Procedure

Select 12 containers of a uniform size and type, and clean the sealing surfaces with a lint-free cloth. Add Desiccant to 10 of the designated test containers, filling each to within 13 mm of the closure. The layer of Desiccant in such a container shall be not less than 5 cm in depth. Close each immediately after adding Desiccant, applying the torque designated in the USP general chapter $\langle 671\rangle$ table, Torque Applicable to Screw-Type Container.

NOTE-The tack seal and liner are provided in the closures as supplied. To each of the remaining 2 containers (designated controls) add a sufficient number of glass beads to attain a weight approximately equal to that of each of the test containers, and close, applying the torque designated in the USP general chapter $\langle 671\rangle$ table, Torque Applicable to Screw-Type Container.
Record the weight of the individual containers so prepared to the nearest 0.1 mg if the container volume is less than 20 mL ; to the nearest mg if the container volume is 20 mL or more but less than 200 mL ; or to the nearest 10 mg if the container volume is 200 mL or more; and store at $75 \pm$ $3 \%$ relative humidity and a temperature of $23 \pm 2^{\circ}$.
After $336 \pm 1$ hour ( 14 days), record the weight of the individual containers in the same manner. Completely fill 5 empty containers of the same size and type as the containers under test with water or a noncompressible, freeflowing solid such as well-tamped fine glass beads, to the level indicated by the closure surface when in place. Trans-
fer the contents of each to a graduated cylinder, and determine the average container volume, in mL . Calculate the rate of moisture permeability, in mg per day per L , by the formula:

$$
(1000 / 14 V)\left[\left(T_{f}-T_{i}\right)-\left(C_{f}-C_{i}\right)\right]
$$

in which $V$ is the volume, in mL , of the container; $\left(T_{f}-T_{i}\right)$ is the difference, in mg , between the final and initial weights of each test container; and $\left(C_{f}-C_{i}\right)$ is the difference, in mg , between the average final and average initial weights of the 2 controls.

## Phase 2

Open each individual bottle, and remove the innerseal. Open and close each bottle 30 times, applying the torque designated in the USP general chapter $\langle 671\rangle$ table when closing the screw-capped containers. Record the weight of the individual containers so prepared to the nearest 0.1 mg if the container volume is less than 20 mL ; to the nearest mg if the container volume is 20 mL or more but less than 200 mL ; or to the nearest 10 mg if the container volume is 200 mL or more; and store at $75 \pm 3 \%$ relative humidity and a temperature of $23 \pm 2^{\circ}$. Repeat the calculation as provided above.

## ACKOWLEDGEMENT

The authors wish to acknowledge the contributions of Judith Haber and Joanne M. Deskus, STR Laboratories.

## NOMENCLATURE

This section includes supplements to the latest edition of the USP Dictionary of USAN and International Drug Names that incorporate new United States Adopted Names (USAN) and revisions to existing Dictionary names. Also listed are Proposed and Recommended International Nonproprietary Names (INN) when they have been announced by the World Health Organization.

Possible names suggested for use as USAN and INN are listed for public review and comment along with information on how nonproprietary names are devised. In addition, readers may find articles relevant to current compendial nomenclature issues that also occasionally report on related matters pertaining to USAN and INN.

# USP Dictionary of USAN and International Drug Names 2004 USP DICTIONARY SUPPLEMENT 2 

IMPORTANT-Save this Supplement. This and all supplements appearing in $P F$ are needed to keep the 2004 edition of the USP Dictionary (USPD) up-to-date. The cumulative contents of the supplements to the current (2004) edition will be included in the next complete edition of the Dictionary.

## New United States Adopted Names (USAN)

The following are newly established United States Adopted Names (USAN). These names will not be listed cumulatively; see preceding and succeeding numbers of $P F$ for other new USAN to supplement the Dictionary main volume.

Dabuzalgron Hydrochloride [2004] (da bue zal' gron).
$\mathrm{C}_{12} \mathrm{H}_{16} \mathrm{ClN}_{3} \mathrm{O}_{3} \mathrm{~S} . \mathrm{HCl}$ 354.26. (1) Methanesulfonamide, $N$ - $[6-$ chloro-3-[(4,5-dihydro-1 H-imidazol-2-yl)methoxy]-2-methylphenyl]-, monohydrochloride; (2) N -[6-Chloro-3-[(4,5-dihydro-1 H -imidazol-2-yl)methoxy]-2-methylphenyl]methanesulfonamide hydrochloride. CAS-219311-43-0. Treatment of stress urinary incontinence. (Hoffmann-LaRoche) $\langle R O 115-1240 / 190$

Pegamotecan [2004] (peg am oh tee' kan). $\mathrm{C}_{50} \mathrm{H}_{44} \mathrm{~N}_{6} \mathrm{O}_{13}$ $\left[\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O}\right]_{n}$. (1) L-Alanine, (4S)-4-ethyl-3,4,12,14-tetrahydro-3,14-dioxo-1H-pyrano[ $3^{\prime}, 4^{\prime}: 6,7$ ]indolizino [1,2-b]quinolin-4yl ester, mono(trifluoroacetate), reaction products with polyethylene glycol bis (carboxymethyl) ether; (2) Derivative of camptothecin and polyethylene glycol produced by amide formation between $[(4 S)$-4-ethyl-3,14-dioxo-3,4,12,14-tetra-hydro-1 $H$-pyrano [ $3^{\prime}, 4^{\prime}: 6,7$ ]indolizino [1,2-b]quinolin-4-yl] (2S)-2-aminopropanoate (camptothecin L-alaninate) and $\alpha$ -(carboxymethyl)- $\omega$-(carboxymethoxy)poly(oxyethylene). CAS-581079-18-7. Treatment of gastric and gastroesophageal junction adenocarcinoma. Prothecan (Enzon) $\langle E Z-246$

Ranolazine [2004] (ra noe la zeen). $\mathrm{C}_{24} \mathrm{H}_{33} \mathrm{~N}_{3} \mathrm{O}_{4}$. 427.54. (1) 1Piperazineacetamide, $N$-(2,6-dimethylphenyl)-4-[2-hydroxy-3-(2-methoxyphenoxy)propyl]-; (2) ( $\pm$ )- $N$-(2,6-Dimethyl-phenyl)-4-[2-hydroxy-3-(2-methoxyphenoxy)propyl]-1-piperazineacetamide; (3) 1-Piperazineacetamide, $N$-(2,6-
dimethylphenyl)-4-[2-hydroxy-3-(2-methoxyphenoxy)pro-pyl]-, ( $\pm$ )-. CAS-95635-55-5. INN. Anti-anginal; anti-ischemic. Ranexa (Dow Chemical) [Note-The trivial names, Ran D and Ran4, have appeared in literature.] $\diamond R S$-43285-003; CVT-303

Rotigotine [2004] (roe' ti goe tine). $\mathrm{C}_{19} \mathrm{H}_{25}$ NOS. 315.48. (1) 1-
Naphthalenol, 5,6,7,8-tetrahydro-6-[propyl [2-(2-thieny-1)ethyl]amino-(6S)-; (2) (-)-(S)-5,6,7,8-Tetrahydro-6-[pro-pyl[2-(2-thienyl)ethyl]amino]-1-naphthol; (3) (6S)-6-[Propyl(2-(2-thienyl)ethyl)amino]-5,6,7,8-tetrahydro-1-naphthalenol.CAS-99755-59-6. INN. Treatment of early and advanced Parkinson's disease and restless leg syndrome. (Cambrex Karlskoga AB, Sweden) $\diamond S P M 962$

Tefibazumab [2004] (tef ee ba' zoo mab). Immunoglobulin G1, anti-(Staphylococcus aureus protein ClfA (clumping factor A)) (human-Mus musculus monoclonal Aurexis heavy chain), disulfide with human-Mus musculus monoclonal Aurexis $\kappa$-chain, dimer. Molecular weight is approximately 147,590 daltons. CAS-521079-87-8. Treatment of Staphylococcus aureus infections. Aurexis (Avid Bioservices) $\checkmark$ INH-H2002

Tocilizumab [2004] (toe si liz' oo mab). Immunoglobulin G1, anti(human interleukin 6 receptor) (human-mouse monoclonal MRA heavy chain), disulfide with human-mouse monoclonal MRA $\kappa$-chain, dimmer. Molecular weight is approximately 144,986 daltons. CAS-375823-41-9. Treatment of Castelman's disease; treatment of multiple myeloma; treatment of systemic lupus erythematosus; treatment of Crohn's disease; treatment of rheumatoid arthritis; treatment of systemic juvenile idiopathic arthritis. (A. Christiaens S.A., Belgium) $\checkmark M R A$

Trabectedin [2004] (tra bek' te din). $\mathrm{C}_{39} \mathrm{H}_{43} \mathrm{~N}_{3} \mathrm{O}_{11} \mathrm{~S} .761 .84$. (1) Spiro[6,16-(epithiopropanoxymethano)-7,13-imino-12H-1,3dioxolo $[7,8]$ isoquino $[3,2-b][3]$ benzazocine- $20,1^{\prime}\left(2^{\prime} H\right)$-iso-quinolin]-19-one, 5-(acetyloxy)-3' $4^{\prime}, 6,6 \mathrm{a}, 7,13,14,16$-octahy-dro-6', 8,14 -trihydroxy-7',9-dimethoxy-4,10,23-trimethyl-, ( $1^{\prime} R, 6 R, 6$ a $R, 7 R, 13 S, 14 S, 16 R$ ) - ; (2) ( $1^{\prime} R, 6 R, 6 \mathrm{a} R, 7 R, 13 S, 14 S, 16 R$ )-6',8,14-Trihydroxy-7',9-di-methoxy-4,10,23-trimethyl-19-oxo-3', $4^{\prime}, 6,7,12,13,14,16$-oc-tahydrospiro[6,16-(epithiopropanooxymethano)-7,13-imino6 a $H$-1,3-dioxolo[7,8]isoquino[3,2-b][3]benzazocine20, 1'(2'H)-isoquinolin]-5-yl acetate. CAS-114899-77-3. INN. Anticancer, antineoplastic and antitumoral. Yondelis (Pharmacia \& Upjohn) $\diamond E T-743$

Valrocemide [2004] (val roe' se mide). $\mathrm{C}_{10} \mathrm{H}_{20} \mathrm{~N}_{2} \mathrm{O}_{2}$. 200.28. (1) Pentanamide, N -(2-amino-2-oxoethyl)-2-propyl-; (2) N -(Car-bamoylmethyl)-2-propylvaleramide; (3) $N$-(2-Amino-2-ox-oethyl)-2-propylpentanamide. CAS-92262-58-3. INN. Antiepileptic; anticonvulsant. (Teva, Israel) $>T V-1901$

## Suggested United States Adopted Names

The United States Adopted Names (USAN) program is the specifically organized effort in the United States directed to producing simple and useful nonproprietary names for drugs while the drugs are still in the investigational stages. The American Medical Association (AMA), the American Pharmaceutical Association (APhA), and the United States Pharmacopeial Convention (USPC) jointly sponsor the USAN program with representation from the FDA.

Each U.S. Adopted Name is chosen with the expectation that it will be suitable for prescribing and dispensing purposes and for designation as the title of the monograph, should the article be recognized in the official United States Pharmacopeia or National Formulary. A measure of the prestige and recognition of the value of the USAN program can be found in the following regulations published by the Commissioner of Food and Drugs and the Secretary of Health and Human Services in the Federal Register of February 1988.

All who are concerned with the prescription, dispens-
ing, use, sale or manufacture of drugs may, in the absence of the designation of an official name by the FDA, rely on the current compendial name or the U.S. Adopted Name (USAN) listed in this volume as being the established name in accordance with the Federal Food, Drug, and Cosmetic Act.
A formal procedure ${ }^{1}$ is followed by the USAN Council in selecting an established name for a drug. The USAN Council Secretary is also an ex officio member of the International Nonproprietary Names (INN) Committee. USAN Guiding Principles are concordant with World Health Organization (WHO) principles, and all

[^190]USANs for substances also named by the INN Committee are systematically processed through the INN Committee. This ensures that, with very rare exceptions, USANs are identical to INNs and available for world-wide use.
A suggestion for a USAN originates usually from a firm or an individual who has developed a substance of potential therapeutic utility to the point where there is a distinct possibility of its being marketed in the United States of America. Occasionally, the initiative is taken by the USAN Council in the form of a request to parties interested in a substance for which a nonproprietary name appears to be lacking.

Submissions to the USAN Council are expected to conform to the established Guiding Principles ${ }^{2}$ and to be reasonably free from conflict with other names, including both trademarks and nonproprietary names. An effort is made to discourage the occasional, undesirable practice of incorporating in trademarks the syllables used in an established nonproprietary name, or syllables recommended for USAN. Such trademarks may act as a bar to the subsequent adoption of appropriate nonproprietary names for closely related drugs.

The suggested nonproprietary names for the drugs described in the following list are under consideration by the USAN Council. The name(s) being considered for each drug substance, and the applicable category, are separated by double spacing from the name(s) and category for the next listed drug substance. Where two or more names are being considered for the same drug substance, the names are single-spaced, and the applicable category term is written only once to the right of the single-spaced group of names.

Any comments or protests should be addressed to Sandra Van Laan, Assistant Secretary, USAN Council, American Medical Association, 515 North State Street, Chicago, Illinois 60610.

## Suggested International Nonproprietary Names

International Nonproprietary Names (INN) are devised by the World Health Organization (WHO). INNs for substances originating within the United States are applied for through the USAN Council. INN and USAN Guiding Principles are concordant, which assures that, with very few exceptions, INNs and USANs are identical.

Under its charter, the WHO is empowered simply to recommend specific actions or procedures to its Member States. This limitation is incorporated into the WHO program concerned with the selection of international nonproprietary names for pharmaceutical substances, in that the WHO first publishes the selected names as proposals ("Proposed International Nonproprietary Names"). A period of four months from the date of publication in WHO Drug Information is allowed for entering comments on, or objections to, any proposal on the part of Member States or other interested parties. In general, an objection reflects a belief that the proposal concerned is confusingly close to (i.e., conflicts with) a name already in use, perhaps in only a restricted area in which the party has a proprietary interest in the form of trademark rights. In the event
that no objection is received, the WHO proceeds with listing and publishing the names so devised as recommendations ("Recommended International Nonproprietary Names"), which many Member States then recognize as the sole or preferred nonproprietary name for use within their respective territories.

The names for the drugs that are categorized in the following list are under consideration for the selection of new Proposed International Nonproprietary Names. The name(s) being considered for each drug substance, and the applicable category, are separated by double spacing from the name(s) and category for the next listed drug substance. Where two or more names are being considered for the same drug substance, the names are single-spaced, and the applicable category term is written only once to the right of the single-spaced group of names.

Any comments or protests should be addressed to Sandra Van Laan, Assistant Secretary, USAN Council, American Medical Association, 515 North State Street, Chicago, Illinois 60610.

| Bemotrizinol | Topical sunscreen active ingredient for OTC use | Eriforan | Endotoxin antagonist for the |
| Bisoctrizole | Topical sunscreen active ingredient for OTC use | Eritoran | treatment of sepsis and other diseases due to reaction to bacterial endotoxin |
| Caremtorib | Antitumor agent; cytostatic | Etagoloxan | Antineoplastic |
| Casorolimus | agent (cell cycle inhibitor) | Etagolukib |  |
| Sirolimus |  | Etalocib |  |
| Temsirolimus |  |  |  |
| Cedratide | Treatment for systemic lupus | Etemucret | Treatment of dry eye (stimulates glycoprotein secretion) |
| Edratide | erythematosus |  |  |
| Leptide |  | Forodesine | Treatment of T-cell malignan- |
| Sletide |  |  | cies such as acute lymphoblastic leukemia (ALL) and |
| Cinacalcet | Treatment of hyperthyroidism |  | cutaneous T-cell lymphoma |
| Cincalcept | and related disorders, such as hypercalcemia |  | (CTCL) |
|  |  | Iboctadekin | Antineoplastic |
| Contusugene (p53 adenovirus) | Treatment of head and neck cancer | Idraparinux | Antithrombotic |

| Suggested INN | Category |
| :---: | :---: |
| Inotropine | Inotropic agent; Na-KATPase |
| Taucor | inhibitor |
| Inotuzumab Ozogamicin | Oncologic treatment |
| Ispinesib | Antineoplastic |
| Lactofertide Alfa Talactoferrin Alfa Teractoferrin Alfa | Anti-infective; anti-inflammatory, antineoplastic |
| Medirazole <br> Neorazole <br> Reserazole | Antifungal agent for treatment of diseases caused by fungi and yeast |
| Navaglitazar <br> Naveglitazar <br> Naviglitazar <br> Neloglitazar | Treatment of type 2 diabetes and associated cardiovascular indications |
| Nibacatin Selcapsin Selcatin | Treatment of osteoporosis (Cathepsin $K$ inhibitor) |
| Oxybate Sodium | Treatment of cataplexy in patients with narcolepsy |
| Peliglitazar | Treatment of type 2 diabetes mellitus, mixed dyslipidemia, atherosclerosis and metabolic syndrome |
| Perflisobane Perflisobutane Perflisobute Perflisotane | Diagnostic aid; ultrasound contrast agent (intravenous) |
| Pralatrexate | Treatment of patients with malignancies |

| Suggested INN | Category |
| :---: | :---: |
| Pratacib | Treatment of rheumatoid arthritis |
| Raxibacumab | Treatment of anthrax infection |
| Remofovir | Synthetic nucleotide antiviral agent |
| Salclobuzate | Facilitates and/or enables the oral delivery of a drug |
| Saxagliptin | Treatment of type 2 diabetes mellitus and metabolic syndrome |
| Talabostat Talamostat | Anti-cancer; hematopoietic stimulant |
| Talaglumetad | Treatment of anxiety and stress disorders (metabotropic glutamate [mGlu] agonist) |
| Targinine Acetate | Treatment of cardiogenic shock complicating acute myocardial infarction (MI) |
| Tegafuplermin | Treatment of immune thrombocytopenic purpura (ITP) |
| Tetraxetan | Radical |
| Yttrium Y 90 Epratuzumab Itraxetan | Radioimmunotherapy for nonHodgkin's B-cell lymphoma |
| Yttrium Y 90 Epratuzumab <br> Tetraxetan <br> Yttrium Y 90 Labetuzumab Tetraxetan | Radioimmunotherapy (RAIT) for non-Hodgkin's B-cell lymphoma patients |
| Yttrium Y 90 Tacatuzumab | Tumor eradication |

## INDEX

This is a cumulative directory for the content of all issues of $P F$ beginning with $P F$ 30(1).
[Note—This index covers Vol. 30 No. 1, pp. 1-381, Vol. 30, No. 2 pp. 383-755, Vol. 30, No. 3 pp. 757-1114, Vol. 30 No. 4, pp. 1115-1531]
GENERAL NOTICES AND REQUIREMENTS (USP)
Significant Figures and Tolerances (USP) 424, 79
General Chapters (USP) 424, 795
Tests and Assays (USP) 425, 795
Preservation, Packaging, Storage, and Labeling (USP) … . . . 428, 798

## MONOGRAPHS

Acepromazine Maleate Injection (USP) . . . . . . . . . . . . . 1161
Acesulfame Potassium (NF) . . . . . . . . . . . . . . . . . . . 591
Acetaminophen Oral Solution (USP) . . . . . . . . . . . . . . 40
Acetaminophen Oral Suspension (USP)
Acetaminophen Extended-Release Tablets (USP) . . . . . . . 1161
Acetaminophen and Aspirin Tablets (USP) . . . . . . . . . . . 40
Tablets Containing at Least Three of the Following-
Acetaminophen and Salts of Chlorpheniramine,
Dextromethorphan, and Phenylpropanolamine (USP) . . . . 42
Capsules Containing at Least Three of the Following-
Acetaminophen and Salts of Chlorpheniramine,
Dextromethorphan, and Pseudoephedrine (USP)
Oral Powder Containing at Least Three of the Following-
Acetaminophen and Salts of Chlorpheniramine,
Dextromethorphan, and Pseudoephedrine (USP)
Oral Solution Containing at Least Three of the FollowingAcetaminophen and Salts of Chlorpheniramine,
Dextromethorphan, and Pseudoephedrine (USP)
Tablets Containing at Least Three of the Following-
Acetaminophen and Salts of Chlorpheniramine,
Dextromethorphan, and Pseudoephedrine (USP)
Acetaminophen and Codeine Phosphate Capsules (USP) . 45
Acetaminophen and Codeine Phosphate Oral Solution (USP) 46
Acetaminophen and Codeine Phosphate Oral Suspension (USP)46
Acetaminophen, Dextromethorphan Hydrobromide, Doxylamine
Succinate, and Pseudoephedrine Hydrochloride Oral Solution (USP)
Acetaminophen and Diphenhydramine Citrate Tablets (USP)
Acetaminophen, Diphenhydramine Hydrochloride, and Pseudoephedrine Hydrochloride Tablets (USP) 47
Acetaminophen and Pseudoephedrine Hydrochloride Tablets (USP)48
Acetohydroxamic Acid Tablets (USP) ..... 49
Acyclovir (USP) ..... 431, 802, 1143
Acyclovir Capsules (USP) . . . . . . . . . . . . . . . . . . . .432, 1143
Acyclovir for Injection (USP) 433, 1144
Acyclovir Ointment (USP) . . . . . . . . . . . . . . . . . . . . . . 434, 1145
Acyclovir Oral Suspension (USP) . . . . . . . . . . . . . . . . 435, 1145
Acyclovir Tablets (USP) . . . . . . . . . . . . . . . . . . . . 436, 1145
Adipic Acid (NF) . . . . . . . . . . . . . . . . . . . . . . . . 593, 1322
Albendazole Oral Suspension (USP) . . . . . . . . . . . . . . 1163
Albuterol Tablets (USP)
Alclometasone Dipropionate Ointment (USP erratum) . . . . . . . . . . . . . 787
Alcohol (USP)
. . . . . . . . . . . . . . . . . . . . . . . . . . 669
Dehydrated Alcohol (USP) 673
Dehydrated Alcohol (USP) . . . . . . . . . . . . . . . . . . . . . . . . . . . . 437
Alendronate Sodium (USP) . . . . . . . . . . . . . 437
Alendronic Acid Tablets (USP) . . . . . . . . . . . . . 440, 804, 1146
Alfadex (NF) . . . . . . . . . . . . . . . . . . . . . . . . . . . . 202
Alprazolam Tablets (USP)
202
51
Amantadine Hydrochloride Capsules (USP) . . . . . . . . . . 51
Amifostine (USP)
52
Aminopentamide Sulfate (USP)
1163
Aminosalicylate Sodium Tablets (USP)
53
Ammonium Sulfate (NF)
966
Amoxicillin and Clavulanate Potassium for Oral Suspension (USP)
53
Amphetamine Sulfate (USP) . . . . . . . . . . . . . . . . . . . 443, 807
Amphetamine Sulfate Tablets (USP) 54
Amphotericin B Lotion (USP) ..... 444
Amphotericin B Topical Emulsion (USP) ..... 445
Ampicillin Capsules (USP) ..... 55
Ampicillin Tablets (USP) ..... 56
Anecortave Acetate (USP) ..... 445
Anecortave Acetate Injectable Suspension (USP) ..... 447
Antithrombin III Human (USP) ..... 56
Arginine Hydrochloride (USP) ..... 449
Ascorbic Acid Tablets (USP) ..... 60
L-Asparagine (NF) ..... 205
Aspartic Acid (USP) ..... 1163
Aspirin (USP) ..... 1164
Aspirin, Caffeine, and Dihydrocodeine Bitartrate Capsules ..... 60(USP) . . . . . . . . . . . . . . .
Atovaquone Oral Suspension (USP) ..... 449
Atracurium Besylate Injection (USP) ..... 450, 808
Avobenzone (USP) ..... 1164
Azithromycin (USP) ..... 450
Aztreonam (USP) ..... 61
Baclofen Tablets (USP) ..... 61
BCG Live (USP) ..... 452
Benzocaine (USP) ..... 809
Benzoyl Peroxide Gel (USP) .....  455, 1165
Benzoyl Peroxide Lotion (USP) ..... 456
Benzoyl Peroxide Topical Emulsion (USP) ..... 456
Benzyl Alcohol (NF) ..... 690
Benzyl Benzoate Lotion (USP) ..... 457
Benzyl Benzoate Topical Emulsion (USP) ..... 457
Betadex (NF) ..... 206, 595, 1323
Betamethasone Dipropionate Lotion (USP) ..... 458
Betamethasone Dipropionate Topical Emulsion (USP) ..... 459
Betamethasone Sodium Phosphate (USP) ..... 1166
Betamethasone Oral Solution (USP) ..... 460
Betamethasone Syrup (USP) ..... 460
Betamethasone Tablets (USP) ..... 62
Betamethasone Valerate Lotion (USP) ..... 461
Betamethasone Valerate Topical Emulsion (USP) ..... 461
Bethanechol Chloride (USP erratum) ..... 1155
Biological Indicators for Moist Heat, Dry Heat, and Gaseous
Modes of Sterilization, Metal, or Plastic Carriers (USP) ..... 63
Biological Indicators for Moist Heat, Dry Heat, and Gaseous
Modes of Sterilization, Liquid Spore Suspensions (USP) ..... 66
Bismuth Subsalicylate Oral Suspension (USP) ..... 1166
Bismuth Subsalicylate Tablets (USP) ..... 1167
Bisoprolol Fumarate (USP erratum) ..... 417
Bisoprolol Fumarate and Hydrochlorothiazide Tablets (USP erratum) ..... 1155
Red Blood Cells (USP) ..... 69
Whole Blood (USP) ..... 76
Brompheniramine Maleate and Pseudoephedrine Sulfate Oral Solution (USP) ..... 79
Brompheniramine Maleate and Pseudoephedrine Sulfate Syrup (USP) ..... 80
Bupropion Hydrochloride Extended-Release Tablets (USP) ..... 810
Butalbital, Acetaminophen, and Caffeine Tablets (USP) ..... 80
Butylparaben (NF) ..... 1431
Caffeine (USP) ..... 1168
Caffeine Injection (USP) ..... 462
Caffeine Oral Solution (USP) ..... 464
Calamine Lotion (USP) ..... 466
Phenolated Calamine Lotion (USP) ..... 466
Calamine Topical Suspension (USP) ..... 467
Phenolated Calamine Topical Suspension (USP) ..... 467
Calcitonin Salmon (USP) ..... 1169
Calcitonin Salmon Injection (USP) ..... 1177
Calcitonin Salmon Nasal Solution (USP) ..... 1178
Calcium Carbonate, Magnesia, and Simethicone Tablets (USP erratum) ..... 787
Calcium Silicate (NF) ..... 595
Calcium Lactate Tablets (USP) ..... 81
Calcium Pantothenate Tablets (USP) ..... 81

|  | 93 |
| :---: | :---: |
| Dexbrompheniramine Maleate and Pseudoephedrine Sulfate O Solution (USP) |  |
| Dextroamphetamine Sulfate (USP) | 476, 831 |
| Dextroamphetamine Sulfate Capsules (USP) |  |
| Dextroamphetamine Sulfate Tablets (USP) | 94 |
| Dextromethorphan Hydrobromide Oral Solution (USP) | 95 |
| Dextromethorphan Hydrobromide Syrup (USP) |  |
| Diatrizoate Meglumine (USP) | 832 |
| Diazepam (USP) | 96 |
| Dibutyl Phthalate (NF) | 974 |
| Diclofenac Sodium Extended-Release Tablets (USP) | 476 |
| Dicyclomine Hydrochloride Capsules (USP) | 832 |
| Dicyclomine Hydrochloride Tablets (USP) | 834 |
| Diethylcarbamazine Citrate Tablets (USP) | 97 |
| Diethylene Glycol Stearates (NF) | 74 |
| Diethylstilbestrol Diphosphate Tablets (USP) | 1187 |
| Diltiazem Hydrochloride Extended-Release Capsules (USP) | 478 |
| Dimenhydrinate Oral Solution (USP) | 1190 |
| Dimenhydrinate Syrup (USP) | 0 |
| Dimenhydrinate Tablets (USP) | 1 |
| Diphenhydramine Hydrochloride Capsules (USP) |  |
| Diphenhydramine and Pseudoephedrine Capsules (USP) |  |
| Divalproex Sodium Delayed-Release Tablets (USP) | 835 |
| Dorzolamide Hydrochloride (USP) | , 48 |
| Doxorubicin Hydrochloride (USP) | 1147 |
| Doxycycline Hyclate (USP) | 836 |
| Dyphylline and Guaifenesin Tablets (USP) | 100 |
| Echinacea angustifolia (USP) | 552 |
| Powdered Echinacea angustifolia Extract (USP) | 554 |
| Echinacea pallida (USP) | 55 |
| Powdered Echinacea pallida Extract (USP) | 556 |
| Echinacea purpurea Aerial Parts (USP) | 557 |
| Powdered Echinacea purpurea Extract (USP) | 561 |
| Echinacea purpurea Root (USP) | 561 |
| Multiple Electrolytes Injection Type 1 (USP) | 836 |
| Multiple Electrolytes Injection Type 2 (USP) |  |
| Multiple Electrolytes and Dextrose Injection Type 1 (USP) | 838 |
| Multiple Electrolytes and Dextrose Injection Type 2 (USP) | 838 |
| Multiple Electrolytes and Dextrose Injection Type 3 (USP) | 839 |
| Ensulizole (USP) | 91 |
| Ephedrine (USP) | 839 |
| Ephedrine Hydrochloride (USP) | 839 |
| Ephedrine Sulfate (USP) | 840 |
| Ephedrine Sulfate Oral Solution (USP) | 482 |
| Ephedrine Sulfate Syrup (USP) | 01 |
| Epinephrine Nasal Solution (USP) | 1192 |
| Epinephryl Borate Ophthalmic Solution (USP) | 1192 |
| Ergoloid Mesylates Tablets (USP) | 3 |
| Ergoloid Mesylates Tablets (USP) | 4 |
| Ergoloid Mesylates Sublingual Tablets (USP) | 119 |
| Ergotamine Tartrate Tablets (USP) | 1198 |
| Ergotamine Tartrate Tablets (USP) | 119 |
| Ergotamine Tartrate Sublingual Tablets (USP) | 1199 |
| Erythromycin Ethylsuccinate Tablets (USP erratum) | 787 |
| Estradiol Transdermal System (USP) | 1201 |
| Conjugated Estrogens (USP) | 0 |
| Conjugated Estrogens Tablets (USP) | 1 |
| Ethosuximide Capsules (USP) | 2 |
| Ethylcellulose (NF) | 6 |
| Ethylene Glycol Stearates (NF) | 74 |
| Ethylparaben (NF) | 侢 |
| Etodolac Extended-Release Tablets (USP) | 03 |
| Etoposide (USP) | 103 |
| Felodipine Extended-Release Tablets (USP) | 482 |
| Fenbendazole (USP) | 1205 |
| Fexofenadine Hydrochloride (USP) | 841, 1208 |
| Fexofenadine Hydrochloride Capsules (USP) | 845 |
| Cryopreserved Human Fibroblast-Derived Dermal Substitute (USP) | 1211 |
| Human Fibroblast-Derived Temporary Skin Substitute (USP) | 1221 |

| Fluconazole (USP) | 103 | Hyoscyamine Sulfate Oral Solution (USP) | 860 |
| :---: | :---: | :---: | :---: |
| Flumazenil (USP) | 1223 | Hyoscyamine Sulfate Tablets (USP) | 861 |
| Fluorodopa F 18 Injection (USP) | 486 | Hypromellose Acetate Succinate (NF) | 976 |
| Fluoxetine Hydrochloride (USP) | 848 | Hypromellose Ophthalmic Solution (USP) | 862 |
| Fluoxetine Capsules (USP) | 849 | Hypromellose Phthalate (NF) | 984 |
| Fluoxetine Delayed-Release Capsules (USP) | 849 | Ibuprofen Oral Suspension (USP) | 110 |
| Fluoxetine Tablets (USP) | 852 | Indinavir Sulfate (USP) | 862 |
| Fluoxymesterone Tablets (USP) | 105 | Indinavir Sulfate Capsules (USP) | 508 |
| Flurandrenolide Lotion (USP) | 489 | Indomethacin Topical Gel (USP) | 866 |
| Flurandrenolide Topical Emulsion (USP) | 489 | Indomethacin Oral Suspension (USP) | 110 |
| Flurazepam Hydrochloride (USP) | 490, 1229 | Ipecac (USP) | 866 |
| Fluticasone Propionate (USP) | 1230 | Powdered Ipecac (USP) | 867 |
| Fluvastatin Sodium (USP) | 1234 | Irbesartan (USP) | 110 |
| Fluvastatin Capsules (USP) | 1237 | Isoflurane (USP) | 1255 |
| Fluvoxamine Maleate (USP) | 1240 | Isoproterenol Hydrochloride Injection (USP) | 510 |
| Fluvoxamine Maleate Tablets (USP) | 1243 | Isosorbide Dinitrate Sublingual Tablets (USP) | 113 |
| Galactose (NF) | 600 | Diluted Isosorbide Mononitrate (USP) | 868 |
| Gellan Gum (NF) | 1328 | Isosorbide Mononitrate Extended-Release Tablets (USP) | 871 |
| Gemcitabine for Injection (USP) | 1246 | Isradipine Capsules (USP) | 510 |
| Gemfibrozil (USP) | 30 | Ivermectin (USP) | 14, 875 |
| Gemfibrozil Capsules (USP) | 1246 | Kanamycin Sulfate Capsules (USP) | 120 |
| Gemfibrozil Tablets (USP) | 1247 | Ketoconazole Tablets (USP) | 1256 |
| American Ginseng (USP) | 563 | Lamivudine (USP) | 881 |
| Powdered American Ginseng (USP) | 564 | Leuprolide Acetate (USP) | 882 |
| Powdered American Ginseng Extract (USP) | 564 | Levodopa (USP) | 888 |
| American Ginseng Capsules (USP) | 565 | Levodopa Tablets (USP) | 890 |
| American Ginseng Tablets (USP) | 567 | Levothyroxine Sodium Tablets (USP) | 120 |
| Asian Ginseng (USP) | 569 | Powdered Licorice Extract (USP) | 574 |
| Powdered Asian Ginseng (USP) | 570 | Lidocaine Hydrochloride (USP) | 1256 |
| Powdered Asian Ginseng Extract (USP) | 570 | Lidocaine Hydrochloride and Epinephrine Injection (USP) | 1257 |
| Asian Ginseng Capsules (USP) | 571 | Lindane Lotion (USP) | 512 |
| Asian Ginseng Tablets (USP) | 573 | Lindane Topical Emulsion (USP) | 512 |
| Glimepiride (USP) | 1247 | Linoleoyl Polyoxylglycerides (NF) | 1328 |
| Glucagon (USP) | 412 | Lisinopril Tablets (USP) | 121 |
| Glucosamine and Chondroitin Sulfate Sodium Tablets (USP) | 201 | Lithium Carbonate Extended-Release Tablets (USP) | 414 |
| Glyceryl Distearate (NF) | 975 | Loperamide Hydrochloride Oral Solution (USP) | 30 |
| Glyceryl Monolinoleate (NF) | 975 | Loperamide Hydrochloride Tablets (USP) | 122 |
| Glyceryl Monooleate (NF) | 975 | Loratadine (USP) | 891 |
| Glyceryl Monostearate (NF) | 975 | Loratadine Oral Solution (USP) | 5, 1258 |
| Glycopyrrolate Tablets (USP) | 105 | Losartan Potassium (USP) | 125 |
| Goldenseal (USP) | 952 | Lovastatin (USP) | 30 |
| Powdered Goldenseal (USP) | 953 | Lycopene (USP) | 574 |
| Powdered Goldenseal Extract (USP) | 954 | Lycopene Preparation (USP) | 576 |
| Gonadorelin Acetate (USP) | 1250 | Lycopene Tomato Extract (USP) | 578 |
| Graftskin (USP) | 490 | Lypressin Nasal Solution (USP) | 893 |
| Guaifenesin Capsules (USP) | 106 | Mafenide Acetate (USP) | 1258 |
| Guaifenesin Oral Solution (USP) | 107 | Mafenide Acetate for Topical Solution (USP) | 1259 |
| Guaifenesin Syrup (USP) | 107 | Magnesium Chloride (USP) | 893 |
| Guaifenesin Tablets (USP) | 107 | Magnesium Stearate (NF) | 340 |
| Guaifenesin and Codeine Phosphate Oral Solution (USP) | 108 | Malathion Lotion (USP) | 513 |
| Guaifenesin and Codeine Phosphate Syrup (USP) | 108 | Malathion Topical Emulsion (USP) | 513 |
| Helium (USP) | 502 | Maleic Acid (NF) | 602 |
| Homatropine Hydrobromide (USP) | 502 | Maltitol Solution (NF) | 984 |
| Homosalate (USP) | 108 | Maltol (NF) | 984 |
| Hydrocodone Bitartrate (USP) | 1148 | Maltose (NF) | 985 |
| Hydrocodone Bitartrate and Homatropine Methylbromide |  | Meclizine Hydrochloride Tablets (USP) | 127 |
| Tablets (USP) | 853 | Mefloquine Hydrochloride (USP) | 1260 |
| Hydrocodone Bitartrate and Acetaminophen Tablets (USP) | 109 | Melengestrol Acetate (USP) | 893 |
| Hydrocortisone Acetate Lotion (USP) | 504 | Meperidine Hydrochloride Oral Solution (USP) | 128 |
| Hydrocortisone Acetate Ointment (USP) | 504 | Meperidine Hydrochloride Syrup (USP) | 129 |
| Hydrocortisone Acetate Topical Emulsion (USP) | 504 | Mephobarbital Tablets (USP) | 415, 514 |
| Hydrocortisone Lotion (USP) | 505 | Meprobamate Tablets (USP) | 129 |
| Hydrocortisone Topical Emulsion (USP) | 506 | Mercaptopurine Tablets (USP) | 1261 |
| Hydromorphone Hydrochloride (USP) | 1254 | Mesalamine Extended-Release Capsules (USP) | 896 |
| Hydroxyethyl Cellulose (NF) | 709 | Mesoridazine Besylate (USP) | 1262 |
| Hydroxypropyl Cellulose (NF) | 335 | Metformin Hydrochloride Tablets (USP) | 897 |
| Low-Substituted Hydroxypropyl Cellulose (NF) | 338 | Methadone Hydrochloride Oral Solution (USP) | 130 |
| Hydroxyzine Hydrochloride Tablets (USP) | 507 | Methenamine Tablets (USP) | 130 |
| Hymetellose (NF) | 975 | Methocarbamol Tablets (USP) | 130 |
| Hyoscyamine Sulfate Elixir (USP) | 857 | Methscopolamine Bromide (USP) | 899 |
| Hyoscyamine Sulfate Injection (USP) | 858 | Methylbenzethonium Chloride Lotion (USP) | 515 |

| Methylbenzethonium Chloride Topical Emulsion (USP) | 515 | Orphenadrine Citrate Injection (USP) | 524 |
| :---: | :---: | :---: | :---: |
| Methylbenzethonium Chloride Topical Powder (USP) | 516 | Oxandrolone (USP) | 148 |
| Methylparaben (NF) | 1445 | Oxybutynin Chloride (USP) | 908 |
| Methylphenidate Hydrochloride (USP) | 731 | Oxybutynin Chloride Extended-Release Tablets (USP) | .525, 1276 |
| Methylphenidate Hydrochloride Extended-Release Tablets |  | Oxycodone Hydrochloride Oral Solution (USP) | 150 |
| (USP) | 1263 | Oxycodone and Acetaminophen Capsules (USP) | 151 |
| Methylphenidate Hydrochloride Tablets (USP) | 131 | Oxycodone and Acetaminophen Tablets (USP) | 151 |
| Metoprolol Succinate (USP) | 1263 | Oxycodone and Aspirin Tablets (USP) | 152 |
| Metrifonate (USP erratum) | 1155 | Oxytocin Injection (USP) | 153 |
| Mirtazapine (USP) | 900 | Paclitaxel (USP) | 1279 |
| Mirtazapine Tablets (USP) | 902 | Padimate O Lotion (USP) | 527 |
| Mitoxantrone Hydrochloride (USP) | 785 | Padimate O Topical Emulsion (USP) | 527 |
| Mitoxantrone Injection (USP) | 785 | Palmitic Acid (NF) | 987 |
| Mitoxantrone Injection (USP erratum) | 1155 | Paroxetine Hydrochloride (USP) | .911, 1282 |
| Mono- and Di-glyclycerides (NF) | 1330 | Paroxetine Tablets (USP) | 919, 1150 |
| Nadolol and Bendroflumethiazide Tablets (USP) | 132 | Penicillamine Capsules (USP) | 153 |
| Nalidixic Acid (USP) | 132 | Penicillin G Procaine, Neomycin and Polymyxin B Sulfate |  |
| Nalidixic Acid Oral Suspension (USP) | 415 | Hydrocortisone Acetate Topical Suspension (USP) | 528 |
| Naproxen (USP) | 904 | Penicillin G Potassium for Injection (USP) | 154 |
| Naproxen Oral Suspension (USP) | 133 | Penicillin G Sodium for Injection (USP) | 154 |
| Naproxen Delayed-Release Tablets (USP) | 1264 | Pentobarbital (USP) | 154 |
| Narasin Granular (USP erratum) | 33 | Pentobarbital Sodium (USP) | 157 |
| Naratriptan Hydrochloride (USP) | 1266 | Pepsin (USP) | 349 |
| Naratriptan Tablets (USP) | 1268 | Camphorated Phenol Topical Solution (USP) | 922 |
| Neomycin Sulfate and Flurandrenolide Lotion (USP) | 516 | Phenolsulfonphthalein (NF) | 988 |
| Neomycin Sulfate and Flurandrenolide Topical Emulsion |  | 2-Phenoxyethanol (NF) | 207 |
| (USP) | 516 | Phentermine Hydrochloride Capsules (USP) | 159 |
| Neomycin Sulfate and Hydrocortisone Acetate Cream (USP) | 517 | Phentermine Hydrochloride Tablets (USP) | 160 |
| Neomycin Sulfate and Hydrocortisone Acetate Lotion (USP) | 517 | Phenylephrine Bitartrate (USP) | 923 |
| Neomycin Sulfate and Hydrocortisone Acetate Ointment (USP) | 518 | Phenylethyl Alcohol (USP) | 1290 |
| Neomycin Sulfate and Hydrocortisone Acetate Ophthalmic |  | Phenylpropanolamine Hydrochloride Capsules (USP) | 161 |
| Ointment (USP) | 518 | Phenylpropanolamine Hydrochloride Oral Solution (USP) | 161 |
| Neomycin Sulfate and Hydrocortisone Acetate Topical Emulsion |  | Phenylpropanolamine Hydrochloride Tablets (USP) | 162 |
| (USP) | 518 | Phenyltoloxamine Citrate (USP) | 162, 1291 |
| Neomycin and Polymyxin B Sulfates, Bacitracin, and |  | Phenytoin Oral Suspension (USP) | 528 |
| Hydrocortisone Acetate Ointment (USP) | 519 | Pimozide Tablets (USP) | 164 |

## USP CATALOG

## New Items at a Glance

See what's new in USP Reference Standards. For your convenient and quick reference, here's a list of Reference Standards released by USP over the past year.

This list is continuously updated with the newest Reference Standards released within the past 12 months.

| Cat. <br> No. | Description | Curr. Lot | Price |
| :---: | :---: | :---: | :---: |
| 1048619 | Benazepril Hydrochloride (125 mg) | F0C250 | \$156 |
| 1048620 | Benazepril Related Compound A ( 15 mg ) | F0C252 | \$487 |
| 1048630 | Benazepril Related Compound B ( 15 mg ) | F0C256 | \$487 |
| 1048641 | Benazepril Related Compound C ( 50 mg ) | F0C425 | \$487 |
| 1071439 | Positive Bioreaction (3 strips; $10 \mathrm{~cm} \times 1$ cm) | F0D014 | \$325 |
| 1098118 | Cefpiramide ( 300 mg ) | F0C203 | \$156 |
| 1098027 | Cefpodoxime Proxetil ( 350 mg ) | F0C192 | \$156 |
| 1105009 | Powdered Chaste Tree Extract (1.5 g) | F0C406 | \$520 |
| 1111001 | Chlorhexidine ( 200 mg ) | F0C306 | \$156 |
| 1111103 | Chlorhexidine Acetate ( 500 mg ) | F0C281 | \$156 |
| 1111307 | Chlorhexidine Related Compounds $(50 \mathrm{mg})$ | F0D017 | \$487 |
| 1115545 | Chlorogenic Acid (50 mg) | F0C420 | \$156 |
| 1140349 | Clonazepam Related Compound C $(25 \mathrm{mg})$ | F0C340 | \$487 |
| 1140393 | Clonidine ( 200 mg ) | F0C401 | \$156 |
| 1140418 | Clonidine Related Compound A ( 25 mg ) | F0C373 | \$487 |
| 1140429 | Clonidine Related Compound B ( 25 mg ) | F0C403 | \$487 |
| 1152701 | Cyclandelate ( 200 mg ) | F0C384 | \$156 |
| 1171900 | Desflurane ( 0.5 mL ) | F0C187 | \$156 |
| 1179708 | Dextran 40 (50 mg) | F0C247 | \$156 |
| 1179741 | Dextran 70 ( 50 mg ) | F0C260 | \$156 |
| 1224959 | Dolasetron Mesylate ( 200 mg ) | F0C319 | \$156 |
| 1224960 | Dolasetron Mesylate Related Compound A $(25 \mathrm{mg})$ | F0C321 | \$487 |
| 1231728 | Powdered Echinacea Purpurea Extract $(1 \mathrm{~g})$ | F0D018 | \$520 |
| 1231706 | Powdered Echinacea Angustifolia Extract (1 g) | F0D019 | \$520 |
| 1234704 | Powdered Eleuthero Extract (1.5 g) | F0C291 | \$520 |
| 1269414 | Fenbendazole Related Compound A ( 30 mg ) | F0D009 | \$487 |
| 1269425 | Fenbendazole Related Compound B ( 30 mg ) | F0D008 | \$487 |
| 1272204 | Fludarabine Phosphate ( 300 mg ) | F0C374 | \$156 |
| 1273808 | Flumazenil ( 200 mg ) | F0C305 | \$780 |
| 1279837 | $\underset{(15 \mathrm{mg})}{\text { Fluoxetine Related Compound C }}$ $(15 \mathrm{mg})$ | F0C352 | \$487 |
| 1288306 | Ganciclovir (200 mg) | F0C287 | \$364 |
| 1288317 | Ganciclovir Related Compound A $(15 \mathrm{mg})$ | F0C288 | \$624 |
| 1294207 | Glucosamine Hydrochloride ( 200 mg ) | F0C363 | \$156 |
| 1305507 | 2E, 4E-Hexadienoic Acid Isobutylamide $(25 \mathrm{mg})$ | F0C353 | \$540 |
| 1311306 | Homopolymer Polypropylene (3 Strips) | F0C096 | \$156 |
| 1349014 | Isoflurane Related Compound A (0.1 mL ) | F0C232 | \$487 |

| Cat. No. | Description | Curr. Lot | Price |
| :---: | :---: | :---: | :---: |
| 1349025 | Isoflurane Related Compound B (0.1 mL ) | F0C233 | \$487 |
| 1355753 | Kawain (200 mg) | F0C160 | \$208 |
| 1356836 | Lamivudine ( 200 mg ) | F0C361 | \$156 |
| 1356847 | Lamivudine Resolution Mixture A ( 10 mg ) | F0D024 | \$487 |
| 1358503 | Leuprolide Acetate (200 mg) | F0C430 | \$1,525 |
| 1367708 | Linoleoyl Polyoxylglycerides (100 mg) | F0C283 | \$156 |
| 1370270 | Loratadine ( 200 mg ) | F0C414 | \$260 |
| 1378012 | Medroxyprogesterone Acetate Related Compound A ( 25 mg ) | F0C427 | \$500 |
| 1434011 | Methylphenidate Hydrochloride Erythro Isomer Solution CII ( 0.5 mL ) | F0C368 | \$560 |
| 1441232 | Metoprolol Related Compound A $(20 \mathrm{mg})$ | F0C343 | \$520 |
| 1441243 | Metoprolol Related Compound B ( 50 mg ) | F0C377 | \$520 |
| 1441254 | Metoprolol Related Compound C ( 20 mg ) | F0C344 | \$520 |
| 1441265 | Metoprolol Related Compound D ( 50 mg ) | F0C378 | \$520 |
| 1441298 | Metoprolol Succinate ( 200 mg ) | F0C415 | \$156 |
| 1445211 | Mitoxantrone System Suitability Mixture $(0.3 \mathrm{mg})$ | F0D010 | \$500 |
| 1457469 | Naratriptan Hydrochloride (125 mg) | F0C360 | \$208 |
| 1460714 | Nevirapine Hemihydrate ( 100 mg ) | F0D034 | \$156 |
| 1460725 | Nevirapine Related Compound A ( 15 mg ) | F0D035 | \$487 |
| 1460736 | Nevirapine Related Compound B ( 15 mg ) | F0D033 | \$487 |
| 1478152 | Oleoyl Polyoxylglycerides (100 mg) | F0C313 | \$156 |
| 1478629 | Ondansetron Related Compound D ( 50 mg ) | F0C226 | \$487 |
| 1483301 | Oxfendazole ( 200 mg ) | F0C128 | \$156 |
| 1485125 | Oxybutynin Related Compound B $(20 \mathrm{mg})$ | F0D061 | \$487 |
| 1485136 | $\begin{array}{\|l} \hline \text { Oxybutynin Related Compound C } \\ (20 \mathrm{mg}) \end{array}$ | F0D062 | \$487 |
| 1500251 | Paroxetine Related Compound D $(15 \mathrm{mg})$ | F0C228 | \$487 |
| 1535020 | Phenytoin Related Compound B ( 50 mg ) | F0C157 | \$487 |
| 1548134 | Potassium Bicarbonate (1 g) (AS) | F0D074 | \$156 |
| 1599500 | Powdered Red Clover Extract (500 mg) | F0C188 | \$260 |
| 1601102 | Residual Solvent Mixture - Class 1 ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C407 | \$156 |
| 1601146 | Residual Solvent Class 1 - Benzene ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C408 | \$156 |
| 1601168 | Residual Solvent Class 1 - Carbon Tetrachloride ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C409 | \$156 |
| 1601180 | Residual Solvent Class 1-1,2Dichloroethane ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C412 | \$156 |
| 1601204 | Residual Solvent Class 1-1,1Dichloroethene ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C411 | \$156 |
| 1601226 | Residual Solvent Class 1-1,1,1Trichloroethane ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C410 | \$156 |
| 1601340 | Residual Solvent Class 2 - Acetonitrile ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0D049 | \$156 |

| 1643485 | Terazosin Related Compound C $(25 \mathrm{mg})$ | F0C257 | $\$ 487$ |
| 1667290 | Tiamulin Fumarate (250 mg) | F0C327 | $\$ 156$ |
| 1667337 | Tiamulin Related Compound A (50 mg) | F0C328 | $\$ 494$ |
| 1708762 | Valsartan (350 mg) | F0C147 | $\$ 156$ |
| 1711155 | Vecuronium Bromide (60 mg) | F0C367 | $\$ 156$ |
| 1714506 | Vinorelbine Tartrate (200 mg) | F0C243 | $\$ 156$ |
| 1714528 | Vinorelbine Related Compound A <br> $(25$ mg) | F0C242 | $\$ 487$ |

## USING AND ORDERING USP REFERENCE STANDARDS

## Official Reference Standards

USP Reference Standards are required for use in pharmacopeial assays and tests in the official standards publication, the United States Pharmacopeia-National Formulary (USP-NF). USP Reference Standards help to ensure compliance with the official, FDA-enforceable quality requirements in the $U S P-N F$. The Reference Standards also lend themselves to many other applications, including measurements required to attain accurate and reproducible results in modern chromatographic and spectrophotometric methods.

## Rigorous Testing and Quality Control

USP Reference Standards are selected for their high purity, critical characteristics, and suitability for the intended purpose. Unless a USP Reference Standard label states a specific potency or content, the USP Reference Standard is taken as being $100 \%$ pure for the USP purposes for which it is provided. As a service to our customers, labeled purity values for Reference Standards and Authentic substances released after January 1, 2004 are listed in this catalog. See p. 9 for explanation of how values are calculated.

Heterogeneous substances, of natural origin, are also designated "Reference Standards" where needed. Usually these are the counterparts of international standards.

USP Reference Standards are established through a process of rigorous testing, evaluation, and quality control. They are independently tested in three or more laboratories-USP, FDA, and academic and industrial laboratories throughout the United States. The Reference Standards are released under the authority of USP's Board of Trustees, on the recommendation of the USP Reference Standards Expert Committee, which approves selection and suitability of each lot.

## Reference Standards Categories

USP offers more than 1,560 Reference Standards for pharmaceuticals, excipients, and dietary supplements. On pages 12-56 of this catalog, you'll find a full list of available USP and NF Reference Standards, with information updated through May 2004. The list includes:

- Reference Standards required by the current official edition of $U S P-N F$.
- Reference Standards not required in the current $U S P-N F$, but for which sufficient demand remains.
- Reference Standards specified in the current edition of the Food Chemicals Codex (FCC).
- Authentic Substances (AS)-highly purified samples of chemicals, including substances of abuse, required by analytical, clinical, pharmaceutical, and research laboratories.

The distribution of controlled substances is subject to the regulations and licensing provisions of the Drug Enforcement Administration (DEA) of the U.S. Department of Justice.

USP also collaborates with the World Health Organization in its program to provide international biological standards and chemical reference materials for antibiotics, biologicals, and chemotherapeutic agents. Some USP Reference Standards are standardized in terms of the corresponding international standards.

## Proper Use of USP Reference Standards

USP Reference Standards are provided primarily for quality control use in conducting the pharmacopeial assays and tests described in the $U S P-N F$. Neither Reference Standards nor Authentic Substances are intended for use as drugs, dietary supplements, or medical devices.

To serve its intended purpose, each USP Reference Standard must be properly stored, handled, and used. Users of USP Reference Standards should refer to General Chapter $\langle 11\rangle$ in the $U S P-N F$ :

## Listing and directions in USP-NF

- Refer to the list of revisions, additions, and deletions of individual USP Reference Standards in USP 27-NF 22. Individual $U S P$ or $N F$ monographs specify the USP Reference Standard(s) required for assay and test procedures. The USP 27-NF 22 General Test Chapter $\langle 11\rangle$ USP Reference Standards provides additional information and instructions for proper use and storage. Note that if specific instructions for use appearing on the label of a USP Reference Standard differ from the instructions in Chapter $\langle 11\rangle$, the instructions on the label take precedence.
- Consult the cumulative updates to Reference Standards information provided in $U S P-N F$ Supplements and also in $U S P-N F$ Interim Revision Announcements, which are published in USP's bimonthly journal, Pharmacopeial Forum.

## Suitability for use

- The user must ascertain that the Reference Standards they are using are an official lot.

## USING AND ORDERING USP REFERENCE STANDARDS

- The user must determine the suitability of Reference Standards for applications and uses not in the $U S P-N F$.

## Storing

- Ensure that the USP Reference Standards are stored in their original stoppered containers, according to any special label directions, away from heat and humidity, and protected from light.

## Weighing

- Ensure that Reference Standard substances are accurately weighed-taking due account of relatively large errors potentially associated with weighing small masses-where it is directed that a standard solution or a standard preparation be prepared for a quantitative determination. See USP 27-NF 22 General Chapters $\langle 41\rangle$ Weights and Balances and $\langle 31\rangle$ Volumetric Apparatus, and USP-NF General Notices, for information regarding appropriate use of USP Reference Standards.

## Drying

- Use a clean and dry vessel, and not the original container, as the drying vessel where a USP Reference Standard is required to be dried before use.
- Make sure not to dry a specimen repeatedly at temperatures above 25 degrees.
- Follow any special drying requirements specified on the Reference Standards label or in specific sections of USP or NF monographs (note that any specific instructions on the label or in the monograph supersede the usual instructions in Procedures under Tests and Assays in $U S P-N F$ General Notices).
- Follow Method I under USP-NF General Chapter $\langle 921\rangle$ Water Determination where the titrimetric determination of water is required at the time a Reference Standard is to be used. Instrumental or microanalytical methods are acceptable for this purpose. When using typical amounts, users must titrate about 50 mg of the Reference Standard with a fourfold dilution of the reagent.

## ORDERING USP REFERENCE STANDARDS

## Four convenient ways to order

1. Phone: Call USP with your requirements: (800) 227-8772 from the U.S. or Canada and (301) 881-0666 from other countries. Please note that DEA controlled substances cannot be placed over the phone.

Hours of operation:

Monday-Friday
8:30AM-5:00PM
Fax: Fax your orders to (301) 816-8148.
Online: Order through the World Wide Web at http://store.usp.org. Please note that DEA controlled substances cannot be ordered online.
Mail: Send all mail orders to:
USP
Customer Service Department
12601 Twinbrook Parkway
Rockville, MD 20852, USA

## Important Order/Policy Information

For fax and mail orders, please use the order form at the back of this catalog. Official purchase orders on company letterhead may also be used to order USP Reference Standards. The purchase orders must have billing and shipping addresses and should include the catalog number, the name of the official Reference Standard, and the number of units ordered. Lot numbers need not be specified on written purchase orders as USP only ships current official lots. Confirmation orders may be sent and must clearly be designated as such. The USP does not assume responsibility for duplication of orders not clearly marked as confirmation orders.

## Pricing

USP Reference Standards must be ordered in whole units. Please note that one unit may include several individual containers.

Reference Standards unit prices included in the product listings from pages 12-56 of this catalog are effective until December 31, 2004. Please note that prices and package sizes are subject to change without notice.

## No Returns or Exchanges

USP Reference Standards may not be returned or exchanged for refund.

## Quantity Discounts

A 5\% discount is allowed for 5-24 units of any one Reference Standard in a single order, and a $10 \%$ discount for 25 or more units of any one Reference Standard in a single order. These discounts are subject to change without notice.

## Shipping

## USING AND ORDERING USP REFERENCE STANDARDS

- Reference Standards orders can only be shipped to a street address and not to P.O. boxes.
- Orders to the U.S. and Ontario, Canada are shipped via air courier of USP's choice at a charge of $\$ 11$ or via air courier of the customer's choice at an additional $\$ 25$ charge.
- Non-controlled substance orders to Canadian provinces other than Ontario are shipped via air courier of USP's choice at a charge of U.S. $\$ 70$. Carriers of the customer's choice incur an additional $\$ 25$ charge.
- Non-controlled substance orders to be shipped outside the U.S. and Canada are accepted directly by USP only when customs forms related to export are not required. They are shipped via air courier of USP's choice at a charge of U.S. $\$ 70$. Carriers of the customer's choice incur an additional $\$ 25$ charge.
- Shipping in cold pack can be done at customer request for an extra charge of $\$ 25$.
- Controlled substance orders to anywhere outside the U.S. are shipped via air courier of USP's choice with a charge of U.S. $\$ 220$.
- An additional shipping charge may be assessed for dangerous goods shipments.
- An additional shipping charge of $\$ 75$ will be assessed for rush/ same-day shipments.
- Customers may provide their shipping account numbers to have shipping charged directly.

## Payment

- Full payment in advance, in U.S. dollars, is required for all U.S. orders unless open account status has been granted by USP's Finance Department. To apply for open account status, an application can be requested by calling (301) 816-8177.
- Full payment in advance, in U.S. dollars, is required for all non-U.S. orders.
- Payment may be made by check, money orders, credit cards (VISA, MasterCard, American Express), and electronic wire transfer (please call (301) 816-8177 to get bank information for wire transfers). The customer is responsible for any bank fees and must include it in the payment. The customer is also responsible for any other fees such as customs duties, taxes, or tariffs.

## List Chemicals

The following Reference Standards are "List Chemicals": Dihydroergotamine Mesylate
*Ephedrine Sulfate
Ergonovine Maleate
Ergotamine Tartrate
Methylergonovine Maleate
Phenylpropanolamine Bitartrate
Phenylpropanolamine HCl
Pseudoephedrine HCl
Pseudoephedrine Sulfate

An organization in the United States seeking to purchase a List Chemical Reference Standard for resale to another customer must have a DEA registration (either a controlled substance or List Chemical registration). If an organization in the United States is purchasing the List Chemical Reference Standard for its own analytical use, it must provide USP with a letter on company letterhead describing the reason for the purchase.

## CONTROLLED DRUG SUBSTANCE ORDER

## DEA Requirements (U.S. Orders)

For all orders for controlled drug substances-regulated by the U.S. Drug Enforcement Administration (DEA)-to be shipped within the U.S., a copy of the customer's current DEA Registration Certificate must be on file with USP. To order Schedule I and II standards, customers must submit, with their order forms or purchase orders, a DEA Form 222-C, properly completed. In addition, customers ordering DEA Schedules III and IV must provide appropriate DEA registration numbers for those schedules on their order forms or purchase orders.

## DEA Requirements (International Orders)

For all international controlled drug substance orders, please contact Julie Smith at (301) 816-8164 or foreigncontrols@ usp.org.

All orders for controlled drug substances-regulated by the U.S. Drug Enforcement Administration (DEA)-to be shipped outside the U.S. must be accompanied by:

1. Full payment.
[^192]
## USING AND ORDERING USP REFERENCE STANDARDS

2. An import permit (in English or with an English translation attached) valid at least 6 months from the date of its receipt by USP Customer Service.
3. A statement of non-reexport and use for medical or scientific purposes (in English or with an English translation attached).
4. Purchase Order or Price Quote given by USP.

On receiving the order, USP takes 2-3 business days to:

- Review all documents to make sure they are adequate and appropriate.
- Complete and legally approve the required DEA forms.
- Forward the forms to the DEA office to obtain the necessary Export Permits.

USP cannot ship items without an Export Permit. While it typically takes 6-10 weeks to get the permit from the DEA, USP has no control over the time in which permits are issued. On receiving the Export Permit, USP completes processing of the order in 1-3 days and ships out the materials through its freight forwarder.

Controlled substances (CI, CII, CIII, CIV, CV) and List Chemicals shipped to an international address, including Canada, add $\$ 25$ per unit.

For controlled substance orders to be shipped to Mexico, in addition to the DEA processing period, an additional week is required to obtain a certificate from the Mexican Embassy, authorizing the shipment to enter the country. Customers will pay an additional $\$ 114$ to cover the fee charged by the Mexican Embassy per import permit.

## Back Orders

USP will ship a back-ordered item if that item becomes available within 30 days of the date the order is placed if there is a valid open P.O. or payment for the item. If the order is more than 30 days old when the item becomes available, the customer will receive a Notice of Availability (NOA), indicating that the item is available. Such items will be shipped only after USP receives written authorization by the customer. The order will be canceled if the Reference Standard does not become available within six months of the original order. NOAs not replied to within 45 days of generation will be cancelled, and the customer account will be credited appropriately.

Customers may send confirmation orders for back-ordered Reference Standards that subsequently become available. They must clearly designate the confirmation orders as such-USP is not responsible for duplication of orders not clearly designated.

## HOW TO READ PRODUCT LISTINGS

Column 1 (Catalog Number): Catalog number currently assigned to each Reference Standard and Authentic Substance. Please include this number in your orders.

Column 2 (Description): Product description as designated in $U S P-N F$, the product label, and / or the Drug Enforcement Administration Control Schedule, as applicable. The quantity of material per container follows the name in parentheses (all materials are in single containers unless otherwise specified).

Column 3 (Current Lot): Current lot designation of each official item being distributed as of the date of this catalog. If the current lot is blank, the item is not in distribution.

Column 4 (Purity Values) Assigned purity value as it appears on the RS or AS label. Code interpretations for the basis of purity assignments are as follows:
Basis Interpretation

## Code

| (ai) | as is |
| :--- | :--- |
| (dr) | dried |
| (an) | anhydrous |
| (fb) | free base |

Column 5 (Change Code): Codes that identify any change in USP Reference Standards status or information since the May/June 2004, official Catalog. Code interpretations are as follows:

| Change <br> Code | Interpretation |
| :---: | :--- |
| 1 | New Reference Standard |
| 2 | New lot |
| 3 | Change in package size or description |
| 4 | Correction of typographical error |
| 5 | New catalog number-use for all orders |
| 6 | Previous lot no longer official; only <br> current lot to be used |
| 7 | Valid use date of previous lot extended <br> Change in catalog number and / or name, <br> 8 |
| see cross-reference section <br> Discontinued |  |

Column 6 (Previous Lot/Valid Use Date): Lot designations for recent lots no longer being distributed. The indicated month and year in parenthesis indicates the date (last day of the month) through which that lot was valid as an official USP Reference Standard. (e.g. "F-1 (06/00)" means lot F-1 is no longer being distributed, but was considered official through June 30, 2000.)

Column 7 (CAS Number)*: Chemical Abstracts Service number, when available, for USP Reference Standards and Authentic Substances. In case of mixtures, typically, the CAS number of the analyte of interest is listed.

Column 8 (Price) List price of the reference standard.

Vol. 30(4) July-Aug. 2004]

NOTICE TO THE EXECUTIVE SECRETARIAT OF INTENT TO COMMENT

I am unable to comment at present, but please be informed of my intent to comment later, as indicated above.

Name $\qquad$
(Please type or print)

Company $\qquad$

## Address

$\qquad$

Telephone No. ( )
(area code)
*Note-Specifying date(s) when you expect to submit comments to the Executive Secretariat will not necessarily result in a deferment of the implementation of the proposal(s) referred to.

# CHROMATOGRAPHIC REAGENTS USED IN $\boldsymbol{U S P} \boldsymbol{- N F}$ AND PHARMACOPEIAL FORUM 

This is an update based on the proposals published in this issue of $P F$.

## CHROMATOGRAPHIC REAGENTS

## Chromatographic Reagents Used in USP-NF and Pharmacopeial Forum

July-August 2004

| <571> VITAMIN A ASSAY |  |  |  | DSD Mgh \#99330 |
| :---: | :---: | :---: | :---: | :---: |
| PF | LGS\# | Reagent Brand | Type of Test | Comments |
| 30(4) | L8 | Zorbax NH2 | Assay | $4.6 \mathrm{~mm} \times 15 \mathrm{~cm}, 5 \mu \mathrm{~m}$, manufacturer Agilent Technologies. |
| FLUMAZENIL |  |  |  | DSD Mgh \#33370 |
| PF | LGS\# | Reagent Brand | Type of Test | Comments |
| 30(4) | L1 | Inertsil ODS-2 | Assay and Related Compounds | $25 \mathrm{~cm} \times 4.6 \mathrm{~mm}, 5 \mu \mathrm{~m}$, manufacturer GL Science. |

Pharmacopeial Forum is covered in Current Contents/Life Sciences and in the Science Citation Index (SCI), in International Pharmaceutical Abstracts, and in Current Awareness in Biological Sciences.

The United States Pharmacopeial Convention comprises representatives from colleges and national and state organizations of medicine and pharmacy. It publishes the U.S. Pharmacopeia and National Formulary, the legally recognized compendia of standards for drugs and products of other health care technologies. The USP and NF include assays and tests for the determination of strength, quality, and purity and requirements for packaging and labeling.

This publication was paginated using Advent 3B2 Publishing Software.

ISSN: 0363-4655

Printed in Canada by Webcom Limited, Toronto, Ontario

[^235]
## STANDARDS DEVELOPMENT

This section presents an overview of the public review and comment process, conducted through Pharmacopeial Forum $(P F)$, for the development of official pharmaceutical standards.

USP publishes Pharmacopeial Forum ( $P F$ ) bimonthly as the working vehicle of the USP Council of Experts. PF provides interested parties an opportunity to review and comment as the Council of Experts develops or revises standards for the United States Pharmacopeia and the National Formulary (USP-NF).
$P F$ includes the following:

1. Potential revisions-entirely new standards, revision ideas, and drafts not yet targeted for official adoption (Pharmacopeial Previews)
2. Proposed revisions - new or revised standards targeted for official adoption (In-Process Revision)
3. Adopted revisions-new or revised standards that become official and binding before the publication of the next $U S P$ NF or Supplement (Interim Revision Announcement)
USP welcomes comments and data on potential, proposed, or official standards. ${ }^{*}$ Comments, along with USP's responses, will be published either in PF Briefings, the Commentary section of $P F$, the Commentary section of Supplements to USP-NF, or the Commentary section of $U S P-N F$.
[^236]The chart below shows the public review and comment process and its relationship to standards development.

# Public Review and Comment Process for Standards Development 

Questions on the process should be addressed to John W. Gasper, M.A., J.D., Director, Office of the Executive Secretariat, U.S. Pharmacopeia, 12601 Twinbrook Parkway, Rockville, MD 20852 (e-mail: jg@usp.org).

## HOW TO USE PF

This section provides descriptions of the various parts of $P F$. It also includes Committee Designations and the Staff Directory.

The contents of the different sections of $P F$ are briefly described below. Readers will get an idea of how each section is relevant to their job functions. They may contact USP scientific staff liaisons or staff members of the Executive Secretariat (listed in the Staff Directory) if they have any questions. A more detailed description of each section is provided at the beginning of that section. A general description of the types and amount of information expected in a Request for Revision is available on the USP website (www.usp.org/standards/revisionguideline/).

Proposed and Adopted Revisions

| Section | Content | How Readers Can Respond |
| :---: | :---: | :---: |
| Pharmacopeial <br> Previews <br> Early ideas for revisions | -Briefing: Scientific rationale for potential inclusion or change. May include other information useful to the analyst such as the brand name of the column used in developing the proposed procedure and the USP scientific staff liaison who handled the issue. <br> -Potential revisions not yet targeted for official adoption that require a longer public review and comment process because of issues such as: <br> - the controversial nature of an item; <br> - the application of new technologies that require further study; and <br> - articles produced by multiple sources. | Review drafts and provide comments to the appropriate staff liaison cited in the Briefing preceding each Preview. |
| In-Process Revision Revisions targeted for adoption | -BriEfing: Scientific rationale for proposed changes. May include other information useful to the analyst such as the brand name of the column used in developing the proposed procedure and the USP scientific staff liaison who handled the issue. <br> -New and revised standards that have been approved for publication by the appropriate USP Committee when it is considering whether to advance standards to official status (see Standards Development). New or revised text is marked with symbols ( ${ }^{\square}$ or ) to specify the tentative earliest date on which the revision would be officially adopted. | Review material and send comments promptly to USP staff liaison (see the Staff Directory). Guidelines on how to comment are found at the end of the Po licies and Announcements section. |
| Harmonization <br> Items the Pharmacopeial Discussion Group (PDG) is trying to harmonize internationally | -Briefing: Scientific rationale for the potential inclusion or change or for the proposed change. The designated stage of harmonization. The stage determines whether an item appears under Pharmacopeial Previews or under In-Process Revision, both separate sections of Harmonization. <br> -For In-Process Revision, new or revised text is marked with symbols (■) to specify the tentative, earliest date on which the revision would be officially adopted. | Review material and provide comments to the appropriate staff liaison cited in the Briefing preceding each Preview or In-Process Revision. |
| Interim Revision <br> Announcement <br> Adopted standards | Standards that have been adopted and will become officially binding on the specified date. Effective date is specified in the section's introductory page or within parentheses following a particular item. New or revised text is set off by the symbols ${ }^{\circ}$. | Review to see if affected by any of the changes. Note effective date when standards become official and ensure compliance. |

## Other Sections

## Committee Designations

Names of the committees (composed of volunteer scientific experts) that USP staff work with on the development of standards.

## Staff Directory

Names of all USP scientific staff liaisons with contact information.

## Policies and Announcements

- General scientific and policy issues affecting $U S P-N F$ standards and processes
- Update on standards-related issues being considered by USP
- Summaries of meetings of the Council of Experts
- Guidelines on how to comment
- Publication and comment schedules

## Stimuli to the Revision Process

- Articles on standards development issues authored by the USP Council of Experts, USP staff, or other interested parties
- Discussions of issues on which USP desires public input prior to further development

## Nomenclature

- Latest adopted United States Adopted Names (USAN) and International Nonproprietary Names (INN) for drugs
- Revisions to existing names as a supplement to the USP Dictionary of USAN and International Drug Names
- Suggested, proposed, and recommended USAN and INN
- Information on how nonproprietary drug names are devised
- Articles relevant to compendial nomenclature issues

## Index

Cumulative directory for the content of all issues of $P F$ beginning with $P F 30(1)$.

## Reference Standards Catalog

List of official USP Reference Standards specified in $U S P-N F$, along with availability and ordering information.

## Chromatographic Reagents Used in USP-NF and Pharmacopeial Forum

Update of chromatographic reagents based on the proposals published in this issue of $P F$.

## EXPERT COMMITTEE DESIGNATIONS*

The names of the Committees and their abbreviations are as follows:

| AER | Aerosols |
| :--- | :--- |
| AMB | Analytical Microbiology |
| BBP | Blood and Blood Products |
| BNA | Bioavailability and Nutrient Absorption |
| BNT | Biotechnology and Natural Therapeutics and Diagnostics |
| BPC | Biopharmaceutics |
| BST | Biostatistics |
| CRX | Compounding Pharmacy |
| DSB | Dietary Supplements-Botanicals |
| DSI | Dietary Supplements-Information |
| DSN | Dietary Supplements-Non-Botanicals |
| EMC | Excipient Monograph Content |
| ETM | Excipients-Test Methods |
| GCT | Gene Therapy, Cell Therapy, and Tissue Engineering |
| GTB | General Toxicity and Biocompatibility |
| NL | Nomenclature and Labeling |
| PA1 | Pharmaceutical Analysis 1 |
| PA2 | Pharmaceutical Analysis 2 |
| PA3 | Pharmaceutical Analysis 3 |
| PA4 | Pharmaceutical Analysis 4 |
| PA5 | Pharmaceutical Analysis 5 |
| PA6 | Pharmaceutical Analysis 6 |
| PA7 | Pharmaceutical Analysis 7-Antibiotics |
| PDF | Pharmaceutical Dosage Forms |
| PPC | Parenteral Products-Compounding and Preparation |
| PPI | Parenteral Products-Industrial |
| PSD | Packaging, Storage, and Distribution |
| PW | Pharmaceutical Waters |
| RMI | Radiopharmaceuticals and Medical Imaging |
| SMU | Safe Medication Use |
| VET | Veterinary Drugs |
| VVI | Vaccines, Virology, and Immunology |
|  |  |

## POLICIES AND ANNOUNCEMENTS

In this section, readers may find statements about general scientific and policy issues that may have an impact on $U S P-N F$ standards and processes, announcements about issues being considered by USP, and summaries of Council of Experts meetings. This section also includes publication and comment schedules.

USP TO HOLD FIRST ANNUAL SCIENTIFIC MEETING. MEETING FOCUSES ON PRODUCT AND PROCESS STANDARDS. The United States Pharmacopeia (USP) is pleased to announce that it will hold its first USP Annual Scientific Meeting at the Sheraton Woodbridge Place in Iselin, N.J. from Sept. 27 to 29,2004 . The new USP Annual Scientific Meeting, which replaces the organization's open conference format, will allow stakeholders the opportunity to learn about and discuss science topics that are the foundation of USP's standards-setting activities.
"We are creating one annual meeting to allow USP to address multiple topics and to allow more people to participate in USP's standards-setting activities," said Roger L. Williams, M.D., USP Executive Vice President and Chief Executive Officer. "This one-stop approach allows stakeholders the opportunity to meet with USP at one time and in one convenient location."

Preliminary USP Annual Scientific Meeting topics to be presented are the following:

- Biologics and Biotechnology Products
- Chromatography
- Dissolution
- Excipients and Pharmaceutical Waters
- Making the $U S P-N F$ Work for You
- Microbiology
- Process Analytical Technology
- Specifications

In addition, USP will offer its Pharmacopeial Education courses on Analytical Method Validation, Basic Statistics and their Practical Applications to USP, Dissolution, Microbiology, and USP 100 and 101. These courses and the USP Annual Scientific Meeting session tracks will be approved for continuing pharmaceutical education units (CEUs). Attendees of the USP Annual Scientific Meeting also can learn about other USP initiatives and how to become involved in USP's processes through the various USP volunteer bodies.

The USP Annual Scientific Meeting is designed for USP$N F$ and USP Reference Standards customers and other USP stakeholders including pharmaceutical scientists focusing on chemistry, microbiology, biologics and biotechnology, Process Analytical Technology, excipients, dissolution, and chromatography.

For further information about the USP Annual Scientific Meeting, please visit www.usp.org/conferences, or call 301-816-8226.

## USAN COUNCIL SECRETARIAT REVISES USAN

 FEE-FOR-SERVICE CHARGES. A revised schedule of fee-for-service charges has been placed in effect as of January 1, 2004. The increased fees appear on the USAN submission forms that are provided under Appendix XI of the 2004 edition of the USP Dictionary of USAN and International Drug Names. This announcement will be important to inform users of the USP Dictionary who are not yet using the revised 2004 edition of the changes.For further information please contact:

United States Adopted Names (USAN) Program<br>American Medical Association<br>515 North State Street<br>Chicago, IL 60610<br>Phone: 312-464-4046<br>Fax: 312-464-4028<br>Web site: http://www.ama-assn.org/go/usan

USP GUIDELINE FOR SUBMITTING REQUESTS FOR REVISION TO THE USP-NF. We are pleased to announce the availability of the USP Guideline for Submitting Requests for Revision to the $U S P-N F$. This document was developed in conjunction with the USP Council of Experts and its Expert Committees, USP Staff, and the Drug Substance, Complex Actives, and Excipients Project Teams of the Prescription/Nonprescription Stakeholders Forum. This document includes information to aid submission of new monographs and revisions to existing monographs for Non-Complex Active Substances and Products, Biological and Biotech Substances and Products, Excipients, and Vaccines. It incorporates many of the concepts and suggestions included in the ICH Q3A, Q3B, Q3C, Q6A, and Q6B guidelines. These include the definition of a specification and incorporate much of the terminology of Q3A for the control of impurities. The guideline clearly defines the information needed for the USP's Council of Experts and its Expert Committees to evaluate a request for revision. The document is approximately 75 pages in length with about 25 pages of addenda and is available in PDF format from the USP website at www.usp.org. Hard copies will be provided upon request.

PHARMACOPEIAL EDUCATION COURSES. USP's Pharmacopeial Education series has been developed to enhance the knowledge, skills, and expertise of pharmaceutical industry personnel.

The following list indicates tentatively scheduled course dates. For further information, contact Laura A. McCurry, Manager, Pharmacopeial Education, lam@usp.org, 301-816-8285; Diana Lenahan, Program Associate, dpl@
usp.org, 301-816-8530; or visit the website at www. usp.org/education to register. Call 301-816-8530 to get information on customized courses offered at USP or at your site.

Calendar of Pharmacopeial Education Courses, 2004

| Date | Name of course | Location |
| :--- | :--- | :--- |
| October 14 | Fundamentals of Microbiological Testing | USP Headquarters, Rockville, MD |
| October 18 and 19 | Fundamentals of Dissolution | USP Headquarters, Rockville, MD |
| November 11 | Analytical Method Validation | USP Headquarters, Rockville, MD |
| November 11 | Standards 100: Fundamentals of the Use of $U S P-$ <br> $N F$ and the Standards Development Process | USP Headquarters, Rockville, MD |
| November 12 | Standards 101: Advanced Use of $U S P-N F$, General <br> Notices, and Monograph Chapters | USP Headquarters, Rockville, MD |
| November 12 | Fundamentals of Dissolution (Lecture) | USP Headquarters, Rockville, MD |
| December 2 | Analytical Method Validation | USP Headquarters, Rockville, MD |
| December 8 | Standards 100: Fundamentals of the Use of $U S P-$ <br> $N F$ and the Standards Development Process | USP Headquarters, Rockville, MD |
| December 9 | Standards 101: Advanced Use of $U S P-N F$, General <br> Notices, and Monograph Chapters | USP Headquarters, Rockville, MD |

VISIT THE USP WEB SITE AT 〈http://www.usp.org $\rangle$. Various resources related to Pharmacopeial standards are presented, including highlights from $P F$.

## USP-NF AVAILABLE IN THREE ELECTRONIC

FORMATS. The trusted reference for official pharmaceutical standards is available in three convenient electronic formats-CD, intranet, and online. The CD is ideal for single users who prefer to have $U S P-N F$ on their hard drives. The intranet format allows Web browser-based access to multiple users within a company, through their own intranet server. The online format can be accessed by individual registered users through the World Wide Web. All three electronic formats provide fast and easy access to official $U S P-N F$ content. More information can be obtained by visiting www.usp.org/products or by calling USP's Customer Service Department at 1-800-227-8772 or 301-881-0666.

## CHROMATOGRAPHIC REAGENTS NOW

 AVAILABLE. Chromatographic Reagents lists the brand names of the column reagents cited in every proposal for new or revised gas- or liquid-chromatographic test methods that has been published in Pharmacopeial Forum (PF) since 1980. Chromatographic Reagents also helps to track which column reagents were used to validate methods that have become official and are included in $U S P-N F$. The branded column reagents list is updated bimonthly through Pharmacopeial Forum.Chromatographic Reagents can be ordered by calling USP's Customer Service Department at 1-800-227-8772 or 301-881-0666.

INTERNATIONAL CORRESPONDENCE. Individuals who wish to correspond with the European and Japanese Pharmacopoeias concerning monographs in the Official Inquiry and Consensus stages of international harmonization should address their comments to the coordinating pharmacopeia for a given article. The addresses for the European and Japanese Pharmacopoeias are as follows:

Technical Secretariat of the
European Pharmacopoeia Commission
B.P. 907

F 67029 Strasbourg Cedex 1
France

NAKASHIMA Nobumasa
Evaluation and Licensing Division Pharmaceutical and Medical Safety Bureau Ministry of Health, Labour and Welfare, Japan Tel. +81-3-3595-2431, Fax. +81-3-3597-9535
E-mail: nakashima-nobumasa@mhlw.go.jp

HOW TO SUBMIT COMMENTS. The USP welcomes and encourages interested parties to submit comments and data regarding potential, proposed, or adopted (official) standards. Submissions concerning a particular item that has appeared in a $P F$ should be submitted to the
appropriate USP scientific staff liaison identified at the end of the Briefing accompanying each item. To submit comments and data to a liaison, use the e-mail address and telephone numbers listed in the Staff Directory included in every $P F$.

Please note that $U S P-N F$ is being published in an annual edition with one main book and two Supplements a year. In addition, the following schedule will repeat every year so that users will know what to expect and become familiar with the deadlines.

The publication and comment schedule for USP 27-NF 22 is as follows:

|  | Comment Deadline | Publication Date | Official Date |
| :--- | :--- | :--- | :--- |
| Main Book | May 15, 2003 | November 2003 | January 2004 |
| Supplement One | October 15, 2003 | February 2004 | April 2004 |
| Supplement Two | February 17, 2004 | June 2004 | August 2004 |

The publication and comment schedule for USP $28-N F 23$ is as follows:

|  | Comment Deadline | Publication Date | Official Date |
| :--- | :--- | :--- | :--- |
| Main Book | May 15, 2004 | November 2004 | January 2005 |
| Supplement One | October 15, 2004 | February 2005 | April 2005 |
| Supplement Two | February 17, 2005 | June 2005 | August 2005 |

In the future, USP anticipates including the comment submission deadline in each briefing of every revision proposal when it is published for public review and comment.

For general inquiries or in cases where a particular liaison is not identified, use the general USP telephone number 301-881-0666 or FAX number 301-816-8373.

All official revisions are published in Supplements to $U S P-N F$ (twice yearly). Between Supplements, official revisions are published in $P F$ in the Interim Revision Announcement; these revisions are also incorporated in the upcoming Supplement. The electronic version of $U S P-N F$ is updated as each Supplement becomes available and, therefore, contains all official text up to and including the contents of the latest Supplement.

Publication Schedules

| Publication | Publication Date | Official Date |
| :---: | :---: | :---: |
| $1^{\text {st }}$ Supplement | Feb. 2004 | Apr. 1, 2004 |
| $P F 30(2)[$ Mar.-Apr. 2004] | Mar. 2004 | Not Applicable |
| $2^{\text {nd }} I R A$ [published in $\left.P F 30(2)\right]$ | Mar. 2004 | Apr. 1, 2004 |

[^238]
## INTERIM REVISION ANNOUNCEMENT

In this section readers will find the following:

- The list of new USP Reference Standards that have become available
- The list of assays or tests that are adopted but held in abeyance pending availability of required USP Reference Standards
- New adopted (official) revisions to the $U S P-N F$ that become effective before the effective date of the next Supplement or that were not ready for adoption by the closing date for the upcoming Supplement. (The effective date for these revisions is stated on the next page.)

Readers should review this section to determine if they are affected by any of the changes.
Symbols-Interim revisions are shown with new text (if any) enclosed in circles, ${ }^{\bullet}$ new text $\boldsymbol{m}_{\bullet}$. Text enclosed in squares, $\boldsymbol{\square}_{\text {new }}$ text $_{\boldsymbol{\bullet}}$, has already been adopted in a Supplement. Where the symbols appear together with no enclosed text, such as ${ }^{\bullet}$ • or $\boldsymbol{m}^{\boldsymbol{\bullet}} \boldsymbol{\square}$, it means that text has been deleted and no new text was proposed to replace it. In all revisions, the closing symbol is accompanied by a number that indicates the $I R A$ or Supplement in which the revision first appeared. For example, $\bullet 2$ indicates that the revision was officially adopted in the Second Interim Revision Announcement, and $\boldsymbol{m}_{2 \mathrm{~S}(\text { USP27) }}$ indicates that the revision was officially adopted in the Second Supplement to USP 27.

Errata-At the end of the Interim Revision Announcement section is a list of errata and corrections to USP 27-NF 22. The page number indicates where the item is found in $U S P-N F$. If necessary, this list will be updated with every issue of $P F$. This information will also be cumulative in the next available Supplement, and will appear in its corrected form in the next annual edition of $U S P-N F$. Errata are considered to be items erroneously published that have not received the approval of the Council of Experts and that do not reflect the official requirement.

## New USP Reference Standards

The following USP Reference Standards, which were indicated in past Supplements to $U S P-N F$ as being not yet available, have since become available. Thus, the official date of each USP 27 or NF 22 standard, test, or assay requiring the use of the following Reference Standards is indicated individually in this list. (AS) indicates Authentic Substances, which are materials that have no specified use in monographs or General Chapters and are offered for the convenience of USF-NF users

USP Alcohol Determination-Acetonitrile RS (March 1, 2005)
USP Alcohol Determination-Alcohol RS (March 1, 2005)
USP Benazepril Related Compound C RS (January 1, 2005)
USP Positive Bioreaction RS (November 1, 2004)
USP Powdered Black Cohosh Extract RS (March 1, 2005)
USP Boric Acid (AS) RS
USP Butylated Hydroxytoluene RS (March 1, 2005)
USP Calcium Choride (AS) RS
USP Candelilla Wax RS (March 1, 2005)
USP Caprylocaproyl Polyoxylglycerides RS (March 1, 2005)
USP Cefpiramide RS (September 1, 2004)
USP Cefpodoxime Proxetil RS (January 1, 2005)
USP Powdered Chaste Tree Extract RS (November 1, 2004)
USP Chlorhexidine Related Compounds RS (November 1, 2004)
USP Chlorogenic Acid RS (November 1, 2004)
USP Clonidine RS (September 1, 2004)
USP Clonidine Related Compound A RS (September 1, 2004)
USP Clonidine Related Compound B RS (November 1, 2004)
USP Cyclandelate RS (September 1, 2004)
USP Dibutyl Phthalate RS (March 1, 2005)
USP Powdered Echinacea purpurea Extract RS (November 1, 2004)

USP Fenbendazole Related Compound A RS (January 1, 2005)
USP Fenbendazole Related Compound B RS (January 1, 2005)
USP Fludarabine RS (September 1, 2004)
USP Gemcitabine Hydrochloride RS (March 1, 2005)
USP Glacial Acetic Acid (AS) RS
USP $2 E, 4 E$-Hexadienoic Acid Isobutylamide RS (November 1, 2004)

USP Homopolymer Polypropylene RS (January 1, 2005)
USP Isoflurane Related Compound A RS (September 1, 2004)
USP Isoflurane Related Compound B RS (September 1, 2004)
USP Lamivudine Resolution Mixture A RS (November 1, 2004)
USP Lauroyl Polyoxylglycerides (AS) RS
USP Leuprolide Acetate RS (January 1, 2005)
USP Linoleoyl Polyoxylglycerides RS (January 1, 2005)
USP Loratadine RS (September 1, 2004)
USP Magnesium Hydroxide (AS) RS
USP Manganese Chloride (AS) RS
USP Medroxyprogesterone Acetate Related Compound A RS (November 1, 2004)
USP Methylphenidate Hydrochloride Erythro Isomer Solution CII RS (November 1, 2004)
USP Metoprolol Related Compound B RS (September 1, 2004)
USP Metoprolol Related Compound C RS (September 1, 2004)
USP Metoprolol Related Compound D RS (September 1, 2004)
USP Metoprolol Succinate RS (November 1, 2004)
USP Mirtazapine RS (March 1, 2005)
USP Mitoxantrone System Suitability Mixture RS (November 1, 2004)

USP Naratriptan Hydrochloride RS (November 1, 2004)
USP Nevirapine Anhydrous RS (March 1, 2005)
USP Nevirapine Hemihydrate RS (January 1, 2005)
USP Nevirapine Related Compound A RS (January 1, 2005)
USP Nevirapine Related Compound B RS (January 1, 2005)

USP Oxybutynin Related Compound B RS (January 1, 2005)
USP Oxybutynin Related Compound C RS (January 1, 2005)
USP Oleoyl Polyoxylglycerides RS (January 1, 2005)
USP Potassium Bicarbonate RS (January 1, 2005)
USP Potassium Carbonate (AS) RS
USP Potassium Chloride (AS) RS
USP Potassium Iodide (AS) RS
USP Propionic Acid (AS) RS
USP Residual Solvent Class 1-Benzene RS (November 1, 2004)
USP Residual Solvent Class 1-1,2 Dichloroethane RS (November 1, 2004)
USP Residual Solvent Class 1-1,2 Dichloroethene RS (November 1, 2004)
USP Residual Solvent Class 1-Carbon Tetrachloride RS (November 1, 2004)
USP Residual Solvent Class 1—1,1,1-Trichloroethane RS (November 1, 2004)
USP Residual Solvent Class 2-Chlorobenzene RS (January 1, 2005)

USP Residual Solvent Class 2-1,2-Dichoroethene RS (March 1, 2005)

USP Residual Solvent Class 2-1,4-Dioxane RS (January 1, 2005)
USP Residual Solvent Class 2-Methanol RS (January 1, 2005)
USP Residual Solvent Class 2-Methylcyclohexane RS (March 1, 2005)

USP Residual Solvent Class 2-Methylene Chloride RS (January 1, 2005)
USP Residual Solvent Class 2-Tetrahydrofuran RS (January 1, 2005)

USP Residual Solvent Class 2-Toluene RS (January 1, 2005)
USP Residual Solvent Class 2-Xylenes RS (January 1, 2005)
USP Residual Solvent Mixture-Class 1 RS (November 1, 2004)
USP Rimantidine Hydrochloride RS
USP Sodium Acetate (AS) RS
USP Sodium Carbonate Anhydrous (AS) RS
USP Sodium Metabisulfite (AS) RS
USP Sodium Nitrite (AS) RS
USP Sodium Sulfate Anhydrous (AS) RS
USP Titanium Dioxide (AS) RS
USP Valsartan RS (November 1, 2004)
USP Vecuronium Bromide RS (September 1, 2004)
USP Zinc Sulfate (AS) RS

The official dates of any $U S P 27$ or $N F 22$ standards, tests, or assays requiring the use of the following new USP Reference Standards are postponed until further notice pending availability of the respective Reference Standards.

[^240]USP Narasin RS
USP Ondansetron Related Compound B RS
USP Potassium Perchlorate RS
USP Pyrethrum Extract RS
USP Sargramostim RS
USP Sulisobenzone RS
USP Terbutaline Related Compound A RS
USP $\Delta^{8}$-tetrahydrocannabinol RS
USP $\Delta^{9}$-tetrahydrocannabinol RS

USP Thiacetarsamide RS
USP Tilmicosin RS
USP Tinidazole Related Compound B RS
USP Trenbolone RS
USP Trenbolone Acetate RS
USP Powdered Valerian RS
USP Vasopressin RS

${ }^{\circ}$ Labeling-When more than one Drug release test is given, the labeling states the Drug release test used only if Test 1 is not used.es

## Change to read:

Drug release $\langle 724\rangle$ -
$\bullet$ TEST 1-•
Medium: water; 900 mL .
Apparatus 2: 50 rpm .
Times: 1, 4, and 8 hours.
Procedure-Determine the amount of $\mathrm{C}_{13} \mathrm{H}_{18} \mathrm{ClNO} \cdot \mathrm{HCl}$ dissolved by employing UV absorption at the wavelength of maximum absorbance at about 298 nm , using a $1.0-\mathrm{cm}$ cell, on filtered portions of the solution under test, suitably diluted with Medium, if necessary, in comparison with a Standard solution having a known concentration of USP Bupropion Hydrochloride RS in the same Medium.
Tolerances-The percentages of the labeled amount of $\mathrm{C}_{13} \mathrm{H}_{18} \mathrm{ClNO} \cdot \mathrm{HCl}$ dissolved at the times specified conform to $A c$ ceptance Table $1\langle 724\rangle$.

| Time (hours) | Amount dissolved |
| :---: | :--- |
| 1 | between $25 \%$ and $45 \%$ |
| 4 | between $60 \%$ and $85 \%$ |
| 8 | not less than $80 \%$ |

- TEST 2-If the product complies with this test, the labeling indicates that it meets USP Drug release Test 2.

Medium: $\quad 0.1 \mathrm{~N}$ hydrochloric acid, $\mathrm{pH} 1.5 ; 900 \mathrm{~mL}$.
Apparatus 1: 50 rpm .
Times: 1, 2, 4, and 6 hours.
Determine the percentages of the labeled amount of $\mathrm{C}_{13} \mathrm{H}_{18} \mathrm{ClNO} \cdot \mathrm{HCl}$ dissolved by employing the following method. Buffer solution-Dissolve 3.45 g of sodium phosphate monobasic monohydrate in 996 mL of water, add 4.0 mL of triethylamine, and mix. Adjust with phosphoric acid to a pH of $2.80 \pm 0.05$.

Mobile phase-Prepare a filtered and degassed mixture of Buffer solution and methanol $(65: 35)$. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Standard solution-Dissolve an accurately weighed quantity of USP Bupropion Hydrochloride RS in Medium, and dilute quantitatively, and stepwise if necessary, with Medium to obtain a solution having a known concentration similar to the one expected in the Test solution.

Test solution-Use portions of the solution under test, and pass through a $0.45-\mu \mathrm{m}$ nylon filter.

Chromatographic system (see Chromatography $\langle 621\rangle$ )-The liquid chromatograph is equipped with a 298 -nm detector and a 4.6 $\mathrm{mm} \times 15-\mathrm{cm}$ column that contains packing L1. The flow rate is about 1.0 mL per minute. Chromatograph the Standard solution, and record the peak responses as directed for Procedure: the column efficiency is not less than 2000 theoretical plates; the tailing factor is not more than 2.0; and the relative standard deviation for replicate injections is not more than $2.0 \%$.

Procedure-Separately inject equal volumes (about $20 \mu \mathrm{~L}$ ) of the Standard solution and the Test solution into the chromatograph, record the chromatograms, and measure the peak responses. Calculate the percentage of bupropion hydrochloride dissolved at each time point.

Tolerances-The percentages of the labeled amount of $\mathrm{C}_{13} \mathrm{H}_{18} \mathrm{ClNO} \cdot \mathrm{HCl}$ dissolved at the times specified conform to Ac ceptance Table $1\langle 724\rangle$.

| Time (hours) | Amount dissolved |
| :---: | :--- |
| 1 | between $25 \%$ and $50 \%$ |
| 2 | between $40 \%$ and $65 \%$ |
| 4 | between $65 \%$ and $90 \%$ |
| 6 | not less than $80 \%$ |

TEST 3-If the product complies with this test, the labeling indicates that it meets USP Drug release Test 3.

Medium, Apparatus, and Procedure-Proceed as directed for Test 1, except using the wavelength of about 250 nm .

Times: 1, 2, 4, and 6 hours.
Tolerances: The percentages of the labeled amount of $\mathrm{C}_{13} \mathrm{H}_{18} \mathrm{ClNO} \cdot \mathrm{HCl}$ dissolved at the times specified conform to Ac ceptance Table $1\langle 724\rangle$.

| Time (hours) | Amount dissolved |
| :---: | :--- |
| 1 | between $30 \%$ and $55 \%$ |
| 2 | between $50 \%$ and $75 \%$ |
| 4 | between $70 \%$ and $90 \%$ |
| 6 | not less than $80 \%$ |

## ERRATA

Following is a list of errata and corrections to USP 27-NF 22. The page number indicates where the item is found in USP 27-NF 22. If necessary, this list will be updated with every issue of $P F$. This information will also be available as a cumulative table in the next available Supplement and will appear in its corrected form in the next annual edition of $U S P-N F$. Errata are considered to be items erroneously published that have not received the approval of the Council of Experts and that do not reflect the official requirement. USP staff are available to respond to questions regarding the accuracy of a particular requirement by calling 1-800-822-USPC.

| Page | Title | Section | Description |
| :--- | :--- | :--- | :--- |
| 691 | Multiple Electrolytes and <br> Dextrose Injection Type 2 | Assay for dextrose | Line 2: Change "Multiple Electrolytes Injection Type <br> l." to: Multiple Electrolytes and Dextrose Injection |

| :--- |
| sponds to not more than 1.0\% of Standard solution 1." |
| to: Test solution corresponds to not more than $1.0 \%$ |
| (Standard solution 1). |

## IN-PROCESS REVISION

This section contains proposals for adoption as official $U S P$ or $N F$ standards (either proposed new standards or proposed revisions of current $U S P$ or $N F$ standards). These may be any of the following: (1) items that previously appeared under Pharmacopeial Previews and are now formally proposed as revisions; (2) proposed revisions placed directly under In-Process Revision; or (3) modifications of revisions previously proposed under In-Process Revision. Readers should review material in this section and provide comments to the staff liaison (use the Staff Directory to find the contact information). Information on how to comment is found in the Policies and Announcements section. It is important to send comments promptly so that the Committee members can consider readers' input as they are deciding whether to advance standards to official status.

Briefings Each Proposal is preceded by a Briefing in the following format:

## BRIEFING

Name of Item, citations of the most recent USP publications in which this item appeared. Rationale for the revision. Other relevant information. (For example, if a chromatographic method is being proposed, column specifications and retention times for compounds of interest.) Finally, the Committee designation (see How to Use PF), the name of the scientific staff liaison who handled the particular issue, and the USP tracking correspondence number, as shown in the example below:
(PA5: K. Russo) RTS-55678-1

Symbols Proposed revisions are shown with language proposed for deletion or replacement crossed off. New text (if any) follows, and is enclosed in symbols and set off from the current official text by a paragraph break and by larger type, as shown in the examples below:
${ }^{\bullet}$ new text
if slated for an Interim Revision Announcement to USP 27-NF 22 (IRA);
$\Delta_{\text {new text }}{ }_{\mathbf{\Delta S P 2 8}}$
if slated for $U S P 28-N F 23$; and
${ }^{-}$new text.
if slated for a Supplement to $U S P-N F$. The same symbols not set off by an extra paragraph break and enclosing text with no increase in type size indicate recent revisions that are already official. Where the symbols appear together with no enclosed text, such as ${ }^{\bullet}$ 。 or $\quad$ or ${ }_{\wedge}$, it means that text has been deleted and no new text was proposed to replace it. In all revisions, the closing symbol is accompanied by an identifier that indicates the particular IRA or Supplement or indicates the USP or NF as the publication where the revision will appear if approved. For example, $\bullet_{2}$ indicates that the revision is proposed for the Second Interim Revision Announcement, and ${ }^{2 S}$ (USP 27) indicates that the proposed revision is slated for the Second Supplement to USP 27, and $\Delta_{\triangle S P 28}$ and $\Delta_{\triangle F 23}$ indicate that the revisions are proposed for USP 28 and $N F 23$, respectively.

Official Title Changes Where the specification "Monograph title change" is found, it indicates that the official title stated after that specification will be substituted for the former title in the appropriate places throughout that monograph once this revision becomes official.

Briefing

General Notices and Requirements，USP 27 page 1，page 3238 of the Second Supplement，and page 794 of PF 30（3） ［May－June 2004］．On the basis of information received from the Consumer Product Safety Commission（CPSC）at the PSD Open Conference on October 12－15，2003，an Expert Committee meet－ ing，and through subsequent correspondence，members of the PSD Expert Committee decided that information about the Poison Pre－ vention Packaging Act（PPPA）should be included in the USP．An appropriate statement was solicited from the CPSC，which was ini－ tially included in the draft of the new chapter Packaging－Unit of Use $\langle 1136\rangle$ ．However，it was pointed out during a teleconference that this information is not only applicable to this chapter but also to other chapters concerned with packaging．Therefore，the sugges－ tion was made that the general concepts of the PPPA as stated in the CPSC document be included in the General Notices under Preser－ vation，Packaging，Storage，and Labeling．Then，in other chapters such as Environmentally－Sensitive Preparations $\langle 386\rangle$ ，Containers〈661〉，Pharmaceutical Compounding－Nonsterile Preparations 495），Pharmaceutical Compounding－Sterile Preparations〈797〉，Good Storage and Shipping Practices 〈1079〉，Packag－ ing－Unit of Use $\langle 1136\rangle$ ，and Packaging Practice－Repackaging a Single Solid Oral Drug Product into a Unit Dose Container $\langle 1146\rangle$ ，a short statement with references to the General Notices would be included．This approach would save needless repetition of the same material．
（PSD：C．Okeke）RTS－41271－2

## Change to read：

## TESTS AND ASSAYS

Apparatus－A specification for a definite size or type of con－ tainer or apparatus in a test or assay is given solely as a recom－ mendation．Where volumetric flasks or other exact measuring， weighing，or sorting devices are specified，this or other equipment of at least equivalent accuracy shall be employed．（See also Ther－ mometers $\langle 21\rangle$ ，Volumetric Apparatus $\langle 31\rangle$ ，and Weights and Bal－ ances $\langle 41\rangle$ ．）Where low－actinic or light－resistant containers are specified，clear containers that have been rendered opaque by ap－ plication of a suitable coating or wrapping may be used．

Where an instrument for physical measurement，such as a spec－ trophotometer，is specified in a test or assay by its distinctive name， another instrument of equivalent or greater sensitivity and accuracy may be used．In order to obtain solutions having concentrations that are adaptable to the working range of the instrument being used，solutions of proportionately higher or lower concentrations may be prepared according to the solvents and proportions thereof that are specified for the procedure．

Where a particular brand or source of a material，instrument，or piece of equipment，or the name and address of a manufacturer or distributor，is mentioned（ordinarily in a footnote），this identifica－ tion is furnished solely for informational purposes as a matter of
convenience，without implication of approval，endorsement，or cer－ tification．Items capable of equal or better performance may be used if these characteristics have been validated．

Where the use of a centrifuge is indicated，unless otherwise specified，the directions are predicated upon the use of apparatus having an effective radius of about 20 cm （ 8 inches）and driven at a speed sufficient to clarify the supernatant layer within 15 min － utes．

Unless otherwise specified，for chromatographic tubes and col－ umns the diameter specified refers to internal diameter（ID）；for other types of tubes and tubing the diameter specified refers to out－ side diameter（OD）．

Steam Bath－Where the use of a steam bath is directed，exposure to actively flowing steam or to another form of regulated heat，cor－ responding in temperature to that of flowing steam，may be used．

Water Bath－Where the use of a water bath is directed without qualification with respect to temperature，a bath of vigorously boil－ ing water is intended．

Foreign Substances and Impurities－Tests for the presence of foreign substances and impurities are provided to limit such sub－ stances to amounts that are unobjectionable under conditions in which the article is customarily employed（see also Impurities in Official Articles 〈1086〉）．

While one of the primary objectives of the Pharmacopeia is to assure the user of official articles of their identity，strength，quality， and purity，it is manifestly impossible to include in each mono－ graph a test for every impurity，contaminant，or adulterant that might be present，including microbial contamination．These may arise from a change in the source of material or from a change in the processing，or may be introduced from extraneous sources． Tests suitable for detecting such occurrences，the presence of which is inconsistent with applicable good manufacturing practice or good pharmaceutical practice，should be employed in addition to the tests provided in the individual monograph．

Other Impurities－Official substances may be obtained from more than one process，and thus may contain impurities not con－ sidered during preparation of monograph assays or tests．Wherever a monograph includes a chromatographic assay or purity test based on chromatography，other than a test for erganic volatile impuri－ ties，
$\mathbf{m}_{\text {residual solvents }}^{\mathbf{m}_{1 S} \text {（USP28）}}$
and that monograph does not detect such an impurity，solvents ex－ cepted，the impurity shall have its amount and identity，where both are known，stated under the heading Other Impurity（ies）by the la－ beling（certificate of analysis）of the official substance．

The presence of any unlabeled impurity in an official substance is a variance from the standard if the content is $0.1 \%$ or greater． Tests suitable for detection and quantitating unlabeled impurities， when present as the result of process change or other identifiable， consistent occurrence，shall be submitted to the USP for inclusion in the individual monograph．Otherwise，the impurity shall be identified，preferably by name，and the amount listed under the heading Other Impurity（ies）in the labeling（certificate of analysis） of the official substance．The sum of all Other Impurities combined with the monograph－detected impurities does not exceed $2.0 \%$（see Ordinary Impurities $\langle 466\rangle$ ），unless otherwise stated in the mono－ graph．

Categories of drug substances excluded from Other Impurities requirements are fermentation products and semi－synthetics de－ rived therefrom，radiopharmaceuticals，biologics，biotechnology－ derived products，peptides，herbals，and crude products of animal or plant origin．Any substance known to be toxic must not be listed under Other Impurities．

■Residual Solvents－The requirements are stated in Or－ ganic Volatile Impurities $\langle 467\rangle$ together with information in Impurities in Official Articles $\langle 1086\rangle$ ．Thus all drug sub－
stances, excipients, and products are subject to relevant control of residual solvents, even when no test is specified in the individual monograph. The requirements have been aligned with the ICH guideline on this topic. If solvents are used during production, they are of suitable quality. In addition, the toxicity and residual level of each solvent are taken into consideration, and the solvents are limited according to the principles defined and the requirements specified in Organic
Volatile Impurities $\langle 467\rangle$, using the general methods presented therein or other suitable methods. $\quad 1 \mathrm{~S}$ (USP28)

Procedures-Assay and test procedures are provided for determining compliance with the Pharmacopeial standards of identity, strength, quality, and purity.

In performing the assay or test procedures in this Pharmacopeia, it is expected that safe laboratory practices will be followed. This includes the utilization of precautionary measures, protective equipment, and work practices consistent with the chemicals and procedures utilized. Prior to undertaking any assay or procedure described in this Pharmacopeia, the individual should be aware of the hazards associated with the chemicals and the procedures and means of protecting against them. This Pharmacopeia is not designed to describe such hazards or protective measures.

Every compendial article in commerce shall be so constituted that when examined in accordance with these assay and test procedures, it meets all of the requirements in the monograph defining it. However, it is not to be inferred that application of every analytical procedure in the monograph to samples from every production batch is necessarily a prerequisite for assuring compliance with Pharmacopeial standards before the batch is released for distribution. Data derived from manufacturing process validation studies and from in-process controls may provide greater assurance that a batch meets a particular monograph requirement than analytical data derived from an examination of finished units drawn from that batch. On the basis of such assurances, the analytical procedures in the monograph may be omitted by the manufacturer in judging compliance of the batch with the Pharmacopeial standards.

Automated procedures employing the same basic chemistry as those assay and test procedures given in the monograph are recognized as being equivalent in their suitability for determining compliance. Conversely, where an automated procedure is given in the monograph, manual procedures employing the same basic chemistry are recognized as being equivalent in their suitability for determining compliance. Compliance may be determined also by the use of alternative methods, chosen for advantages in accuracy, sensitivity, precision, selectivity, or adaptability to automation or computerized data reduction or in other special circumstances. Such alternative or automated procedures or methods shall be validated. However, Pharmacopeial standards and procedures are interrelated; therefore, where a difference appears or in the event of dispute, only the result obtained by the procedure given in this Pharmacopeia is conclusive.

In the performance of assay or test procedures, not fewer than the specified number of dosage units should be taken for analysis. Proportionately larger or smaller quantities than the specified weights and volumes of assay or test substances and Reference Standards may be taken, provided the measurement is made with at least equivalent accuracy and provided that any subsequent steps, such as dilutions, are adjusted accordingly to yield concentrations equivalent to those specified and are made in such manner as to provide at least equivalent accuracy. To minimize environ-
mental impact or contact with hazardous materials, apparatus and chemicals specified in Pharmacopeial procedures also may be proportionally changed.

Where it is directed in an assay or a test that a certain quantity of substance or a counted number of dosage units is to be examined, the specified quantity or number is a minimal figure (the singlet determination) chosen only for convenience of analytical manipulation; it is not intended to restrict the total quantity of substance or number of units that may be subjected to the assay or test or that should be tested in accordance with good manufacturing practices.

Where it is directed in the assay of Tablets to "weigh and finely powder not fewer than" a given number, usually 20, of the Tablets, it is intended that a counted number of Tablets shall be weighed and reduced to a powder. The portion of the powdered tablets taken for assay is representative of the whole Tablets and is, in turn, weighed accurately. The result of the assay is then related to the amount of active ingredient per Tablet by multiplying this result by the average Tablet weight and dividing by the weight of the portion taken for the assay.

Similarly, where it is directed in the assay of Capsules to remove, as completely as possible, the contents of not fewer than a given number, usually 20, of the Capsules, it is intended that a counted number of Capsules should be carefully opened and the contents quantitatively removed, combined, mixed, and weighed accurately. The portion of mixed Capsules contents taken for the assay is representative of the contents of the Capsules and is, in turn, weighed accurately. The result of the assay is then related to the amount of active ingredient per Capsule by multiplying this result by the average weight of Capsule content and dividing by the weight of the portion taken for the assay.
Where the definition in a monograph states the tolerances as being "calculated on the dried (or anhydrous or ignited) basis," the directions for drying or igniting the sample prior to assaying are generally omitted from the Assay procedure. Assay and test procedures may be performed on the undried or unignited substance and the results calculated on the dried, anhydrous, or ignited basis, provided a test for Loss on drying, or Water, or Loss on ignition, respectively, is given in the monograph.
-Results are calculated on an "as-is" basis unless otherwise
specified in the monograph. 1 IS (USP28)
Where the presence of moisture or other volatile material may interfere with the procedure, previous drying of the substance is specified in the individual monograph and is obligatory.

Throughout a monograph that includes a test for Loss on drying or Water, the expression "previously dried" without qualification signifies that the substance is to be dried as directed under Loss on drying or Water (gravimetric determination).

Unless otherwise directed in the test or assay in the individual monograph or in a general chapter, USP Reference Standards are to be dried before use, or used without prior drying, specifically in accordance with the instructions given in the chapter USP Reference Standards $\langle 11\rangle$, and on the label of the Reference Standard. Where the label instructions differ in detail from those in the chapter, the label text is determinative.

In stating the appropriate quantities to be taken for assays and tests, the use of the word "about" indicates a quantity within $10 \%$ of the specified weight or volume. However, the weight or volume taken is accurately determined and the calculated result is based upon the exact amount taken. The same tolerance applies to specified dimensions.
Where the use of a pipet is directed for measuring a specimen or an aliquot in conducting a test or an assay, the pipet conforms to the standards set forth under Volumetric Apparatus $\langle 31\rangle$, and is to be used in such manner that the error does not exceed the limit stated for a pipet of its size. Where a pipet is specified, a suitable buret, conforming to the standards set forth under Volumetric Apparatus $\langle 31\rangle$, may be substituted. Where a "to contain" pipet is specified, a suitable volumetric flask may be substituted.

Expressions such as " 25.0 mL " and " 25.0 mg ," used with respect to volumetric or gravimetric measurements, indicate that the quantity is to be "accurately measured" or "accurately weighed" within the limits stated under Volumetric Apparatus $\langle 31\rangle$ or under Weights and Balances $\langle 41\rangle$.

The term "transfer" is used generally to specify a quantitative manipulation.

The term "concomitantly," used in such expressions as "concomitantly determine" or "concomitantly measured," in directions for assays and tests, is intended to denote that the determinations or measurements are to be performed in immediate succession. See also Use of Reference Standards under Spectrophotometry and Light-Scattering $\langle 851\rangle$.

Blank Determination-Where it is directed that "any necessary correction" be made by a blank determination, the determination is to be conducted using the same quantities of the same reagents treated in the same manner as the solution or mixture containing the portion of the substance under assay or test, but with the substance itself omitted.
Desiccator-The expression "in a desiccator" specifies the use of a tightly closed container of suitable size and design that maintains an atmosphere of low moisture content by means of silica gel or other suitable desiccant.

A "vacuum desiccator" is one that maintains the low-moisture atmosphere at a reduced pressure of not more than 20 mm of mercury or at the pressure designated in the individual monograph.

Dilution-Where it is directed that a solution be diluted "quantitatively and stepwise," an accurately measured portion is to be diluted by adding water or other solvent, in the proportion indicated, in one or more steps. The choice of apparatus to be used should take into account the relatively larger errors generally associated with using small-volume volumetric apparatus (see Volumetric Apparatus $\langle 31\rangle$ ).

Drying to Constant Weight-The specification "dried to constant weight" means that the drying shall be continued until two consecutive weighings do not differ by more than 0.50 mg per g of substance taken, the second weighing following an additional hour of drying.

Filtration-Where it is directed to "filter," without further qualification, the intent is that the liquid be filtered through suitable filter paper or equivalent device until the filtrate is clear.

Identification Tests-The Pharmacopeial tests headed Identification are provided as an aid in verifying the identity of articles as they are purported to be, such as those taken from labeled containers. Such tests, however specific, are not necessarily sufficient to establish proof of identity; but failure of an article taken from a labeled container to meet the requirements of a prescribed identification test indicates that the article may be mislabeled. Other tests and specifications in the monograph often contribute to establishing or confirming the identity of the article under examination.

Ignition to Constant Weight-The specification "ignite to constant weight" means that the ignition shall be continued, at $800 \pm 25^{\circ}$ unless otherwise indicated, until two consecutive weighings do not differ by more than 0.50 mg per g of substance taken, the second weighing following an additional 15 -minute ignition period.

Indicators-Where the use of a test solution ("TS") as an indicator is specified in a test or an assay, approximately 0.2 mL , or 3 drops, of the solution shall be added, unless otherwise directed.

Logarithms-Logarithms used in the assays are to the base 10.
Microbial Strains-Where a microbial strain is cited and identified by its ATCC catalog number, the specified strain shall be used directly or, if subcultured, shall be used not more than five passages removed from the original strain.

Negligible-This term indicates a quantity not exceeding 0.50 mg.

Odor-Terms such as "odorless," "practically odorless," "a faint characteristic odor," or variations thereof, apply to examination, after exposure to the air for 15 minutes, of either a freshly opened package of the article (for packages containing not more than 25 g ) or (for larger packages) of a portion of about 25 g of the article that has been removed from its package to an open evaporating dish of about $100-\mathrm{mL}$ capacity. An odor designation is descriptive only and is not to be regarded as a standard of purity for a particular lot of an article.

Pressure Measurements-The term "mm of mercury" used with respect to measurements of blood pressure, pressure within an apparatus, or atmospheric pressure refers to the use of a suitable manometer or barometer calibrated in terms of the pressure exerted by a column of mercury of the stated height.

Solutions-Unless otherwise specified in the individual monograph, all solutions called for in tests and assays are prepared with Purified Water.

An expression such as "(1 in 10)" means that 1 part by volume of a liquid is to be diluted with, or 1 part by weight of a solid is to be dissolved in, sufficient of the diluent or solvent to make the volume of the finished solution 10 parts by volume.

An expression such as " $(20: 5: 2)$ " means that the respective numbers of parts, by volume, of the designated liquids are to be mixed, unless otherwise indicated.

The notation "VS" after a specified volumetric solution indicates that such solution is standardized in accordance with directions given in the individual monograph or under Volumetric Solutions in the section Reagents, Indicators, and Solutions, and is thus differentiated from solutions of approximate normality or molarity.

Where a standardized solution of a specific concentration is called for in a test or an assay, a solution of other normality or molarity may be used, provided allowance is made for the difference in concentration and provided the error of measurement is not increased thereby.

Specific Gravity-Unless otherwise stated, the specific gravity basis is $25^{\circ} / 25^{\circ}$, i.e., the ratio of the weight of a substance in air at $25^{\circ}$ to the weight of an equal volume of water at the same temperature.

Temperatures-Unless otherwise specified, all temperatures in this Pharmacopeia are expressed in centigrade (Celsius) degrees, and all measurements are made at $25^{\circ}$. Where moderate heat is specified, any temperature not higher than $45^{\circ}\left(113^{\circ} \mathrm{F}\right)$ is indicated. See Storage Temperature under Preservation, Packaging, Storage, and Labeling for other definitions.

Time Limit-In the conduct of tests and assays, 5 minutes shall be allowed for the reaction to take place unless otherwise specified.

Vacuum-The term "in vacuum" denotes exposure to a pressure of less than 20 mm of mercury unless otherwise indicated.
Where drying in vacuum over a desiccant is directed in the individual monograph, a vacuum desiccator or a vacuum drying pistol, or other suitable vacuum drying apparatus, is to be used.

Water-Where water is called for in tests and assays, Purified Water is to be used unless otherwise specified. For special kinds of water such as "carbon dioxide-free water," see the introduction to the section Reagents, Indicators, and Solutions. For High-purity Water see Containers $\langle 661\rangle$.

Water and Loss on Drying-Where the water of hydration or adsorbed water of a Pharmacopeial article is determined by the titrimetric method, the test is generally given under the heading Water. Monograph limits expressed as a percentage are figured on a weight/weight basis unless otherwise specified. Where the determination is made by drying under specified conditions, the test is generally given under the heading Loss on drying. However, Loss on drying is most often given as the heading where the loss in weight is known to represent residual volatile constituents including organic solvents as well as water.

Test Results, Statistics, and Standards-Interpretation of results from official tests and assays requires an understanding of the nature and style of compendial standards, in addition to an understanding of the scientific and mathematical aspects of laboratory analysis and quality assurance for analytical laboratories.

Confusion of compendial standards with release tests and with statistical sampling plans occasionally occurs. Compendial standards define what is an acceptable article and give test procedures that demonstrate that the article is in compliance. These standards apply at any time in the life of the article from production to consumption. The manufacturer's release specifications, and compliance with good manufacturing practices generally, are developed and followed to assure that the article will indeed comply with compendial standards until its expiration date, when stored as directed. Thus, when tested from the viewpoint of commercial or regulatory compliance, any specimen tested as directed in the monograph for that article shall comply.

Tests and assays in this Pharmacopeia prescribe operation on a single specimen, that is, the singlet determination, which is the minimum sample on which the attributes of a compendial article should be measured. Some tests, such as those for Dissolution and Uniformity of dosage units, require multiple dosage units in conjunction with a decision scheme. These tests, albeit using a number of dosage units, are in fact the singlet determinations of those particular attributes of the specimen. These procedures should not be confused with statistical sampling plans. Repeats, replicates, statistical rejection of outliers, or extrapolations of results to larger populations are neither specified nor proscribed by the compendia; such decisions are dependent on the objectives of the testing. Commercial or regulatory compliance testing, or manufacturer's release testing, may or may not require examination of additional specimens, in accordance with predetermined guidelines or sampling strategies. Treatments of data handling are available from organizations such as ISO, IUPAC, and AOAC.
$\square$ Where the Content Uniformity determinations have been made using the same procedure specified in the Assay, the average of all of the individual Content Uniformity determinations may be used as the Assay value. 1 1S (USP27)

Description-Information on the "description" pertaining to an article, which is relatively general in nature, is provided in the reference table Description and Relative Solubility of USP and NF Articles in this Pharmacopeia for those who use, prepare, and dispense drugs and/or related articles, solely to indicate properties of an article complying with monograph standards. The properties are not in themselves standards or tests for purity even though they may indirectly assist in the preliminary evaluation of an article.

Solubility-The statements concerning solubilities given in the reference table Description and Relative Solubility of USP and NF Articles for Pharmacopeial articles are not standards or tests for purity but are provided primarily as information for those who use, prepare, and dispense drugs and/or related articles. Only where a quantitative solubility test is given, and is designated as such, is it a test for purity.

The approximate solubilities of Pharmacopeial substances are indicated by the descriptive terms in the accompanying table. Soluble Pharmacopeial articles, when brought into solution, may show traces of physical impurities, such as minute fragments of filter paper, fibers, and other particulate matter, unless limited or excluded by definite tests or other specifications in the individual monographs.

|  | Parts of Solvent <br> Required for <br> Descriptive <br> Term |
| :--- | :--- |
| Very soluble | Less than 1 |
| Freely soluble | From 1 to 10 |
| Soluble | From 10 to 30 |
| Sparingly soluble | From 30 to 100 |
| Slightly soluble | From 100 to 1000 |

|  | Parts of Solvent <br> Required for <br> Descriptive <br> Term |
| :--- | :--- |
| Very slightly soluble | From 1000 to 10,000 |
| Practically insoluble, <br> or Insoluble | Greater than or equal to 10,000 |

Interchangeable Methods-Certain general chapters contain a statement that the text in question is harmonized with the corresponding text of the European Pharmacopoeia and/or the Japanese Pharmacopoeia and that these texts are interchangeable. Therefore, if a substance or preparation is found to comply with a requirement using an interchangeable method from one of these pharmacopeias, it should comply with the requirements of the United States Pharmacopeia. However, where a difference appears, or in the event of dispute, only the result obtained by the procedure given in this Pharmacopeia is conclusive.

## Change to read:

## PRESERVATION, PACKAGING, STORAGE, AND LABELING

Containers-The container is that which holds the article and is or may be in direct contact with the article. The immediate contain$e r$ is that which is in direct contact with the article at all times. The closure is a part of the container.

Prior to its being filled, the container should be clean. Special precautions and cleaning procedures may be necessary to ensure that each container is clean and that extraneous matter is not introduced into or onto the article.

The container does not interact physically or chemically with the article placed in it so as to alter the strength, quality, or purity of the article beyond the official requirements.

The Pharmacopeial requirements for the use of specified containers apply also to articles as packaged by the pharmacist or other dispenser, unless otherwise indicated in the individual monograph.

Tamper-Evident Packaging - The container or individual carton of a sterile article intended for ophthalmic or otic use, except where extemporaneously compounded for immediate dispensing on prescription, shall be so sealed that the contents cannot be used without obvious destruction of the seal.

Articles intended for sale without prescription are also required to comply with the tamper-evident packaging and labeling requirements of the FDA where applicable.

Preferably, the immediate container and/or the outer container or protective packaging utilized by a manufacturer or distributor for all dosage forms that are not specifically exempt is designed so as to show evidence of any tampering with the contents.

Light-Resistant Container (see Light Transmission under Containers $\langle 661\rangle$ )-A light-resistant container protects the contents from the effects of light by virtue of the specific properties of the material of which it is composed, including any coating applied to it. Alternatively, a clear and colorless or a translucent container may be made light-resistant by means of an opaque covering, in which case the label of the container bears a statement that the opaque covering is needed until the contents are to be used or administered. Where it is directed to "protect from light" in an individual monograph, preservation in a light-resistant container is intended.

Where an article is required to be packaged in a light-resistant container, and if the container is made light-resistant by means of an opaque covering, a single-use, unit-dose container or mnemonic pack for dispensing may not be removed from the outer opaque covering prior to dispensing.

Well-Closed Container-A well-closed container protects the contents from extraneous solids and from loss of the article under the ordinary or customary conditions of handling, shipment, storage, and distribution.

Tight Container-A tight container protects the contents from contamination by extraneous liquids, solids, or vapors, from loss of the article, and from efflorescence, deliquescence, or evaporation under the ordinary or customary conditions of handling, shipment, storage, and distribution, and is capable of tight re-closure. Where a tight container is specified, it may be replaced by a hermetic container for a single dose of an article.

A gas cylinder is a metallic container designed to hold a gas under pressure. As a safety measure, for carbon dioxide, cyclopropane, helium, nitrous oxide, and oxygen, the Pin-index Safety System of matched fittings is recommended for cylinders of Size E or smaller.

NOTE-Where packaging and storage in a tight container or a well-closed container is specified in the individual monograph, the container utilized for an article when dispensed on prescription meets the requirements under Containers-Permeation $\langle 671\rangle$.

Hermetic Container-A hermetic container is impervious to air or any other gas under the ordinary or customary conditions of handling, shipment, storage, and distribution.

Single-Unit Container-A single-unit container is one that is designed to hold a quantity of drug product intended for administration as a single dose or a single finished device intended for use promptly after the container is opened. Preferably, the immediate container and/or the outer container or protective packaging shall be so designed as to show evidence of any tampering with the contents. Each single-unit container shall be labeled to indicate the identity, quantity and/or strength, name of the manufacturer, lot number, and expiration date of the article.

Single-Dose Container (see also Containers for Injections under Injections $\langle 1\rangle$ )—A single-dose container is a single-unit container for articles intended for parenteral administration only. A singledose container is labeled as such. Examples of single-dose containers include pre-filled syringes, cartridges, fusion-sealed containers, and closure-sealed containers when so labeled.

Unit-Dose Container-A unit-dose container is a single-unit container for articles intended for administration by other than the parenteral route as a single dose, direct from the container.

Unit-of-Use Container-A unit-of-use container is one that contains a specific quantity of a drug product and that is intended to be dispensed as such without further modification except for the addition of appropriate labeling. A unit-of-use container is labeled as such.

Multiple-Unit Container-A multiple-unit container is a container that permits withdrawal of successive portions of the contents without changing the strength, quality, or purity of the remaining portion.

Multiple-Dose Container (see also Containers for Injections under Injections $\langle 1\rangle$ )-A multiple-dose container is a multiple-unit container for articles intended for parenteral administration only.
-Poison Prevention Packaging Act-This act (see the
Website, www.cpsc.gov/businfo/pppa.html) requires special packaging of most human oral prescription drugs, oral controlled drugs, certain nonoral prescription drugs, certain dietary supplements, and many over-the-counter (OTC) drug preparations in order to protect the public from personal injury or illness from misuse of these preparations (16 CFR § 1700.14).

The immediate packaging of substances regulated under the PPPA must comply with the special packaging standards (16 CFR § 1700.15 and 16 CFR § 1700.20). The PPPA regulations for special packaging apply to all packaging types including reclosable, nonclosable, and unit-dose types.

Special packaging is not required for drugs dispensed within a hospital setting for inpatient administration. Manufacturers and packagers of bulk-packaged prescription drugs do not have to use special packaging if the drug will be repackaged by the pharmacist. PPPA-regulated prescription drugs may be dispensed in nonchild-resistant packaging upon the request of the purchaser or when directed in a legitimate prescription (15 U.S.C. § 1473).

Manufacturers or packagers of PPPA-regulated OTC preparations are allowed to package one size in nonchild-resistant packaging as long as popular-size, special packages are also supplied. The nonchild-resistant package requires special labeling (18 CFR § 1700.5).

Various types of child-resistant packages are covered in ASTM International Standard D-3475, Standard Classification of Child-Resistant Packaging. Examples are included as an aid in the understanding and comprehension of each type of classification.■2S (USP28)

Storage Temperature and Humidity-Specific directions are stated in some monographs with respect to the temperatures and humidity at which Pharmacopeial articles shall be stored and distributed (including the shipment of articles to the consumer) when stability data indicate that storage and distribution at a lower or a higher temperature and a higher humidity produce undesirable results. Such directions apply except where the label on an article states a different storage temperature on the basis of stability studies of that particular formulation. Where no specific storage directions or limitations are provided in the individual monograph, but the label of an article states a storage temperature that is based on stability studies of that particular formulation, such labeled storage directions apply (see also Stability under Pharmaceutical Dosage Forms $\langle 1151\rangle$ ). The conditions are defined by the following terms.

Freezer-A place in which the temperature is maintained ther-mostat-ically between $-25^{\circ}$ and $-10^{\circ}\left(-13^{\circ}\right.$ and $\left.14^{\circ} \mathrm{F}\right)$.

Cold-Any temperature not exceeding $8^{\circ}\left(46^{\circ} \mathrm{F}\right)$. A refrigerator is a cold place in which the temperature is maintained thermostatically between $2^{\circ}$ and $8^{\circ}\left(36^{\circ}\right.$ and $\left.46^{\circ} \mathrm{F}\right)$.

Cool-Any temperature between $8^{\circ}$ and $15^{\circ}\left(46^{\circ}\right.$ and $\left.59^{\circ} \mathrm{F}\right)$. An article for which storage in a cool place is directed may, alternatively, be stored and distributed in a refrigerator, unless otherwise specified by the individual monograph.

Room Temperature-The temperature prevailing in a working area.

Controlled Room Temperature-A temperature maintained thermostatically that encompasses the usual and customary working environment of $20^{\circ}$ to $25^{\circ}\left(68^{\circ}\right.$ to $77^{\circ} \mathrm{F}$ ); that results in a mean kinetic temperature calculated to be not more than $25^{\circ}$; and that allows for excursions between $15^{\circ}$ and $30^{\circ}\left(59^{\circ}\right.$ and $86^{\circ} \mathrm{F}$ ) that are experienced in pharmacies, hospitals, and warehouses. Provided the mean kinetic temperature remains in the allowed range, transient spikes up to $40^{\circ}$ are permitted as long as they do not exceed 24 hours. Spikes above $40^{\circ}$ may be permitted if the manufacturer so instructs. Articles may be labeled for storage at "controlled room temperature" or at "up to $25^{\circ}$ ", or other wording based on the same mean kinetic temperature. The mean kinetic temperature is a calculated value that may be used as an isothermal storage temperature that simulates the nonisothermal effects of storage temperature variations. (See also Stability under Pharmaceutical Dosage Forms $\langle 1151\rangle$. )

An article for which storage at Controlled room temperature is directed may, alternatively, be stored and distributed in a cool place, unless otherwise specified in the individual monograph or on the label.
Warm-Any temperature between $30^{\circ}$ and $40^{\circ}\left(86^{\circ}\right.$ and $104^{\circ} \mathrm{F}$ ).
Excessive Heat-Any temperature above $40^{\circ}\left(104^{\circ} \mathrm{F}\right)$.
Protection from Freezing-Where, in addition to the risk of breakage of the container, freezing subjects an article to loss of strength or potency, or to destructive alteration of its characteristics, the container label bears an appropriate instruction to protect the article from freezing.
Dry Place-The term "dry place" denotes a place that does not exceed $40 \%$ average relative humidity at Controlled Room Temperature or the equivalent water vapor pressure at other temperatures. The determination may be made by direct measurement at the place or may be based on reported climatic conditions. Determination is based on not less than 12 equally spaced measurements that encompass either a season, a year, or, where recorded data demonstrate, the storage period of the article. There may be values of up to $45 \%$ relative humidity provided that the average value is $40 \%$ relative humidity.
Storage in a container validated to protect the article from moisture vapor, including storage in bulk, is considered a dry place.
${ }^{\Delta}$ Storage under Nonspecific Conditions-Where no specific directions or limitations are provided in the packaging and storage section of individual monographs or in the article's labeling, the conditions of storage shall include storage at controlled room temperature, protection from moisture, and, where necessary, protection from light. Articles shall be protected from moisture, freezing, and excessive heat, and, where necessary, from light during shipping and distribution. Active pharmaceutical ingredients are exempt from this requirement. $\triangle$ USP27
-Repackaging Instructions-Except where a drug prod-
uct is packaged in a container intended to be dispensed directly to the patient, such as a unit-of-use or unit-dose container, the labeling shall contain directions specifying the types of containers suitable for repackaging the drug product so as to maintain its identity, strength, quality, and purity. Such directions shall be sufficient to allow a repackager or dispenser to select an adequate container and shall include a description of the composition of the container(s),
e.g., glass, polyethylene, polyvinyl chloride, and any moisture vapor transmission rate characteristics required. The labeling shall also indicate whether or not the container is to afford light protection, and shall include any storage or shipping temperature restrictions to which the drug as repackaged shall be limited (see 21 CFR 201.100).■1S (USP28)
Labeling-The term "labeling" designates all labels and other written, printed, or graphic matter upon an immediate container of an article or upon, or in, any package or wrapper in which it is enclosed, except any outer shipping container. The term "label" designates that part of the labeling upon the immediate container.

A shipping container containing a single article, unless such container is also essentially the immediate container or the outside of the consumer package, is labeled with a minimum of product identification (except for controlled articles), lot number, expiration date, and conditions for storage and distribution.
Articles in this Pharmacopeia are subject to compliance with such labeling requirements as may be promulgated by governmental bodies in addition to the Pharmacopeial requirements set forth for the articles.
Amount of Ingredient per Dosage Unit-The strength of a drug product is expressed on the container label in terms of micrograms or milligrams or grams or percentage of the therapeutically active moiety or drug substance, whichever form is used in the title, unless otherwise indicated in an individual monograph. Both the active moiety and drug substance names and their equivalent amounts are then provided in the labeling.
Pharmacopeial articles in capsule, tablet, or other unit dosage form shall be labeled to express the quantity of each active ingredient or recognized nutrient contained in each such unit; except that, in the case of unit-dose oral solutions or suspensions, whether supplied as liquid preparations or as liquid preparations that are constituted from solids upon addition of a designated volume of a specific diluent, the label shall express the quantity of each active ingredient or recognized nutrient delivered under the conditions prescribed in Deliverable Volume $\langle 698\rangle$. Pharmacopeial drug products not in unit dosage form shall be labeled to express the quantity of each active ingredient in each milliliter or in each gram, or to express the percentage of each such ingredient (see Percentage Measurements), except that oral liquids or solids intended to be constituted to yield oral liquids may, alternatively, be labeled in terms of each $5-\mathrm{mL}$ portion of the liquid or resulting liquid. Unless otherwise indicated in a monograph or chapter, such declarations of strength or quantity shall be stated only in metric units (see also Units of Potency in these General Notices).
Use of Leading and Terminal Zeros-In order to help minimize the possibility of errors in the dispensing and administration of drugs, the quantity of active ingredient when expressed in whole numbers shall be shown without a decimal point that is followed by a terminal zero (e.g., express as 4 mg [not 4.0 mg$]$ ). The quantity of active ingredient when expressed as a decimal number smaller than one shall be shown with a zero preceding the decimal point (e.g., express as 0.2 mg [not .2 mg$]$ ).

Labeling of Salts of Drugs-It is an established principle that Pharmacopeial articles shall have only one official name. For purposes of saving space on labels, and because chemical symbols for the most common inorganic salts of drugs are well known to practitioners as synonymous with the written forms, the following alternatives are permitted in labeling official articles that are salts: HCl for hydrochloride; HBr for hydrobromide; Na for sodium; and K for potassium. The symbols Na and K are intended for use in abbreviating names of the salts of organic acids; but these symbols are not used where the word Sodium or Potassium appears at the beginning of an official title (e.g., Phenobarbital Na is acceptable, but Na Salicylate is not to be written).

Labeling Vitamin-Containing Products-The vitamin content of an official drug product shall be stated on the label in metric units per dosage unit. The amounts of vitamins A, D, and E may be stated also in USP Units. Quantities of vitamin A declared in metric units refer to the equivalent amounts of retinol (vitamin A alcohol). The label of a nutritional supplement shall bear an identifying lot number, control number, or batch number.

## ${ }^{4}$ Labeling Botanical-Containing Products-The label

of an herb or other botanical intended for use as a dietary supplement bears the statement, "If you are pregnant or nursing a baby, seek the advice of a health professional before using this product." $\mathbf{\Delta U S P 2 8}$

Labeling Parenteral and Topical Preparations-The label of a preparation intended for parenteral or topical use states the names of all added substances (see Added Substances in these General Notices and Requirements, and see Labeling under Injections $\langle 1\rangle$ ), and, in the case of parenteral preparations, also their amounts or proportions, except that for substances added for adjustment of pH or to achieve isotonicity, the label may indicate only their presence and the reason for their addition.

Labeling Electrolytes-The concentration and dosage of electrolytes for replacement therapy (e.g., sodium chloride or potassium chloride) shall be stated on the label in milliequivalents ( mEq ). The label of the product shall indicate also the quantity of ingredient(s) in terms of weight or percentage concentration.

Labeling Alcohol-The content of alcohol in a liquid preparation shall be stated on the label as a percentage ( $\mathrm{v} / \mathrm{v}$ ) of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$.

Special Capsules and Tablets-The label of any form of Capsule or Tablet intended for administration other than by swallowing intact bears a prominent indication of the manner in which it is to be used.

Expiration Date and Beyond-Use Date-The label of an official drug product, nutritional or dietary supplement product shall bear an expiration date. All articles shall display the expiration date so that it can be read by an ordinary individual under customary conditions of purchase and use. The expiration date shall be prominently displayed in high contrast to the background or sharply embossed, and easily understood (e.g., "EXP 6/89," "Exp. June 89," or "Expires 6/89"). [NOTE-For additional information and guidance, refer to the Nonprescription Drug Manufacturers Association's Voluntary Codes and Guidelines of the OTC Medicines Industry.]

The monographs for some preparations state how the expiration date that shall appear on the label is to be determined. In the absence of a specific requirement in the individual monograph for a drug product or nutritional supplement, the label shall bear an expiration date assigned for the particular formulation and package of the article, with the following exception: the label need not show an expiration date in the case of a drug product or nutritional supplement packaged in a container that is intended for sale without prescription and the labeling of which states no dosage limitations, and which is stable for not less than 3 years when stored under the prescribed conditions.

Where an official article is required to bear an expiration date, such article shall be dispensed solely in, or from, a container labeled with an expiration date, and the date on which the article is dispensed shall be within the labeled expiry period. The expiration date identifies the time during which the article may be expected to meet the requirements of the Pharmacopeial monograph, provided it is kept under the prescribed storage conditions. The expiration date limits the time during which the article may be dispensed or used. Where an expiration date is stated only in terms of the month and the year, it is a representation that the intended expiration date is the last day of the stated month. The beyond-use
date is the date after which an article must not be used. The dispenser shall place on the label of the prescription container a suitable beyond-use date to limit the patient's use of the article based on any information supplied by the manufacturer and the General Notices and Requirements of this Pharmacopeia. The beyond-use date placed on the label shall not be later than the expiration date on the manufacturer's container.

For articles requiring constitution prior to use, a suitable be-yond-use date for the constituted product shall be identified in the labeling.

For all other dosage forms, in determining an appropriate period of time during which a prescription drug may be retained by a patient after its dispensing, the dispenser shall take into account, in addition to any other relevant factors, the nature of the drug; the container in which it was packaged by the manufacturer and the expiration date thereon; the characteristics of the patient's container, if the article is repackaged for dispensing; the expected storage conditions to which the article may be exposed; any unusual storage conditions to which the article may be exposed; and the expected length of time of the course of therapy. The dispenser shall, on taking into account the foregoing, place on the label of a multipleunit container a suitable beyond-use date to limit the patient's use of the article. Unless otherwise specified in the individual monograph, or in the absence of stability data to the contrary, such be-yond-use date shall be not later than (a) the expiration date on the manufacturer's container, or (b) one year from the date the drug is dispensed, whichever is earlier. For nonsterile solid and liquid dosage forms that are packaged in single-unit and unit-dose containers, the beyond-use date shall be one year from the date the drug is packaged into the single-unit or unit-dose container or the expiration date on the manufacturer's container, whichever is earlier, unless stability data or the manufacturer's labeling indicates otherwise.

The dispenser must maintain the facility where the dosage forms are packaged and stored, at a temperature such that the mean kinetic temperature is not greater than $25^{\circ}$. The plastic material used in packaging the dosage forms must afford better protection than polyvinyl chloride, which does not provide adequate protection against moisture permeation. Records must be kept of the temperature of the facility where the dosage forms are stored, and of the plastic materials used in packaging.

Pharmaceutical Compounding-The label on the container or package of an official compounded preparation shall bear a be-yond-use date. The beyond-use date is the date after which a compounded preparation is not to be used. Because compounded preparations are intended for administration immediately or following short-term storage, their beyond-use dates may be assigned based on criteria different from those applied to assigning expiration dates to manufactured drug products.

The monograph for an official compounded preparation typically includes a beyond-use requirement that states the time period following the date of compounding during which the preparation, properly stored, is to be used. In the absence of stability information that is applicable to a specific drug and preparation, recommendations for maximum beyond-use dates have been devised for nonsterile compounded drug preparations that are packaged in tight, light-resistant containers and stored at controlled room temperature unless otherwise indicated (see Stability Criteria and Beyond-Use Dating under Stability of Compounded Preparations in the general tests chapter ${ }^{\boldsymbol{\wedge}}$ Pharmaceutical Compounding-Nonsterile Preparations $\mathbf{\Delta U S P 2 7}$ (795〉).
-Guidelines for Packaging and Storage Statements in USP-NF Monographs

In order to provide users of the $U S P-N F$ with proper guidance on how to package and store compendial articles, every monograph in the $U S P-N F$ is required to have a packaging and storage specification.

For those instances where, for some reason, storage information is not yet found in the Packaging and storage specification of a monograph, the section Storage Under NonSpecific Conditions is included in the General Notices as interim guidance. The Storage Under Nonspecific Conditions statement is not meant to substitute for the inclusion of proper, specific storage information in the Packaging and storage statement of any monograph.

For the packaging portion of the statement, the choice of containers is given in the General Notices and includes Light-Resistant Container, Well-Closed Container, Tight Container, Hermetic Container, Single-Unit Container, Sin-gle-Dose Container, Unit-Dose Container, and Unit-of-Use Container. For most preparations, the choice is determined by the container in which it is to be dispensed (e.g., tight, well-closed, hermetic, unit-of-use, etc). For active pharmaceutical ingredients (APIs), the choice would appear to be tight, well-closed, or, where needed, a light-resistant container. For excipients, given their typical nature as large-volume commodity items, with containers ranging from drums to tank cars, a well-closed container is an appropriate default. Therefore, in the absence of data indicating a need for a more protective class of container, the phrase "Preserve in well-closed containers" should be used as a default for excipients.

For the storage portion of the statement, the choice of stor age temperatures presented in the General Notices includes Freezer, Cold, Cool, Room Temperature, Controlled Room Temperature, Warm, Excessive Heat, and Protection from Freezing. The definition of a dry place is provided if protection from humidity is important.

For most preparations, the choice is determined by the experimentally determined stability of the preparation and may include any of the previously stated storage conditions as determined by the manufacturer. For APIs that are expected to be retested before incorporation into a preparation, a more general and nonrestrictive condition may be desired. In this case, the specification "room temperature" (the temperature prevailing in a working area) should suffice. The use of the permissive room temperature condition reflects the stability of an article over a wide temperature range. For excipients, the phrase "No storage requirements specified" in the Packaging and storage statement of the monograph would be appropriate.
Because most APIs in the $U S P-N F$ have associated Reference Standards, special efforts should be considered to ensure that the Reference Standards' storage conditions correspond to the conditions indicated in the $U S P-N F$ monographs.

The Packaging, Storage, and Distribution Expert Committee may review questionable Packaging and storage statements on a case-by-case basis. In cases where the Packaging and storage statements are incomplete, the monographs would move forward to publication while the Packaging and storage statements are temporarily deferred. 1 (USP28)

## MONOGRAPHS (USP)

## BRIEFING

> Acetaminophen Oral Suspension, USP 27 page 18, page 3037 of the First Supplement, and page 40 of PF $30(1)$ [Jan.-Feb. 2004$]$. On the basis of comments received, it is proposed to add a limit test for 4-aminophenol.
(PA2: C. Anthony) RTS-41505-1

## Change to read:

USP Reference standards $\langle 11\rangle$ —USP Acetaminophen $R S$.

## Add the following:

${ }^{\Delta}$ Uniformity of dosage units $\langle 905\rangle-$
FOR ORAL SUSPENSION PACKAGED IN SINGLE-UNIT CON-
TAINERS: meets the requirements. $\triangle$ USP 28

## Add the following:

${ }^{\Delta}$ Deliverable volume $\langle 698\rangle$ -
FOR ORAL SUSPENSION PACKAGED IN MULTIPLE-UNIT CON-
TAINERS: meets the requirements. $\Delta$ USP28

## Add the following:

## -Limit of 4-aminophenol-

Diluent-Prepare a mixture of water, methanol, and formic acid ( $425: 75: 2$ ).

Mobile phase-Prepare a filtered and degassed mixture of 0.01 M sodium butanesulfonate in Diluent. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Standard solution-Dissolve an accurately weighed quantity of USP 4-Aminophenol RS, and dilute quantitatively, and stepwise if necessary, with Mobile phase to obtain a solution having a known concentration of about $24 \mu \mathrm{~g}$ per mL .
Test solution-Transfer an accurately measured portion of Oral Suspension, equivalent to about 120 mg of acetaminophen, to a $25-\mathrm{mL}$ volumetric flask, dissolve in and dilute with Mobile phase to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a $272-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 20-\mathrm{cm}$ column that contains $10-\mu \mathrm{m}$ packing L1. The flow rate is about 2.0 mL per minute. Chromatograph the Standard solution and Test solution, and record the peak areas as directed for Procedure.

Procedure-Separately inject equal volumes (about $20 \mu \mathrm{~L}$ ) of the Standard solution and the Test solution into the chromatograph, record the chromatograms, and measure the areas for the major peaks: the peak area of 4-aminophenol obtained from the Test solution is not greater than the corresponding peak area obtained from the Standard solution. nS $^{\text {S (USP28) }}$

## Briefing

Acetohydroxamic Acid, USP 27 page 43. It is proposed to clarify the calculations in the test for Limit of hydroxylamine.
(PA4: E. Gonikberg) RTS-41555-1

## Change to read:

## Limit of hydroxylamine-

Phosphate buffer-Dissolve 1.36 g of monobasic potassium phosphate in about 950 mL of water, adjust with 1 M potassium hydroxide to a pH of 7.4 , dilute with water to 1000 mL , and mix.

Pyridoxal 5-phosphate solution-Dissolve 50 mg of pyridoxal 5-phosphate monohydrate in 50 mL of Phosphate buffer in a low-actinic flask. Prepare fresh before use.
Standard solutions-Dissolve an accurately weighed quantity of hydroxylamine hydrochloride in water to obtain a final concentration of 2.0 mg per mL . To separate $100-\mathrm{mL}$ volumetric flasks, transfer $5.0,10.0$, and 15.0 mL of the hydroxylamine stock solution, respectively, dilute each flask with water to volume, and mix.

Test solution-Transfer an accurately weighed quantity of about 1500 mg of Acetohydroxamic Acid, previously dried, to a $100-\mathrm{mL}$ beaker, and dissolve in a sufficient amount of water to cover the electrode of a calibrated pH meter (about 60 mL ). While stirring, adjust with 0.05 M potassium hydroxide to a pH of 7.4. Quantitatively transfer the contents of the beaker, with the aid of small portions of water, to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix.

Procedure-Transfer 2.0 mL of each Standard solution and the Test solution into separate $100-\mathrm{mL}$ volumetric flasks. Pipet 2.0 mL of water into a $100-\mathrm{mL}$ volumetric flask for the reagent blank. To each flask, add 4.0 mL of Pyridoxal 5-phosphate solution, and mix. After 8 minutes, accurately timed, dilute the contents of each flask with Phosphate buffer to volume. Immediately determine the fluorescence intensities of the solutions from the Standard solutions and the Test solution in a fluorometer at an excitation wavelength of 350 nm and an emission wavelength of 450 nm , setting the instrument to zero with the reagent blank. Determine the best-fit straight line from the fluorescence intensities of the three Standard solutions versus the hydroxylamine hydrochloride concentrations, in $\mu \mathrm{g}$ per mL . From the best-fit straight line, determine the concentration, in $\mu \mathrm{g}$ per mL , of hydroxylamine hydrochloride
$■_{\text {in }}$ the Test solution. Calculate the percentage of hydroxyl-
amine $_{\text {п2S }}$ (USP28)
in the portion of Acetohydroxamic Acid taken by the formula:

$$
(33.03 / 69.50)(10 C / W)
$$

in which 33.03 and 69.50 are the molecular weights of hydroxylamine and hydroxylamine hydrochloride, respectively; $C$ is the concentration, in $\mu \mathrm{g}$ per mL , of hydroxylamine hydrochloride in the Test solution; and $W$ is the weight, in mg , of Acetohydroxamic Acid taken. Not more than $0.5 \%$ is found.

Acyclovir, USP 27 page 47, page 3039 of the First Supplement, and page 1143 of $P F 30$ (4) [July-Aug. 2004]. On the basis of comments received, it is proposed to revise the column dimensions for the Chromatographic system in the Assay and limit for guanine.
(PA7b: B. Davani) RTS-41388-1

## Add the following:

-Labeling-Where it is intended for use in preparing injectable dosage forms, the label states that it is sterile or must be subjected to further processing during the preparation of injectable dosage forms.■1S (USP28)

## Add the following:

-Other requirements-Where the label states that Acyclovir is sterile, it meets the requirements for Sterility and Bacterial endotoxins under Acyclovir for Injection. Where the label states that Acyclovir must be subjected to further processing during the preparation of injectable dosage forms, it meets the requirements for Bacterial endotoxins under Acyclovir for Injection.■1S (USP28)

## Change to read:

## Assay and limit for guanine-

Mobile phase-Prepare a filtered and degassed solution of glacial acetic acid in water ( 1 in 1000). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).
-System suitability solution 1-Dissolve accurately weighed quantities of USP Acyclovir RS and guanine in 0.1 N sodium hydroxide, and dilute quantitatively, and stepwise if necessary, with water to obtain a solution having known concentrations of about 0.1 mg of each per mL .

System suitability solution 2-Dissolve an accurately weighed quantity of guanine in 0.1 N sodium hydroxide, and dilute quantitatively, and stepwise if necessary, with water to obtain a solution having a known concentration of about $0.7 \mu \mathrm{~g}$ per $\mathrm{mL} . \bullet 4$

Guanine standard preparation-Transfer about 8.75 mg of guanine, accurately weighed, to a $500-\mathrm{mL}$ volumetric flask. Dissolve in 50 mL of 0.1 N sodium hydroxide, dilute with water to volume, and mix. ${ }^{\bullet}$ Transfer 2.0 mL of this solution to a $50-\mathrm{mL}$ volumetric flask, dilute with 0.01 N sodium hydroxide to volume, and mix to obtain a solution having a known concentration of about $0.7 \mu \mathrm{~g}$ per $\mathrm{mL} . \bullet 4$

Standard preparation-Dissolve about 25 mg of USP Acyclovir RS, accurately weighed, in 5 mL of 0.1 N sodium hydroxide in a $50-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. Transfer 10.0 mL of this solution ${ }^{\circ}$ to a $50-\mathrm{mL}$ volumetric flask, dilute with 0.01 N sodium hydroxide to volume, and mix to obtain a solution having ${ }^{\bullet}$ a known concentration of about 0.1 mg of USP Acyclovir RS per mL.

Assay preparation-Dissolve about 100 mg of Acyclovir, accurately weighed, in 20 mL of 0.1 N sodium hydroxide in a 200mL volumetric flask, dilute with water to volume, and mix. Transfer 10.0 mL of this solution to a $50-\mathrm{mL}$ volumetric flask, dilute with 0.01 N sodium hydroxide to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )—The liquid chromatograph is equipped with a $254-\mathrm{nm}$ detector and a $4.2 \mathrm{~mm} \times 30 \mathrm{~cm}$
-4.6-mm $\times 25-\mathrm{cm}_{\square 2 \mathrm{~S}}$ (USP28)
column that contains packing L1. The flow rate is about 3 mL per minute. Chromatograph ${ }^{\bullet}$ System suitability solution $1, \bullet 4$ and record the peak responses as directed for Procedure: the resolution, $R$, between acyclovir and guanine is not less than 2.0 ; the tailing factor for the analyte peak is not more than 2 ; and the relative standard deviation for replicate injections ${ }^{\bullet}$ for the acyclovir peak ${ }_{\bullet 4}$ is not more than $2.0 \%$. Chromatograph System suitability solution 2, and record the peak responses as directed for Procedure: the relative standard deviation for replicate injections is not more than 2.0\%. $\quad 4$

Procedure-Separately inject equal volumes (about $20 \mu \mathrm{~L}$ ) of the Standard preparation, ${ }^{\bullet}$ Guanine standard preparation, $\bullet_{4}$ and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for all the peaks. Calculate the quantity, in $\mu \mathrm{g}$, of guanine in the portion of Acyclovir taken by the formula:

$$
1000 C\left(r_{U} / r_{S}\right)
$$

in which $C$ is the concentration, in $\mu \mathrm{g}$ per mL , of guanine in the ${ }^{\bullet}$ Guanine standard preparation; and $r_{U}$ and $r_{S}$ are the peak responses due to guanine in the Assay preparation and the ${ }^{\bullet}$ Guanine standard preparation, $\bullet 4$ respectively: not more than $0.7 \%$ of guanine is found. Calculate the quantity, in mg, of $\mathrm{C}_{8} \mathrm{H}_{11} \mathrm{~N}_{5} \mathrm{O}_{3}$ in the portion of Acyclovir taken by the formula:

$$
1000 C\left(r_{U} / r_{S}\right)
$$

in which $C$ is the concentration, in mg per mL , of USP Acyclovir RS in the Standard preparation; and $r_{U}$ and $r_{S}$ are the peak responses due to acyclovir in the Assay preparation and the Standard preparation, respectively.

## BriEfing

Alcohol in Dextrose Injection, USP 27 page 61 and page 3041 of the First Supplement; Anticoagulant Citrate Dextrose Solution, USP 27 page 157; Bretylium Tosylate in Dextrose Injection, $U S P 27$ page 264; Bupivacaine Hydrochloride in Dextrose Injection, USP 27 page 277; Ciprofloxacin Injection, USP 27 page 456 and page 813 of $P F 30(3)$ [May-June 2004]; Dextrose Injection, USP 27 page 582; Dextrose and Sodium Chloride Injection, USP 27 page 582; Dobutamine in Dextrose Injection, USP 27 page 652; Dopamine Hydrochloride and Dextrose Injection, $U S P 27$ page 661; Multiple Electrolytes and Dextrose Injection Type 1, USP 27 page 690 and page 838 of PF 30(3) [May-June 2004]; Lidocaine Hydrochloride and Dextrose Injection, USP 27 page 1089; Potassium Chloride in Dex-
trose Injection, USP 27 page 1516; Potassium Chloride in Dextrose and Sodium Chloride Injection, USP 27 page 1517; Oral Rehydration Salts, USP 27 page 1630; Ringer's and Dextrose Injection, USP 27 page 1657 and page 1293 of $P F$ 30(4) [July-Aug. 2004]; Sodium Chloride and Dextrose Tablets, USP 27 page 1702; Tetracaine Hydrochloride in Dextrose Injection, $U S P 27$ page 1799; Theophylline in Dextrose Injection, USP 27 page 1815. It is proposed to revise the Assay for dextrose procedure by updating the formula to directly calculate the percentage (g per 100 mL ) of dextrose. Formulas are provided to accommodate the use of either anhydrous dextrose or dextrose monohydrate, as specified in each monograph. The proposed formula uses a value of $52.9^{\circ}$, the midpoint of the current specific rotation range for anhydrous dextrose, as indicated in the Dextrose monograph. This replaces the current factor of 1.0425 percent per degree, which was based on a superseded value of $52.75^{\circ}$ for the specific rotation for anhydrous dextrose. Because the procedure contains a reference to Optical Rotation $\langle 781\rangle$, which specifies performing the test at $25^{\circ}$ unless otherwise specified in the individual monograph, all monograph references to $25^{\circ}$ are proposed for deletion.
(PA1: K. Russo; PA2: C. Anthony) RTS-41401-14

## Change to read:

Assay for dextrose-Transfer an accurately measured volume of Injection, containing from 2 to 5 g of dextrose, to a $100-\mathrm{mL}$ volumetric flask. Add 0.2 mL of 6 N ammonium hydroxide, dilute with water to volume, and mix. Determine the angular rotation in a 200 man tube at $25^{\circ}$ (see Optical Rotation- 784 ) ). The observed rota tion in degrees, multiplied by 1.0425 , represents the weight, in $\frac{g}{5}$, of $\mathrm{C}_{6} \mathrm{H}_{42} \mathrm{\theta}_{6} \cdot \mathrm{H}_{2} \mathrm{O}$ - in the volume of Injection taken.
 Calculate the percentage ( g per 100 mL ) of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}$ in the portion of Injection taken by the formula:
$(100 / 52.9)(198.17 / 180.16) A R$,
in which 100 is percent; 52.9 is the midpoint of the specific rotation range for anhydrous dextrose, in degrees; 198.17 and 180.16 are the molecular weights for dextrose monohydrate and anhydrous dextrose, respectively; $A$ is 100 mm divided by the length of the polarimeter tube, in mm ; and $R$ is the observed rotation, in degrees. $\quad$ 2S (USP28)

## Briefing

Alprazolam Tablets, $U S P 27$ page 65 and page 51 of $P F 30(1)$ [Jan.-Feb. 2004]. It is proposed to delete the wavelengths in which it has been demonstrated that excipients could present signals that interfere in the Identification test.
(PA3: S. Salado) RTS-41359-1

## Change to read:

Identification-Dissolve an amount of finely powdered Tablets, equivalent to about 15 mg of alprazolam, in 10 mL of sodium carbonate solution ( 1 in 100 ). Add 15 mL of chloroform, and shake vigorously for 30 minutes. Centrifuge, withdraw the aqueous layer, and transfer the chloroform to a clean container. Add about 200 mg of potassium bromide. Evaporate the chloroform from this mixture to dryness, and dry the dispersion in vacuum at $60^{\circ}$ for 24 hours. Grind this dispersion into a fine powder. Prepare a suitable pellet for testing by placing about 100 mg of dried potassium bromide into a die. Sprinkle about 20 mg of the finely ground, alprazo-lam-potassium bromide dispersion onto the dried potassium bromide layer, and cover with another specimen of about 100 mg of dried potassium bromide: the IR absorption spectrum of the potassium bromide dispersion so obtained exhibits maxima characteristic of alprazolam, as compared to that of a similar preparation of USP Alprazolam RS, at the following wavenumbers: at 1609 , 1578, 1566, 1539, 1530,

```
■_2S (USP28)
1487,4.445, 1428,
■■2S(USP28)
and 1379,4337, and 1320
```

■ $\mathbf{m}_{2 S}$ (USP28)
wavenumbers in the region of 1650 to $1300 \mathrm{~cm}^{-1}$; at 970,
■ $\mathbf{m}_{2 S}$ (USP28)
932, 891, 826, 797,
■ $\mathbf{n}_{2 S}$ (USP28)
$779,746,696$, and 669,

Buffer solution-Prepare a 1 in 10 dilution of Stock buffer solution in water to obtain a Working buffer solution having a pH of $6.0 \pm 0.1$.

Medium: Buffer solution; 500 mL .
Apparatus 1: 100 rpm .
Time: 30 minutes.
Procedure-
Stock standard solution-Prepare a solution in methanol of USP Alprazolam RS having a known concentration of about 0.05 mg per mL.
Standard solution-Add 50 mL of Stock buffer solution and 250 mL of water to a $500-\mathrm{mL}$ volumetric flask. Add to the flask 5.0 mL of Stock standard solution for every 0.25 mg of alprazolam contained in the Tablet being assayed. Dilute with water to volume, and mix.

Mobile phase-Prepare a degassed and filtered solution of Buffer solution, acetonitrile, and tetrahydrofuran ( $60: 35: 5$ ). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Chromatographic system (see Chromatography $\langle 621\rangle$ )—The liquid chromatograph is equipped with a $254-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 10-\mathrm{cm}$ analytical column that contains packing L7. The flow rate is about 1 mL per minute. Chromatograph the Standard solution, and record the peak responses as directed for Procedure: the column efficiency is not less than 500 theoretical plates, and the relative standard deviation for replicate injections is not more than $3.0 \%$.

Procedure-
-Proceed as directed for Procedure for Capsules, Uncoated Tablets, and Plain Coated Tablets under Dissolution $\langle 711\rangle$. Combine equal volumes of the filtered solutions of the 6 or 12 individual specimens withdrawn, and use the pooled
sample as the test solution.■1S (USP28)
Separately inject equal volumes of a filtered pertion of the solution under test
$\mathbf{m}_{\text {of the pooled sample }}{ }_{\text {Q1S (USP28) }}$
and the Standard solution into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the quantity of $\mathrm{C}_{17} \mathrm{H}_{13} \mathrm{ClN}_{4}$ dissolved based on the peak responses obtained from the solution under test and the Standard solution.

Tolerances-Not less than $80 \%(Q)$ of the labeled amount of $\mathrm{C}_{17} \mathrm{H}_{13} \mathrm{ClN}_{4}$ is dissolved in 30 minutes:
-the requirements are met if the quantities of active ingredients dissolved from the pooled sample conform to the accompanying Acceptance Table for a Pooled Sample. Continue testing through the three stages unless the results conform at either $\mathrm{S}_{1}$ or $\mathrm{S}_{2}$. The quantity, $Q$, is the amount of dissolved active ingredient of interest expressed as a percentage of the labeled content.

Acceptance Table for a Pooled Sample
Number
Stage Tested Acceptance Criteria
$\mathrm{S}_{1} \quad 6 \quad$ Average amount dissolved is not less than $Q+10 \%$.
$\mathrm{S}_{2} \quad 6 \quad$ Average amount dissolved $\left(\mathrm{S}_{1}+\mathrm{S}_{2}\right)$ is equal to or greater than $Q+5 \%$.
$\mathrm{S}_{3} \quad 12$ Average amount dissolved $\left(\mathrm{S}_{1}+\mathrm{S}_{2}+\right.$ $\mathrm{S}_{3}$ ) is equal to or greater than $Q$.

Amoxicillin Capsules, USP 27 page 139. It is proposed to revise the Apparatus in the test for Dissolution to include the Capsules strength in accordance with the approved test for this product.

Dissolution $\langle 711\rangle$ -
Medium: water; 900 mL .
Apparatus 1: 100 rpm ,

- for Capsules containing 250 mg .

Apparatus 2: 75 rpm , for Capsules containing 500
mg. ■2S $_{\text {(USP28) }}$
Time: 60 minutes.
Procedure-Determine the amount of $\mathrm{C}_{16} \mathrm{H}_{19} \mathrm{~N}_{3} \mathrm{O}_{5} \mathrm{~S}$ dissolved by employing UV absorption at the wavelength of maximum absorbance at about 272 nm on filtered portions of the solution under test, suitably diluted with water, if necessary, in comparison with a Standard solution having a known concentration of USP Amoxicillin RS in the same Medium.

Tolerances-Not less than $80 \%(Q)$ of the labeled amount of $\mathrm{C}_{16} \mathrm{H}_{19} \mathrm{~N}_{3} \mathrm{O}_{5} \mathrm{~S}$ is dissolved in 60 minutes.

Briefing

Anticoagulant Citrate Dextrose Solution, USP 27 page 157See briefing under Alcohol in Dextrose Injection.

## Change to read:

Assay for dextrose-Determine the angular rotation of Solution in a 200 -mm tube, using sodium light at $25^{\circ}$. The observed rotation in degrees, multiplied by 1.0425 , represents the weight of $\mathrm{E}_{6} \mathrm{H}_{12} \Theta_{6} \cdot \mathrm{H}_{2} \mathrm{Q}$ in 100 mL of the solution.

■suitable polarimeter tube (see Optical Rotation $\langle 781\rangle$ ). Where the Solution is labeled to contain anhydrous dextrose, calculate the percentage (g per 100 mL ) of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ in the portion of Solution taken by the formula:

$$
(100 / 52.9) A R
$$

in which 100 is percent; 52.9 is the midpoint of the specific rotation range for anhydrous dextrose, in degrees; $A$ is 100 mm divided by the length of the polarimeter tube, in mm ; and $R$ is the observed rotation, in degrees. Where the Solution is labeled to contain dextrose monohydrate, calculate the percentage ( g per 100 mL ) of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}$ in the portion of Solution taken by the formula:

$$
(100 / 52.9)(198.17 / 180.16) A R
$$

in which 100 is percent; 52.9 is the midpoint of the specific rotation range for anhydrous dextrose, in degrees; 198.17 and 180.16 are the molecular weights for dextrose monohydrate and anhydrous dextrose, respectively; $A$ is 100 mm divided by the length of the polarimeter tube, in mm ; and $R$ is the observed rotation, in degrees.■2S (USP28)

## Briefing

Betahistine Hydrochloride, page 1008 of $P F$ 29(4) [July-Aug. 2003]. On the basis of comments received, it is proposed to replace the TLC analysis in the Related compounds section with an HPLC method. An analogous method is also proposed for the Assay. Validation of the method was done using Zorbax Eclipse XDB-C18, $5-\mu \mathrm{m}$, brand of L1 packing. The typical retention time for the betahistine peak is 8 minutes.
(PA5: A. Wilk) RTS-40643-1

2-[2-(Methylamino)ethyl]pyridine dihydrochloride [5579-84-0].
» Betahistine Hydrochloride contains not less than 99.0 percent and not more than 101.0 percent of $\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{~N}_{2} \cdot 2 \mathrm{HCl}$, calculated on the dried basis. sistant containers.

USP Reference standards $\langle 11\rangle$ —USP Betahistine Hydrochloride RS.

## Identification-

A: Infrared Absorption $\langle 197 \mathrm{~K}\rangle$.
B: The $R_{L}$ value and intensity of the prineipal spet in the ehromatogram of Test solution 2 correspend to these in the ehromatogram of Stadeld solution 1, obtained as directed

The Rels. The retention time of the major peak in the chromatogram of the Assay preparation corresponds to that in the chromatogram of the Standard preparation, as obtained in the Assay.
$\mathbf{p H}\langle 791\rangle$ : between 2.0 and 3.0, in a solution (1 in 10).
Loss on drying $\langle 731\rangle$ - Dry it between $100^{\circ}$ and $105^{\circ}$ to constant weight: it loses not more than $0.5 \% 1.0 \%$ of its weight.

Residue on ignition $\langle 281\rangle$ : not more than $0.1 \%$.
Related compounds-

gel mixture.
Diltent Prepare a mixture-of aleohel and water (3:1).
Fest solution 1 Dissolve about 250 mg of Betahistime
Hydrechloride, aceurately weighed, in 5.0 mL of Piltumt.
Test selution 2 Dilute 1.0 mL of Test solution 1 with Dil tent $40-25.0 \mathrm{~mL}$, and mix.
Resolution solution Pepare a solution of USP Betahis tine Hydrochloride RS and 2 vinylpyridine in Diluent containing 1.0 mg of each per mL .
Standerd solution - Prepare a solution of USP Betahistine Hydrochloride RS in Diltent containing 2.0 mg per mL. Standard solution 2 Dilute 1.0 mL of Standard solution -with Diluent to 20.0 mL . Dilute 1.0 mL of this solution with Diluent to 20.0 mL , and mix.

Standerd solution - 3 Dilute 5.0 mL of Standard solution
2 with Diluent to 5.0 mL , and mix.
Application valtme: $5 \mu \mathrm{H}$.
Beveloping solvent system:-a mixttre of toluene, abso-
tute aleohel, and ammenimm hydroxide ( $10: 5: 1$ ).
Procedure Proceed as directed for Thin Lamer Chroma tography under Chromatography $\langle 624$ ), except to developdrythe plate under actrrent of wam air, in a hood, and then dryfollowed by heating for 10 minter at $110^{\circ}$. Examine the plate under short wavelength UV light using a quantitative seanner. The resolution, $R$, between the peaks due to 2 vi
nylpyridine and betahistine in the sean of the chremategram of the Resolution selution is not less than 3.0. The area obtained for any individual impurity is not greater than that obtained for the major peak in the chromatogram of Stan tatrd solution 2: net more than $0.25 \%$ of any individtal im purity is found. The total ameunt of impurities found is net greater than twice the area of the major peak in the same solution: not more than $0.5 \%$ of total impurities is feumd.

Mobile phase and Chromatographic system-Proceed as directed in the Assay.

Test solution-Transfer about 38 mg of Betahistine Hydrochloride, accurately weighed, to a $100-\mathrm{mL}$ volumetric flask, dissolve in and dilute with Mobile phase to volume, and mix.

Procedure-Inject about $10 \mu \mathrm{~L}$ of the Test solution into the chromatograph, record the chromatogram, and measure the peak responses. Calculate the percentage of each impurity in the portion of Betahistine Hydrochloride taken by the formula:

$$
100 F\left(r_{i} / r_{s}\right)
$$

in which $F$ is the response factor of the respective impurity (see Table 1) and 1.0 for all other peaks; $r_{i}$ is the peak response for each impurity; and $r_{s}$ is the sum of the responses of all of the peaks, adjusted for the relative response factor. In addition to not exceeding the limits for impurities in Ta ble 1 , not more than $0.1 \%$ of any other individual impurity is found, and not more than $0.5 \%$ of total impurities is found.

Table 1

| Impurity Name | Relative <br> Retention <br> Time | Response <br> Factor (F) | Limit <br> $(\%)$ |
| :---: | :---: | :---: | :---: |
| 2-(2-Hydroxyethyl) <br> pyridine | 0.3 | 0.5 | 0.2 |
| 2-Vinylpyridine | 0.4 | 0.4 | 0.2 |
| $N$-Methyl- $N, N$-bis(2- <br> pyridin-2-yl-ethyl)- <br> amine | 2.4 | 1.4 | 0.2 |

Assay- Dissolve about 80 mg of Betahistine Hydrechleride, acemrately weighed, in 60 mL of a mixtare of glaciat acetic acid and acetic anhydride ( $5: 1$ ). Titrate with 0.1 N perehloric acid VS, determining the endpoint potentiometrieally, using suitable electrodes (see Titrimetry $\langle 544\rangle$ ). Perform a blank determination, and make any necessary eorrection. Each mL of 0.1 N perchloric acid is equivalent 5 10.455 mg of $\mathrm{G}_{8} \mathrm{H}_{42} \mathrm{~N}_{2}-2 \mathrm{HCl}$.

Ammonium acetate buffer-Dissolve about 0.69 g of ammonium acetate in 1000 mL of water. Adjust with glacial acetic acid to a pH of 4.7 .

Mobile phase-Prepare a filtered and degassed mixture of 350 mL of acetonitrile and 650 mL of Ammonium acetate buffer, containing 2.88 g of sodium lauryl sulfate. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Standard preparation-Dissolve an accurately weighed quantity of USP Betahistine Hydrochloride RS in Mobile phase to obtain a solution having a known concentration of about 0.38 mg per mL .

Assay preparation-Transfer about 38 mg of Betahistine Hydrochloride, accurately weighed, to a $100-\mathrm{mL}$ volumetric flask, dissolve in and dilute with Mobile phase to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )-
The liquid chromatograph is equipped with a 254 -nm detector and $3.0-\mathrm{mm} \times 15-\mathrm{cm}$ column that contains packing L1. The column temperature is maintained at $40^{\circ}$. The flow rate is about 0.5 mL per minute. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the column efficiency is not less than 5000 theoretical plates; the tailing factor for the betahistine peak is not more than 2.0 ; and the relative standard deviation for replicate injections is not more than $2.0 \%$.

Procedure-Separately inject equal volumes (about 10 $\mu \mathrm{L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the quantity, in mg , of $\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{~N}_{2} \cdot 2 \mathrm{HCl}$ in the portion of Betahistine Hydrochloride taken by the formula:

$$
100 C\left(r_{U} / r_{s}\right)
$$

in which $C$ is the concentration, in mg per mL, of USP Betahistine Hydrochloride RS in the Standard preparation; and $r_{U}$ and $r_{S}$ are the peak responses obtained from the Assay preparation and the Standard preparation, respectively. ${ }^{2 S}$ (USP28)

## BRIEFING

Bethanechol Chloride, USP 27 page 242 and page 1848 of $P F$ 29(6) [Nov.-Dec. 2003]. It is proposed to revise the test for Related compounds and the Assay to modify the resolution between 2-hydroxypropyltrimethyl ammonium chloride and bethanechol according to the typical resolution values found for the System
suitability solution. In addition, it is proposed to revise the Buffer solution in the Assay to indicate the use of edetic acid instead of edetate disodium.
(PA3: S. Salado) RTS-41191-1; 41627-1

Add 0.2 mL of 6 N ammonium hydroxide, dilute with water to volume, and mix. Determine the angular rotation in a suitable polarimeter tube at $25^{\circ}$ (see-Optical Rotation $\langle 784$ )). The observed fotation, in degrees, multiplied by 1.0425 , in which 4 is the ratio

200 divided by the length, in mm, of the polarimeter employed, represents the weight, in $\frac{8}{\delta}$, of dextrose $\left(\mathrm{C}_{6} \mathrm{H}_{42} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}\right)$ in the vol ume of Injection taken.
-(see Optical Rotation $\langle 781\rangle$ ). Calculate the percentage ( g per 100 mL ) of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}$ in the portion of Injection taken by the formula:

$$
(100 / 52.9)(198.17 / 180.16) A R
$$

in which 100 is percent; 52.9 is the midpoint of the specific rotation range for anhydrous dextrose, in degrees; 198.17 and 180.16 are the molecular weights for dextrose monohydrate and anhydrous dextrose, respectively; $A$ is 100 mm divided by the length of the polarimeter tube, in mm ; and $R$ is the observed rotation, in degrees. $\quad$ 2S (USP28)

## BRIEFING

Bupivacaine Hydrochloride, USP 27 page 276 and page 1432 of PF 29(5) [Sept.-Oct. 2004]. It is proposed to revise the Chromatographic system in the test for Limit of residual solvents to indicate the use of a $4-\mathrm{mm} \times 2-\mathrm{m}$ column.
(PA1: K. Russo) RTS-41601-1

## Add the following:

-Labeling-Where it is intended for use in preparing injectable dosage forms, the label states that it is sterile or must be subjected to further processing during the preparation of injectable dosage forms.■1S (USP28)

## Change to read:

USP Reference standards $\langle 11\rangle —$ USP Bupivacaine Hydrochloride $R S$.

- USP Endotoxin RS.■1S (USP28)

## Change to read:

## Limit of residual solvents-

Alcohol standard solution-Pipet 2 mL of dehydrated alcohol into a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. Transfer 2.0 mL of this solution to a $50-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. The resulting solution contains $0.08 \%$ of alcohol.

Isopropyl alcohol standard solution-Pipet 2 mL of isopropyl alcohol into a $1000-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. Transfer 2.0 mL of this solution to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. The resulting solution contains $0.004 \%$ of isopropyl alcohol.

Test solution-Transfer 1.0 g of Bupivacaine Hydrochloride, accurately weighed, to a $25-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix.

Chromatographic system-Under typical conditions, the instrument is equipped with a flame-ionization detector and a $2 \rightarrow-6$ mm
-4-mm $\times 2-\mathrm{m}_{\text {nes (USP28) }}$
column that contains packing S3. The carrier gas is nitrogen, flowing at a rate of about 40 mL per minute. The column temperature is maintained at about $175^{\circ}$, the injection port temperature is maintained at about $200^{\circ}$, and the detector temperature is maintained at about $280^{\circ}$.

Procedure-Inject equal volumes (about $5 \mu \mathrm{~L}$ ) of the Test solution, the Alcohol standard solution, and the Isopropyl alcohol standard solution successively into the gas chromatograph. Measure the responses of the alcohol peak and the isopropyl alcohol peak in each chromatogram. Determine the percentage of alcohol taken by the formula:

$$
2\left(r_{U} / r_{S}\right)
$$

and determine the percentage of isopropyl alcohol taken by the formula:

$$
0.1\left(r_{U} / r_{S}\right)
$$

in which $r_{U}$ and $r_{S}$ are the responses of the respective analytes in the Test solution and of the corresponding analytes in the Alcohol standard solution and the Isopropyl alcohol standard solution, respectively. The sum of the content of alcohol and the content of isopropyl alcohol does not exceed $2 \%$.

## Add the following:

-Other requirements-Where the label states that Bupivacaine Hydrochloride is sterile, it meets the requirements for Sterility and Bacterial endotoxins under Bupivacaine Hydrochloride Injection. Where the label states that Bupivacaine Hydrochloride must be subjected to further processing during the preparation of injectable dosage forms, it meets the requirements for Bacterial endotoxins under Bupivacaine Hydrochloride Injection.■1S (USP28)

## Briefing

Assay for dextrose-Determine the angular rotation of Injection in a suitable polarimeter tube (see Optical Rotation $\langle 781\rangle$ ). The ebserved rotation, in degrees, multiplied by $9.452 A$, in whieh $A$ is the ratio of 200 divided by the length, in mm, of the pelarimeter tube mployed, represents the weight, in mg, of dextrese $\left(\mathrm{C}_{6} \mathrm{H}_{42} \Theta_{6}\right)$ in each mL of the Injection.
-Calculate the percentage (g per 100 mL ) of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ in the portion of Injection taken by the formula:
(100/52.9)AR,
in which 100 is percent; 52.9 is the midpoint of the specific rotation range for anhydrous dextrose, in degrees; $A$ is 100 mm divided by the length of the polarimeter tube, in mm ; and $R$ is the observed rotation, in degrees.■2S (USP28)

## Briefing

Caffeine Citrate Injection, page 462 of $P F$ 30(2) [Mar-Apr. 2004]; Caffeine Citrate Oral Solution, page 464 of $P F 30(2)$ [Mar-Apr. 2004]. It is proposed to modify the monographs to express the results in terms of caffeine citrate, the moiety indicated in the title.
(PA3: S. Salado) RTS-41398-1

## Add the following:

## © Caffeine Citrate Injection

## Change to read:

» Caffeine Citrate Injection is a sterile solution containing Gitric Acid and an amount of Caffeine equivalento Caffeine and citric acid in Water for Injection. It contains not less than 90.0 percent and not more than 110.0 percent of the labeled amount of caffeine $\left(\mathrm{C}_{8} \mathrm{H}_{4} \mathrm{~N}_{4} \mathrm{O}_{z}\right) \cdot \mathbf{c}$ citrate
 or other preservative.

Packaging and storage-Preserve in single-dose, tight containers of Type I glass, and store at a temperature between $15^{\circ}$ and $30^{\circ}$.

USP Reference standards $\langle 11\rangle$ —USP Caffeine RS. USP Endotoxin RS.

## Identification-

A: The retention time of the major peak in the chromatogram of the Assay preparation corresponds to that in the chromatogram of the Standard preparation, as obtained in the Assay.

B: It meets the requirements of the test for Citrate $\langle 191\rangle$.

C: Transfer about 4 g of potassium iodide to a $100-\mathrm{mL}$ volumetric flask. Add 10 mL of water, and shake until the potassium iodide is dissolved. Transfer 2 g of iodine to the volumetric flask, and shake until dissolved. Dilute with water to volume, and mix. Transfer 5 drops of the solution so obtained to a $25-\mathrm{mL}$ centrifuge tube containing 5.0 mL of the Injection, and mix. Add 0.5 mL of 2.0 M hydrochloric
acid solution, and mix: a brown precipitate is produced that dissolves on neutralization with 0.5 mL of sodium hydroxide TS.

Color and clarity—Transfer a suitable portion of the Injection to a clear glass test tube, and visually examine the solution in a well-lighted area: the solution is colorless and free of haze, obvious turbidity, and precipitate.

Bacterial endotoxins $\langle 85\rangle$ : not more than 0.25 USP Endotoxin Unit per mg of caffeine.

Sterility $\langle 71\rangle$-It meets the requirements when tested as directed for Membrane Filtration in Test for Sterility of the Product To Be Examined.
$\mathbf{p H}\langle 791\rangle$ : between 4.2 and 5.2.
Particulate matter $\langle 788\rangle$ : not more than 150 particles are equal to or greater than $10 \mu \mathrm{~m}$, and not more than 25 particles are equal to or greater than $25 \mu \mathrm{~m}$.

## Change to read:

## Related compounds-

Mobile phase and Theophylline solution-Proceed as directed in the Assay.
Standard solution-Use the Standard preparation, prepared as directed in the Assay.

System sensitivity solution-Transfer 2.5 mL of the Standard solution to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix.

Test solution-Use the Assay preparation, prepared as directed in the Assay.

Chromatographic system (see Chromatography $\langle 621\rangle$ )Proceed as directed in the Assay. Chromatograph the System sensitivity solution, and record the peak responses as directed for Procedure: the theophylline peak produces a discernible peak response at its retention time.

Procedure-Separately inject equal volumes (about 10 $\mu \mathrm{L}$ ) of the Standard solution and the Test solution into the chromatograph, record the chromatograms, and measure the peak responses. Calculate the percentage of any related compound in the portion of Injection taken by the formula:

$$
100 F\left(G_{s}+G_{\mu}\right)\left(r_{i}+F_{s}\right)
$$

- $100 F(386.31 / 194.19)\left(C_{S} / C_{W}\right)\left(r_{i} / r_{S}\right)$, ■ $^{\text {2S (USP28) }}$
in which $F$ is the relative response factor and is equal to 0.878 for theobromine at a relative retention time of about 0.4 , equal to 1.10 for paraxanthine at a relative retention time of about 0.6 , equal to 0.905 for theophylline at a relative retention time of about 0.7 , and equal to 1.0 for any other related compound; $\mathbf{~} 386.31$ and 194.19 are the molecular weights of caffeine citrate and caffeine, respective$1 \mathrm{y} ; \boldsymbol{m}_{2 S}(U S P 28) C_{S}$ is the concentration, in mg per mL, of USP Caffeine RS in the Standard solution; $C_{W}$ is the caffeine $\mathbf{- c i t r a t e}^{\mathbf{\omega 2 S}}{ }_{(U S P 28)}$ concentration, in mg per mL, in the Test solution, as obtained in the Assay; $r_{i}$ is the individual peak response for each related compound obtained from the Test solution; and $r_{S}$ is the caffeine peak response obtained from the Standard solution: not more than $0.10 \%$ of any individual related compound is found; and not more than $0.1 \%$ of total impurities is found.

Other requirements-It meets the requirements under Injections $\langle 1\rangle$.

## Change to read:

## Assay-

Mobile phase-Prepare a mixture of 0.01 M sodium acetate, acetonitrile, and tetrahydrofuran (191:5:4). Adjust with glacial acetic acid to a pH of 4.5 , filter, and degas. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).
Theophylline solution-Dissolve an accurately weighed quantity of theophylline in water, and dilute quantitatively, and stepwise if necessary, with water, to obtain a solution having a concentration of about 0.02 mg per mL .

Standard preparation-Transfer about 5 mg of USP Caffeine RS, accurately weighed, to a $25-\mathrm{mL}$ volumetric flask. Add 5 mL of Theophylline solution, dissolve in and dilute with water to volume, and mix.

Assay preparation-Transfer an accurately measured volume of Injection, equivalent to about 50 mg of caffeine, to a $250-\mathrm{mL}$ volumetric flask. Dilute with water to volume, mix, and pass through a polyvinylidene difluoride or equivalent membrane having a porosity of $0.45 \mu \mathrm{~m}$.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a $275-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 150-\mathrm{cm}$ column that contains $5-\mu \mathrm{m}$ packing L1. The flow rate is about 1 mL per minute. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the relative retention times are about 0.7 for theophylline and 1.0 for caffeine; the resolution, $R$, between theophylline and caffeine is not less than 6.0 ; the tailing factor, determined from the theophylline and caffeine peaks, is not more than 2.0 ; and the relative standard deviation for replicate injections, determined from the caffeine peaks, is not more than $2.0 \%$.

Procedure-Separately inject equal volumes (about 10 $\mu \mathrm{L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and
measure the caffeine peak responses. Calculate the quantity, in mg, of caffeine $\left(\mathrm{C}_{8} \mathrm{H}_{48} \mathrm{~N}_{4} \mathrm{O}_{2}\right)$ - citrate $\left(\mathrm{C}_{14} \mathrm{H}_{18} \mathrm{~N}_{4}\right.$ $\left.\mathrm{O}_{9}\right)_{■ 2 \text { (USP28) }}$ in the volume of Injection taken by the formula:

$$
250 C\left(r_{4}++_{s}\right)
$$

in which $\quad 386.31$ and 194.19 are the molecular weights of caffeine citrate and caffeine respectively; ${ }^{2 S}$ (USP28) $C$ is the concentration, in mg per mL , of USP Caffeine RS in the Standard preparation; and $r_{U}$ and $r_{S}$ are the peak responses obtained from the Assay preparation and the Standard preparation, respectively.aUSP28

## Change to read:

## Content of benzyl alcohol (if present)-

Solvent mixture-Mix chloroform and methanol ( $4: 1$ ).
Internal standard solution-Prepare a solution of 1-nonyl alcohol in Solvent mixture containing about 1.75 mg per mL .
Standard preparation-Dilute an accurately weighed quantity of benzyl aleohel,
-USP Benzyl Alcohol RS, ${ }_{\text {2S }}$ (USP28)
quantitatively and stepwise, with Solvent mixture to obtain a solution having a known concentration of about 2 mg per mL . Transfer 5.0 mL of this solution and 5.0 mL of Internal standard solution to a $50-\mathrm{mL}$ volumetric flask, dilute with Solvent mixture to volume, and mix.
Test preparation-Transfer 1.0 g of Cream to a $50-\mathrm{mL}$ volumetric flask, add about 30 mL of Solvent mixture, and mix. Add 5.0 mL of Internal standard solution, dilute with Solvent mixture to volume, and mix to obtain a clear solution.
Chromatographic system (see Chromatography $\langle 621\rangle$ )—The gas chromatograph is equipped with a flame-ionization detector and contains a $4-\mathrm{mm} \times 2-\mathrm{m}$ glass column packed with $3 \%$ phase G3 on 100 - to $120-$ mesh support S1AB. The column is maintained at a temperature of about $100^{\circ}$, the injection port and detector temperatures are maintained at about $315^{\circ}$, and nitrogen is used as the carrier gas at a flow rate of about 45 mL per minute. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the resolution, $R$, between the peaks is not less than 1.6; the tailing factor for the benzyl alcohol peak and the internal standard peak is not greater than 3.5 ; and the relative standard deviation for replicate injections is not more than $3 \%$.
Procedure-Separately inject equal volumes (about $2 \mu \mathrm{~L}$ ) of the Standard preparation and the Test preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. [nOTE-After 6 injections, raise the column temperature to about $300^{\circ}$ for about 5 minutes, then cool to $100^{\circ}$.] Calculate the percentage of benzyl alcohol in the Cream taken by the formula:

$$
C\left(R_{U} / R_{S}\right),
$$

in which $C$ is the concentration, in mg per mL , of benzyl alcohol in the Standard preparation; and $R_{U}$ and $R_{S}$ are the peak response ratios of the benzyl alcohol peak to the internal standard peak obtained from the Test preparation and the Standard preparation, respectively: between $90.0 \%$ and $110.0 \%$ of the claimed amount is present.

## Assay-

Mobile phase-Dissolve 10.54 g of monobasic potassium phosphate in 775 mL of water, and adjust with phosphoric acid to a pH of 2.5. Add 225 mL of acetonitrile, mix, and filter. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ). [NOTE-Ensure that the concentration of acetonitrile in the Mobile phase is not less than $22 \%$ and not more than $25 \%$ in order to retain the correct elution order.]

Standard preparation-Dissolve an accurately weighed quantity of USP Clindamycin Phosphate RS in Mobile phase to obtain a solution having a known concentration of about 0.24 mg per mL .

Assay preparation-Transfer an accurately measured volume of Injection, equivalent to about 300 mg of clindamycin, to a $100-\mathrm{mL}$ volumetric flask, dilute with Mobile phase to volume, and mix. Transfer 7.0 mL of the resulting solution to a $100-\mathrm{mL}$ volumetric flask, dilute with Mobile phase to volume, and mix.

Resolution solution-Prepare a solution of benzylaleohel
-USP Benzyl Alcohol RS $\mathbf{R}^{\text {ns }}$ (USP28)
in Mobile phase to obtain a solution having a concentration of about 0.1 mg per mL . Add about 25 mL of this solution to a $100-\mathrm{mL}$ volumetric flask containing about 25 mg of USP Clindamycin Phosphate RS, dilute with Mobile phase to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )—The liquid chromatograph is equipped with a $210-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 25-\mathrm{cm}$ column that contains packing L7. The flow rate is about 1 mL per minute. Chromatograph the Resolution solution, and record the peak responses as directed for Procedure: the relative retention times are 1.0 for clindamycin phosphate and about 1.2 for benzyl alcohol; and the resolution, $R$, between clindamycin phosphate and benzyl alcohol is not less than 2.0. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the relative standard deviation for replicate injections is not more than $2.5 \%$.

Procedure-Separately inject equal volumes (about $20 \mu \mathrm{~L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the quantity, in mg , of clindamycin $\left(\mathrm{C}_{18} \mathrm{H}_{33} \mathrm{ClN}_{2} \mathrm{O}_{5} \mathrm{~S}\right)$ in each mL of the Injection taken by the formula:

$$
(10 / 7)(C P / V)\left(r_{U} / r_{S}\right)
$$

in which $C$ is the concentration, in mg per mL , of USP Clindamycin Phosphate RS in the Standard preparation; $P$ is the potency, in $\mu \mathrm{g}$ of $\mathrm{C}_{18} \mathrm{H}_{33} \mathrm{ClN}_{2} \mathrm{O}_{5} \mathrm{~S}$ per mg, of USP Clindamycin Phosphate RS;
$V$ is the volume, in mL , of Injection taken; and $r_{U}$ and $r_{S}$ are the clindamycin phosphate peak responses obtained from the Assay preparation and the Standard preparation, respectively.

## Briefing

Codeine Phosphate, USP 27 page 505, page 3249 of the Second Supplement, and page 1864 of PF 29(6) [Nov.-Dec. 2003]. On the basis of comments received regarding revisions that appeared in the Second Supplement to USP 27, further revisions to the Packaging and storage section are proposed.
(PA2: C. Anthony) RTS-41188-1

## Change to read:

Packaging and storage-Preserve in tight, light-resistant containers. -Store $25^{\circ}$, exeursions permitted between $15^{\circ}$ and $30^{\circ} \cdot \mathbf{~} 2 S$ (USP27)

- up to $40^{\circ}$, as permitted by the manufacturer.■2S (USP28)

## Add the following:

-Labeling-Where it is intended for use in preparing injectable dosage forms, the label states that it is sterile or must be subjected to further processing during the preparation of injectable dosage forms.■1S (USP28)

## Change to read:

USP Reference standards $\langle 11\rangle$ —USP Codeine Phosphate RS.

- USP Endotoxin RS.■1S (USP28)

## Add the following:

-Other requirements-Where the label states that Codeine Phosphate is sterile, it meets the requirements for Sterility and Bacterial endotoxins under Codeine Phosphate Injection. Where the label states that Codeine Phosphate must be subjected to further processing during the preparation
of injectable dosage forms, it meets the requirements for Bacterial endotoxins under Codeine Phosphate Injection.■1S (USP28)

## BRIEFING

Cysteine Hydrochloride, USP 27 page 535. It is proposed to make a correction in the text of the Assay.
(HDQ: M. Marques) RTS-41554-1

## Change to read:

Assay-Accurately weigh about 250 mg of Cysteine Hydrochloride into an iodine flask. Add 20 mL of water and 4 g of potassium iodide, and mix to dissolve. Cool the solution in an ice bath, and add 5 mL of 3 N hydrochloric acid and 25.0 mL of 0.1 N iodine VS. Insert the stopper, and allow to stand in the dark for $20 \mathrm{~min}-$ utes. Titrate the excess iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N line
$\mathbf{■}_{\text {Sodium thiosulfate }}{ }_{\square 2 S}$ (USP28)
is equivalent to 15.76 mg of $\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{NO}_{2} \mathrm{~S} \cdot \mathrm{HCl}$.

## BRIEFING

Dalteparin Sodium. Because there is no existing USP monograph for this article, a new monograph is being proposed. The liquid chromatographic procedure for the determination of Molar ratio of sulfate to carboxylate is based on analyses performed on a Dowex 1X8 ( $1.5 \mathrm{~cm} \times 2.5 \mathrm{~cm}$, 200-400 mesh, Fluka) anion exchange column and a Dowex $50 \mathrm{WX} 2\left(\mathrm{H}^{+}\right)(1.5 \mathrm{~cm} \times 7.5 \mathrm{~cm}, 100-$ 200 mesh, Fluka) cation exchange column, in series.
(BBP: R. Tirumalai) RTS-41501-1

■Dalteparin Sodium

[9041-08-1].
» Dalteparin Sodium is the sodium salt of a low-molecular-weight heparin obtained by nitrous acid depolymerization of heparin from pork intestinal mucosa, followed by a chromatographic purification designed to minimize the presence of $\mathrm{N}-\mathrm{NO}$ groups. The majority of the components have a $2-O$-sulfo- $\alpha$-L-idopyranosuronic acid structure at the nonreducing end and a $6-O$-sul-fo-2,5-anhydro-D-mannitol structure at the reducing end of their chains. The weight-average molecular weight of Dalteparin Sodium is 6,000 Da , the range being between $5,600 \mathrm{Da}$ and $6,400 \mathrm{Da}$. The percentage of chains lower than the molecular weight, 3000 Da , is not more than 13.0 percent and the percentage of the chains higher than the molecular weight, 8000 Da , ranges between 15.0 percent and 25 percent. The degree of sulfation is 2.0 to 2.5 per disaccharide unit. The potency is not less than 110 and not more than 210 Anti-Factor $\mathrm{X}_{a}$ International Units of activity per
mg , calculated with reference to the dried substance. The anti-factor $\mathrm{II}_{a}$ activity is not less than 35 International Units and not more than 100 International Units per mg , calculated with reference to the dried substance. The ratio of antifactor $\mathrm{X}_{a}$ activity to anti-factor $\mathrm{II}_{a}$ activity is between 1.9 and 3.2.

Packaging and storage-Preserve in tight, light-resistant containers, and store below $40^{\circ}$, preferably at room temperature.

Labeling-Label it to state the number of Anti-Factor $\mathrm{X}_{a}$ International Units of activity per mg and the number of An-ti-Factor $\mathrm{II}_{a}$ International Units of activity per mg. Label it to state the weight-average molecular weight and the percentage of molecules within the defined molecular weight ranges.

USP Reference standards $\langle 11\rangle$ —USP Dalteparin Sodium RS. USP Endotoxin RS. USP Low-Molecular-Weight Heparin Molecular Weight $R S$.

## Identification-

A: ${ }^{13}$ C NMR spectrum (see Nuclear Magnetic Resonance $\langle 761\rangle$ ).

Standard solution-Dissolve 200 mg of USP Dalteparin Sodium RS in a mixture of 0.2 mL of deuterium oxide and 0.8 mL of water. Add 1 drop of deuterated methanol to serve as an internal reference.

Test solution-Dissolve 200 mg of Dalteparin Sodium in a mixture of 0.2 mL of deuterium oxide and 0.8 mL of water. Add 1 drop of deuterated methanol.

Procedure-Transfer the Standard solution and the Test solution to NMR tubes of $5-\mathrm{mm}$ diameter. Using a pulsed (Fourier transform) NMR spectrometer operating at not less
than 75 MHz for ${ }^{13} \mathrm{C}$, record the ${ }^{13} \mathrm{C}$ NMR spectra of the Standard solution and the Test solution at $40^{\circ}$. The spectra are similar.

B: Molecular weight distribution and weight-average molecular weight (see Chromatography $\langle 621\rangle$ )-

Mobile phase-Prepare a 0.5 M lithium nitrate solution. Pass through a membrane filter having a porosity of 0.45 $\mu \mathrm{m}$ or less, and degas with helium.

Calibration solutions-Prepare two calibration solutions, $A$ and $B$, by dissolving about 2 mg of each of the USP Low-Molecular-Weight Heparin Molecular Weight RS in 1 mL of the Mobile phase. Distribute the molecular weight reference standards in alternating order of magnitude between solutions $A$ and $B$.

Standard solution-Dissolve about 10 mg of USP Dalteparin Sodium RS, accurately weighed, in 1 mL of Mobile phase.
Test solution-Dissolve about 10 mg of Dalteparin Sodium, accurately weighed, in 1 mL of Mobile phase.

Chromatographic system (see Chromatography $\langle 621\rangle$ )— The high performance size exclusion chromatographic system is equipped with a differential refractive index detector, a $6-\mathrm{mm} \times 40-\mathrm{mm}$ guard column, and a $7.8-\mathrm{mm} \times 300-\mathrm{mm}$ analytical column; both analytical and guard columns are prepacked with L20 packing (see Chromatography $\langle 621\rangle$ ). The flow rate is about 0.6 mL per minute, maintained constant to $\pm 0.1 \%$.

Procedure-Separately inject $20 \mu \mathrm{~L}$ of the Calibration solutions $A$ and $B$, record the chromatograms, and measure the retention times. Inject in duplicate, $20 \mu \mathrm{~L}$ of each of the Standard solution and the Test solution, and record the chromatograms for a length of time to ensure complete elution, including salt and solvent peaks. Calculate the total area under each of the Standard solution and Test solution chromatograms, excluding salt and solvent peaks at the end.

Calibration curve-Plot the retention times on the $y$-axis against the peak molecular weights on the $x$-axis for the peaks in the chromatograms of the Calibration solutions $A$ and $B$, and fit the data to a third-order polynomial, using suitable gel permeation chromatography (GPC) software.

Calculations-Compute the data, using the same GPC software, to determine the weight-average molecular weight, $M_{w}$, for each of the duplicate chromatograms of the Standard solution and the Test solution; and take the average for each solution. Correct the mean value of $M_{W}$ to the nearest 50. The Chromatographic system is suitable if $M_{w}$ of USP Dalteparin Sodium RS is within 150 Da of the labeled $M_{W}$ value. The $M_{W}$ for the Test solution is between 5,600 and 6,400 Da . Using the same software, determine for each of the duplicate Test solution chromatograms, the percentage of dalteparin sodium chains with molecular weights lower than $3000 \mathrm{Da}, M_{3000}$; the percentage of dalteparin sodium chains with molecular weights in the range 3000 and 8000 $\mathrm{Da}, M_{3000-8000}$; and the percentage of dalteparin sodium chains with molecular weights greater than 8000 Da , $M_{8000}$. Average the duplicate values and express to the nearest $0.5 \%: M_{3000}$ is not greater than $13.0 \%$, and $M_{8000}$ is between 15.0 \% and 25.0 \%.

C: The ratio of the numerical value of the anti-factor $\mathrm{X}_{a}$ activity, in Anti-Factor $\mathrm{X}_{a}$ International Units per mg, to the numerical value of the anti-factor $\mathrm{II}_{a}$ activity, in Anti-Factor $\mathrm{II}_{a}$ International Units per mg , as determined by the Assay (anti-factor $X_{a}$ activity) and the Anti-factor $I I_{a}$ activity, respectively, is not less than 1.9 and not more than 3.2.

Bacterial endotoxins $\langle 85\rangle$-It contains less than 0.01 Endotoxin International Unit of activity per International Unit of Anti-Factor $X_{a}$ activity.
$\mathbf{p H}\langle 791\rangle$ : between 5.5 and 8.0 of a $1.0 \%$ solution in water.

Loss on drying $\langle 731\rangle$ —Dry 1 g at $60^{\circ}$ over phosphorus pentoxide under a pressure that is not more than 670 Pa for 3 hours: it loses not more than $5.0 \%$ of its weight.

Heavy metals, Method $I\langle 231\rangle$ : not more than 30 ppm .
Nitrogen, Method $I I\langle 461\rangle$ : between 1.5 \% to 2.5 \%, calculated on the dried basis.

Limit of nitrite (see Liquid Chromatography $\langle 621\rangle$ )-
Mobile phase-Prepare a solution containing 13.6 g of sodium acetate in carbon dioxide-free water, adjust with phosphoric acid to a pH of 4.3, and dilute with the same solvent to 1000 mL .

Standard solution A-Dissolve 60.0 mg of sodium nitrite in carbon dioxide-free water and dilute with the same solvent to 1000.0 mL .

Standard solution B-Dilute 1.00 mL of Standard solution $A$ to 50.0 mL with carbon dioxide-free water using a pipette previously rinsed with Standard solution $A$.

Standard solutions $C, D$, and $E-[$ NOTE-Before preparing Standard solutions $C, D$, and $E$, rinse all pipettes with Standard solution B.] Dilute $1.00 \mathrm{~mL}, 3.00 \mathrm{~mL}$, and 5.00 mL of Standard solution B each to 100 mL with carbon di-oxide-free water ( $1 \mathrm{ppm}, 3 \mathrm{ppm}$, and 5 ppm nitrite, respectively).

Test solution-Dissolve 80.0 mg of Dalteparin Sodium in carbon dioxide-free water, and dilute with the same solvent to 10.0 mL . Allow to stand for at least 30 minutes.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with an electrochemical detector containing a working electrode with the potential of +1.00 V against a silver-silver chloride reference electrode, and a detector sensitivity of $0.1 \mu \mathrm{~A}$ full scale. The chromatograph is also equipped with a $4.3-\mathrm{mm} \times$ $12.5-\mathrm{cm}$ column prepacked with styrene-divinylbenzene an-
ion exchange resin. The flow rate is 1.0 mL per minute. Chromatgraph Standard solution D as directed for Procedure: the number of theoretical plates is at least 7000 per meter of the column for the nitrite peak; the tailing factor is not more than 3.0; and the relative standard deviation of the peak area obtained from six injections is not more than 3.0\%. Chromatograph Standard solutions $C$ and $E$ as directed for Procedure: the signal-to-noise ratio for Standard solution $C$ is not less than 5. A blank injection of carbon dioxide-free water does not give rise to false peaks.

Procedure-Inject $100 \mu \mathrm{~L}$ of the Test solution. [NOTEDalteparin sodium may block the binding sites of the stationary phase and cause shorter retention times and lower separation efficiency; the initial performance of the column may be restored using a 58 g per L solution of sodium chloride at a flow rate of 1.0 mL per minute for 1 hour; after regeneration the column is rinsed with 200 to 400 mL of carbon dioxide-free water.]

Calculation-Plot the areas of the nitrite peaks from the chromatograms of the Standard solutions $C, D$, and $E$ against respective concentrations of nitrite. Draw a best-fit regression line through the points. The correlation coefficient is not less than 0.995 . Calculate the concentration of nitrite from the area of the nitrite peak in the chromatogram of the Test solution: not more than 5 ppm of nitrite is found.

## Limit of boron-

Blank solution-Prepare a $1 \%(\mathrm{v} / \mathrm{v})$ solution of nitric acid in water.

Test solution-Dissolve 0.6250 g of Dalteparin Sodium in about 5 mL of the Blank solution, and dilute with the same solvent to 25 mL .

Spiked solution-Add $10 \mu \mathrm{~L}$ of a 5.7 mg per mL solution of boric acid in the Blank solution to 10.0 mL of Test solution, and mix.

Procedure-Boron is determined by measurement of the emission from inductively coupled plasma (ICP) at 249.733 nm . Use an appropriate apparatus whose settings have been optimized as directed by the manufacturer.

Calculation-Calculate the content of boron, in mg per mL of the solution, using the following formula:

$$
\left(Y_{T}-Y_{B}\right) /\left(Y_{S}-Y_{T}\right) \times C / 1000,
$$

in which $Y_{T}, Y_{B}$, and $Y_{S}$ are the responses of the Test solution, Blank solution, and Spiked solution, respectively, at 249.733 nm ; and $C$ is the concentration of boron, in mg per mL , in the boric acid solution spiked. Not more than 1 ppm is found.

Sodium content (see Spectrophotometry and Light-Scattering $\langle 851\rangle$ )-

Cesium chloride stock solution-Prepare a solution of cesium chloride in 0.1 N hydrochloric acid containing 1.27 mg per mL.

Cesium chloride solutions-Dissolve an accurately weighed quantity of sodium chloride in Cesium chloride stock solution to obtain a solution having a concentration of about $0.2 \%$ of sodium. Dilute accurately measured volumes of this solution with Cesium chloride stock solution to obtain solutions having concentrations of $0.0025 \%$, $0.0050 \%$, and $0.0075 \%$ of sodium.

Test solution-Transfer 50.0 mg of Dalteparin Sodium, accurately weighed, to a $100-\mathrm{mL}$ volumetric flask, dissolve in and dilute with Cesium chloride stock solution to volume.

Procedure-Determine the absorbences of the Test solution and Cesium chloride solutions at 330.3 nm using a sodium hollow-cathode lamp as a source of radiation and an air-acetylene flame. The sodium content is between $9.5 \%$ and $12.5 \%$, calculated on the dried basis.

Molar ratio of sulfate to carboxylate (see Chromatography $\langle 621\rangle$ )-

Mobile phase-Use carbon dioxide-free water.
Test solution-Dissolve about 50 mg of Dalteparin Sodium, accurately weighed, in 10 mL of carbon dioxide-free water.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatographic system consists of two peristaltic pumps, a six-port injection valve, an ion detector, and two columns-one $1.5-\times 2.5-\mathrm{cm}$ column packed with L\#\# (see Chromatography $\langle 621\rangle$ ) anion-exchange resin packing and one $1.5-\times 7.5-\mathrm{cm}$ column packed with $\mathrm{L} \# \#$ (see Chromatography $\langle 621\rangle$ ) cation-exchange resin packing. The outlet of the anion-exchange column is connected to the inlet of the cation-exchange column. The flow rate is about 1 mL per minute.

Procedure-[NOTE-Regenerate the anion-exchange column and the cation-exchange column with 1 N sodium hydroxide and 1 N hydrochloric acid, respectively, and equilibrate each with the Mobile phase, between two injections.] Inject the Test solution into the anion-exchange column and collect the eluate from the cation-exchange column in a beaker at the outlet until the ion detector reading returns to the baseline value. Transfer the eluate quantitatively to a titration vessel containing a magnetic stirring bar, and dilute with carbon dioxide-free water as necessary. Position the titration vessel on a magnetic stirrer and immerse the electrodes. Note the initial conductivity reading and titrate with 0.1 N sodium hydroxide in carbon dioxide-free water added in $100 \mu \mathrm{~L}$ portions. Record the burette reading and the conductivity meter reading after each addition of the sodium hydroxide solution.

Calculation-Plot the conductivity measurements on the $y$-axis against the volumes of sodium hydroxide added on the $x$-axis. The graph will have three linear sections-an ini-
tial downward slope, a middle slight rise, and a final rise. For each of these sections draw the best-fit straight lines using linear regression analysis. At the points where the first and second straight lines intersect and where the second and third line intersect, draw perpendiculars to the x -axis to determine the volumes of sodium hydroxide taken up by the sample at those points. The point where the first and second lines intersect corresponds to the volume of sodium hydroxide taken up by the sulfate groups $\left(V_{s}\right)$. The point where the second and third lines intersect gives the volume of sodium hydroxide consumed by the sulfate and the carboxylate groups together $\left(V_{T}\right)$. Calculate the molar ratio of sulfate to carboxylate by the formula:

$$
V_{S} /\left(V_{T}-V_{S}\right)
$$

## Anti-factor II $_{\mathrm{a}}$ activity-

Acetic acid solution, pH 7.4 Polyethylene glycol 6000 buffer, pH 7.4 Buffer, pH 8.4 Buffer, and Antithrombin III solution-Proceed as directed in the Assay (anti-factor $X_{a}$ activity ), except that the concentration of the Antithrombin III solution is 0.5 Antithrombin III Unit per mL.

Thrombin human solution-Reconstitute thrombin human (see Reagents Specifications in the section Reagents, Indicators, and Solutions) in water, and dilute in pH 7.4 Polyethylene glycol 6000 buffer to obtain a solution having a concentration of 5 thrombin Units per mL .

Chromogenic substrate solution-Dissolve D-phenylala-nyl-L-pipecolyl-L-arginine-4-nitroaniline dihydrochloride in water to yield about a 3.0 mM solution. Dilute in pH 8.4 Buffer to 0.5 mM immediately before use.

Standard solutions-Dissolve USP Dalteparin Sodium RS in and dilute with $p H$ 7.4 Buffer to obtain at least four dilutions in the concentration range between 0.015 and 0.075 Anti-Factor $\mathrm{II}_{a}$ International Units of activity per mL.

Test solutions-Proceed as directed under Standard solutions to obtain concentrations of Dalteparin Sodium similar to those obtained for the Standard solutions.

Procedure—Proceed as directed under Assay (anti-factor $X_{a}$ activity), except to use Thrombin human solution instead of Factor $X_{a}$ solution and use the Antithrombin III solution described above.

Calculation-Plot the absorbance values of the Standard solutions and the Test solutions against log concentrations of the dalteparin in mg. Construct separate straight lines of best fit using least-squares linear regression analyses for the Standard solutions and the Test solutions. Determine the slope for each regression line. Calculate the anti-factor $\mathrm{II}_{a}$ activity of Dalteparin Sodium by the formula:

$$
P^{\prime}\left(S^{\prime}{ }_{T} / S_{S}^{\prime}{ }_{S}\right)
$$

in which $P^{\prime}$ is the anti-factor $\mathrm{II}_{a}$ activity of dalteparin, in mg , of USP Dalteparin Sodium RS; and $S^{\prime}{ }_{T}$ and $S^{\prime}{ }_{S}$ are the slopes of the lines from Test solutions and Standard solutions, respectively. Express the anti-factor $\mathrm{II}_{\mathrm{a}}$ activity of Dalteparin Sodium per mg.

## Assay (anti-factor $\mathbf{X}_{a}$ activity)-

Acetic acid solution-Transfer 42 mL of glacial acetic acid to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix.
pH 7.4 Polyethylene glycol 6000 buffer—Dissolve 6.08 g of tris(hydroxymethyl)aminomethane and 8.77 g of sodium chloride in 500 mL water. Add 1.0 g of polyethylene glycol 6000 (see Reagents Specifications in the section Reagents, Indicators, and Solutions), and adjust with hydrochloric acid to a pH of 7.4. Dilute with water to 1000 mL .
pH 7.4 Buffer-Dissolve 6.08 g of tris(hydroxy-methyl)aminomethane and 8.77 g of sodium chloride in 500 mL of water. Adjust with hydrochloric acid to a pH of 7.4. Dilute with water to 1000 mL .
pH 8.4 Buffer-Dissolve 3.03 g of tris(hydroxy-methyl)aminomethane, 5.12 g of sodium chloride, and 1.40 g of edetate sodium in 250 mL of water. Adjust with hydrochloric acid to a pH of 8.4. Dilute with water to 500 mL .

Antithrombin III solution-Reconstitute a vial of antithrombin III (see Reagents Specifications in the section Reagents, Indicators, and Solutions) in water to obtain a 5.0 antithrombin III Units per mL solution. Dilute this solution in pH 7.4 Polyethylene glycol 6000 buffer to obtain a solution having a concentration of 1.0 antithrombin III Unit per mL .

Factor $X_{a}$ solution-Reconstitute an accurately weighed quantity of bovine factor $X_{a}$ (see Reagents Specifications in the section Reagents, Indicators, and Solutions) in pH 7.4 Polyethylene glycol 6000 buffer to obtain a solution that gives an increase in absorbance value at 405 nm of 0.15 to 0.20 absorbance units per minute when assayed as described below, but using as an appropriate volume ( $V$, in $\mu \mathrm{L}$ ) of $p H$ 7.4 Buffer instead of $V \mu \mathrm{~L}$ of the dalteparin solution.

Chromogenic substrate solution-Prepare a solution of a suitable chromogenic substrate for amidolytic test (see Reagents Specifications in the section Reagents, Indicators, and Solutions) specific for factor $X_{a}$ in water to obtain a concentration of about 3.0 mM . Dilute this solution with pH 8.4 Buffer to obtain a solution having a concentration of 0.5 mM .

Standard preparations-Dissolve USP Dalteparin Sodium RS in and dilute with $p H$ 7.4 Buffer to obtain four dilutions in the concentration range between 0.025 and 0.2 AntiFactor $X_{a}$ International Units per mL.

Assay preparations-Proceed as directed for Standard preparations to obtain concentrations of Dalteparin Sodium similar to those obtained for the Standard preparations.

Procedure-Label 18 suitable tubes: B1 and B2 for blanks; T1, T2, T3, and T4 (each in duplicate) for the dilutions of the Assay preparations; and S1, S2, S3, and S4
(each in duplicate) for the dilutions of the Standard preparations. [NOTE-Treat the tubes in the order B1, S1, S2, S3, S4, T1, T2, T3, T4, T1, T2, T3, T4, S1, S2, S3, S4, B2.] To each tube add the same volume $V(20$ to $50 \mu \mathrm{~L})$ of $A n$ tithrombin III solution and an equal volume, $V$, of either the blank, pH 7.4 buffer, or an appropriate dilution of the Assay preparations or the Standard preparations. Mix, but do not allow bubbles to form. Incubate at $37^{\circ}$ for 1.0 minute. Add to each tube volume $2 V(40$ to $100 \mu \mathrm{~L})$ of Factor $X_{a}$ solution and incubate for 1.0 minute. Add $5 V(100$ to $250 \mu \mathrm{~L})$ volume of Chromogenic substrate solution. Stop the reaction after 4.0 minutes with $5 V(100$ to $250 \mu \mathrm{~L})$ volume of Acetic acid solution. Measure the absorbance of each solution at 405 nm using a suitable spectrophotometer (see Spectrophotometry and Light-Scattering $\langle 851\rangle$ ) against the blank B1. The reading of the blank B2 is not more than $\pm 0.01$ absorbance units.

Calculation-Plot the absorbance values of the Standard preparations and the Assay preparations against log concentrations of dalteparin in mg. Construct separate straight lines of best fit using least-squares linear regression analyses for the Standard preparations and the Assay preparations. Determine the slope for each regression line. Calculate the potency of Dalteparin Sodium by the formula:

$$
P\left(S_{U} / S_{S}\right),
$$

in which $P$ is potency of dalteparin, in mg, of USP Dalteparin Sodium RS; and $S_{U}$ and $S_{S}$ are the slopes of the lines from Assay preparations and Standard preparations, respectively. Express the anti-factor $\mathrm{X}_{a}$ potency of Dalteparin Sodium per mg. $\mathbf{m}^{2 S}$ (USP28)

## Briefing

Desogestrel and Ethinyl Estradiol Tablets, page 823 of $P F$ 30(3) [May-June 2004]. A correction to the calculation in the amount dissolved is proposed in Test 1 of the Dissolution test.
(BPC: M. Marques) $\quad$ RTS-41560-1

## Add the following:

## Desogestrel and Ethinyl Estradiol Tablets

» Desogestrel and Ethinyl Estradiol Tablets contain not less than 90.0 percent and not more than 110.0 percent of the labeled amounts of desogestrel $\left(\mathrm{C}_{22} \mathrm{H}_{30} \mathrm{O}\right)$ and ethinyl estradiol $\left(\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{O}_{2}\right)$.

Packaging and storage-Preserve in well-closed containers.

Labeling-When more than one Dissolution test is given, the labeling states the Dissolution test used only if Test 1 is not used.

USP Reference standards $\langle 11\rangle — U S P$ Desogestrel $R S$. USP Desogestrel Related Compernd B RS. USP Desoges Rel Coll CS. USP Ethinyl Estradiol RS. USP Ethinyl Estradiol Related Compound A RS.

Thin-layer chromatographic identification test $\langle 201\rangle$ -
Adsorbent: octadecylsilanized chromatographic siliea gel mixture.

Fest solution Transfer a quantity of finely ground Tab-
lets, equivalent to about 2.4 mg of desegestrel, to a stop-
pered 10 mL centrifuge tube, add 4.8 mL of acetone, and
shake vigorously for 1 mintute. Centrifuge for 5 minutes, and transfer 2.7 mL of the clear supernatant into a suitable
eentainer, pretected from light. Evaporate to dryness in a hood using nitregen at reom temperature, and dissolve the residue so obtained in 0.45 mL of methylene chloride. 0.25 mL of a mixture of hexanes, methanel, and isepropyl aleehal(90:15:5).

Standard solttions- Prepare-separate-solutions in methy lene chloride, a mixture of hexanes, methanol, and isopropyl alcehol ( $90: 15: 5$ ) to contain about 23 mg of USP Dese gestrel RS per mL and $0.5-0.6 \mathrm{mg}$ of USP Ethinyl Estradiol RS per mL.

Application velume: $110 \mu \mathrm{\mu}$.
Developing solvent system: a mixture of toluene and ethyl acetate (80: 20).

Procedure Proceed as directed in the chapter. Spray the plate with a solution of sulfuric acid in alcohel(1 in -50), and dry at $110^{\circ}$ for 5 to 10 mintutes. Visualize the-spets under long wavelength UV light: ethinyl estradiol and desegestrel exhibit $R_{\perp}$ values of about 0.30 and 0.58 , respectively.

Test solution-Transfer 25 Tablets to a suitable container, add 50 mL of water, and sonicate until the Tablets disintegrate (if necessary, remove any coating with water before sonication). Place the sample in a separatory funnel, add 25 mL of ether, and shake well to extract the actives. Using a glass pipet, transfer the ether layer to a clean beaker, and evaporate to about 10 mL .

Standard solution-Dissolve a quantity of USP Desogestrel RS and USP Ethinyl Estradiol RS in methanol to obtain a solution containing about 0.15 mg per mL and 0.03 mg per mL , respectively.

Application volume: $\quad 30 \mu \mathrm{~L}$.
Developing solvent system: a mixture of chloroform and alcohol (96:4).

Procedure-Proceed as directed in the chapter, and then air-dry. Spray the plate with a mixture of methanol and sulfuric acid (50:50), place in an oven at $105^{\circ}$ for about 5 min utes, and examine the plate: meets the requirements.

## Change to read:

Dissolution $\langle 711\rangle$ —
TEST 1-
Medium: $\quad 0.05 \%$ sodium-latryl-sulfate dodecylsodium sulfate sodium lauryl sulfate with an assay content of not less than $95 \% ; 500 \mathrm{~mL}$.

Apparatus 2: 50 rpm .
Time: 30 minutes.
Determine the amounts of desogestrel $\left(\mathrm{C}_{22} \mathrm{H}_{30} \mathrm{O}\right)$ and ethinyl estradiol $\left(\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{O}_{2}\right)$ dissolved by employing the following method.

Piltent, Solution A, Soltion B, and Mobile phase Proceed as directed in the $A$ ssay.

Standard solution- Dissolve aceurately weighed quantities of USP Desogestrel RS and USP Ethinyl Estradiel RS, and dilute quantitatively, and stepwise if necessary, with Pissolution Medium to obtain a solution having knowncen eentrations equivalent to the expected concentrations of the selution under test. [NOTE-A volume of acetonitrile-Diltuent not exceeding $6 \%$ of the final total volume of the Standard solution may be used to dissolve USP Desogestrel RS, and a veltume of a mixture of methanel and water (90:10) Piltent net exceeding $4 \%$ of the fand total volume of the Standard solution may be used to dissolve USP Ethinyl Estradiol RS.] Chrematographic system- Proceed as directed in the $A s$ say. To evaluate the system suitability requirements, use the Standard preparation prepared as directed in the Assaty.

Procedure Separately inject equal volumes (about 200 $\mu \mathrm{L})$ of the Standed solution and a filtered centriftged per tion of the selution under test into the chrematograph, record the chromatograms, and measure the responses for
the major peaks. Caleulate the quantities of desogestrel $\left(\mathrm{C}_{22} \mathrm{H}_{30} \Theta\right)$ and ethinyl estradiol $\left(\mathrm{C}_{20} \mathrm{H}_{24} \Theta_{2}\right)$ dissolved by eomparisen with the correspending peak respenses obtained
from the Standard solution and the solution under test.
Mobile phase-Prepare a filtered and degassed mixture of acetonitrile and 20 mM potassium phosphate buffer, pH 6.0 ( $50: 50$ ). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Desogestrel standard stock solution-Dissolve an accurately weighed quantity of USP Desogestrel RS in methanol, and dilute quantitatively, and stepwise if necessary, with methanol to obtain a solution having a known concentration of about 0.25 mg per mL .

Ethinyl estradiol standard stock solution-Dissolve an accurately weighed quantity of USP Ethinyl Estradiol RS in methanol, and dilute quantitatively, and stepwise if necessary, with methanol to obtain a solution having a known concentration of about 0.25 mg per mL .

Desogestrel diluted standard solution-Transfer 1.0 mL of Desogestrel standard stock solution to a $50-\mathrm{mL}$ volumetric flask. Dilute with Dissolution Medium to volume, and mix. This solution contains about 0.005 mg per mL of USP Desogestrel RS.
Ethinyl estradiol diluted standard solution-Transfer 1.0 mL of Ethinyl estradiol standard stock solution to a $50-\mathrm{mL}$ volumetric flask. Dilute with Dissolution Medium to volume, and mix. This solution contains about 0.005 mg per mL of USP Ethinyl Estradiol RS.

Standard solution-Dilute quantitative portions of Desogestrel diluted standard solution and Ethinyl estradiol diluted standard solution with Dissolution Medium to obtain a solution containing about $0.3 \mu \mathrm{~g}$ per mL and $0.06 \mu \mathrm{~g}$ per mL of USP Desogestrel RS and USP Ethinyl Estradiol RS, respectively.

Test solution-Centrifuge a portion of the dissolution sample, and use the clear supernatant.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a $210-\mathrm{nm}$ detector (for desogestrel analysis), a spectrofluorometric detector (for ethinyl estradiol analysis) with an excitation wavelength of 285 nm and an emission wavelength of 310 nm ; a $4.6-\mathrm{mm} \times 15-\mathrm{cm}$ column that contains packing L 11 ; and a $4.6-\mathrm{mm} \times 12.5-\mathrm{mm}$ guard column that also contains packing L11. The flow rate is about 2 mL per minute. Chromatograph the Standard solution, and record the peak responses as directed for Procedure: the relative retention times are about 0.2 for ethinyl estradiol and 1.0 for desogestrel, and the relative standard deviation is not more than $3.0 \%$.

Procedure-Separately inject equal volumes (about 200 $\mu \mathrm{L}$ ) of the Standard solution and the Test solution into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the percentage of $\mathrm{C}_{22} \mathrm{H}_{30} \mathrm{O}$ and $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{O}_{2}$ dissolved by the formula:

## $(0.05 C)(100 / K)\left(r_{4} \nmid+s\right)$,

$$
\mathbf{\bullet}(0.5 C)(100 / K)\left(r_{U} / r_{S}\right), \mathbf{■}^{2 S}(U S P 28)
$$

in which $C$ is the concentration, in $\mu \mathrm{g}$ per mL , of USP Desogestrel RS or USP Ethinyl Estradiol RS in the Standard solution; $K$ is the labeled amount, in mg per Tablet, of $\mathrm{C}_{22} \mathrm{H}_{30} \mathrm{O}$ or $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{O}_{2}$; and $r_{U}$ and $r_{s}$ are the peak responses for desogestrel or ethinyl estradiol obtained from the Test solution and the Standard solution, respectively.

Tolerances-Not less than $80 \%(Q)$ of each of the labeled amounts of $\mathrm{C}_{22} \mathrm{H}_{30} \mathrm{O}$ and $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{O}_{2}$ is dissolved in 30 minutes.

TEST 2-If the product complies with this test, the labeling indicates that it meets USP Dissolution Test 2.

Medium: $\quad 0.3 \%$ sodium lauryl sulfate; 500 mL .
Apparatus 2: 100 rpm .
Time: 30 minutes.
Determine the amounts of desogestrel $\left(\mathrm{C}_{22} \mathrm{H}_{30} \mathrm{O}\right)$ and ethinyl estradiol $\left(\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{O}_{2}\right)$ dissolved by the chromatographic method used in Test 1.

Tolerances-Not less than $80 \%(Q)$ of each of the labeled amounts of $\left(\mathrm{C}_{22} \mathrm{H}_{30} \mathrm{O}\right)$ and $\left(\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{O}_{2}\right)$ is dissolved in 30 minutes.

Uniformity of dosage units $\langle 905\rangle$ : meet the requirements for Content Uniformity with respect to desogestrel and to ethinyl estradiol.

Loss on drying $\langle 731\rangle$ —Powder z0-40 40 Tablets, and dry the portion at $105^{\circ}$ for 3 hours: it loses not more than $4.0 \%$ of its weight.

Water, Method Ic $\langle 921\rangle$ : mere than 5.4\%, using 35 me of Tablets her $170^{\circ}$ not more than $5.4 \%$ using a portion of the Tablet containing about 35 mg and a suitable evaporation technique that releases the water by heating the specimen in a stream of dry inert gas, this gas then being passed into the cell.

## Related compounds-

Diluent, Solution A, Solution B, Mobile phase, Desoges trel standard stock solution, and Ethinyl estradiol standard stock solution Prepare as directed in the Assat.

Related compounds standard stock solution-Separately dissolve aceurately weighed quantities of USP Ethinyl Es madiol Related Compound A RS, USP Desogestrel Related Compound B RS, and USP Desogestrel Related Compound GRS in Dildent, and dilute quantitatively, and-stepwise if necessary, with Diluent to obtain a solution having a known eoneentrations of about 0.006 mg per mL, 0.00375 mg per
mL , and 0.00375 mg per mL , respectively. concentration of about $50 \%$ relative to the expected concentration of ethinyl estradiol and desogestrel in the Test solution.

Standatd solution Transfer 5.0 mL of Ethinyl estradiel standurd stock solution and 2.0 mL of Related compeunds standerd stock solution to a $100-\mathrm{ml}$ veltmetric flack, add an accurately measured volume of Desogestrel standard stock solution to obtain a final solution having a concentra tion, in my per mL, correspending to the expected concentration of desogestrel in the Test solution. Dilute with Diltent to volume, and mix. Transfer 2.0 mL of Related eompounds standard stock solution and an accurately measured volume each of Ethimyl estradiol standard stock solthtion and Desogestrel standard stock solution to a 100 mb velumetric flask to obtain a final selution having an ac eurately known concentration in mg per mL , correspending approximately to the expected concentration of desogestrel and ethinyl estradiol in the Test solution. Dilute with Diluent to volume, and mix.

Fest solution Use the Assay preparation.
Chromatographic system- Prepare as directed in the As say. [NOTE The related compernds $A$ and C Ethinyl estradiol related compound $A$ and desogestrel related compennd C are menitored using a wavelength of $230-250 \mathrm{~nm}$, and alt ether compounds are menitered at 210 205 nm.] Chromat egraph the Standard solution, and record the peak respenses as directed for Precedtre: the coltumnefficieney determined from the ethinyl estradiol peak is not less than 2500 theoret ieal plates; the tailing factor for the ethinyl estradiol peak is between 0.9 and 1.5; and the relative standard deviation for replicate injections determined from the desogestrel andethinyl estradiol peaks is net mere than $2.0 \%$, and net mere than $5.0 \%$ determined from the peaks for each related com peund.

Procedtre Separately inject equal volumes (about 25 $200-\mu \mathrm{L})$ of the Standard solution and the Test solution inte the chrematograph, record the chrematograms, and measure the peak heights areas responses for ethinyl estradiol related compeund $A$, desegestrel related compound $B$, and desogestrel related compeund $C$. disfegarding the peak, if any, with a retention time of about 12 minntes. Caleutate the pereentage of ethinyl estradiol related compound $A$ in the per tion of Tablets taken by the formmat:-

$$
4166.6 \mathrm{C}\left(r_{i}, r_{s}\right),
$$

$$
200(C L L)\left(r_{i}++_{s}\right)
$$

in whieh $C$ is the concentration, in mg per mL, Of USP Ethinyl Estradiol Related Compennd $A$ RS in the Standerd sotution; $L$ is the labeled ameunt, in mg, of ethinyl estradiolim each Tablet; andriandrs are the peak heights areas respenses for ethinyl estradiol related compound A obtained from the Test solution and the Standard solution, respectively: net mere than $0.5 \% 2.0 \%$ of ethinylestradiol related compenad $A$ is found. Caleulate the percentages of desogestrel related eompound B and desogestrel related compound $C$ in the pertion of Tablets taken by the formula:

$$
-666.6 \mathrm{C}\left(r_{i}+x_{s}\right)
$$

$$
200(C L)\left(r_{i}+r_{s}\right)
$$

in whieh $C$ is the concentration, in mg per mL, of USP Desegestrel Related Compound B-RS-or USP Desogestrel Re tated Compeund C RS in the-Standard solution; $L$ is the tabeled amount, in mg, of desogestrel in each Tablet; and

Frand s $_{\text {s are the peak heights areas respenses for desegestrel }}$ related compeund $B$ or desogestrel related compound $C$, as appropriate, obtained frem the Test solution and the Standard solution, respectively: not more than $0.5 \%$ each 2.0\% of desegestrel related compennd B is fennd; not more than 3.0\% of desogestrel related compound C is found; and not more than $2.0 \% 5.0 \%$ of total related compounds is found.

Solution A-Prepare a mixture of acetonitrile and 20 mM potassium phosphate buffer, pH 6.0 ( $50: 50$ ).

Solution B—Prepare a mixture of acetonitrile and 20 mM potassium phosphate buffer, pH 6.0 ( $80: 20$ ).

Mobile phase-Use variable mixtures of Solution $A$ and Solution B as directed for Chromatographic system. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Diluent-Prepare a mixture of acetonitrile and water (50:50).

Desogestrel standard stock solution-Dissolve an accurately weighed quantity of USP Desogestrel RS in methanol, and dilute quantitatively, and stepwise if necessary, with methanol to obtain a solution having a known concentration of about 0.3 mg per mL .
Ethinyl estradiol standard stock solution-Dissolve an accurately weighed quantity of USP Ethinyl Estradiol RS in methanol, and dilute quantitatively, and stepwise if necessary, with methanol to obtain a solution having a known concentration of about 0.3 mg per mL .

Standard solution-Dilute quantitative portions of Desogestrel standard stock solution and Ethinyl estradiol standard stock solution with Diluent to obtain a solution containing about $0.6 \mu \mathrm{~g}$ per mL and $0.12 \mu \mathrm{~g}$ per mL of USP Desogestrel RS and USP Ethinyl Estradiol RS, respectively.

Test solution 1-Transfer 20 Tablets to a $200-\mathrm{mL}$ volumetric flask. Add about 120 mL of Diluent, and shake for about 30 minutes. Dilute with Diluent to volume, and mix. Centrifuge a portion of the dissolution sample, and use the clear supernatant.

Test solution 2-Dilute a portion of Test solution 1 with Diluent to obtain a solution containing about $0.6 \mu \mathrm{~g}$ per mL of ethinyl estradiol.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a programmable variable wavelength UV detector and a spectrofluorometric detector with an excitation wavelength of 285 nm and an emission wavelength of 310 nm ; a $4.6-\mathrm{mm} \times 15-\mathrm{cm}$ column that contains packing L11; and a $4.6-\mathrm{mm} \times 12.5$ mm guard column that also contains packing L11. The chromatograph is programmed as follows.

| Time (minutes) | Solution A (\%) | Solution B <br> (\%) | Elution | $\begin{aligned} & \text { UV Detector } \\ & (\mathrm{nm}) \\ & \hline \end{aligned}$ | Flow Rate (mL/min.) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 100 | 0 | equilibration | 210 | 2 |
| 0-4 | 100 | 0 | isocratic | 210 | 2 |
| 4-10 | 100 | 0 | isocratic | 244 | 2 |
| 10-20 | 100 | 0 | isocratic | 210 | 2 |
| 20-25 | 0 | 100 | linear gradient | 210 | 2.5 |
| 25-30 | 0 | 100 | isocratic | 210 | 3 |
| 30-32 | 100 | 0 | linear gradient | 210 | 2 |
| 32-35 | 100 | 0 | re-equilibration | 210 | 2 |

Chromatograph the Standard solution, and record the peak responses as directed for Procedure: the relative retention times are 0.18 for ethinyl estradiol and 1.0 for desogestrel; the resolution, $R$, between ethinyl estradiol and desogestrel is not less than 2.0; the tailing factor is not more than 2.0 for ethinyl estradiol and desogestrel; and the relative standard deviation for replicate injections is not more than $2.0 \%$.

Procedure-Inject a volume (about $200 \mu \mathrm{~L}$ ) of Test solution 2 into the chromatograph, record the chromatograms, and measure the peak heights for the major peaks obtained within 20 minutes. Calculate the percentage of $17 \beta$-ethinyl estradiol in the portion of Tablets taken by the formula:

$$
100\left(r_{U} / r_{S}\right)
$$

in which $r_{U}$ is the height of any peak at a relative retention time of 0.20 ; and $r_{s}$ is the peak height of ethinyl estradiol obtained with the spectrofluorometric detector. Inject a volume (about $200 \mu \mathrm{~L}$ ) of Test solution 1 into the chromatograph, record the chromatograms, and measure the peak heights for the major peaks obtained within 20 minutes. Calculate the percentage of estrone in the portion of Tablets taken by the formula:

$$
100\left(r_{U} / r_{s}\right)-E
$$

in which $r_{U}$ is the height of any peak at a relative retention time of 0.20 ; $r_{s}$ is the peak height of ethinyl estradiol obtained with the UV detector at 210 nm ; and $E$ is the percent-
age of $17 \beta$-ethinyl estradiol obtained in the Tablets. Calculate the percentage of 3-ketodesogestrel in the portion of Tablets taken by the formula:

$$
100(1 / F)\left(r_{U} / r_{s}\right)
$$

in which $r_{U}$ is the height of any peak at a relative retention time of 0.32 obtained with the UV detector at $244 \mathrm{~nm} ; r_{s}$ is the peak height of desogestrel obtained with the UV detector at 210 nm ; and $F$ is the relative response factor, equal to 4.1. Calculate the percentage of any other impurity taken by the formula:

$$
100\left(r_{i} / r_{s}\right)
$$

in which $r_{i}$ is the height of any peak other than those mentioned above; and $r_{s}$ is the peak height of ethinyl estradiol obtained with the UV detector. Any peak below $0.1 \%$ is not considered. Not more than $0.5 \%$ of ethinyl estradiol impurities is found; not more than $0.5 \%$ of desogestrel impurities is found; and not more than $2.0 \%$ of total impurities is found.

Assay-
Biltent Prepare a mixttre of acetonitrile methanol and Water ( $4: 1$ ). ( $60: 40$ ).

## Solution A Use acenitrile.

Solution $B$ - Prepare a filtered and degassed mixture of acetonitrile and water ( $1: 1$ ).
Mobile phase Use variable mixtures of Solution 4 and Solution B as directed for Chromatographic system. Make adjustments if neeessary (see System Suitability under Chromatography (624)).

Desogestrel standert stock solution-Dissolve an ac etrately weighed quantity of USP Desogestrel RS in Dilt ent methanol to obtain a solution having a known eoncentran of 0.250 .35 mg per mL .

Ethinyl estradiol standard stock solution-Dissolve an accurately weighed quantity of USP Ethinyl Estradial RS in Diltent methanel to obtain a selution having a known eoncentration of about 0.250 .21 mg per mL .

Standard preparation Transfer 5.0 mL of Ethinyl estrat diol standed stock solution to a 100 mL volumetric flask, and add an aceurately measured volume of Desogestrel standerd stock solution to obtain a solution having a known eencentration, in mg per mL , correspending to the expected evneentration of desogestrel in the Assay preparation. Ditete with Diltent to voltme, and mix. Transfer an aceurately measured volume each of Ethinyl estradiol standard stock solution and Desogestrel standerd stoek solution to a 100 ml voltmetric flask to obtain a final solution having an acetrately known concentration in mg per mL , correspending approximately to the expected concentration of desogestrel and ethinyl estradiol in the Assay preparation. Dilute with Biltent to voltume, and mix.

Assay preparation Transfer 101410 Tabletstoa $30-\mathrm{mL}$ 50 mL stoppered centrifuge tube, add $20.0-30 \mathrm{~mL}$ of Dilt ent, and sonicate for 25 mintutes with intermittent mixing on a vortex mixer, until all Tablets have broken apart. Extract for 30 minutes on a benchtop shaker. Centrifuge, and use the elear supernatant. [NOTE-Retain a pertion of this solutionto use as the Test solution in the test for Related eompeatats.]

Chrematographic system (see-Chrematography $\langle 621\rangle$ The liquid-chromatograph-is equipped with either a programmable variable wavelength detector or two separate detectors capable of menitering at $210-205$ nm and at 230250 230 mm and a $4.6 \mathrm{~mm} \times 15-\mathrm{cm} 25-\mathrm{cm}$ coltumn that contains stable bonded $5 \mu \mathrm{~m}$ packing L 1 . The flow rate is about 21.5 mL per mintte, and the eoltmm temperature is maintained at 40. The ehremategraph is programmed as follows.

| Time (minutes) | Solution-4 $(\%)$ | Solution $B$ $(\%)$ | Elution |
| :---: | :---: | :---: | :---: |
| 0-4.5 | $\theta$ | 100 | isecratic |
| $\theta-12.0$ |  |  |  |
| 4.5-4.6 | $\theta \rightarrow 10 \theta$ | $\xrightarrow{+0} \rightarrow$ | linear gradient |
| 12.0-12.4 |  |  |  |
| $4.6-10.7$ | 100 | $\theta$ | isperatic |
| 12.125 .0 |  |  |  |
| 10.7-10.8 | $\xrightarrow{100 \rightarrow 0}$ | $\theta \rightarrow 100$ | linear gradient |
| 25.0-25.4 |  |  |  |
| 25.1-30.0 | $\theta$ | 100 | isocratic |

Chromatograph the Standard preparation, and record the peak respenses as directed for Procedure: the columm effe eieney determined from the ethinyl estradiol peak is not less than 2500 theoretical plates; the tailing factor for the ethinyl estradiol peak is between 0.9 and 1.5 ; and the relative stan dard deviation for repliente injections is net more than $2.0 \%$ $1.5 \%$, determined from the desogestrel and ethinyl estradiol peaks.

Proedure Separately inject equal volumes (about 25 $\mu \mathrm{L})$ of the Standard preparation and the - sisay preparation into the chrematograph, record the chrematograms, and measure the peak areas at $210-205 \mathrm{~nm}$. Separately caleulate the amounts, in $\mu \mathrm{g}$, of desogestrel $\left(\mathrm{C}_{22} \mathrm{H}_{39} \Theta\right)$ and ethinylesmadiel $\left(\mathrm{C}_{20} H_{24} \Theta_{2}\right)$ in the pertion of Tablets taken by the for mula:-

$$
\left( \pm G_{s}+G_{\downarrow}\right)\left(F_{L}++_{s}\right),
$$

in whieh $L$ is the labeled quantity, in $\mu \mathrm{g}$, of the relevant ant Hyte in each Tablet; $G_{s}$ is the concentration, in $\mu \mathrm{g}$ per mL , of the apprepriate-USP Reference-Standard in the-Standard preparation; $G_{\&}$-is the concentration, in $\mu \mathrm{g}$ per mL , of the eerrespending analyte in the Assay preparation, based on
the labeled quantity per Tablet and the extent of dilution; and $r_{5}$-and $\Psi_{s}$ are the peak responses areas obtained from the Assay preparation and the Standard preparation, respectively.

Mobile phase_Prepare a filtered and degassed mixture of acetonitrile and 20 mM potassium phosphate buffer, pH 6.0 (50:50). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Diluent-Prepare a mixture of acetonitrile and water (50:50).

Desogestrel standard stock solution-Dissolve an accurately weighed quantity of USP Desogestrel RS in methanol, and dilute quantitatively, and stepwise if necessary, with methanol to obtain a solution having a known concentration of about 0.3 mg per mL .

Ethinyl estradiol standard stock solution-Dissolve an accurately weighed quantity of USP Ethinyl Estradiol RS in methanol, and dilute quantitatively, and stepwise if necessary, with methanol to obtain a solution having a known concentration of about 0.3 mg per mL .

Standard preparation-Dilute appropriate aliquots of Desogestrel standard stock solution and Ethinyl estradiol standard stock solution with Diluent to obtain a solution having a known concentration of about $0.6 \mu \mathrm{~g}$ per mL and $0.12 \mu \mathrm{~g}$ per mL of USP Desogestrel RS and USP Ethinyl Estradiol RS, respectively.

Assay preparation-Transfer 20 Tablets into a 200-mL volumetric flask. Add about 120 mL of Diluent, and shake for about 30 minutes. Dilute with Diluent to volume, and mix. Centrifuge a portion of the sample, and transfer an accurately measured volume to a $50-\mathrm{mL}$ volumetric flask to obtain a final concentration of about $0.6 \mu \mathrm{~g}$ per mL of desogestrel. Dilute with Diluent to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )-
The liquid chromatograph is equipped with a $210-\mathrm{nm}$ detector (for desogestrel analysis), a spectrofluorometric detector (for ethinyl estradiol analysis) with an excitation wavelength of 285 nm and an emission wavelength of 310 nm ; a $4.6-\mathrm{mm} \times 15-\mathrm{cm}$ column that contains packing L11; and a $4.6-\mathrm{mm} \times 12.5-\mathrm{mm}$ guard column that also contains packing L11. The flow rate is about 2 mL per minute. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the relative retention times are about 0.2 for ethinyl estradiol and 1.0 for desogestrel; the tailing factor for both analytes is not more than 2.0 ; and the relative standard deviation is not more than $2.0 \%$.

Procedure-Separately inject equal volumes (about 200
$\mu \mathrm{L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the quantity, in mg, of desogestrel $\left(\mathrm{C}_{22} \mathrm{H}_{30} \mathrm{O}\right)$ and ethinyl estradiol $\left(\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{O}_{2}\right)$ in the portion of Tablets taken by the formula:

$$
(500 C / V)\left(r_{U} / r_{s}\right),
$$

in which $C$ is the concentration, in mg per mL , of USP Desogestrel RS or USP Ethinyl Estradiol RS in the Standard preparation; $V$ is the volume of the aliquot of solution taken ses for desogestrel or ethinyl estradiol obtained from the $A s$ say preparation and the Standard preparation, respectively.■1S (USP28)

## Briefing

Dextroamphetamine Sulfate Elixir, USP 27 page 577. It is proposed to delete this monograph from the $U S P$ because there is no marketed product for this dosage form.
(PA3: S. Salado) RTS-41478-1

## Delete the following:

## Dextroamphetamine-Stlfate-Elixir

## (Current title-not to change untildume 1, 2005)

Alonograph title-change-to-become-officialdume-1, 2005 See-Dextroamphetamine-Sulfate-Oral-Solution
\#-Dextroamphetamine Sulfate Elixir contains, in each 100 mL , net less tham 90.0 mg and net mere than 110.0 me of $\left(\mathrm{C}_{2} \mathrm{H}_{13} \mathrm{~N}\right)_{2} \cdot \cdot \mathrm{H}_{2} \mathrm{SO}_{4}$ -

Packaging and-storage Preserve in tight, light resistant containers.
USP Reference standards- $\langle 14\rangle$ _ USP Dextroamphetamine Sul fate RS.
Identifieation Transfer 25 mL of Elixir to a 250 mL separator, ade 25 mL of water and 5 mL of 2.5 N sodium hydroxide, mix, and extract with 60 mL of ether. Wash the ether extract with ww 5 mL pertions of 0.25 N sedium hydroxide, and diseard the washings. Filter the ether extract threugh a pledget of entton, previously saturated with ether, into a $100-\mathrm{mL}$ beaker, and evaporate-on a steam bath in a current of air to about 1 mL . Dissolve the residue in 3 mL of aleohol, and transfer to a gilass-stoppered, 125 mL coniealflask containimg 25 mL of water. Rinse the beaker with 3 mL of aleohel, and transfer to the flask. Cool to about $15^{\circ}$, add 3 mL of 1 Nsoditam hydroxide, then add 1 mL of a mixtureof 1 volume of benzoyl ehtoride and 2 volumes of anhydreus ethyl ether, and shake for 2 minutes. Filter the precipitate, wash with about 15 mL of cold water, and reerystallize twiee from diluted alcohol: the benzoylderivative of dextroamphetamine so obtained, after be ing dried at $105^{\circ}$ for 1 heur, melts between $154^{\circ}$ and $160^{\circ}$.
Aleohelcontent $\langle 614\rangle$ : between $9.0 \%$ and $11.0 \%$ of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$.
Isomeric purity Transfer 150 mL of Elixir to a 500 mL separa tor, add 15 mL Of 2.5 N sodium hydroxide, andextract with 0 ne 60 mL and -40 mL pertiens ofether. Wash the cembined etherex tracts with 010 mL pertions of 0.25 N sodium hydrexide. Wash the aqueeus alkaline extracts with 20 mL of ether, adding the ether washing to the combined ether extracts. Filter the ether extracts through a pledget of cotton, previously saturated with ether, inte a 250 mL beaker, rinse the cotton with a small amount of ether, and evaperate on a steam bath im a current of air to about 2 mL . Dissolve the residue-in 20 mL of chloroform, and transfer to a separator containing 35 mL of 0.1 N sulfuric acid. Complete the transfer with two additienal 20 mL pertiens of chloroferm. Shake the-separater vigereusly for 1 minute, allow the layers to separate, and discard the ehloroform. Adeto the liquid in the separator 2.5 s of sodium bicarbenate, preventing it frem coming in contact with the mouth of the separater, and swirl until mest of the bicarbenate has dissolved. By means of a 1 mL syringe, rapidly inject 1.0 mL
of acetic anhydride directly into the contents of the separator. Immediately insert the stopper in the separator, and shake vigorously until the evolution of earben dioxide has ceased, releasing the pressure as neeessary through the stopeock. Allow to stand for 5 min utes, and extract the solution with 50 mL of chleroform, shaking vigoreusly for 1 minute. Filter the chloroform extact through a pledget of flter cotten into a 100 mL beaker, rimse the cotton with a small amount of ehloreform, and evaporate on a steam bath in a eurrent of air or nitrogen to dryness. Heat and triturate the residue until the oder of chloreform is no longer pereeptible. Allow the residut to cool, induring it to erystallize. Reduce the erystats to a fine powder, heat at $80^{\circ}$ for 30 minttes, and cool: the specific retation of the ace lamphetamine so obtained, determined in a so lation in chloreform containing 20 mg per mL, a 200 mm semimi ero polarimeter tube being used, is between- $37.5^{\circ}$ and $44.0^{\circ}$.

## Assay -

Chromatographic edumn Proeed as direeted for Coltman Partition Chromatography under Chromatography $\langle 621$ ), packing achromatographic tube with a mix ture of 2 gof Solid Support and 1 mL of 0.06 N hydrochleric acid.

Standardpreparation Dissolve an aecurately weighed quantity of USP Dextrommphetamine-Sulfate $R$ S in 1.8 N sulfuric acid (previously saturated with chloreform), and dilute quantitatively and stepwise with the same solvent to obtain a solution having a known encentration of about 0.5 mg per mL .

Assay preparation Pipet 5 mL of Elixir into a 100 mL beaker, add 1 drop of 3 N hydrechloric acid, and swinl to mix. Add 6 g of puriffed siliceous anth, and mix with a glass rod until a fluffy mix fare is obtained.

Procedtre- Transfer the Assay preparation to the-Chromato graphic oluma, and complete the preparation of the columa. Wash the prepared column with 100 mL of chloreform that previeusly has been saturated with water, and diseard the washing. Arrange to collect the eluate in a separator containing 10.0 mL of 1.8 N sul furie acid that previously has been saturated with chloroform. Pass through the coltmmn 60 mL of a freshly prepared ammeniacal chlo reform solution, made by shaking 50 velumes of chloreform with 4 volume of ammenium hylroxide for 1 to 2 minutes and discarding the queeus phase. Complete the elution with 60 mL of chloroform (previously saturated with water). Shake the separator vigoreusly for 1 minute, allow the layers to separate, and diseard the chloroform. Coneomitantly determine the abserbances of the Standard preparation and the Assay preparation in 1 cm cells at 280 nm and at the maximum at about 257 nm , with a suitable-spectrophetometer, using 1.8 N sulftric acid (previously saturated with chloroform) as the blank. Caleulate the quantity, in me, of $\left(\mathrm{G}_{2} \mathrm{H}_{4} \mathrm{~N}_{2}\right)_{2} \cdot \mathrm{H}_{3} \mathrm{SO}_{4}$ in the pertion of Elixir taken by the formula:

$$
10 C\left(A_{2 s 7}-A_{200}\right)_{l}+\left(A_{2 s 7}-A_{200}\right)_{s}
$$

in which $C$ is the ene phetamine-Sulfate RS in the-Standard preparation; and the paren thetic expressions are the differences in the absorbanees of the two solutions at the wavelengths indicated by the subseripts, for the $A s$ say preptration (U) and the Stand preparaion (S), respective-サ-W2S (USP28)

## ■Dextroamphetamine Sulfate Oral Solution

(AHonograph under this new-title-to-become-official dume-1, 2005)
(Current monegraph title-is Dextreamphetamine-Sulfate-Elixir)
\#-Dextroamphetamine Sulfate Oral Solution contains, in each 100 mL , not less than- 90.0 mg and not more than 110.0 mg of dextroamphetamine sulfate $\left[\left(\mathrm{G}_{2} \mathrm{H}_{43} \mathrm{~N}\right)_{2}-\mathrm{H}_{2} \mathrm{~S}_{4}\right\}$.

Paekaging and-storage- Preserve in tight, light resistant conminers.
USP Referenee-standards- $\langle 4\rangle$ - USP Dextant fate RS.
Identifiention_Transfer 25 mL of Oral Solution to - 250 mL separator, add 25 mL of water and 5 mL of 2.5 N soditm hydrox ide, mix, and extract with 60 mL of ether. Wash the ether extract with wo- 5 mL pertions of 0.25 N sodium hydroxide, and diseard the washings. Filter the ether extract through a pledget of cetten, previously sattrated with ether, into a 100 ml beaker, andevape rateon a steam bath in acemrent of air to about 1 mL . Dissolve the residue in 3 mL of aleohol, and transfer to a glass stoppered, 125 mL conieal flack eon aining 25 mL of water. Pinse the benker with 3 mL of aleohol, and transfer to the flack. Cool to about $15^{\circ}$, add 3 mL of 1 N sodium hydroxide, then add 1 mL of a mixture of 1 vol ume of benzoyl chloride and 2 volumes of anhydrous ethyl ether, and shake for 2 minutes. Filter the precipitate, wash with about 15 mL of cold water, and recrystallize twiee from diluted aleohel: the benzoyl derivative of dextroamphetmine so obtained, after being dried at $105^{\circ}$ for 1 heur, melts between $154^{\circ}$ and $160^{\circ}$.
Aleohol content $\langle 614\rangle$ :- between $9.0 \%$ and $11.0 \%$ of $\mathrm{C}_{2} \mathrm{H}_{5} \Theta H$.
Isomerie purity Transfer 150 mL of Oral Solution to a 500 mL separater, add 15 mL of 2.5 N soditm hydroxide, andeetract with ene 60 mL and two -40 mL pertions of ether. Wash the combined ether extracts with two 10 mL portions of 0.25 N sodium hydrox ide. Wash the aqueeus alkaline extracts with 20 mL of ether, add ing the ether washing to the combined ether extracts. Filler the ether extracts hrough a pledget of eotton, previously sattrated with ether, into a 250 mL beaker, rinse the cotten with a small a momnt of ether, and evaporate on a steam bath in actirent of air to about 2 mL . Dissolve the residue in 20 mL of chloroform, and transfer to a-separator containing 35 mL of 0.1 N sulfuric acid. Gomplete the transfer with two additional $20-\mathrm{mL}$ portions of ehloreform. Shake the separator vigoreusly for 1 minute, allow the lay ers to separate, and diseard the chloreform. Add to the liquid in the separator 2.5 g of sodium bieabenate, preventing it from coming
in contact with the mouth of the separator, and swirl until most of the biearbenate has dissolved. By means of a 1 mL syringe, rapidly inject 1.0 mL of acetic mhydride directly into the contents of the separator. Immediately insent the stopper in the separator, and shake vigerously until the volution of carben dioxide has eeased, releasing the pressure as neeessary through the stopeock. Allow to stand for 5 minutes, and extract the solution with 50 mL of ehlo reform, shaking vigorously for 1 minute. Pass the chloroformer tract through a pledget of filter cotton into a 100 mL beaker, rinse the cotton with a small amount of chloroform, and evaporate on a steam bath in a current of air or nitrogen to drymess. Heat and trit trate the residue until the odor of chloreform is no lenger pereep tible. Allow the residue to eool, induring it to crystallize. Reduee the erystals to a fine powder, heat at $80^{\circ}$ for 30 mintuter, and cool: the specific rotation of the ace ylamphetamine so obtained, deter mined in a solution in chloroform eontaining 20 mg per mL, a 200 mm semimiere polarimeter tube being used, is between $37.5^{\circ}$ and $-44.0^{\circ}$.

## Assay

Chromatographic olumn Proeed as direeted for Coltman
 achromatographic tube with a mix of 2 g of Solid Suppert and 1 mL of 0.06 N hydrechloric acid.

Standardpreparation Dissolve an aceurately weighedquantity ef USP Dextreamphetamine Sulfate $R S$ in $1.8 N$ sulfuric acid (previously saturated with chloroform), and dilute quantitatively and stepwise with the same solvent obtain a solution having a known eoneentration of about 0.5 mg per mL .

Assay preparation Pipet 5 mL of Oral Solation inte a 100 mL beaker, add 1 drop of 3 N hydrochloric acid, and swirl to mix. Add 6 of purified silieeous enth, andmix with a glass roduntila fluffy mixture is obtained.

Procedure Transfer the Assay preparation to the Chromatographic columa, and complete the preparation of the column. Wash the prepared columa with 100 mL of chloroform that previously has been sattrated with water, and diseard the washing. Arrange to collee the eltate in a separator containing 10.0 mL of 1.8 N sut furie acid that previously has been saturated with ehloreform. Pass through the coltumm 60 mL of a freshly prepared ammeniacal chloroform solution, made by shaking 50 volumes of chloroform with 4 volume of ammonium hydroxide for 1 to 2 minutes and disearding the aqueous phase. Complete the elution with 60 mL of chloreform (previously saturated with water). Shake the separater vigoreusly for 1 minute, allow the layers to separate, and diseard the chloreform. Coneomitantly determine the abserbances of the Standard preparation and the Assay preparation in 1 cm cells at 280 mm and at the maximum at about 257 nm , with a suitable-spectrophetometer, using 1.8 N sulfaric acid (previously saturated with chloroform) as the blank. Calculate the quantity, in me, of dextreamphetamine sulfate $\left[\left(\mathrm{G}_{4} \mathrm{H}_{43} \mathrm{~N}\right)_{2}-\mathrm{H}_{2} \mathrm{~S}_{4}\right.$ \} in the pertion of $\theta$ ral Solution taken by the formula:-

$$
10 C\left(A_{257}-A_{280}\right)_{6}+\left(A_{257}-A_{280}\right)_{5}
$$

in which $C$ is the eoneentration, in mg per mL, of USP Dextroamphetamine Sulfate RS in the Standard preparation; and the paren thetic expressions are the differences in the absorbances of the two solutions at the wavelengths indieated by the subseripts, for the $-4 s$ say preparation (U) and the Standard preparation (S),respectively.

## BRIEFING

Etidronate Disodium, USP 27 page 769; Etidronate Disodium Tablets, USP 27 page 770. It is proposed to replace the current titration procedure in the test for Limit of phosphite with a high performance ion chromatography method that provides an upgrade in technology, with an increase in sensitivity, selectivity, and accuracy as compared with the current $U S P$ method. This liquid chromatographic procedure is based on analyses performed with the Dionex IonPac AS11 brand of L46 column and Dionex IonPac AG11 brand of Lxx guard column. The typical retention times for the phosphite and phosphate peaks are about 4 and 6 minutes, respectively.

It is also proposed to replace the current titration Assay with a new high performance ion chromatography method that eliminates the use of radioactive thorium nitrate and provides an upgrade in technology. The liquid chromatographic procedure in the Assay is based on analyses performed with Waters IC-Pak Anion HC brand of L23 column. The typical retention time for etidronate peak is about 3 minutes.

Limit of phosphite-
Buffer solution- Dissolve 6.9 g of monobasie sodium phosphate in 500 mL of water, add 400 mL of 0.1 N sodimm hydroxide, and mix.

Fest preparation Transfer about 3.5 g of Etidronate Disodium, aceurately weighed, to a glass stoppered, 250 mL conieal flask, and dissolve in 70 mL of water.

Procedure Add 20 mL of Buffer solution to the Test prepara tion, and adjust with sodium hydroxide solution (25 in 100), using a pH meter, to a pH of $7.3 \pm 0.2$. Add 20 mL of iodine TS in di vided portions, with mixing, and insert the stopper securely in the flask. [NOTE If mere tham half of the iodine TS is absorbed (deeolerized) by the pertion of Etidrenate Disodium taken, discard the mixture, and use a Test preparation containing a smaller quantity ef Etidrenate Disodium. Allow to stand for 3 hours protected from light, and adjust with 6 N acetic acid to a pH-of $4.5 \pm 0.2$. Titrate with 0.1 N sodium thiosulfate VS. When the iodine color beeomes pale, add 2 mL of stareh TS, and continue the titration until the blue evlor is diseharged. Perform a blank determination (see Titrimetry $\langle 544\rangle$, and make any neeessary correction. Caleulate the pereent age of phosphite in the pertion of Etidrenate Disodimm taken by the formula:-

$$
0.520 Y / H=
$$

in which $V$ is the volume, in mL, of titrant constmed, and Wis the weight, in g , of Etidronate Disodimm taken: not more than $1.0 \%$ is found.

■Solution $A$-Prepare an aqueous solution containing 0.65 mg per mL of anhydrous sodium carbonate and 0.40 mg per mL of sodium bicarbonate.

Solution B-Prepare an aqueous solution containing 4.68 mg per mL of anhydrous sodium carbonate and 2.89 mg per mL of sodium bicarbonate.

Mobile phase—Use variable mixtures of Solution $A$ and Solution B as directed for Chromatographic system. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Standard solution-Dissolve suitable quantities of USP Etidronate Disodium Related Compound A RS and dibasic sodium phosphate in Solution $A$ to obtain a solution having a known concentration of 0.027 mg of sodium phosphite di-
basic pentahydrate and 0.015 mg of dibasic sodium phosphate in each mL. [NOTE-Etidronate Disodium Related compound A is sodium phosphite dibasic pentahydrate.]

Suppressor regenerant solution-Use 12.5 mM sulfuric acid.

Test solution-Transfer approximately 50 mg of Etidronate Disodium, accurately weighed, to a suitable flask. Dissolve in 10.0 mL of Solution $A$.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a conductivity detector, a $4-\mathrm{mm} \times 25-\mathrm{cm}$ column and a $4-\mathrm{mm} \times 50-$ mm guard column that contain packing L46 and a $4-\mathrm{mm}$ anion self-regenerating suppressor. The flow rate is about 1.0 mL per minute for the Mobile phase and 3 to 5 mL per minute for the Suppressor regenerant solution. The chromatograph is programmed as follows:

| Time | Solution A | Solution B |  |
| :---: | :---: | :---: | :--- |
| (minutes) | $(\%)$ | $(\%)$ | Elution |
| $0-6.0$ | 100 | 0 | isocratic |
| $6.0-6.1$ | $100 \rightarrow 0$ | $0 \rightarrow 100$ | linear gradient |
| $6.1-8.0$ | 0 | 100 | isocratic |
| $8.0-8.1$ | $0 \rightarrow 100$ | $100 \rightarrow 0$ | linear gradient |
| $8.1-15$ | 100 | 0 | isocratic |

Chromatograph the Standard solution, and record the peak responses as directed for Procedure: the elution order is phosphite, followed by phosphate; the resolution, $R$, between the peaks due to phosphite and those due to phosphate is not less than 2.5 ; and the relative standard deviation for replicate injections is not more than $10 \%$ for each peak.

Procedure—Separately inject equal volumes (about 20 $\mu \mathrm{L})$ of the Standard solution and the Test solution into the chromatograph, record the chromatograms, and measure the
responses for the phosphite peaks. Calculate the percentage of phosphite, determined as monobasic sodium phosphite, in the portion of Etidronate Disodium taken by the formula:

$$
1000(103.98 / 216.06)(C / W)\left(r_{U} / r_{S}\right)
$$

in which 103.98 and 216.06 are the molecular weights of sodium phosphite monobasic pentahydrate and sodium phosphite dibasic pentahydrate, respectively; $C$ is the concentration, in mg per mL, of USP Etidronate Disodium Related Compound A RS in the Standard solution; $W$ is the weight, in mg , of the Etidronate Disodium taken to prepare the Test solution; and $r_{U}$ and $r_{s}$ are the phosphite peak responses obtained from the Test solution and the Standard solution, respectively: not more than $1.0 \%$ of phosphite, determined as monobasic sodium phosphite, is found. $\mathbf{2 S}$ (USP28)

## Assay-

Fitrant Transfer 6.9 of therimm nitrate, aceurately weighed, a 1000 mL beaker, and dissolve in 25 mL of 1 N nitric acid. Dis solve 4.7 g of $(1,2$ cycloherylenedinitrilo)tetrancetic acid in 41 mL of 1 N sodium hydroxide, and transfer to the 1000 mL benker. Add about 600 mL of water, and adjust with methenamine to a pH of between 5.0 and 5.5. Transfer to a 1000 mb volumetric flask, dilute with water to volume, and mix. Allow to stand for 1 week be fore use. This solution is about 0.0125 M in thoritum eyclohexylenedinitrilotetrancetic acid complex. Each mL is equiv alent to approximately 1.5 mg of $\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{Na}_{2} \mathrm{O}_{7} \mathrm{P}_{3}$ :

Standedrd preparation-Transfer 180 mg of USP Etidrenic Acid Monohydrate PS to a 100 mL volumetric flask, dissolve in 50 mL of water, add 16 mL of 0.1 N sodium hydroxide, dilute with water to volume, and mix.

Assely preparation Transfer about 400 mg of Etidrenate Diso dium, aceurately weighed, to a 200 mL volumetric flask, dissolve in 100 mL of water, dilute with water to volume, and mix.

Procedure Pipet 15 mL each of the Standard preparation and the Assay preparation into separate 100 mL beakers. To each bea ker add 20 mL of water, 1 mL of $a 0.1 \%$ solution of xylenol orange, and 2 mL of methenamine solution ( 20 in 100), and mix. Adjust with 0.1 N nitric acid to apHof $6.50 \pm 0.05$. Coneomitantly titrate the resulting solutions to a reddlish violet endpeint. Caleulate the quantity, in me, of $\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{Na}_{2} \mathrm{O}_{7} \mathrm{P}_{2}$ in the pertion of Etidrenate Dise dium taken by the formma:-

$$
z(249.99 / 224.05) H_{s}\left(V_{s}+V_{s}\right)
$$

in whieh 249.99 and 224.05 are the molecular weights of etidre nate disodium and etidronic acid monohydrate, respectively, $\Pi_{s}$ is the weight, in mg, of USP Etidronic Acid Monohydrate RS tak en, and $Y_{t}$ and $Y_{s}$ sare the volumes, in mb, of Titrant consumed by the Assaly preparation and the Standurd preparation, respectively.

- Mobile phase—Prepare a 35 mM to 40 mM ammonium nitrate solution in water, and adjust with dilute ammonium hydroxide to a pH of 7.0.

Standard preparation-Dissolve an accurately weighed quantity of USP Etidronic Acid Monohydrate RS in a mixture of 1 mL of 1 N sodium hydroxide solution and 150 mL of Mobile phase, to obtain a solution having a known concentration of between 0.73 and 0.75 mg of etidronic acid monohydrate per mL.

Assay preparation-Transfer between 42.0 and 43.0 mg of Etidronate Disodium, accurately weighed, to a $50-\mathrm{mL}$ volumetric flask, and dissolve in and dilute with Mobile phase to volume.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a refractive index detector and a $4.6-\times 150-\mathrm{mm}$ column that contains packing L23. The column and the detector temperature are maintained at $32^{\circ}$. The flow rate is about 1.5 mL per minute. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the relative standard deviation for replicate injections is not more than $1.5 \%$.

Procedure-Separately inject equal volumes (about 20 $\mu \mathrm{L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the percentage of $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{Na}_{2} \mathrm{O}_{7} \mathrm{P}_{2}$ in the portion of Etidronate Disodium taken by the formula:

$$
100(250.00 / 224.05)\left(C_{S} / C_{U}\right)\left(r_{U} / r_{S}\right)
$$

in which 250.00 and 224.05 are the molecular weights of etidronate disodium and etidronic acid monohydrate, respectively; $C_{S}$ is the concentration, in mg per mL , of USP Etidronic Acid Monohydrate RS in the Standard preparation; $C_{U}$ is the concentration, in mg per mL , of Etidronate

Disodium in the Assay preparation; and $r_{U}$ and $r_{S}$ are the peak responses obtained from the Assay preparation and the Standard preparation, respectively.■2S (USP28)

## BRIEFING

Etidronate Disodium Tablets, USP 27 page 770. See briefing under Etidronate Disodium. The liquid chromatographic procedure in the Dissolution test and in the Assay is based on analyses performed with Waters IC-Pak Anion HC brand of L23 column. The typical retention time for etidronate peak is about 3 minutes.
(PA4: E. Gonikberg) RTS-40992-2; 40992-3

## Dissolution $\langle 711\rangle$ -

Medium: water; 900 mL .
Apparatus 1: 100 rpm .
Time: 30 minutes.
Proedtre Determine the amount of $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{Na}_{2} \mathrm{O}_{7} \mathrm{P}_{2}$-dissolved, employing the proeedure set forth in the Asisty making any neeessary volumetric adjustments.
-Determine the amount of $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{Na}_{2} \mathrm{O}_{7} \mathrm{P}_{2}$ dissolved by employing the following method.
Mobile phase and Chromatographic system-Proceed as directed in the Assay for Etidronate Disodium.

## Standard solution-

 FOR PRODUCTS LABELED TO CONTAIN 200 MG OF ETIDRONATE DISODIUM-Transfer approximately 20 mg of USP Etidronic Acid Monohydrate RS to a $100-\mathrm{mL}$ volumetric flask, dissolve in 50 mL of water, add 2.0 mL of 0.1 N sodium hydroxide, dilute with water to volume, and mix.FOR PRODUCTS LABELED TO CONTAIN 400 MG OF ETIDRO-
NATE DISODIUM-Transfer approximately 20 mg of USP Etidronic Acid Monohydrate RS to a $50-\mathrm{mL}$ volumetric flask, dissolve in 25 mL of water, add 2.0 mL of 0.1 N sodium hydroxide, dilute with water to volume, and mix.

Test solution-Transfer a portion of the solution under test to an HPLC vial.

Procedure-Separately inject equal volumes (about 100 $\mu \mathrm{L}$ for products labeled to contain 200 mg of Etidronate Disodium, and about $50 \mu \mathrm{~L}$ for products labeled to contain 400 mg of Etidronate Disodium) of the Standard solution and the Test solution into the chromatograph, record the chromatograms, and measure the areas for the major peaks. Calculate the quantities of $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{Na}_{2} \mathrm{O}_{7} \mathrm{P}_{2}$ dissolved, employing the procedure set forth in the Assay, making any necessary volumetric adjustments. ²S $_{\text {2S }}$ (USP28)
Tolerances-Not less than $70 \%$ ( $Q$ ) of the labeled amount of $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{Na}_{2} \mathrm{O}_{7} \mathrm{P}_{2}$ is dissolved in 30 minutes.

## Change to read:

## Assay-

Titrant and Standed preparation- Prepare as directed in the $-4 s$ say under Etidronate Disodium.
Assay preparation Weigh and finely powder not less than 20 fablets. Transfer an aceurately weighed portion of the powder, equivalent to about 200 me of etidrenate disoditm, to a 100 mL volumetric flask, and dilute with water to volume. Stir on a mag netic stirrer for about 10 minutes, and filter.
Procedure Proceed as directed for Procedure in the Assay under Etidrat Dis dium. Caleulate the quantity, in me, of $\mathrm{G}_{2} \mathrm{H}_{6} \mathrm{Na}_{2} \mathrm{O}_{7} \mathrm{P}_{2}$ in the pertion of Tablets taken by the formula:

$$
200\left(H_{4}+H_{s}\right),
$$

in which $Y_{t}$ and $Y_{s}$ are the volumes, in mL, of Titrant consumed by the Assaty preparation and the Standurd preparation, respectively.

- Mobile phase, Standard preparation, and Chromatographic system-Proceed as directed in the Assay under Etidronate Disodium.

Assay preparation-Weigh and finely powder not fewer than 20 tablets. Transfer an accurately weighed portion of the powder, equivalent to 160 to 170 mg of Etidronate Disodium, to a $200-\mathrm{mL}$ volumetric flask, and dilute with Mo bile phase to volume. Agitate the solution for at least 5 minutes, and pass through a $0.45-\mu \mathrm{m}$ nylon filter.

Procedure-Proceed as directed for Procedure in the $A s$ say under Etidronate Disodium. Calculate the quantity, in mg , of etidronate disodium $\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{Na}_{2} \mathrm{O}_{7} \mathrm{P}_{2}\right)$ in the portion of Tablets taken by the formula:

$$
C_{S} V_{U}(250.00 / 224.05)\left(r_{U} / r_{S}\right)
$$

in which 250.00 and 224.05 are the molecular weights of etidronate disodium and etidronic acid monohydrate, respectively; $C_{S}$ is the concentration, in mg per mL , of USP Etidronic Acid Monohydrate RS in the Standard preparation; $V_{U}$ is the volume, in mL , of the Assay preparation; and $r_{U}$ and $r_{S}$ are the peak responses obtained from the Assay preparation and the Standard preparation, respectively.■2S (USP28)

## Briefing

Finasteride Tablets, USP 27 page 795. It is proposed to revise the Dissolution section to include separate tests for products labeled as $5-\mathrm{mg}$ Tablets and for products labeled as $1-\mathrm{mg}$ Tablets. The chromatographic procedure in the Dissolution test for products labeled as 1-mg Tablets was developed using a Zorbax SB-Phenyl brand of L11 column.
(BPC: M. Marques) RTS—41002-1; 41588-1

## Change to read:

Dissolution $\langle 711\rangle$ -
Medium: water; 900 mL
Apparatus 2: 50 rpm .
${ }^{\boldsymbol{■}} \mathrm{FOR}$ PRODUCTS LABELED AS 5-MG TABLETS: ${ }^{\text {2S }}$ (USP28)

## Time: 45 minutes.

Determine the amount of $\mathrm{C}_{23} \mathrm{H}_{36} \mathrm{~N}_{2} \mathrm{O}_{2}$ dissolved by employing the following method.

Mobile phase-Prepare a filtered and degassed mixture of acetonitrile and water ( $29: 21$ ). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Diluting solution-Prepare a solution of acetonitrile and water (7:3).

Standard solution-Dissolve an accurately weighed quantity of USP Finasteride RS in Diluting solution, and dilute quantitatively, and stepwise if necessary, with Diluting solution to obtain a solution having a known concentration approximately equivalent to the sample under test.

Chromatographic system (see Chromatography $\langle 621\rangle$ )—The liquid chromatograph is equipped with a $220-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 5-\mathrm{cm}$ column that contains packing L1. The column temperature is maintained at $45^{\circ}$. The flow rate is about 2 mL per minute. Chromatograph the Standard solution, and record the peak responses as directed for Procedure: the capacity factor $\left(k^{\prime}\right)$ is not less than 2.0; the column efficiency is not less than 1000 theoretical plates; the tailing factor is not more than 2.0 ; and the relative standard deviation for replicate injections is not more than 2.0\%.

Procedure-Separately inject equal volumes (about $200 \mu \mathrm{~L}$ ) of the solution under test and the Standard solution into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the quantity of $\mathrm{C}_{23} \mathrm{H}_{36} \mathrm{~N}_{2} \mathrm{O}_{2}$ dissolved.

Tolerances-Not less than $75 \%(Q)$ of the labeled amount of $\mathrm{C}_{23} \mathrm{H}_{36} \mathrm{~N}_{2} \mathrm{O}_{2}$ is dissolved in 45 minutes.

■ FOR PRODUCTS LABELED AS $1-M G ~ T A B L E T S: ~_{\text {P }}$
Time: 30 minutes.
Mobile phase-Prepare a degassed mixture of acetonitrile and water (11:9). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).
Diluting solution-Prepare a solution of water and acetonitrile (7:3).
Standard solution-Dissolve an accurately weighed quantity of USP Finasteride RS in Diluting solution, to obtain a solution having a known concentration of 0.1 mg per mL . Dilute this solution quantitatively, and stepwise if necessary, in $0.5 \%$ sodium lauryl sulfate to yield a solution containing 0.001 mg of finasteride per mL .

Chromatographic system (see Chromatography $\langle 621\rangle$ )-
The liquid chromatograph is equipped with a $220-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 15-\mathrm{cm}$ column that contains $5-\mu \mathrm{m}$ packing L11. The column temperature is maintained at $45^{\circ}$. The flow rate is about 1.5 mL per minute. Chromatograph the Standard solution, and record the peak responses as directed for Procedure: the column efficiency is not less than 5000 theoretical plates; the tailing factor is not more than 2.0 ; and the relative standard deviation for replicate injections is not more than $2.0 \%$.

Procedure-Separately inject equal volumes (about 100 $\mu \mathrm{L}$ ) of the solution under test and the Standard solution into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the quantity of finasteride $\left(\mathrm{C}_{23} \mathrm{H}_{36} \mathrm{~N}_{2} \mathrm{O}_{2}\right)$ dissolved.

Tolerances-Not less than $80 \%(Q)$ of the labeled amount of $\mathrm{C}_{23} \mathrm{H}_{36} \mathrm{~N}_{2} \mathrm{O}_{2}$ is dissolved in 30 minutes. $\mathbf{m}^{2 S}$ (USP28)

## BRIEFING

Flucytosine, USP 27 page 798. Editorial revisions are proposed for the test for Fluorouracil to be consistent with USP style.
(PA7b: B. Davani) RTS-41389-1

## Change to read:

Fluorouracil-Dissolve 250 mg in 10 mL of a mixture of glacial acetic acid and water (8:2).
$\boldsymbol{m}_{(4: 1)} \cdot \boldsymbol{m}_{2 S}$ (USP28)
Apply $20 \mu \mathrm{~L}$ of this solution to a thin-layer chromatographic plate (see Chromatography $\langle 621\rangle$ ) coated with a $0.5-\mathrm{mm}$ layer of chromatographic silica gel mixture. To the same plate apply $20 \mu \mathrm{~L}$, in $10-\mu \mathrm{L}$ increments, of a + in 40,000
$\bullet_{0.025} \mathrm{mg}$ per $\mathrm{mL}_{\text {■ } 2 \text { (USP28) }}$
solution of USP Fluorouracil RS in a mixture of glacial acetic acid and water ( $4: 1$ ). Develop the chromatogram in a mixture of chloroform and glacial acetic acid (13:7) until the solvent front has moved not less than 14 cm from the origin. Remove the plate from the developing chamber, and allow the solvent to evaporate. Locate the spots on the plate by observing under short-wavelength UV radiation: any spot from the solution under test is not greater in size and intensity than the spot at the respective $R_{F}$ produced by the Standard solution, corresponding to not more than $0.1 \%$ of fluorouracil.

## BRIEFING

Fludarabine Phosphate, USP 27 page 800. It is proposed to revise the test for Chloride to reflect the procedure provided in the original proposal submitted by the manufacturer. The calculation of the formula in the Assay is also corrected.
(PA6: L. Evans) RTS-41590-1

## Change to read:

Chloride-not mere than 0.2\%
■Standard chloride solution-Transfer 82.4 mg of sodium chloride to a $100-\mathrm{mL}$ volumetric flask, and dissolve in and dilute with water to volume. Transfer 1.0 mL of this solution to a $10-\mathrm{mL}$ volumetric flask, and dilute with water to volume. Transfer 2.0 mL of this solution to a test tube, add 13.0 mL of water, and mix.

Test solution-Transfer about 50.0 mg of fludarabine phosphate, accurately weighed, to a test tube, dissolve in 15 mL of water, and heat gently if necessary.

Procedure—Add 1.0 mL of nitric acid to the Standard chloride solution and the Test solution, and place each in separate colorless test tubes, containing 1.0 mL of silver nitrate TS. The Test solution shows less turbidity than the Standard chloride solution ( $0.2 \%$ ).■2S (USP28)

## Change to read:

## Assay-

Mobile phase-Prepare a mixture of filtered, degassed $10-\mathrm{mM}$ monobasic potassium phosphate and methanol ( $47: 3$ ).

Standard preparation-Dissolve an accurately weighed quantity of USP Fludarabine Phosphate RS in Mobile phase, and dilute quantitatively, and stepwise if necessary, in Mobile phase to obtain a solution having a known concentration of 0.02 mg per mL .

Assay preparation-Transfer 50 mg of Fludarabine Phosphate, accurately weighed, to a $50-\mathrm{mL}$ volumetric flask, dissolve in and dilute with Mobile phase to volume, and mix. Transfer 5.0 mL of the solution to a $250-\mathrm{mL}$ volumetric flask, dilute with Mobile phase to volume, and mix.

Chromatographic system-The liquid chromatograph is equipped with a $260-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 15-\mathrm{cm}$ column containing $5-\mu \mathrm{m}$ packing L1. The flow rate is 1.0 mL per minute. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the relative standard deviation for replicate injections is not more than $1.0 \%$.

Procedure-Separately inject equal volumes (about $10 \mu \mathrm{~L}$ ) of the Standard preparation and Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the fludarabine phosphate peak. Calculate the quantity, in mg , of $\mathrm{C}_{10} \mathrm{H}_{13} \mathrm{FN}_{5} \mathrm{O}_{7} \mathrm{P}$ in the portion of Fludarabine Phosphate taken by the formula:

$$
\begin{gathered}
500 C\left(r_{t}+r_{s}\right), \\
-2500 C\left(r_{U} / r_{S}\right), \llbracket 2 S(U S P 28)
\end{gathered}
$$

in which $C$ is the concentration, in mg per mL , of USP Fludarabine Phosphate in the Standard preparation; and $r_{U}$ and $r_{S}$ are the peak responses for fludarabine in the Assay preparation and the Standard preparation, respectively.

## BRIEFING

Fluvoxamine Maleate Tablets, page 1243 of PF 30(4) [JulyAug. 2004]. It is proposed to add a Dissolution test to this new monograph.
(BPC: M. Marques) RTS-40316-6

## Add the following:

## ■Fluvoxamine Maleate Tablets

» Fluvoxamine Maleate Tablets contain not less than 90.0 percent and not more than 110.0 percent of the labeled amount of fluvoxamine maleate $\left(\mathrm{C}_{15} \mathrm{H}_{21} \mathrm{~F}_{3} \mathrm{~N}_{2} \mathrm{O}_{2} \cdot \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{4}\right)$.

Packaging and storage-Preserve in tight containers. Store at $25^{\circ}$, excursions permitted between $15^{\circ}$ and $30^{\circ}$.

USP Reference standards $\langle 11\rangle$ —USP Fluvoxamine Maleate $R S$.

Identification-The retention time of the major peak in the chromatogram of the Assay preparation corresponds to that in the chromatogram of the Standard preparation, as obtained in the Assay.

Dissolution $\langle 711\rangle$ -
Medium: water; 900 mL , degassed.
Apparatus 2: 50 rpm .
Time: 30 minutes.
Procedure-Determine the amount of fluvoxamine maleate $\left(\mathrm{C}_{15} \mathrm{H}_{21} \mathrm{~F}_{3} \mathrm{~N}_{2} \mathrm{O}_{2} \cdot \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{4}\right)$ dissolved by employing UV absorption at the wavelength of maximum absorbance at about 246 nm on portions of the solution under test centrifuged at 2000 rpm for 10 minutes, suitably diluted with Me dium, if necessary, in comparison with a Standard solution having a known concentration of USP Fluvoxamine Maleate RS in the same Medium.

Tolerances-Not less than $80 \%(Q)$ of the labeled amount of $\mathrm{C}_{15} \mathrm{H}_{21} \mathrm{~F}_{3} \mathrm{~N}_{2} \mathrm{O}_{2} \cdot \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{4}$ is dissolved in 30 minutes.

Uniformity of dosage units $\langle 905\rangle$ : meet the requirements.

## Related compounds-

Buffer solution, Mobile phase, Resolution solution, and Chromatographic system-Proceed as directed in the Assay.

Identification solution-Dissolve a quantity of maleic acid in Mobile phase, and dilute quantitatively, and stepwise if necessary, with Mobile phase to obtain a solution having a concentration of about 0.35 mg per mL .
Standard solution-Use the Standard preparation, prepared as directed in the Assay.

Test solution-Use the Assay stock preparation, prepared as directed in the Assay.

Procedure-Separately inject equal volumes (about 20 $\mu \mathrm{L}$ ) of the Standard solution, the Test solution, and the Identification solution into the chromatograph, record the chro-
matograms, and measure the responses for the major peaks. Calculate the percentage of impurities in the portion of Tablets taken by the formula:

$$
100(C / D) F\left(r_{i} / r_{s}\right)
$$

in which $C$ is the concentration, in mg per mL , of USP Fluvoxamine Maleate RS in the Standard solution; $D$ is the expected concentration, in mg per mL , of fluvoxamine maleate
taking into account the labeled amount and the amount of sample taken to prepare the Test solution; $F$ is the response factor of each impurity as given in Table 1; $r_{i}$ is the individual peak area of each impurity in the Test solution; and $r_{s}$ is the peak area of fluvoxamine maleate in the Standard solution. The limits of impurities are specified in Table 1. [NOTE--Disregard any peak due to maleic acid or to the reagent blank.]

Table 1

| Compound name | Relative retention time | Response <br> Factor | Limit \% |
| :---: | :---: | :---: | :---: |
| Maleic acid | about 0.19 | - | - |
| 5-Methoxy-1-[4-(trifluoromethyl)phenyl]-1-pentanone-(E)-O-[2-[(2-succinyl)amino]ethyl]oxime | about 0.50 | 1.0 | 0.8 |
| 5-Methoxy-4'-(trifluoromethyl)valerophenone ( $E$ )- $O$ -(2-aminoethyl)aminoethyl oxime maleate | about 0.67 | 1.4 | 0.2 |
| $Z$-isomer | about 0.79 | 1.0 | 0.5 |
| Fluvoxamine | 1.0 | - | - |
| 4'-(Trifluoromethyl)valerophenone (E)-O-2-(2-amino ethyl)aminoethyl oxime maleate | about 1.18 | 1.0 | 0.2 |
| (E)-O-2-(2-Aminoethyl)-4-(trifluoromethyl)- $\alpha$-phenylacetophenone oxime maleate | about 1.74 | 1.0 | 0.2 |
| 4'-(Trifluoromethyl)valerophenone( $E$ )-O-(2-aminoethyl) oxime maleate | about 2.00 | 1.0 | 0.2 |
| 5-Methoxy-4'-(trifluoromethyl)valerophenone oxime | about 3.45 | 0.6 | 0.2 |
| 5-Methoxy-1-[4-(trifluoromethyl)phenyl]-1-pentanone-(E)-O-(2-aminoethyl] oxime maleic acid monoamide | about 4.3 | 1.0 | 0.2 |
| 5-Methoxy-4'-(trifluoromethyl)valerophenone ketone | about 4.2 | 0.3 | 0.2 |
| Unknown impurities | - | 1.0 | 0.1 |
| Total | - | - | 1.8 |

## Assay-

Buffer solution-Dissolve approximately 5 g of 1-pentanesulfonic acid sodium salt and 0.7 g of monobasic potassium phosphate in 620 mL of water. Adjust with phosphoric acid to a pH of $3.00 \pm 0.05$.

Mobile phase-Prepare a filtered and degassed mixture of Buffer solution and acetonitrile ( $62: 38$ ). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).
Resolution solution-Transfer approximately 6 mg of fluvoxamine maleate to a $50-\mathrm{mL}$ volumetric flask. Heat the sample at $120^{\circ}$ for 10 minutes. Cool down to room temperature, and add 3.0 mL of 0.1 N hydrochloric acid. Heat the solution in a water bath for 10 minutes. Cool down to room temperature, add 50 mg of fluvoxamine maleate, and dissolve in 25 mL Mobile phase. Dilute with Mobile phase to volume, and mix.

Standard preparation-Dissolve an accurately weighed quantity of USP Fluvoxamine Maleate RS in Mobile phase, and dilute quantitatively, and stepwise if necessary, with Mobile phase to obtain a solution having a known concentration of about 0.05 mg per mL .

Assay stock preparation-Weigh and finely powder not fewer than 20 Tablets. Transfer an accurately weighed portion of the powder, equivalent to about 500 mg of fluvoxamine maleate, to a $500-\mathrm{mL}$ volumetric flask, add about 250 mL of Mobile phase, sonicate for about 15 minutes, shake by mechanical means for about 15 minutes, dilute with Mobile phase to volume, and mix. Centrifuge a portion of this solution for 10 minutes.

Assay preparation-Transfer 5.0 mL of the supernatant from the Assay stock preparation to a $100-\mathrm{mL}$ volumetric flask. Pass a portion of this solution through a filter having a $45-\mu \mathrm{m}$ or finer porosity, and use the filtrate.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a $234-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 25-\mathrm{cm}$ column that contains packing L7. The flow rate is about 1.7 mL per minute. The column temperature is maintained at $40^{\circ}$. Chromatograph the Resolution solution, and record the peak responses as directed for Procedure: the relative retention times are about 0.19 for maleic acid, 0.5 for 5-methoxy-1-[4-(trifluoromethyl)phe-nyl]-1-pentanone-(E)-O-[2-[(2-succinyl)amino]ethyl]oxime, 0.79 for the $Z$-isomer, and 1.0 for fluvoxamine maleate; and the resolution, $R$, between the $Z$-isomer and fluvoxamine maleate is not less than 2.0 and not less that 5.0 between 5-methoxy-1-[4-(trifluoromethyl)phenyl]-1-pentanone- $(E)-O-[2-[(2$-succinyl)amino]ethyl]oxime and the $Z$-isomer. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the column efficiency is not less than 5000 theoretical plates; the tailing factor is not more than 2.0 ; and the relative standard deviation for replicate injections is not more than $2.0 \%$.

Procedure-Separately inject equal volumes (about 20 $\mu \mathrm{L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the fluvoxamine maleate peaks. Calculate the quantity, in mg , of fluvoxamine maleate $\left(\mathrm{C}_{15} \mathrm{H}_{21} \mathrm{~F}_{3} \mathrm{~N}_{2} \mathrm{O}_{2} \cdot \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{4}\right)$ in the portion of Tablets taken by the formula:

$$
10,000 C\left(r_{U} / r_{s}\right)
$$

in which $C$ is the concentration, in mg per mL , of USP Fluvoxamine Maleate RS in the Standard preparation; and $r_{U}$ and $r_{s}$ are the peak areas obtained from the Assay preparation and the Standard preparation, respectively. $\quad$ 2S (USP28)

Briefing

Glucagon, USP 27 page 869, page 3260 of the Second Supplement, and page 1894 of $P F 29(6)$ [Nov.--Dec. 2003]. It is proposed to allow for the Assay to be repeated if the test fails to meet the confidence interval requirements. In the absence of any significant adverse comment, it is proposed to implement this revision via the First Interim Revision Announcement pertaining to USP 28-NF 23, with an official date of February 1, 2005.
(BNT: L. Callahan) RTS-41447-1

## Add the following:

-Labeling-Where it is intended for use in preparing injectable dosage forms, the label states that it is sterile or must be subjected to further processing during the preparation of injectable dosage forms.■1S (USP28)

Assay-[NOTE-All buffers have a final pH of 7.4, unless otherwise indicated.]

HEPATOCYTE PREPARATION-
Calcium-free perfusion buffer with dextrose-Prepare a solution containing, in each L, 7.92 g of sodium chloride, 0.35 g of potassium chloride, 1.80 g of dextrose, 0.19 g of edetic acid, and 2.38 g of $N$-2-hydroxyethylpiperazine- $N$ '2-ethanesulfonic acid. Oxygenate prior to circulation.

Collagenase buffer-Prepare a solution containing, in each L, 3.62 g of sodium chloride, 23.83 g of N -2-hydroxyethylpipera-zine- $N^{\prime}$-2-ethanesulfonic acid, 0.35 g of potassium chloride, 0.52 g of calcium chloride, and 1.8 g of dextrose. Adjust to a pH
of 7.6, and oxygenate. Immediately before perfusion, dissolve a quantity of collagenase in this solution to obtain a concentration of $0.02 \%$ to $0.05 \%$.
Wash buffer-Prepare a solution containing, in each L, 7.92 g of sodium chloride, 0.35 g of potassium chloride, 0.19 g of edetic acid, 2.38 g of $N-2$-hydroxyethylpiperazine- $N^{\prime}-2$-ethanesulfonic acid, 0.22 g of calcium chloride, and 0.12 g of magnesium sulfate.

Incubation buffer-Prepare a solution containing, in each L, 6.19 g of sodium chloride, 0.35 g of potassium chloride, 0.22 g of calcium chloride, 0.12 g of magnesium sulfate, 0.16 g of monobasic potassium phosphate, 11.915 g of N -2-hydroxyethylpipera-zine- $N^{\prime}-2$-ethanesulfonic acid, and $1 \%$ bovine serum albumin. Adjust to a pH of 7.5 .

Test animals-Male Sprague-Dawley rats are maintained on a standard rat chow diet and freely given water. On the morning of the test, select a healthy rat weighing approximately 300 g , and administer 100 Units of Heparin Sodium subcutaneously.

Procedure-[NOTE-Conduct this procedure in the morning to ensure that the rat has optimal glycogen in its liver.] Anesthetize the rat with an appropriate anesthetic. Open the abdominal cavity, and isolate the portal vein. Insert an angiocatheter connected to a perfusion pump, and tie into the portal vein at the general location of the lienal branch. Start the perfusion ( 25 mL per minute) in situ with Calcium-free perfusion buffer with dextrose, equilibrated with oxygen, at a temperature of $37^{\circ}$. As the liver enlarges, cut the inferior vena cava to allow pressure equilibrium. [NOTE-About 300 mL of the perfusate is needed to clear the liver of red blood cells at a flow rate of 30 to 60 mL per minute.] Then circulate Collagenase buffer at a flow rate of 30 to 60 mL per minute for about $10 \mathrm{~min}-$ utes. The exact concentration of collagenase (within the range of $0.02 \%$ to $0.05 \%$ ) is determined empirically for each lot of enzyme. The concentration of collagenase is that necessary to consistently cause a breakdown of the liver about 10 minutes after initial entry of the Collagenase buffer into the liver. When the liver significantly increases in size, changes color and consistency, and starts to leak perfusate out of the lobes, change the system to the oxygenated prewarmed Wash buffer. About 100 mL of Wash buffer is needed to wash the liver of collagenase at a flow rate of 25 mL per minute. Surgically remove the liver from the animal and place in a prewarmed tray containing oxygenated Wash buffer $\left(37^{\circ}\right)$. Gently comb the liver with a stainless steel, fine-toothed comb to free the hepatocytes. Wash the hepatocytes with Wash buffer, and filter through cheesecloth (or a 150- $\mu \mathrm{m}$ mesh polyethylene net) into a plastic beaker. Centrifuge the cell suspension for about 2 minutes at about $25 \times g$ to form a loosely packed pellet. Discard the supernatant, and resuspend the pellet in Wash buffer. Repeat the washing procedure twice for a total of three washes. Resuspend the final pellet in 100 to 200 mL of Incubation buffer, depending on cell yield. [NOTE-If the Assay procedure is interrupted, cool the cells by collecting the cells in a beaker placed in ice. The cells are washed with ice-cold Wash buffer, and stored on ice until ready for use. At that point the cells are pelleted once more, and resuspended in ice-cold Incubation buffer.]

Suitability-The concentrations of cells may vary due to the collagenase activity and the viability of the hepatocytes. To check cell viability and to determine viable cell concentration, dilute duplicate $100-\mu \mathrm{L}$ aliquots of cell suspension with $400 \mu \mathrm{~L}$ of Wash buffer and $500 \mu \mathrm{~L}$ of isotonic $0.4 \%$ trypan blue. The aliquots are counted in a hemocytometer. The cells are suspended in Incubation buffer to obtain a viable cell concentration of not less than $3 \times 10^{6}$ per mL . Count several distinct fields. [NOTE-Viable cells are those cells that exclude the trypan blue.]

NEGATIVE CONTROL SOLUTION-Prepare a solution containing $0.5 \%$ bis(trimethylsilyl)acetamide (BSA) in sterile water.

INCUBATION FLASKS-Use $25-\mathrm{mL}$ conical flasks, the bottoms of which have been heated and pushed inward to form a conically raised center.
STANDARD PREPARATIONS_-In duplicate, dissolve a suitable quantity of USP Glucagon RS, accurately measured, in 0.01 N hydrochloric acid or other suitable diluent to obtain a solution containing 1.0 USP Glucagon Unit per mL.■2S (USP27) All dilutions
thereafter are made using $0.5 \%$ BSA (w/v) in water. Accurately dilute measured volumes of each solution with Negative control solution to obtain five concentrations-200, 100, 50, 25, and 12.5 micro-Units per mL - of each solution (Standard preparations). Pipet 0.2 mL of each Standard preparation into separate Incubation flasks. Pipet 0.2 mL of Negative control solution into each of two flasks (Negative control solutions 1 and 2). Then add the hepatocytes into each of the 12 flasks.

ASSAY PREPARATIONS-_Using accurately weighed quantities of Glucagon, proceed as directed for Standard preparations.

D-GLUCOSE DETERMINATION-
Standard stock solution-Transfer 2.0 g of USP Dextrose RS, accurately weighed, to a $200-\mathrm{mL}$ volumetric flask; and dissolve in and dilute with saturated benzoic
$\bullet{ }^{\text {acid }}{ }_{\bullet}$
solution to volume.
Standard solutions-Transfer suitable quantities of Standard stock solution to three flasks, and dilute with saturated benzoic acid solution to obtain solutions having known concentrations of 0.5 , 1.0 , and 1.5 times the typical sample glucose concentration.

Potassium ferrocyanide solution-Dissolve 1.25 g of trihydrate potassium ferrocyanide in 125 mL of Sterile Water for Injection. System suitability—Analyze the Potassium ferrocyanide solution, the Standard solutions, and five replicates of the middle Standard solution. Prepare a standard curve using the Standard solutions as directed for Procedure: the relative standard deviation of the standard curve is not more than $2.0 \%$; the response of the Potassium ferrocyanide solution is not more than 30 mg per L; and the relative standard deviation is not more than $2.0 \%$ for the replicate analyses of the middle Standard solution.

PROCEDURE-Dispense 5 mL of Hepatocyte preparation into the special incubation flasks in sequence from high glucagon concentration to low glucagon concentration, alternating the Standard preparations with the Assay preparations. The flasks are swirled in an orbiting water bath at 125 rpm at $30^{\circ}$ for approximately 30 to 60 minutes. [NOTE-The exact incubation time must be determined to optimize the signal-to-noise ratio.] Following incubation, place 0.5 - to $1.0-\mathrm{mL}$ aliquots, in duplicate, from each incubation flask into labeled tubes, and centrifuge at $12,500 \times g$. Determine the percentage of glucose concentration in each flask's supernatant.

To conform to the linear range of the instrument being used, it may be necessary to adjust by dilution each of the preparations. Use a glucose analyzer that has demonstrated appropriate specificity, accuracy, precision, and linear response over the range of concentrations being determined. [NOTE-A suitable analyzer may use an immobilized, oxidase-enzyme membrane or jacket-generating hydrogen peroxide, which is then detected at the electrode.] Perform the glucose analysis in the following sequence: Negative control solution 1, Standard preparations, Assay preparations, and Negative control solution 2. Determine the percentage of glucose against the Negative control solution for each preparation.

CALCULATIONS-
Linearity test-Use an analysis of variance (ANOVA) with one sample assayed against a standard, and using two replicates each, construct a table (see Table 1). Compare the value of the ratio MSNL/MSRES ${ }_{1}$ to a critical value obtained from a table for an $F$ distribution with $m-2$ and $3 m-3$ degrees of freedom, where $m$ is the number of dose levels for each preparation. If the ratio MSNL/ MSRES $_{1}$ does not indicate the presence of significant nonlinearity (ratio value is lower than the critical value), then proceed to the test for parallelism. If the ratio exceeds the critical value (significance level of 0.05 ), the nonlinearity is statistically significant and the test is repeated, discarding the results from either the highest or lowest dose of both the Standard preparations and the Assay preparations (four dose levels). If the ratio MSNL/MSRES ${ }_{1}$ does not indicate the presence of significant nonlinearity, then proceed to the test for parallelism.

Parallelism test-Compare the ratio MSNP/MSRES 2 to a critical value obtained from an $F$ distribution having 1 and $4 m-5$ degrees of freedom. If the ratio $\mathrm{MSNP}^{2} \mathrm{MSRES}_{2}$ does not indicate the presence of significant nonparallelism, then the assay is considered valid. Use the appropriate dose levels for the estimation of the relative potency.

Relative potency-Calculate the relative potency, $R$, of the Assay preparations as compared with the Standard preparations as follows.
(1) $X_{j}$ is defined as the $\log _{10}$ of the $j^{\text {th }}$ dose of the Standard preparations or the Assay preparations. The glucagon dose varies from 12.5 to $200 \times 10^{-6}$ USP Glucagon Units per mL . For ease in the subsequent calculations, these doses are respectively represented by 1 through 5 , as shown in the table below.

| $j$ | 1 | 2 | 3 | 4 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Dose | 12.5 | 25 | 50 | 100 | 200 |
| $X_{j}$ | 1.10 | 1.40 | 1.70 | 2.00 | 2.30 |

(2) To differentiate between the Standard preparations and the Assay preparations in the calculations, the subscript $i$ will be used, with $i=1$ to designate the Standard preparations and $i=2$ to designate the Assay preparations. $Y_{i j k}$ will denote the glucose concentration associated with the $k^{\text {th }}$ replicate of the $j^{\text {th }}$ dose of the $i^{\text {th }}$ preparation. For example, $Y_{l j k}$ is the glucose concentration associated with the $k^{\text {th }}$ replicate of the $j^{\text {th }}$ dose of the appropriate Standard preparation; $Y_{l l k}$ is the glucose concentration associated with the $k^{\text {th }}$ replicate of dose 1 of the Standard preparation; and $Y_{2 l k}$ is the glucose concentration associated with the $k^{\text {th }}$ replicate of dose 1 of the Assay preparation. Dose 1 represents a glucose dose of $12.5 \times 10$ ${ }^{6}$ USP Glucagon Units per mL. Finally, $Y_{132}$ represents the glucose concentration associated with the $2^{\text {nd }}$ replicate of dose 3 for the Standard preparation.
(3) $Y_{S}$ and $Y_{t}$ denote the average glucose concentrations for the Standard preparations and the Assay preparations, respectively.
(4) Calculate the least-squares slope estimate, $b$, for a linear regression relating the $Y_{i j k}$ 's to the $X_{j}^{\prime}$ 's as follows: $b=S_{x y} / S_{x x}$, with $S_{x y}$ and $S_{x x}$ calculated using the equations in Table 2.
(5) The $\log$ potency, $M$, is calculated using $M=-1\left[\left(Y_{S}-Y_{t}\right) / b\right]$.
(6) $R=\operatorname{antilog}(M)$.
(7) Calculate the confidence limits (upper and lower) for the relative potency, $R$, using the value $s^{2}=$ MSRES $_{3}$ (see Table 1 and Table 2) as follows. Obtain $t$ from a table for a $t$ distribution having $4 m-4$ degrees of freedom. For the $95 \%$ limits, the $t$ values can be obtained from Table 9 under Design and Analysis of Biological Assays $\langle 111\rangle$.

NOTE-For confidence limits having other probability levels (i.e., $100(1-a) \%$ ), the right tail $t$ critical value having $a / 2$ area to its right is used.

$$
\begin{aligned}
& \text { Calculate } g=t^{2} S^{2} / b^{2} S_{x x} \\
& \qquad \text { and } F=(t s / b) \sqrt{(1 / m)(1-g)+\left(M^{2} / S_{x x}\right)},
\end{aligned}
$$

and calculate

$$
M_{L}=(M-F) /(1-g),
$$

and

$$
M_{U}=(M+F) /(1-g)
$$

where $M$ is the $\log$ potency and $M_{L}$ and $M_{U}$ are the log potency lower and upper confidence limits. The lower and upper confidence limits for the relative potency, $R$, are given by

$$
\begin{aligned}
& R L=\operatorname{antilog}\left(M_{L}\right) \\
& R U=\operatorname{antilog}\left(M_{U}\right)
\end{aligned}
$$

It meets the requirements if the potency is between 0.8 and 1.25 USP Glucagon Units per mg, and the confidence interval width at $P=0.95$ does not exceed $45 \%$ of the computed potency.
${ }^{\bullet}$ Repeat the assay if the confidence interval width exceeds $45 \%$ of the computed potency.

Table 1. ANOVA for the Rat Hepatocyte Assay for Glucagon

| Source | Degrees of <br> Freedom | SS (Sum of <br> Squares) | MS (Mean <br> Square) |
| :--- | :---: | :---: | :---: |
| Preparations | 1 | SSPREP | MSPREP |
| Replicates | 1 | SSREP | MSREP |
| Linear Slope $_{\text {Residual }_{3}}$ | 1 | SSLIN | MSLIN |
| Nonparallelism $_{\text {Residual }_{2}}$ | $1 m-4$ | SSRES $_{3}$ | MSRES $_{3}$ |
| Nonlinearity $_{\text {Residual }_{1}}$ | $4 m-5$ | SSNP $_{2}$ | MSNP $^{2}$ |
| TOTAL $^{2}$ | $3 m-2$ | SSNL $_{2}$ | MSRES $_{2}$ |

NOTES-This analysis pertains to one sample assayed against a standard, using two replicates each.

The number of dose levels for each preparation is denoted by $m$. Table 2 gives the equations for calculating the SS terms.
In each row of the ANOVA table, the MS is obtained by dividing the SS term by the degrees of freedom.

Table 2. Equations for Calculating the Sums of Squares in the Analysis of Variance*

$$
\begin{aligned}
& Y_{i .}=\sum \sum_{j k} y_{i j k} \\
& Y_{j}=\sum_{i k} y_{i j k} \\

## Briefing

Hydrocodone Bitartrate, USP 27 page 919, page 3062 of the First Supplement, and page 1148 of the Fourth Interim Revision Announcement in PF 30(4) [May-June 2004]. It is proposed to resubmit the text that previously appeared in PF 28(1) [Jan.-Feb. 2002], which replaces the test for Ordinary impurities with a test for Related compounds. This impurity test uses a stability-indicating high-pressure liquid chromatographic method that resolves all known process impurities. The proposal from PF 29(1) [Jan.-Feb. 2003] that was postponed in the Fourth Interim Revision Announcement and will appear in USP 28 is hereby cancelled; it would have revised the Assay and added a new test for Related compounds.
(PA2: C. Anthony) RTS-41642-1

## Change to read:

USP Reference standards $\langle 11\rangle$ —USP Dihydrocodeine Bitartrate RS. USP Hydrocodone Bitartrate RS.
-USP Hydrocodone Bitartrate Related Compound A $R S$. п $^{\text {2S (USP28) }}$

## Delete the following:

日 Ordinary imptrities $\langle 466$ )-
Test solution: a mixture of methanel and water ( $1: 1$ ).
Standard solution: a mixture of methanol and water ( $1: 1$ ).
Elutat: a mixture of hexanes, ueetone, methanel, and ammo nitm hydroxide $(60: 40: 20: 1.5)$.
†isualization: 3, followed by overspraying with hydregen per oxide TS. [NOTE Gover the thin layer chromatographic plate with a glass plate stow fading of the spots. Exelude the rigin spet, if present, from the determination of the total impurities.] 12 (USP28)

## Add the following:

-Related compounds- [NOTE-Dry both the USP Hydrocodone Bitartrate RS and the Hydrocodone Bitartrate materials in vacuum at $105^{\circ}$ for 2 hours. Immediately transfer the dried materials to a desiccator containing phosphorus pentoxide. Weigh each dried material individually within 1 minute, and proceed with the Related compounds test.]

Solution A-Prepare a filtered and degassed mixture of 0.15 M monobasic sodium phosphate buffer, adjust with phosphoric acid to a pH of $3.3 \pm 0.1$.
Solution B-Prepare a filtered and degassed mixture of acetonitrile and Solution $A$ (50:50).

Mobile phase-Use variable mixtures of Solution A and Solution B as directed for Chromatographic system. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Diluent: a mixture of methanol and water ( $50: 50$ ).
Benzophenone stock solution-Transfer about 16 mg of benzophenone, accurately weighed, to a $100-\mathrm{mL}$ volumetric flask. Dissolve in and dilute with dehydrated alcohol to volume, and mix.

System suitability solution-Transfer about 25 mg of previously dried USP Hydrocodone Bitartrate RS to a $100-\mathrm{mL}$ volumetric flask, add about 25 mg of USP Dihydrocodeine Bitartrate RS, 17 mg of USP Hydrocodone Bitartrate Related Compound A RS, and 5 mL of phosphoric acid. Add 5.0 mL of Benzophenone stock solution, dilute with water, and mix.

Test solution-Transfer an accurately weighed quantity of previously dried Hydrocodone Bitartrate, equivalent to about 100 mg of hydrocodone bitartrate $\left(\mathrm{C}_{18} \mathrm{H}_{21} \mathrm{NO}_{3}\right.$. $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{6}$ ), to a $100-\mathrm{mL}$ volumetric flask, dissolve in and dilute with Diluent to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a $278-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 25-\mathrm{cm}$ column that contains a $5-\mu \mathrm{m}$ packing L7. The column temperature is maintained at $50^{\circ}$. The flow rate is about 2.2 mL per minute. The chromatograph is programmed as follows.

| Time <br> (minutes) | Solution A <br> $(\%)$ | Solution B <br> $(\%)$ | Elution |
| :---: | :---: | :---: | :--- |
| 0 | 95 | 5 | equilibrium |
| $0-17$ | $95 \rightarrow 90$ | $5 \rightarrow 10$ | linear gradient |
| $17-24$ | $90 \rightarrow 88$ | $10 \rightarrow 12$ | linear gradient |
| $24-40$ | $88 \rightarrow 30$ | $12 \rightarrow 70$ | linear gradient |
| $40-50$ | 30 | 70 | isocratic |
| $50-54$ | $30 \rightarrow 95$ | $70 \rightarrow 5$ | linear gradient |

Chromatograph the System suitability solution, and record the peak responses as directed for Procedure: the resolution, $R$, between hydrocodone and hydrocodone bitartrate related compound A is not less than 4.1; the capacity factor, $k^{\prime}$, is in the range of 17 to 20 for hydrocodone bitartrate; and the relative standard deviation, determined from analyte peaks, is not more than $15 \%$.

Procedure-Inject a volume ( $20 \mu \mathrm{~L}$ ) of the Test solution into the chromatograph, record the chromatogram, and measure the peak responses. Calculate the percentage of each individual impurity in the portion of Hydrocodone Bitartrate taken by the formula:

$$
100\left(F r_{i} / r_{s}\right)
$$

in which $F$ is the relative response factor and is equal to 1.24 for dihydrocodeine bitartrate, 2.27 for hydrocodone bitartrate related compound A, and 13.73 for benzophenone; $r_{i}$ is the individual peak response of hydrocodone related compound A, dihydrocodeine bitartrate, and benzophenone in the Test solution; and $r_{s}$ is the sum of all peak responses. Not more than $0.5 \%$ each of hydrocodone bitartrate related compound A, dihydrocodeine bitartrate, and benzophenone is found; and the sum of all impurities is not more than $2.0 \%$.■2S (USP28)

## BRIEFING

Hydrogen Peroxide Concentrate, USP 27 page 935. It is proposed to revise the test for Acidity to specify that 25 mL of the diluted solution is titrated to be consistent with the same test under Hydrogen Peroxide Topical Solution.
(PA7b: B. Davani) RTS-41018-1

## Change to read:

Acidity-Dilute 25 g with water to 250 mL ,
■and mix thoroughly. Take 25 mL of the solution, $\mathbf{m}_{2 S}$ (USP28) add phenolphthalein TS, and titrate with 0.10 N sodium hydroxide: not more than 2.5 mL is required for neutralization.

## BRIEFING

Insulin, USP 27 page 981 and page 1906 of PF 29(6) [Nov.Dec. 2003]. It is proposed to change the dimensions of the column used in the test for Limit of high molecular weight proteins. The liquid chromatographic procedure was validated using a MacMod Zorbax GF250 brand of L20 column.
(BNT: L. Callahan) RTS-41635-1

## Change to read:

Labeling-Label it to indicate the one or more animal species to which it is related, as pork, as beef, or as a mixture of pork and beef. If the Insulin is purified, label it as such.
-Where it is intended for use in preparing injectable dosage forms, the label states that it is sterile or must be subjected to further processing during the preparation of injectable dosage forms.■1S (USP28)

## Change to read:

## Limit of high molecular weight proteins-

Arginine solution-Prepare a solution of L-arginine in water containing 1 mg per mL .

Mobile phase-Prepare a filtered and degassed mixture of Arginine solution, acetonitrile, and glacial acetic acid (65:20:15). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Resolution solution-Dissolve 4 mg of Insulin containing more than $0.4 \%$ high molecular weight proteins in 1 mL of 0.01 N hydrochloric acid. Store this solution in a refrigerator, and use within 7 days. [NOTE--Insulin containing the indicated percentage of high molecular weight proteins may be prepared by allowing Insulin to stand at room temperature for about 5 days.]

Test solution-Transfer about 4 mg of Insulin to a small vial, add 1 mL of 0.01 N hydrochloric acid, and mix to dissolve. Store in a refrigerator, and use within 7 days.

Chromatographic system (see Chromatography $\langle 621\rangle$ )—The liquid chromatograph is equipped with a $276-\mathrm{nm}$ detector and a $7.8 \mathrm{~mm} \times 30 \mathrm{~cm}$

■9.4-mm $\times 25-\mathrm{cm}_{■ 2 \mathrm{~S}}$ (USP28)
column that contains packing L20. The flow rate is about 0.5 mL per minute. Chromatograph the Resolution solution, and record the peak responses as directed for Procedure: the retention times are between 13 and 17 minutes for the polymeric insulin complexes, about 17.5 minutes for the covalent insulin dimer, and between 18 and 22 minutes for the insulin monomer, with salts eluting after the insulin monomer; and the ratio of the height of the covalent insulin dimer peak to the height of the valley between the covalent insulin dimer peak and the insulin monomer peak is not less than 2.0.

Procedure-Inject a volume (about $100 \mu \mathrm{~L}$ ) of the Test solution into the chromatograph, record the chromatogram, and measure the areas of the peak responses, disregarding any peaks having retention times greater than that of the insulin monomer. Calculate the percentage of high molecular weight proteins in the portion of Insulin taken by the formula:

$$
100 \Sigma r_{H} /\left(\Sigma r_{H}+r_{M}\right)
$$

in which $\Sigma r_{H}$ is the sum of the responses for all peaks having retention times less than that of the insulin monomer, and $r_{M}$ is the peak response of the insulin monomer: not more than $1.0 \%$ is found.

## Add the following:

-Other requirements-Where the label states that Insulin is sterile, it meets the requirements for Sterility under Insulin Injection.■1S (USP28)

Briefing

Insulin Human Injection, USP 27 page 984. On the basis of data and comments received for Insulin Injection, it is proposed to lower the limit of high molecular weight proteins.
(BNT: L. Callahan) RTS-41107-2

## Add the following:

-Limit of high molecular weight proteins-Proceed as directed in the test for Limit of high molecular weight proteins under Insulin Injection: not more than $1.7 \%$ is found.■2S (USP28)

## Change to read:

Other requirements-It meets the requirements under Injections $\langle 1\rangle$ and for $p H$, Zine emtent, and Limit of high moleculdr weight proteins under Insulin Injection.
$\square_{p H}$ and Zinc content.■2S (USP28)

## Briefing

Levothyroxine Sodium, USP 27 page 1084; Liothyronine Sodium, USP 27 page 1094; Liotrix Tablets, USP 27 page 1096. Because of the poor solubility of levothyroxine and liothyronine in the Mobile phase, it is proposed to modify the Standard preparation in the Assay. This change also affects the test for Limit of liothyronine. It also affects the Assay and test for Limit of liothyronine under Levothyroxine Sodium Tablets.
(PA4: E. Gonikberg) RTS-41634-1

## Change to read:

## Assay-

Mobile phase-Prepare a degassed and filtered mixture of water and acetonitrile ( $60: 40$ ) that contains 0.5 mL of phosphoric acid in each 1000 mL . Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Standard preparation Transfer aceurately weighed quantities of USP Levothyroxine PS and USP Liothyronine PS to a-suitable eontainer, dissolve in and dilute quantitatively and stepurise with Mobile phase to obtain a solution having known concentrations of about $10 \mu \mathrm{~g}$ of levethyroxine per mL and $0.2 \mu \mathrm{~g}$ of liothyronine per mb.
-0.01 M Methanolic sodium hydroxide——Dissolve 400 mg of sodium hydroxide in 500 mL of water. Cool, add 500 mL of methanol, and mix.

Levothyroxine stock solution-Dissolve an accurately weighed quantity of USP Levothyroxine RS in 0.01 M Methanolic sodium hydroxide to obtain a solution having a known concentration of about 0.4 mg of levothyroxine per mL .

Liothyronine stock solution-Dissolve an accurately weighed quantity of USP Liothyronine RS in 0.01 M Methanolic sodium hydroxide to obtain a solution having a known concentration of about 0.4 mg of liothyronine per mL . Make a 1:100 dilution of this solution using Mobile phase.

Standard preparation-Transfer appropriate volumes of Levothyroxine stock solution and Liothyronine stock solution to a suitable container, and dilute quantitatively and stepwise, if necessary, with Mobile phase to obtain a solu-
tion having known concentrations of about $10 \mu \mathrm{~g}$ of levothyroxine per mL and $0.2 \mu \mathrm{~g}$ of liothyronine per mL . ${ }^{2 S}$ (USP28)

Assay preparation-Transfer an accurately weighed portion of about $100 \mu \mathrm{~g}$ of Levothyroxine Sodium into a centrifuge tube, add 2 glass beads, pipet 10 mL of Mobile phase into the tube, and mix using a vortex mixer for 3 minutes. Centrifuge to obtain a clear supernatant, filtering if necessary.

Chromatographic system (see Chromatography $\langle 621\rangle$ )-The liquid chromatograph is equipped with a $225-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 25-\mathrm{cm}$ column that contains packing L10. The flow rate is about 1.5 mL per minute. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the resolution, $R$, between the liothyronine and levothyroxine is not less than 5.0; and the relative standard deviation for replicate injections is not more than $2.0 \%$ for levothyroxine.
Procedure-Separately inject equal volumes (about $100 \mu \mathrm{~L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the quantity, in $\mu \mathrm{g}$, of $\mathrm{C}_{15} \mathrm{H}_{10} \mathrm{I}_{4} \mathrm{~N}$ $\mathrm{NaO}_{4}$ in the portion of Levothyroxine Sodium taken by the formula:

$$
(798.85 / 776.87)(10 C)\left(r_{U} / r_{S}\right)
$$

in which 798.85 and 776.87 are the molecular weights of levothyroxine sodium and levothyroxine, respectively; $C$ is the concentration, in $\mu \mathrm{g}$ per mL , of USP Levothyroxine RS in the Standard preparation; and $r_{U}$ and $r_{S}$ are the levothyroxine peak responses obtained from the Assay preparation and the Standard preparation, respectively.

## Briefing

Lidocaine Hydrochloride and Dextrose Injection, USP 27 page 1089 -See briefing under Alcohol in Dextrose Injection.
(PA1: K. Russo) RTS-41401-4

## Change to read:

Assay for dextrose-Determine the angular rotation of Injection in a suitable polarimeter tube at $25^{\circ}$ (see Optical Rotation-(781)). The observed ratation in degrees, multiplied by 1.04254 , im which $A$ is the ratio 200 divide by the length, in mm, of the polarimeter tube employed, represents the weight, in ${ }^{5}$, of $_{6} H_{42} \Theta_{6} \cdot H_{2} \Theta$ in 100 mL of the Injection.
-(see Optical Rotation $\langle 781\rangle$ ). Calculate the percentage ( g per 100 mL ) of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}$ in the portion of Injection taken by the formula:

$$
(100 / 52.9)(198.17 / 180.16) A R,
$$

in which 100 is percent; 52.9 is the midpoint of the specific rotation range for anhydrous dextrose, in degrees; 198.17 and 180.16 are the molecular weights for dextrose monohydrate and anhydrous dextrose, respectively; $A$ is 100 mm divided by the length of the polarimeter tube, in mm ; and $R$ is the observed rotation, in degrees. $\quad$ 2S (USP28)

## Briefing

Liothyronine Sodium, USP 27 page 1094—See briefing under Levothyroxine Sodium. This change also affects the test for Limit of levothyroxine. It also affects the Assay and test for Limit of levothyroxine under Liothyronine Sodium Tablets.

## Assay-

Mobile phase-Prepare a filtered and degassed mixture of water and acetonitrile ( $60: 40$ ) that contains 0.5 mL of phosphoric acid in each 1000 mL . Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).
standard preparation Transfer aceurately weighed quantities ef USP Liothyronine PS and USP Levethyroxine PS, and dissolve in and dilute quantitatively and stepwise with Mobile phase to obtain a solution having known concentrations of about 10 - g of li ethyronine per mL and 0.5 ug of levethyroxine per mL .

- 0.01 M Methanolic sodium hydroxide—Dissolve 400 mg of sodium hydroxide in 500 mL of water. Cool, add 500 mL of methanol, and mix.

Liothyronine stock solution-Dissolve an accurately weighed quantity of USP Liothyronine RS in 0.01 M Methanolic sodium hydroxide to obtain a solution having a known concentration of about 0.4 mg of liothyronine per mL .

Levothyroxine stock solution-Dissolve an accurately weighed quantity of USP Levothyroxine RS in 0.01 M Methanolic sodium hydroxide to obtain a solution having a known concentration of about 0.4 mg of levothyroxine per mL .Make a $1: 100$ dilution of this solution using Mobile phase.

Standard preparation-Transfer appropriate volumes of Liothyronine stock solution and Levothyroxine stock solution to a suitable container, and dilute quantitatively and stepwise, if necessary, with Mobile phase to obtain a solution having known concentrations of about $10 \mu \mathrm{~g}$ of liothyronine per mL and $0.5 \mu \mathrm{~g}$ of levothyroxine per mL . $\mathbf{m}^{2 S}$ (USP28) Assay preparation-Transfer an accurately weighed portion of $100 \mu \mathrm{~g}$ of Liothyronine Sodium to a centrifuge tube, add 2 glass beads, pipet 10 mL of Mobile phase into the tube, and mix using a vortex mixer for 3 minutes. Centrifuge to obtain a clear supernatant, filtering if necessary.
Chromatographic system (see Chromatography $\langle 621\rangle$ )-The liquid chromatograph is equipped with a $225-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 25-\mathrm{cm}$ column that contains packing L10. The flow rate is about 1.5 mL per minute. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the resolution, $R$, between the levothyroxine and liothyronine is not less than 5.0; and the relative standard deviation for replicate injections is not more than $2.0 \%$ for liothyronine.

Procedure-Separately inject equal volumes (about $100 \mu \mathrm{~L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the quantity, in $\mu \mathrm{g}$, of $\mathrm{C}_{15} \mathrm{H}_{11} \mathrm{I}_{3} \mathrm{~N}$ $\mathrm{NaO}_{4}$ in the portion of Liothyronine Sodium taken by the formula:

$$
(672.96 / 650.97)(10 C)\left(r_{U} / r_{S}\right)
$$

in which 672.96 and 650.97 are the molecular weights of liothyronine sodium and liothyronine, respectively; $C$ is the concentration, in $\mu \mathrm{g}$ per mL , of USP Liothyronine RS in the Standard preparation; and $r_{U}$ and $r_{S}$ are the liothyronine peak responses obtained from the Assay preparation and the Standard preparation, respectively.

## Assay-

Mobile phase-Prepare a filtered and degassed mixture of water and acetonitrile ( $65: 35$ ) that contains 2 mL of trifluoroacetic acid in each 1000 mL of solution. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Standud preparation Transfer aceurately weighed quantities ef USP Levothyroxine RS and USP Liothyrenine RS to a suitable eontainer, dissolve in and dilute quantitatively and stepwise with Mobile phase to obtain a solution having known concentrations of about $10 \mu \mathrm{~g}$ of levothyroxine per mL and $2.5 \mu \mathrm{~g}$ of liothyronine per mb.

- 0.01 M Methanolic sodium hydroxide—Dissolve 400 mg of sodium hydroxide in 500 mL of water. Cool, add 500 mL of methanol, and mix.

Levothyroxine stock solution-Dissolve an accurately weighed quantity of USP Levothyroxine RS in 0.01 M Methanolic sodium hydroxide to obtain a solution having a known concentration of about 0.4 mg of levothyroxine per mL.

Liothyronine stock solution-Dissolve an accurately weighed quantity of USP Liothyronine RS in 0.01 M Methanolic sodium hydroxide to obtain a solution having a known concentration of about 0.4 mg of liothyronine per mL . Make a 1:10 dilution of this solution using Mobile phase.

Standard preparation-Transfer appropriate volumes of Levothyroxine stock solution and Liothyronine stock solution to a suitable container, and dilute quantitatively and stepwise, if necessary, with Mobile phase to obtain a solution having known concentrations of about $10 \mu \mathrm{~g}$ of levothyroxine per mL and $2.5 \mu \mathrm{~g}$ of liothyronine per mL . ${ }^{2 S}$ (USP28)

Assay preparation-Transfer 20 Tablets to a $200-\mathrm{mL}$ volumetric flask, add 180 mL of Mobile phase, and sonicate for 15 minutes, occasionally swirling the flask to accelerate the disintegration of
the Tablets. Cool to room temperature, and dilute with Mobile phase to volume. Transfer a portion of the solution to a centrifuge tube, and centrifuge for 10 minutes at 5000 rpm . Quantitatively dilute a portion of the clear supernatant with Mobile phase to obtain concentrations of about $10.0 \mu \mathrm{~g}$ of levothyroxine sodium per mL and $2.5 \mu \mathrm{~g}$ of liothyronine sodium per mL .

Chromatographic system-Proceed as directed in the Assay under Levothyroxine Sodium.

Procedure-Proceed as directed for Procedure in the Assay under Levothyroxine Sodium. Calculate the quantity, in $\mu \mathrm{g}$, of levothyroxine sodium $\left(\mathrm{C}_{15} \mathrm{H}_{10} \mathrm{I}_{4} \mathrm{NNaO}_{4}\right)$ in the portion of Tablets taken by the formula:

$$
(798.86 / 776.87)(10 C)\left(r_{U} / r_{S}\right)
$$

in which 798.86 and 776.87 are the molecular weights of levothyroxine sodium and levothyroxine, respectively; $C$ is the concentration, in $\mu \mathrm{g}$ per mL , of USP Levothyroxine RS in the Standard preparation; and $r_{U}$ and $r_{S}$ are the levothyroxine peak responses obtained from the Assay preparation and the Standard preparation, respectively.
Calculate the quantity, in $\mu \mathrm{g}$ of liothyronine sodium $\left(\mathrm{C}_{15} \mathrm{H}_{11} \mathrm{I}_{3} \mathrm{~N}\right.$ $\mathrm{NaO}_{4}$ ) in the portion of Tablets taken by the formula:

$$
(672.96 / 650.98)(10 C)\left(r_{U} / r_{S}\right),
$$

in which 672.96 and 650.98 are the molecular weights of liothyronine sodium and liothyronine, respectively; $C$ is the concentration, in $\mu \mathrm{g}$ per mL , of USP Liothyronine RS in the Standard preparation; and $r_{U}$ and $r_{S}$ are the liothyronine peak responses obtained from the Assay preparation and the Standard preparation, respectively.

BRIEFING

Loperamide Hydrochloride Tablets, USP 27 page 1103 and page 122 of PF 30(1) [Jan.-Feb. 2004]. Because of the poor solubility of Loperamide Hydrochloride in water, it is proposed to modify the Standard preparation in the Assay.

Dissolution Proedtre for a Pooted Sample
-71S (USP28)
Medium: $\quad 0.01 \mathrm{~N}$ hydrochloric acid; 900 mL .
Apparatus 2: 50 rpm .
Time: 30 minutes.
Determine the amount of $\mathrm{C}_{29} \mathrm{H}_{33} \mathrm{ClN}_{2} \mathrm{O}_{2} \cdot \mathrm{HCl}$ dissolved by employing the following method.

Mobile phase and Chromatographic system-Proceed as directed in the Assay.

Procedure-
-Proceed as directed for Procedure for Capsules, Uncoated Tablets, and Plain Coated Tablets under Dissolution $\langle 711\rangle$. Combine equal volumes of the filtered solutions of the 6 or 12 individual specimens withdrawn, and use the pooled sample as the test solution. 1 (USP28)
Separately inject equal volumes (about $50 \mu \mathrm{~L}$ ) of a filtered portion of the solution under test
-the pooled sample $_{\mathbf{m}_{1 S}(U S P 28)}$
into the chromatograph, record the chromatogram, and measure the response for the major peak. Calculate the quantity of $\mathrm{C}_{29} \mathrm{H}_{33} \mathrm{ClN}_{2} \mathrm{O}_{2} \cdot \mathrm{HCl}$ dissolved in comparison with a Standard solution having a known concentration of USP Loperamide Hydrochloride RS in the same Medium and similarly chromatographed. Tolerances-Not less than $80 \%(Q)$ of the labeled amount of $\mathrm{C}_{29} \mathrm{H}_{33} \mathrm{ClN}_{2} \mathrm{O}_{2} \cdot \mathrm{HCl}$ is dissolved in 30 minutes:

- the requirements are met if the quantities of active ingredient dissolved from the pooled sample conform to the accompanying Acceptance Table for a Pooled Sample. Continue testing through the three stages unless the results conform at either $\mathrm{S}_{1}$ or $\mathrm{S}_{2}$. The quantity $Q$, is the amount of dissolved active ingredient, expressed as a percentage of the labeled content.

| Acceptance Table for a Pooled Sample |  |  |  |
| :---: | :---: | :---: | :---: |
| Number |  |  |  |
| Stage | Tested | Acceptance Criteria |  |
| $\mathrm{S}_{1}$ | 6 | Average amount dissolved is not less than $Q+10 \%$. |  |
| $\mathrm{S}_{2}$ | 6 | Average amount dissolved $\left(\mathrm{S}_{1}+\mathrm{S}_{2}\right)$ is equal to or greater than $Q+5 \%$. |  |
| $\mathrm{S}_{3}$ | 12 | Average amount dissolved $\left(\mathrm{S}_{1}+\mathrm{S}_{2}+\right.$ <br> $\mathrm{S}_{3}$ ) is equal to or greater than $Q$. | F <br> 10 <br> 0 <br> 8 <br> 8 |
| Change | read: | -1S (USP28) | \% 0 0 0 0 0 0 |
| Assay- <br> Buffer solution-Transfer 3.0 g of triethylamine hydrochloride and 1.0 mL of phosphoric acid to a 1-L flask, add 550 mL of water, |  |  |  |

-methanol to obtain a solution having a known concentration of about 2 mg per mL . Quantitatively dilute this solution with ${ }_{\text {2S (USP28) }}$
water to obtain a solution having a known concentration of about 0.2 mg per mL . Transfer 10.0 mL of this solution to a $250-\mathrm{mL}$ volumetric flask, add 5.0 mL of $5 \%$ phosphoric acid solution and 25 mL of methanol, dilute with water to volume, and mix.

Assay preparation-Weigh and finely powder not fewer than 20 Tablets. Transfer an accurately weighed portion of the powder, equivalent to about 16 mg of loperamide hydrochloride, to a $2000-\mathrm{mL}$ volumetric flask. Add 40 mL of $5 \%$ phosphoric acid solution and 200 mL of methanol, dilute with water to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )-The liquid chromatograph is equipped with a $214-\mathrm{nm}$ detector and a $4-\mathrm{mm} \times 8-\mathrm{cm}$ column that contains $5-\mu \mathrm{m}$ packing L7. The flow rate is about 2 mL per minute. Chromatograph the Standard preparation, and record the peak responses as directed for Procedure: the tailing factor is not more than 2.0 ; and the relative standard deviation for replicate injections is not more than $2.0 \%$.
Procedure-Separately inject equal volumes (about $20 \mu \mathrm{~L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the quantity, in mg, of loperamide hydrochloride ( $\mathrm{C}_{29} \mathrm{H}_{33} \mathrm{ClN}_{2} \mathrm{O}_{2} \cdot \mathrm{HCl}$ ) in the portion of Tablets taken by the formula:

$$
2000 C\left(r_{U} / r_{s}\right),
$$

in which $C$ is the concentration, in mg per mL , of USP Loperamide Hydrochloride RS in the Standard preparation; and $r_{U}$ and $r_{s}$ are the peak responses obtained from the Assay preparation and the Standard preparation, respectively.

## BRIEFING

Modafinil; Modafinil Tablets. Because there are no existing USP monographs for this drug substance and dosage form, new monographs are proposed based on a manufacturer's tests and acceptance criteria. The reverse phase HPLC procedures for the Related compounds and Assay tests were validated using an Inertsil ODS-2 brand of L1 column; modafinil elutes at approximately 3.9 minutes.
(PA1: K. Russo; PSD: C. Okeke; NL: C. Barnstein) RTS-39507-1; 39869-1

## Add the following:

## Modafinil

$\mathrm{C}_{15} \mathrm{H}_{15} \mathrm{NO}_{2} \mathrm{~S} \quad 273.35$

Acetamide, 2-[(diphenylmethyl)sulfinyl]-.
2-[(Diphenylmethyl)sulfinyl]-acetamide [68693-11-8].
» Modafinil contains not less than 98.0 percent and not more than 101.5 percent of $\mathrm{C}_{15} \mathrm{H}_{15} \mathrm{NO}_{2} \mathrm{~S}$, calculated on the anhydrous basis.

Packaging and storage-Preserve in well-closed containers. Store at controlled room temperature.

USP Reference standards $\langle 11\rangle$ —USP Modafinil RS. USP
Salicylic Acid RS.
Identification-Infrared Absorption $\langle 197 \mathrm{~K}\rangle$.
Water, Method $I\langle 921\rangle$ : not more than $0.2 \%$.
Residue on ignition $\langle 281\rangle$ : not more than $0.1 \%$.

Particle size—Using suitable laser diffraction equipment, set the dry powder feed instrument to run 5 to 10 g of sample per run in the Fraunhofer mode. Adjust the feed ration to achieve a mean obscuration of 3 to 5 . Run a suitable check standard (e.g., garnet) to establish a practical, operational system. The sample is to be run in triplicate, separated by blank runs. The results of the individual runs are to be averaged for the mean, and all other parameters required: the relative standard deviation for each specified volume of sample is not more than $10 \%$; not less than $50 \%$ of the particles are less than $45 \mu \mathrm{~m}$, not less than $80 \%$ of the particles are less than $110 \mu \mathrm{~m}$, and not less than $95 \%$ of the particles are less than $220 \mu \mathrm{~m}$.

Heavy metals, Method $I\langle 231\rangle$ —Dissolve the sample in methanol and water solution ( $60: 40$ ): not more than $0.002 \%$.

## Related compounds-

Buffer, Mobile phase, and System suitability prepara-tion-Prepare as directed in the Assay.

Test solution-Use the Assay preparation.
Chromatographic system (see Chromatography $\langle 621\rangle$ )Proceed as directed under Assay. Chromatograph the System suitability preparation, and record the peak responses as directed for Procedure: the relative retention times are listed in the table below; the resolution, $R$, between salicylic acid and modafinil is not less than 1.3; the tailing factor is not more than 1.5 ; and the relative standard deviation for replicate injections is not more than $2.0 \%$ based on the modafinil peak.

|  | Relative Re- <br> tention Time <br> (relative to <br> modafinil) |
| :--- | :---: |
| Impurity | 1.1 |
| Salicylic acid* $_{\text {Modafinil acid [2-[(diphenylmethyl)sul- }}$ | 1.4 |
| Minyl]acetic acid] | 1.7 |
| sulfonyl]acetamide] <br> Modafinil ester [2-[(diphenylmethyl)sul- <br> finyl]acetic acid methyl ester] | 3.0 |

* Salicylic acid is used for calculating resolution and is not a potential impurity.

Procedure-Inject a volume (about $20 \mu \mathrm{~L}$ ) of the Test solution into the chromatograph, record the chromatogram, and measure the peak responses. Calculate the percentage of each related compound in the portion of Modafinil taken by the formula:

$$
100(1 / F)\left(r_{i} / r_{s}\right)
$$

in which $F$ is the relative response factor for an impurity ( $F$ is 0.90 for modafinil sulfone; $F$ is 1 for all other known and unknown impurities); $r_{i}$ is the individual peak response of each impurity; and $r_{s}$ is the sum of the responses of all the peaks: not more than $0.5 \%$ of any individual known impurity is found, not more than $0.05 \%$ of any individual unknown impurity is found, and not more than $1.0 \%$ of total impurities is found.

Organic volatile impurities, Method $V\langle 467\rangle$ : meets the requirements.
Solvent: $n$-methylpyrrolidone.

Assay-
Buffer-Dissolve 6.8 g of potassium dihydrogen phosphate in 500 mL of water in a $1000-\mathrm{mL}$ flask. Dilute with water to volume, and mix. Adjust with phosphoric acid to a pH of 2.3.

Mobile phase-Prepare a filtered and degassed mixture of Buffer and acetonitrile ( $65: 35$ ). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Diluent-Prepare a mixture containing water and acetonitrile ( $65: 35$ ), and mix.

System suitability preparation-Dissolve suitable quantities of USP Modafinil RS and USP Salicylic Acid RS in Diluent to obtain a solution containing about 0.005 mg per mL and 0.05 mg per mL , respectively.

Standard preparation-Dissolve an accurately weighed quantity of USP Modafinil RS in Diluent, and dilute quantitatively, and stepwise if necessary, with Diluent to obtain a solution having a known concentration of about 0.1 mg per mL .

Assay preparation-Transfer about 100 mg of Modafinil, accurately weighed, to a $100-\mathrm{mL}$ volumetric flask, dissolve in and dilute with Diluent to volume, and mix. Dilute 5.0 mL of this solution with Diluent to 50 mL , and mix well.

Chromatographic system (see Chromatography $\langle 621\rangle$ )-
The liquid chromatograph is equipped with a $220-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 15-\mathrm{cm}$ column that contains $5-\mu \mathrm{m}$ packing L1. The flow rate is about 1.0 mL per minute. The column temperature is maintained at $40^{\circ}$. Chromatograph the System suitability preparation, and record the peak responses as directed for Procedure: the relative reten-
tion times are about 1.1 for salicylic acid and 1.0 for modafinil; the resolution, $R$, between modafinil and salicylic acid is not less than 1.3; the tailing factor of the modafinil peak is not more than 1.5; and the relative standard deviation for replicate injections is not more than $2.0 \%$ based on the modafinil peak.
Procedure-Separately inject equal volumes (about 20 $\mu \mathrm{L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the modafinil peaks. Calculate the quantity, in mg, of $\mathrm{C}_{15} \mathrm{H}_{15} \mathrm{NO}_{2} \mathrm{~S}$ in the portion of Modafinil taken by the formula:

$$
1000 C\left(r_{U} / r_{s}\right)
$$

in which 1000 is the dilution factor for the Assay preparation; $C$ is the concentration, in mg per mL , of USP Modafinil RS in the Standard preparation; and $r_{U}$ and $r_{S}$ are the peak responses obtained from the Assay preparation and the Standard preparation, respectively.■2S (USP28)

[^241]
## Add the following:

## Modafinil Tablets

» Modafinil Tablets contain not less than 90.0 percent and not more than 110.0 percent of the labeled amount of modafinil $\left(\mathrm{C}_{15} \mathrm{H}_{15} \mathrm{NO}_{2} \mathrm{~S}\right)$.

Packaging and storage-Preserve in tight containers. Store at controlled room temperature.

USP Reference standards $\langle 11\rangle$ —USP Modafinil RS. USP Salicylic Acid RS.

## Identification-

A: Infrared Absorption $\langle 197 \mathrm{~K}\rangle$-Grind 1 Tablet and add 50 mL each of dichloromethane and water. Shake the mixture and allow the layers to separate. Filter a portion of the upper (dichloromethane) layer and evaporate to dryness, using a stream of nitrogen if necessary. Prepare a potassium bromide pellet of the residue. To prepare the Reference Standard potassium bromide dispersion, transfer a quantity (in mg ) of USP Modafinil RS, equivalent to the labeled amount of modafinil, to a suitable container, and proceed as directed above beginning with "add 50 mL each of dichloromethane and water."

## Dissolution $\langle 711\rangle$ -

Medium: $\quad 0.1 \mathrm{~N}$ hydrochloric acid; 900 mL .
Apparatus 2: 50 rpm.
Time: 30 minutes.
Procedure-Determine the amount of $\mathrm{C}_{15} \mathrm{H}_{15} \mathrm{NO}_{2} \mathrm{~S}$ dissolved by employing UV absorption at the wavelength of maximum absorbance at about 222 nm on filtered portions of the solution under test, suitably diluted with Medium if
necessary, in comparison with a Standard solution having a known concentration of USP Modafinil RS in the same Medium.

Tolerances-Not less than $75 \%(Q)$ of the labeled amount of $\mathrm{C}_{15} \mathrm{H}_{15} \mathrm{NO}_{2} \mathrm{~S}$ is dissolved in 30 minutes.

Uniformity of dosage units $\langle 905\rangle$ : meet the requirements.

## Related compounds-

Buffer, Mobile phase, and System suitability prepara-tion-Prepare as directed in the Assay under Modafinil. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Diluent-Prepare as directed in the Assay.
Test solution-Use the Assay preparation.
Chromatographic system (see Chromatography $\langle 621\rangle$ )Proceed as directed in the Assay. Chromatograph the System suitability preparation, and record the peak responses as directed for Procedure: the relative retention times are presented in the table below; the resolution, $R$, between modafinil and salicylic acid is not less than 1.3; and the relative standard deviation for replicate injections is not more than $2.0 \%$ based on the modafinil peak.

|  | Relative Re- <br> tention Time <br> (relative to <br> modafinil) |
| :--- | :---: |
| Impurity | 1.1 |
| Salicylic acid* | 1.4 |
| Modafinil acid [2-[(diphenylmethyl)sul- <br> finyl]acetic acid] |  |

|  | Relative Re- <br> tention Time <br> (relative to <br> modafinil) |
| :--- | :---: |
| Impurity | 1.7 |
| Modafinil sulfone [2-[(diphenylmethyl) <br> sulfonyl]acetamide] |  |
| Modafinil ester [2-[(diphenylmethyl)sul- <br> finyl]acetic acid methyl ester] | 3.0 |

* Salicylic acid is used for calculating resolution and is not a potential impurity.

Procedure-Inject a volume (about $5 \mu \mathrm{~L}$ ) of the Test solution into the chromatograph, record the chromatogram, and measure all of the peak responses. Calculate the percentage of each impurity in the portion of Tablets taken by the formula:

$$
100(1 / F)\left(r_{i} / r_{s}\right)
$$

in which $F$ is the relative response factor for an impurity ( $F$ is 0.90 for modafinil sulfone; $F$ is 1 for all other known and unknown impurities); $r_{i}$ is the peak response for each impurity; and $r_{s}$ is the sum of the responses of all the peaks: not more than $0.5 \%$ of any individual impurity is found, not more than $0.1 \%$ of any individual unknown impurity is found, and not more than $1.5 \%$ of total impurities is found.

## Assay-

Buffer, Mobile phase, and System suitability prepara-tion-Prepare as directed in the Assay under Modafinil.

Diluent-Prepare a mixture containing water, acetonitrile, and acetic acid ( $65: 35: 1$ ), and mix.

Standard preparation-Dissolve an accurately weighed quantity of USP Modafinil RS in Diluent, and dilute quantitatively, and stepwise if necessary, with Diluent to obtain a solution having a known concentration of about 0.4 mg per mL .

Assay preparation-Weigh and finely powder not fewer than 20 Tablets. Transfer an accurately weighed portion of the powder, equivalent to about 100 mg of modafinil, to a $250-\mathrm{mL}$ volumetric flask, add 200 mL of Diluent, and sonicate for about 5 minutes with intermittent manual shaking. Dilute with Diluent to volume, and mix. Pass a portion of this solution through a filter having a $0.45-\mu \mathrm{m}$ or finer porosity, and use the filtrate.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a $220-\mathrm{nm}$ detector and $4.6-\mathrm{mm} \times 15-\mathrm{cm}$ column that contains $5-\mu \mathrm{m}$ packing L1. The flow rate is about 1.0 mL per minute. The column temperature is maintained at $40^{\circ}$. Chromatograph the System suitability preparation, and record the peak responses as directed for Procedure: the relative retention times are about 1.1 for salicylic acid and 1.0 for modafinil; the resolution, $R$, between modafinil and salicylic acid is not less than 1.3 ; the tailing factor is not more than 1.5 ; and the relative standard deviation for replicate injections is not more than $2.0 \%$ based on the modafinil peak.

Procedure-Separately inject equal volumes (about $5 \mu \mathrm{~L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure
the responses for the modafinil peaks. Calculate the quantity, in mg , of modafinil $\left(\mathrm{C}_{15} \mathrm{H}_{15} \mathrm{NO}_{2} \mathrm{~S}\right)$ in the portion of Tablets taken by the formula:

$$
250 C\left(r_{U} / r_{S}\right)
$$

in which $C$ is the concentration, in mg per mL , of USP Modafinil RS in the Standard preparation; and $r_{U}$ and $r_{S}$ are the peak responses obtained from the Assay preparation and the Standard preparation, respectively. ${ }^{\mathbf{n} 2 \mathrm{~S}}$ (USP28)

BRIEFING

Morphine Sulfate, USP 27 page 1263 and page 3277 of the Second Supplement. On the basis of comments received concerning revisions proposed in PF 29(6) [Nov.-Dec. 2003], further revisions to the Packaging and storage are proposed, and the proposed revisions to the Labeling, Reference standards, and Other requirements sections are hereby canceled.

## Assay for protein-

Diluted antifoam reagent-Transfer $100 \mu \mathrm{~L}$ of antifoam reagent ${ }^{8}$ to a suitable container, and dilute with water to 10 mL .
Blank preparation-Transfer $500 \mu \mathrm{~L}$ of Sodium Chloride Injection to a culture tube. Dilute the contents of the tube with water to 2 mL , and add $10 \mu \mathrm{~L}$ of Diluted antifoam reagent.

Standard preparations-Transfer 25-, 50-, 62.5-, $75-$, and $100-$ $\mu \mathrm{L}$ aliquots of protein standard solution ${ }^{9}$ containing 8 g per dL into separate tubes. Dilute the contents of each tube with water to 2.00 mL , and add $10 \mu \mathrm{~L}$ of the Diluted antifoam reagent to each tube. During the Procedure the addition of 3.0 mL of biuret reagent TS to each of the tubes produces Standard preparations with protein concentrations of $0.4,0.8,1.0,1.2$, and 1.6 mg per mL .

Assay preparation-Equilibrate each container of Perflutren Protein-Type A Microspheres for Injection to room temperature, and mix each for at least 5 minutes to ensure a homogenous suspension. Vent the container, and transfer $500-\mu \mathrm{L}$ aliquots into separate tubes. Dilute the contents of each tube with water to 2 mL , and add $10 \mu \mathrm{~L}$ of Diluted antifoam reagent.

Procedure-To each of the tubes containing the Blank preparation, Standard preparations, and Assay preparation add 3.0 mL of biuret reagent TS, mix, and allow to stand for 30 minutes, accurately timed, for maximum color development. The Blank preparation, Standard preparations, and Assay preparation are treated identically. Using the Blank preparation, set the absorbance equal to zero. Determine the absorbance of each of the Standard preparations and the Assay preparation in $1-\mathrm{cm}$ cells with a suitable spectrophotometer at a wavelength of 540 nm . Using linear regression, analyze the data obtained for each of the Standard preparations. Calculate the correlation coefficient, slope, and $y$-intercept values: the correlation coefficient is not less than 0.995 . Calculate the quantity, in mg , of protein in each mL of the Perflutren ProteinType A Microspheres for Injection by the formula:

$$
10\left[\left(A_{U}-y \text {-intercept }\right) / \text { slope }\right]
$$

in which 10 is the dilution factor; and $A_{U}$ is the absorbance of the Assay preparation: the calculated quantity of protein in the Perflutren Protein-Type A Microspheres for Injection is between 8 mg per mL and 12 mg per mL .

Perflutren Protein-Type A Microspheres for Injection, USP 27 page 1446; Perflutren Protein-Type A Microspheres Injectable Suspension, USP 27 page 1448. It is proposed to revise footnote 9 in the Assay for protein to identify a new source for the
${ }^{8}$ Available as Antifoam Reagent, catalog number 2210, from Dow Corning Corporation, Midland, MI.

# Perflutren Protein-Type A Microspheres Injectable Suspension 

(Monograph under this new title-to become official February
1, 2005)
(Current monograph title is Perflutren Protein-Type A
Microspheres for Injection)

## Change to read:

## Assay for protein-

Diluted antifoam reagent-Transfer $100 \mu \mathrm{~L}$ of antifoam reagent ${ }^{8}$ to a suitable container, and dilute with water to 10 mL .

Blank preparation-Transfer $500 \mu \mathrm{~L}$ of Sodium Chloride Injection to a culture tube. Dilute the contents of the tube with water to 2 mL , and add $10 \mu \mathrm{~L}$ of Diluted antifoam reagent.

Standard preparations-Transfer $25-$, $50-$, $62.5-$ - $75-$, and 100$\mu \mathrm{L}$ aliquots of protein standard solution ${ }^{9}$ containing 8 g per dL into separate tubes. Dilute the contents of each tube with water to 2.00 mL , and add $10 \mu \mathrm{~L}$ of the Diluted antifoam reagent to each tube. During the Procedure, the addition of 3.0 mL of biuret reagent TS to each of the tubes produces Standard preparations with protein concentrations of $0.4,0.8,1.0,1.2$, and 1.6 mg per mL .

Assay preparation-Equilibrate each container of Injectable Suspension to room temperature, and mix each for at least 5 min utes to ensure a homogeneous suspension. Vent the container, and transfer $500-\mu \mathrm{L}$ aliquots into separate tubes. Dilute the contents of each tube with water to 2 mL , and add $10 \mu \mathrm{~L}$ of Diluted antifoam reagent.

Procedure-To each of the tubes containing the Blank preparation, Standard preparations, and Assay preparation add 3.0 mL of biuret reagent TS, mix, and allow to stand for 30 minutes, accurately timed, for maximum color development. The Blank preparation, Standard preparations, and Assay preparation are treated identically. Using the Blank preparation, set the absorbance equal to zero. Determine the absorbance of each of the Standard preparations and the Assay preparation in $1-\mathrm{cm}$ cells with a suitable spectrophotometer at a wavelength of 540 nm . Using linear regression, analyze the data obtained for each of the Standard preparations. Calculate the correlation coefficient, slope, and $y$-intercept
values: the correlation coefficient is not less than 0.995 . Calculate the quantity, in mg , of protein in each mL of the Injectable Suspension by the formula:

$$
10\left[\left(A_{U}-y \text {-intercept }\right) / \text { slope }\right],
$$

in which 10 is the dilution factor; and $A_{U}$ is the absorbance of the Assay preparation: the calculated quantity of protein in the Injectable Suspension is between 8 and 12 mg per mL .

BRIEFING

Potassium Chloride in Dextrose Injection, USP 27 page 1516-See briefing under Alcohol in Dextrose Injection.
(PA1: K. Russo) RTS-41401-9

## Change to read:

» Potassium Chloride in Dextrose Injection is a sterile solution of Potassium Chloride and Dextrose in Water for Injection. It contains not less than 95.0 percent and not more than 110.0 percent of the labeled amount of

- Potassium Chloride ${ }_{\text {n2S }}$ (USP28)
$(\mathrm{KCl})$ and not less than 95.0 percent and not more than 105.0 percent of the labeled amount of
-dextrose ${ }_{\text {■2S }}{ }^{\text {(USP28) }}$
$\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}\right)$. It contains no antimicrobial agents.

## Change to read:

Assay for dextrose-Transfer an accurately measured volume of Injection, containing between 2 and 5 g of dextrose, to a $100-\mathrm{mL}$ volumetric flask. Add 0.2 mL of 6 N ammonium hydroxide, dilute with water to volume, and mix. Determine the angular rotation in a suitable polarimeter tube at $25^{\circ}$ (see Optical Rotion (781)). The observed rotation, in degrees, multiplied by 1.04254 , in which 4 is the ratio 200 divided by the length, in mm, of the polarimeter tube employed, represents the weight, in of, of $\mathrm{G}_{6} \mathrm{H}_{42} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}$ in the wot tme of Injection taken.

[^242]■(see Optical Rotation $\langle 781\rangle$ ). Calculate the percentage ( g per 100 mL ) of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}$ in the portion of Injection taken by the formula:

$$
(100 / 52.9)(198.17 / 180.16) A R
$$

in which 100 is percent; 52.9 is the midpoint of the specific rotation range for anhydrous dextrose, in degrees; 198.17 and 180.16 are the molecular weights for dextrose monohydrate and anhydrous dextrose, respectively; $A$ is 100 mm divided by the length of the polarimeter tube, in mm ; and $R$ is the observed rotation, in degrees.■2S (USP28)

## BRIEFING

Potassium Chloride in Dextrose and Sodium Chloride Injection, USP 27 page 1517-See briefing under Alcohol in Dextrose Injection.
(PA1: K. Russo) RTS-41401-8

## Change to read:

Assay for dextrose-Transfer an accurately measured volume of Injection, containing between 2 g and 5 g of dextrose, to a $100-\mathrm{mL}$ volumetric flask. Add 0.2 mL of 6 N ammonium hydroxide, dilute with water to volume, and mix. Determine the angular rotation in a suitable polarimeter tube $25^{\circ}$ (se-Optind Rot (784)). The observed retation, in degrees, multiplied by $1.0425 A$, in whieh $A$ is the ratio 200 divided by the length, in mm, of the polarimeter tube employed, represents the weight, in of, of $\mathrm{G}_{6} \mathrm{H}_{42} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}$ in the wh ume of Injection taken.
-(see Optical Rotation $\langle 781\rangle$ ). Calculate the percentage (g per 100 mL ) of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}$ in the portion of Injection taken by the formula:
$(100 / 52.9)(198.17 / 180.16) A R$,
in which 100 is percent; 52.9 is the midpoint of the specific rotation range for anhydrous dextrose, in degrees; 198.17 and 180.16 are the molecular weights for dextrose monohydrate and anhydrous dextrose, respectively; $A$ is 100 mm divided by the length of the polarimeter tube, in mm; and $R$ is the observed rotation, in degrees. $\quad$ 2S (USP28)

BRIEFING

Prednisolone, USP 27 page 1537 and page 1440 of $P F$ 28(5) [Sept-Oct. 2002]. It is proposed to resubmit the proposal that previously appeared in PF 28(5) to replace the test for Ordinary impurities with a test for Chromatographic purity that provides superior separation and more rigid acceptance criteria for the limit of impurities. It is also proposed to cancel text postponed indefinately in USP 27.
(PA1: C. Anthony) RTS-41660-1

## Add the following:

## -Chromatographic purity-

Solution $A$-Prepare a filtered and degassed mixture of water and acetonitrile (77:23).

Solution B-Prepare a filtered and degassed mixture of water and acetonitrile (60:40).

Mobile phase—Use variable mixtures of Solution $A$ and Solution B as directed for Chromatographic system. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Diluent: a mixture of water and acetonitrile (1:1).
Standard solution-Dissolve an accurately weighed quantity of USP Prednisolone RS in Diluent, and dilute quantitatively, and stepwise if necessary, with Diluent to obtain a solution having a known concentration of about 0.01 mg per mL .

System suitability solution-Dissolve an accurately weighed quantity of USP Prednisolone RS and hydrocortisone in Diluent to obtain a solution having a known concentration of about 1 mg per mL and 0.06 mg per mL , respectively.
Test solution-Transfer about 25 mg of Prednisolone, accurately weighed, to a $25-\mathrm{mL}$ volumetric flask, dissolve in and dilute with Diluent to volume, and mix.
Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a $254-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 30-\mathrm{cm}$ column that contains $5-\mu \mathrm{m}$ packing L1. The flow rate is about 1.5 mL per minute. The column temperature is maintained at $40^{\circ}$. The chromatograph is programmed as follows.

| Time | Solution A <br> (minutes) | Solution B <br> $(\%)$ | Elution |
| :---: | :---: | :---: | :--- |
| 0 | 100 | 0 | equilibration |
| $0-25$ | 100 | 0 | isocratic |
| $25-45$ | $100 \rightarrow 0$ | $0 \rightarrow 100$ | linear gradient |
| $45-60$ | 0 | 100 | isocratic |
| $60-61$ | $0 \rightarrow 100$ | $100 \rightarrow 0$ | linear gradient |
| $61-100$ | 100 | 0 | re-equilibration |

Chromatograph the System suitability solution, and record the peak responses as directed for Procedure: the relative retention times for prednisolone and hydrocortisone are about 1.0 and 1.06 , respectively; and the height of the smallest peak is not less than 2 times the height of the valley between the prednisolone and hydrocortisone peaks. Chromatograph the Standard solution, and record the peak responses as directed for Procedure: the relative standard deviation for replicate injections is not more than $5.0 \%$ for the prednisolone peak.

Procedure-Separately inject equal volumes (about 20 $\mu \mathrm{L}$ ) of the Standard solution and Test solution into the chromatograph, record the chromatograms, and measure the re-
sponses for the major peaks. Calculate the percentage of each impurity in the portion of Prednisolone taken by the formula:

$$
2500(C / W)\left(r_{i} / r_{s}\right),
$$

in which $C$ is the concentration, in mg per mL , of USP Prednisolone RS in the Standard solution; $W$ is the weight, in mg , of prednisolone used to prepare the Test solution; $r_{i}$ is the peak response for each impurity in the Test solution; and $r_{s}$ is the peak response obtained from the Standard solution: no impurity greater than $1.0 \%$ and only one peak greater than $0.5 \%$ is found; and not more than $2.0 \%$ of total impurities is found. ${ }^{2 S}$ (USP28)

## Delete the following:

- Ordinary imptrities- 466 ) -

Solvent: a mixture of aleohol and water (1:1).
Eltunt: amixture of toluene andisepropyl aleohel $(70: 30)$, in
a nenequilibrated chamber.
Yistulization: teehnique-1.■2S (USP28)

## BRIEFING

Prednisolone Acetate, USP 27 page 1540, page 3295 of the Second Supplement, and page 1564 of PF 29(5) [Sept.-Oct. 2003]. It is proposed to delete test $C$ under Identification to avoid inhalation of ethyl acetate.
(PA1: C. Anthony) RTS-41625-1

## Add the following:

-Labeling-Where it is intended for use in preparing injectable dosage forms, the label states that it is sterile or must be subjected to further processing during the preparation of injectable dosage forms.■1S (USP28)

## Change to read:

## Identification-

A: Infrared Absorption $\langle 197 \mathrm{~K}\rangle$.
B: Ultraviolet Absorption $\langle 197 \mathrm{U}\rangle$ -
Solution: $10 \mu \mathrm{~g}$ per mL.
Medium: methanol.
Absorptivities at 242 nm , calculated on the dried basis, do not differ by more than $2.5 \%$.

C: To about 50 mg entained in a test tube add 2 mL of aleo
hol and 2 mL of dilute sulfaric acid ( 1 in -3.5 ), and boil gently for about 1 minte: the oder of ethylacetate is pereeptible.

■ ${ }^{\text {2S }}$ (USP28)

## Add the following:

-Other requirements-Where the label states that Prednisolone Acetate is sterile, it meets the requirements for Sterility under Prednisolone Acetate Injectable Suspension.■1S (USP28)

## Briefing

Prilocaine. Because there is no existing USP monograph for this drug substance, a new monograph is proposed. The tests for Limit of prilocaine related compound $A$ and Related compounds were validated using a Symmetry C18 brand of L1 column. Typical retention times are approximately 9,24 , and 28 minutes for $o$-toluidine (prilocaine related compound A), prilocaine, and (RS)-N-(4-methylphenyl)-2-(propylamino)propanamide (prilocaine related compound B), respectively.
(PA1: K. Russo; NL: C. Barnstein; PSD: C. Okeke) RTS-41125-1; 41125-2; 41125-3

## Add the following:

## © Prilocaine

$\mathrm{C}_{13} \mathrm{H}_{20} \mathrm{~N}_{2} \mathrm{O} \quad 220.31$
Propranamide, $N$-(2-methylphenyl)-2-(propylamino).
2-(Propylamino)-o-propionotoluidide.
(RS)-N-(2-methylphenyl)-2-(propylamino)propanamide [721-50-6].
» Prilocaine contains not less than 99.0 percent and not more than 101.0 percent of $\mathrm{C}_{13} \mathrm{H}_{20} \mathrm{~N}_{2} \mathrm{O}$, calculated on the anhydrous basis.

Packaging and storage-Preserve in well-closed containers and store below $25^{\circ}$.

USP Reference standards $\langle 11\rangle —$ USP Prilocaine RS. USP Prilocaine Related Compound A RS. USP Prilocaine Related Compound B RS.

Identification, Infrared Absorption $\langle 197 \mathrm{~K}\rangle$-Because of the low melting point of prilocaine, the mortar, pestle, and potassium bromide must be at ambient temperature. Record the IR spectrum using the diffuse reflectance technique.

Melting range, Class $1 a\langle 741\rangle$ : between $36^{\circ}$ and $39^{\circ}$, without previous drying.

Water, Method Ia $\langle 921\rangle$ : not more than $0.5 \%$, determined on 1.00 g of sample.

Residue on ignition $\langle 281\rangle$ : not more than $0.1 \%$.
Limit of prilocaine related compound A-
Mobile phase-Prepare as directed under Related compounds.
Standard solution-Dissolve an accurately weighed quantity of USP Prilocaine Related Compound A RS in Mobile phase, and dilute quantitatively, and stepwise if necessary, with Mobile phase to obtain a solution having a known concentration of about $1.3 \mu \mathrm{~g}$ per mL .

Test solution-Transfer about 100 mg of Prilocaine, accurately weighed, to a $10-\mathrm{mL}$ volumetric flask, dissolve and dilute with Mobile phase to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )Use the system as described under Related compounds. Chromatograph the Standard solution, and record the peak responses as directed for Procedure: the signal-to-noise ratio of the major peak should be greater than 10 .
Procedure-Separately inject equal volumes (about 20 $\mu \mathrm{L}$ ) of the Standard solution and the Test solution into the chromatograph, record the chromatograms, and measure the responses for the major peaks: any peak corresponding to prilocaine related compound A (o-toluidine) in the Test solution is not greater than the response of the major peak in the Standard solution $(0.01 \%)$.

## Related compounds-

Buffer-Dilute 1.3 mL of a 1 M sodium phosphate monobasic solution ( 1.38 g diluted with water to 10 mL ) and 32.5 mL of a 0.5 M anhydrous disodium hydrogen phosphate solution ( 7.1 g diluted with water to 100 mL ) with water to 1 L. The pH of this solution is 8.0. Make adjustments as needed.

Mobile phase—Prepare a degassed mixture of Buffer and acetonitrile ( $73: 27$ ). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).
System suitability solution-Dissolve accurately weighed quantities of USP Prilocaine RS and USP Prilocaine Related Compound B RS in Mobile phase, and dilute quantitatively, and stepwise if necessary, with Mobile phase to obtain a solution having known concentrations of about $2.5 \mu \mathrm{~g}$ per mL and $3.0 \mu \mathrm{~g}$ per mL , respectively.

Test solution-Transfer about 25 mg of Prilocaine, accurately weighed, to a $10-\mathrm{mL}$ volumetric flask, dilute with Mobile phase to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a $240-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 15-\mathrm{cm}$ column that contains $5-\mu \mathrm{m}$ packing L1. The flow rate is about 1 mL per minute. Chromatograph the System suitability solution, and record the peak responses as directed for Procedure: the relative retention times are about 1.19 for prilocaine related compound B and 1.0 for prilocaine; the resolution, $R$, between prilocaine and prilocaine related compound $B$ is not less than 3.0 ; and the signal-to-noise ratio for the prilocaine peak is not less than 10 .

Procedure-Inject a volume (about $20 \mu \mathrm{~L}$ ) of the Test solution into the chromatograph, record the chromatograms, and measure the peak responses. Run the chromatograms for at least 1.5 times the retention of prilocaine. Check the stability of the baseline by injecting Mobile phase. Calculate the percentage of each impurity in the portion of Prilocaine taken by the formula:

$$
100\left(r_{i} / r_{s}\right)
$$

in which $r_{i}$ is the individual peak response of each impurity; and $r_{s}$ is the sum of the responses of all the peaks: not more than $0.2 \%$ of any individual impurity is found; not more than one impurity exceeds $0.1 \%$, and not more than $0.5 \%$ of total impurities is found.

Assay—Dissolve 400 mg of Prilocaine, accurately weighed, in 50 mL of glacial acetic acid. Titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction (see Titrimetry $\langle 541\rangle$ ). Each mL of 0.1 perchloric acid is equivalent to 22.03 mg of $\mathrm{C}_{13} \mathrm{H}_{20}$ $\mathrm{N}_{2} \mathrm{O}$. ${ }^{2 S}$ (USP28)

Propofol, page 3296 of the Second Supplement. It is proposed to revise the Packaging and storage statement to indicate storage at room temperature rather than restricting the excursions to between $15^{\circ}$ and $30^{\circ}$. The Labeling statement is revised to specify that the labeling only needs to indicate a Related compounds test other than Test 1. It is proposed to revise the preparation of the Resolution solution for Test 1 by changing the name of USP Propofol Resolution RS to USP Propofol Resolution Mixture RS and adding USP Propofol Related Compound C RS [2-(1-methylethoxy)-1,3-bis(1methylethyl)benzene]. The preparation of System suitability solution 2 in Related compounds Test 2 is revised to indicate use of individual related compound reference standards rather than USP Propofol for System Suitability RS, originally intended as a mixture; and the Procedure for Test 2 is revised to delete the reference to the limit of 2-(1-methylethoxy)-1,3-bis(1-methylethylbenzene), since 2,6-diisopropylphenylisopropyl ether is already listed and these are two names for the same related compound. The USP Reference standards section is revised to reflect the changes in the procedures.
(PA1: K. Russo; PSD: C. Okeke; NL: C. Barnstein) RTS-41122-1; 41592-1; 41592-2; 41592-3

Related compounds-[NOTE-On the basis of knowledge of the manufacturing process, either (1) Related compounds Test 1 is performed in conjunction with the Limit of propofol related compound A, Limit of propofol related compound B Test 1, and Assay Test 1 procedures; or (2) Related compounds Test 2 is performed in conjunction with the Limit of propofol related compound B Test 2 and the Assay Test 2 procedures.]

TEST 1-
Resolution solution-Dissolve an accurately weighed quantity of USP Propefol Resolution PS
-USP Propofol Resolution Mixture $\mathrm{RS}_{\mathbf{m}^{2 S}}$ (USP28)
in methanol, and dilute quantitatively, and stepwise if necessary, with methanol to obtain a solution having a concentration of about 100 mg per mL .
Standard solution-Dissolve an accurately weighed quantity of USP Propofol RS in methanol, and dilute quantitatively, and stepwise if necessary, with methanol to obtain a solution having a concentration of about 0.1 mg per mL .

Test solution - Transfer about 1000 mg of Propofol, accurately weighed, to a $10-\mathrm{mL}$ volumetric flask, dissolve in and dilute with methanol to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )——Proceed as directed under Assay Test 1, except to chromatograph the Standard solution six times and chromatograph the Resolution solution: the relative retention time is about 0.18 for 2,6-diisopropylphenyl isopropylether, 1.0 for propofol, and about 1.1 for 2-isopropyl-6- $n$-propylphenol; the resolution, $R$, between propofol and 2-isopropyl-6-n-propylphenol is not less than 2. Chromatograph the Standard solution six times, and record the peak responses as directed for Procedure: the column efficiency determined from the propofol peak is not less than 5000 theoretical plates; and the relative standard deviation for replicate injections is not more than $3.5 \%$.
Procedure-Separately inject equal volumes (about $1.0 \mu \mathrm{~L}$ ) of the Resolution solution, the Standard solution, and the Test solution into the chromatograph, record the chromatograms, and measure all the peak responses. Calculate the percentage of each impurity in the portion of Propofol taken by the formula:

$$
0.1\left(r_{i} / r_{s}\right)
$$

in which $r_{i}$ is the peak response for each impurity obtained from the Test solution; and $r_{S}$ is the peak response for propofol obtained from the Standard solution: not more than $0.1 \%$ of 2,6-diisopropylphenyl isopropylether is found; not more than $0.1 \%$ of each other individual impurity is found; and not more than $0.3 \%$ of total impurities is found.

TEST 2-
Mobile phase-Prepare as directed in Assay Test 2.
System suitability solution 1-Transfer $5 \mu \mathrm{~L}$ of USP Propofol RS and $15 \mu \mathrm{~L}$ of USP Propofol Related Compound B RS to a $50-\mathrm{mL}$ volumetric flask, dissolve in and dilute with hexane to volume, and mix.

System suitability solution 2- Pissolve 1 mL of USP Propefor for System Sutability RS with hewane to make- 10 -mL.
-Dissolve an accurately weighed quantity of USP Propofol Related Compound A RS and accurate volumes of the propofol that is under test and USP Propofol Related Compound $C R S$ in hexane, and dilute quantitatively, and stepwise if necessary, with hexane to obtain a solution hav-
ing known concentrations of 0.25 mg propofol related compound A per $\mathrm{mL}, 100 \mu \mathrm{~L}$ of propofol per mL , and $5 \mu \mathrm{~L}$ of propofol related compound C per mL. $\mathbf{n}_{2 \text { S }}$ (USP28)

Test solution-Transfer about 1000 mg of Propofol, accurately weighed, to a $10-\mathrm{mL}$ volumetric flask, dissolve in and dilute with hexane to volume, and mix.

Reference solution-Dilute 1 mL of the Test solution with hexane to 100 mL , and mix. Dilute 1 mL of this solution with hexane to 10 mL , and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )—Proceed as directed in Assay Test 2. Chromatograph System suitability solution 1 and System suitability solution 2, and record the peak responses as directed for Procedure: the relative retention times are about 0.8 for propofol related compound B from System suitability solution 1, 0.5 for 2-(1-methylethoxy)-1,3-bis(1-methylethylbenzene), 1.0 for propofol, and 5.0 for propofol related compound A from System suitability solution 2; the resolution, $R$, between propofol related compound B and propofol is at least 4.0.

Procedure-Separately inject a volume (about $10 \mu \mathrm{~L}$ ) of the Test solution and the Reference solution into the chromatograph, record the chromatogram, and measure all peak responses. Calculate the percentage of each impurity in the portion of Propofol taken by the formula:

$$
0.1\left(r_{i} / r_{S}\right)(1 / F)
$$

in which $r_{i}$ is the peak response for each impurity obtained from the Test solution; $r_{S}$ is the peak response for propofol obtained from the Reference solution; and $F$ is the response factor. $F$ is 0.2 for 2,6diisopropylphenylisopropyl ether and 4.0 for propofol related compound A: more than $0.2 \%$ of 2 ( 1 methylethoxy) 1,3 bis ( $1-$ methylethylbenzene) is found;

## ■ ${ }^{\text {■ }}$ (USP28)

not more than $0.2 \%$ of 2,6-diisopropylphenylisopropyl ether is found; not more than $0.01 \%$ of propofol related compound A is found; not more than $0.05 \%$ of each of the other individual impurities is found; and not more than $0.3 \%$ of total impurities is found.
remaining stock solution for the Assay for sodium and potassium, the Assay for chloride, the Assay for bicarbonate, and the Assay for citrate.] Determine the angular rotation in a suitable polarimeter tube at $25^{\circ}$ (see-9ptical Rotation- 781 ) ). Caleulate the quantity, in $\frac{5}{2}$, of anhydrous dextrese $\left(\mathrm{C}_{6} \mathrm{H}_{42} \mathrm{O}_{6}\right)$ in the unit dose container er containers taken or in the portion of powder taken from the mul tiple unit container, by the formula:

## $(200152.7)(a t)$,

in which 52.7 is the specifie rotation of anhydrous dextrose, a is the eerrected observed rotation, in degrees, and $l$ is the length, in dm, of the pelarimeter tabe. Where the-Oral-Rehydration-Salts is lat beledtocentain Dextrose-Menehydrate, ealeulate the quantity of dextrese menehydrate $\left(\mathrm{C}_{6} \mathrm{H}_{42} \Theta_{6} \cdot \mathrm{H}_{2} \Theta\right)$ by the same formula, substituting the figure 47.9, the specific rotation of dextrose monohy Arate, in place of 52.7.
-(see Optical Rotation $\langle 781\rangle$ ). Where the Oral Rehydration Salts is labeled to contain anhydrous dextrose, calculate the percentage ( g per 100 mL ) of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ in the portion of Oral Rehydration Salts taken by the formula:
(100/52.9)AR,
in which 100 is percent; 52.9 is the midpoint of the specific rotation range for anhydrous dextrose, in degrees; $A$ is 100 mm divided by the length of the polarimeter tube, in mm; and $R$ is the observed rotation, in degrees. Where the Oral Rehydration Salts is labeled to contain dextrose monohydrate, calculate the percentage (g per 100 mL ) of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \cdot \mathrm{H}_{2} \mathrm{O}$ in the portion of Oral Rehydration Salts taken by the formula:

$$
(100 / 52.9)(198.17 / 180.16) A R
$$

in which 100 is percent; 52.9 is the midpoint of the specific rotation range for anhydrous dextrose, in degrees; 198.17 and 180.16 are the molecular weights for dextrose monohydrate and anhydrous dextrose, respectively; $A$ is 100 mm divided by the length of the polarimeter tube, in mm ; and $R$ is the observed rotation, in degrees. $\quad$ 2S (USP28)

Ringer's and Dextrose Injection, USP 27 page 1657 and page 1293 of PF 30(4) [July-Aug. 2004]-See briefing under Alcohol in Dextrose Injection.

## BRIEFING

Tiagabine Hydrochloride, USP 27 page 1841 and page 3305 of the Second Supplement. It is proposed to revise the test for Chromatographic purity to add the names of the impurities listed by retention times in the table of Relative Response Factors.
(PA3: S. Salado) RTS-41610-1

## Change to read:

## Chromatographic purity-

Solution A-Use a filtered and degassed solution of water adjusted with phosphoric acid to a pH of 2.3 .
Solution B-Use filtered and degassed acetonitrile.
Mobile phase-Use variable mixtures of Solution A and Solution $B$ as directed for Chromatographic system. Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

Standard stock solution-Dissolve an accurately weighed quantity of USP Tiagabine Hydrochloride RS in water to obtain a solution having a known concentration of about 1 mg per mL .
Standard solution-Dilute a portion of the Standard stock solution quantitatively, and stepwise if necessary, with water to obtain a solution having a known concentration of about 0.001 mg per mL .

Resolution solution-Dissolve an accurately weighed quantity of -USP Tiagabine Related Compound $\mathrm{A} \mathrm{RS}_{\text {I2S }}$ (USP27) in water to obtain a solution having a known concentration of about 1 mg per mL. Transfer 1.0 mL of this solution and 1.0 mL of the Standard stock solution to a $10-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix.

Test solution-Transfer about 100 mg of Tiagabine Hydrochloride, accurately weighed, to a $100-\mathrm{mL}$ volumetric flask. Dissolve in and dilute with water to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )—The liquid chromatograph is equipped with a $254-\mathrm{nm}$ detector and a $4.6-\mathrm{mm} \times 15-\mathrm{cm}$ column that contains $5-\mu \mathrm{m}$ packing L1. The flow rate is about 1.0 mL per minute. The chromatograph is programmed as follows.

| Time <br> (minutes) | Solution $A$ <br> $(\%)$ | Solution $B$ <br> $(\%)$ | Elution |
| :---: | :---: | :---: | :--- |
| 0 | 75 | 25 | equilibration |
| $0-30$ | $75 \rightarrow 45$ | $25 \rightarrow 55$ | linear gradient |
| $30-40$ | $45 \rightarrow 10$ | $55 \rightarrow 90$ | linear gradient |
| $40-45$ | 10 | 90 | isocratic |

Chromatograph the Resolution solution, and record the peak responses as directed for Procedure: the resolution, $R$, between tiag-
 is not less than 9.0; chromatograph the Standard solution, and record the peak responses as directed for Procedure: the relative standard deviation for replicate injections is not more than $2.0 \%$.
Interference check-Inject water as the blank: no interfering peaks are observed.
Procedure-Separately inject equal volumes (about $20 \mu \mathrm{~L}$ ) of the Standard solution and the Test solution into the chromatograph, record the chromatograms, and measure all the peak responses. Calculate the percentage of each impurity in the portion of Tiagabine Hydrochloride taken by the formula:

$$
100 F\left(r_{i} / r_{s}\right)
$$

in which $F$ is the relative response factor (see the accompanying table for values) for each impurity; $r_{i}$ is the peak response for each impurity obtained from the Test solution; and $r_{s}$ is the sum of the responses of all the peaks, excluding the solvent peaks. (See the accompanying table for limits of individual impurities.) Not more than $1.0 \%$ of total impurities is found.

Relative Response Factors

| ${ }^{\text {- }}$ Compound ${ }^{\text {Name }}{ }_{\text {m2S }}$ (USP28) | Relative Retention Time <br> $\mathbf{n}^{(\text {approximated })}{ }_{\text {ne (USP28) }}$ | $F$ | Limit (\%) |

## Briefing

Water for Injection, USP 27 page 1949 and page 3087 of the First Supplement. The Pharmaceutical Waters Expert Committee proposes, with the concurrence of the Analytical Microbiology Expert Committee, a revision in the test for Bacterial endotoxins to harmonize with the European Pharmacopoeia and to be consistent with the language in Bacterial Endotoxins Test $\langle 85\rangle$.
(PW: F. Barletta; AMB: D. Porter) RTS—41213-2; 41215-1

## Change to read:

" Water for Injection is water purified by distillation or $\Delta$ a purification process that is equivalent or superior to distillation in the removal of chemicals and microorganisms. $\triangle$ USP27 It is prepared from water complying with the U.S. Environmental Protection Agency National Primary Drinking Water Regulations or comparable regulations of the European Union, Japan,
-or the World Health Organization's Guidelines
for Drinking Water Quality.n2S (USP28)
It contains no added substance.
NOTE-Water for Injection is intended for use in the preparation of parenteral solutions. Where used for the preparation of parenteral solutions subject to final sterilization, use suitable means to minimize microbial
growth, or first render the Water for Injection sterile and thereafter protect it from microbial contamination. For parenteral solutions that are prepared under aseptic conditions and are not sterilized by appropriate filtration or in the final container, first render the Water for Injection sterile and, thereafter, protect it from microbial contamination. The tests for Total organic carbon and Water conductivity apply to Water for Injection produced on site for use in manufacturing. Water for Injection packaged in bulk for commercial use elsewhere meets the requirement of the test for Bacterial endotoxins as indicated below and the requirements of all the tests under Sterile Purified Water, except $L a-$ beling.

## Change to read:

Bacterial endotoxins $\langle 85\rangle$ - It contains
$\boldsymbol{- l}^{\text {lesS }}{ }_{\text {2S }}$ (USP28)
than 0.25 USP Endotoxin Unit per mL.

Pure Steam. During the Open Conference held in New Orleans in May 1998, it was concluded that there is no universally accepted standard for Pure Steam and it was recommended that the USP address this issue. The Pharmaceutical Waters Expert Committee proposes this new monograph and encourages public comment. The Committee has assigned specific requirements to the steam or vapor phase while the testing is performed on the condensate, which must meet the requirements for Water for Injection (WFI). Comments should be addressed to Frank Barletta, the Committee Liaison.

$$
\text { (PW: F. Barletta) } \quad \text { RTS }-41332-1
$$

## Add the following:

## ■ Pure Steam

NOTE-For microbiological guidance see general information chapter Water for Pharmaceutical
Purposes $\langle 1231\rangle$.
» Pure Steam is water that has been heated above $100^{\circ}$ and vaporized in a manner which prevents source water entrainment. It is prepared from water complying with the U.S. Environmental Protection Agency National Primary Drinking Water Regulations or drinking water regulations of the European Union, Japan or the WHO drinking water guidelines. It contains no added substance. The level of steam saturation or dryness, and the amount of non-condensable gases are to be determined by the Pure Steam application.

NOTE-Pure Steam quality is difficult to assess in its vapor state; therefore the attributes of its condensate are used to indirectly test its quality. The process used to create and collect the condensate for analysis must not adversely impact these quality attributes.

USP Reference standards $\langle 11\rangle$ —USP 1,4 Benzoquinone RS. USP Endotoxin RS. USP Sucrose RS.

Bacterial endotoxins $\langle 85\rangle$-The condensate contains less than 0.25 USP Endotoxin Unit per mL.

Total Organic Carbon $\langle 643\rangle$ : the condensate meets the requirement.

Water Conductivity $\langle 645\rangle$ : the condensate meets the re-
quirement.■2S (USP28)

## Briefing

Small Intestinal Submucosa Wound Matrix, page 538 of $P F$ 30(2) [Mar.-Apr. 2004]. On the basis of comments and data received, it is proposed to simplify the preparation of the Test solution in the test for Fibroblast growth factor-2 content. This proposed new preparation procedure is less time consuming and results in lower loss of material during the tissue extraction process. Interested parties are invited to submit comments.
(GCT: I. DeVeau) RTS-41434-1

## Add the following:

## ■Small Intestinal Submucosa Wound Matrix

» Small Intestinal Submucosa Wound Matrix is a biologically derived, collagen-based wound care product, translucent and off-white in color. It is obtained from the small intestinal submucosa layer of the domestic pig (Sus scrofa L.). This layer has been mechanically separated from the adjoining layers of the intestine to remove the serosal, mucosal, and muscular elements. The isolated submucosa is chemically cleaned, decellularized, freeze-dried, and terminally sterilized. Small Intestinal Submucosa Wound Matrix also undergoes a viral inactivation; the inactivation method is validated using parvovirus, reovirus, pseudorabies virus, and leukemia retrovirus as the test viruses. By dried weight, Small Intestinal Submucosa Wound Matrix consists of about 70 percent protein, about 20 percent carbohydrate, and about 7 percent lipid. The protein component is primarily
collagen type I (approximately 90 percent), with minor amounts of elastin and collagen type III, collagen type IV, and collagen type VI. In addition to these components, additional extracellular matrix components, such as glycosaminoglycans and basic fibroblast growth factor, are also retained.

Packaging and storage-Package in single-use, peel-open pouches that are gas permeable for sterilization purposes. Store under clean, dry conditions at $25^{\circ}$, excursions permitted between $15^{\circ}$ and $30^{\circ}$.

Labeling-The package is labeled to indicate the dimensions of the enclosed Small Intestinal Submucosa Wound Matrix, the expiry date, required storage conditions, and the lot number. The label indicates that the Wound Matrix is sterile if the package is intact, and that the Wound Matrix is designed for single patient, one-time use.

USP Reference standards $\langle 11\rangle$ —USP Endotoxin RS.
USP Authentic Visual References-USP Cultured Rat Pheochromocytoma Reference Photomicrographs. These photomicrographs represent examples of normal and differentiated rat pheochromocytoma cells and are used to assist in ascertaining bioactivity.

Bacterial endotoxins $\langle 85\rangle$-Immerse $70 \mathrm{~cm}^{2}$ of Small Intestinal Submucosa Wound Matrix in 40 mL of LAL Reagent Water. Extract for 60 minutes at $37^{\circ}$ with shaking. Remove a $100-\mu \mathrm{L}$ aliquot to measure the amount of bacterial endotoxins. It contains not more than 20.0 USP Endotoxin Units per $70 \mathrm{~cm}^{2}$.

Sterility $\langle 71\rangle$ : meets the requirements.

## Fibroblast growth factor-2 content-

8M Urea Dissolve-480.4g of urea in about 700 mL of water. Dilute with water to - L. [Cattion Urea is highly toxic. Avoid skin comtact.]

Extraction buffer Mix 250 mL of 8 M Urea and 750 mL of water. To this solution add 6.0 g of tromethamine and 2.5 of heparin, and mix to dissolve.

N Ethylmateimide solution Dissolve 25 g of N ethylmateimide in 90 mL of aleohel. Dilute with aleohel to 100 mL . Phenylmethylsulfomylfturide solution- Dissolve-3.5 gof phenylmethylsulfonyl fluride in 100 mL of alcohel with gentle heating. [Caution Phenylmethylsulfonyl flurride is highly toxic. Avid skin contact and inhaling dust and va pers.]

Benzamidine hydrochloride solution- Dissolve-15.7g of benzamidine hydrochloride hydrate in $90-\mathrm{mL}$ of water. Di lete with water to 100 mL .

> IgG: agarose suspension Prepare a-suspension cen
taining 5-10-10 mg of human immeneghebulin G: agarese in 0.5 M sodium chloride with $0.01 \%$ thimerisal. ${ }^{+}$

Ealibrator diltent Prepare an aqueous buffered protein solution, with preservative, suitable for the performance of ELISA (see Biotechnology Derived Products $\langle 1045$ ).).²

IgG: agarese diluent Remove an aliquot of the IfG: agatiose suspension, allow the agarese beads to settle, and discard the supernatant. Measure the volume of the remaining agarese gel, add anequal volume of Calibrator dil went, and mix the slurry for 1 hour at $4^{\circ}$. Prepare immediately before use.

Sterile PBS solution-Prepare a sterile solution that contains 8065.0 mg and 200.0 mg of sodium chloride and potassium chloride, respectively, per L of 0.01 M sodium phosphate buffer, pH 7.4 .

Test solution Pulverize the Small-Intestinal Submueosa Wound Matrix in liquid nitrogen using a mortar and pestle that has been prechilled to- $80^{\circ}$. Transfer 10 of powdered tissue to 100 mL of Extraction buffer. Mix 0.5 mL each of A Ethylmateimide solution, Phenylmethylsulfonyl flumide soltuien, and Benzamidine hydrechloride soltaion, and ad just to a pH of 7.4 using sterile selutions of either $0.5 \mathrm{M}-\mathrm{se}$ dium hydroxide or 0.5 M hydrochloric acid. Extract the powdered Small Intestinal Submueosa-Wound Matrix with censtant stirring at $4^{\circ}$ for 24 hours. Centrifuge the extract at $12,000 \times 8$ for 30 minntes at $4^{\circ}$. Place the supernatant inte dialysis tubing with a molecular weight eut offof 3500 dat tons; dialyze at $4^{\circ}$ with stirring against about 20 Lof water. Change the dialysis water 3 times a day for 2 days. Colleet the solution frem the dialysis tubing, and centrifuge at $12,000 \times$ of for 30 minutes at $4^{\circ}$. Lyophilize the supernatant and reconstitute the lyophilisate in water, with vortexing, to aconeentration of 10 mg per mL . Centrifuge at $5000 \times 8$ for 3 minttes, and diseard the pellet. Add $50 \mu \mathrm{H}$ of $I \mathrm{~g} G$ : agarose diluent to the lyophilisate solution, and mix for 4 heur at $4^{\circ}$. Centriftuge at $12,000 \times \frac{8}{}$ for 5 mintes at $4^{\circ}$, recover the supernatant, and store at $4^{\circ}$. Usewithin 24 hours ef preparation. Obtain a $1-\mathrm{cm}^{2}$ sample of Small Intestinal Submucosa Wound Matrix, weigh, and submerge in 400 $\mu \mathrm{L}$ of Sterile PBS solution. Pulverize the tissue for 90 seconds using a tissue grinder, intermittently checking to be sure the tissue remains immersed in the Sterile PBS solution and becomes homogenized. Centrifuge at $12,000 \times g$ for 5 minutes at $4^{\circ}$. Use immediately upon preparation. [NOTE-

[^243]The Test solution may be stored for short periods at $4^{\circ}$ or on ice.]

Procedure-Examine duplicate aliquots of the Test solution by a suitably sensitive ELISA method: ${ }^{1}$ the analysis is considered valid if the ELISA kit generates a linear standard curve with the square of the correlation coefficient $\left(r^{2}\right)$ not less than 0.95 , and if the duplicate aliquots of the Test solution yield results that are within $20 \%$ of each other. The average content of fibroblast growth factor-2 is not less than $10,000 \mathrm{pg}$ per g of Small Intestinal Submucosa Wound Matrix.

## Glycosaminoglycan content-

1,9-Dimethylmethylene blue solution-Mix 95 mL of 0.1 M hydrochloric acid in 500 mL of water. Add 16 mg of 1,9-dimethylmethylene blue, 3.04 g of aminoacetic acid, and 2.37 g of sodium chloride. Dilute with water to 1 L and adjust to a pH of 3.0 using sterile solutions of either 1.0 M sodium hydroxide or 1.0 M hydrochloric acid. Store in lowactinic glassware.

Sterile PBS solution -Prepare - sterile solution that eontains 8065.0 mg and 200.0 mg of sodium chloride and $\mathrm{pe}-$ fassitum ehloride, respectively, per L of 0.01 M soditum phesfer, pH 7.4. Prepare as directed under Fibroblast growth factor-2 content.

Proteinase K solution-Prepare a solution of Tritirachium album proteinase K in water having an activity of 600 units per mL.
Stock heparin standard solution-Prepare a solution containing 1 mg of heparin per mL of water.

Heparin standard curve solutions-Using the Stock heparin standard solution, prepare three solutions containing $20 \mu \mathrm{~g}$ per $\mathrm{mL}, 50 \mu \mathrm{~g}$ per mL , and $100 \mu \mathrm{~g}$ per mL of heparin, respectively.

[^244]Blank solution-Use water.
Test solution-Prepare test samples in duplicate. Accurately weigh about 25 mg of Small Intestinal Submucosa Wound Matrix and cut into small pieces (roughly $2 \mathrm{~mm} \times 2$ mm ). Transfer to a $1.5-\mathrm{mL}$ microcentrifuge tube, and add $180 \mu \mathrm{~L}$ of Sterile PBS solution and $20 \mu \mathrm{~L}$ of Proteinase $K$ solution. Mix, and incubate the sample at $56^{\circ}$ for 15 min utes; during the incubation mix intermittently on a vortex mixer. Cool the sample to room temperature. Dilute with water to obtain a concentration of 12.5 mg of digested Small Intestinal Submucosa Wound Matrix per mL.
Collagen control solution-Accurately weigh about 25 mg of a bovine collagen, type I, that contains less than 1 $\mu \mathrm{g}$ of glycosaminoglycan per mg . Transfer to a $1.5-\mathrm{mL}$ microcentrifuge tube, and add $180 \mu \mathrm{~L}$ of Sterile PBS solution and $20 \mu \mathrm{~L}$ of Proteinase $K$ solution. Mix, and incubate the sample at $56^{\circ}$ for 15 minutes; during the incubation mix intermittently on a vortex mixer. Cool the sample to room temperature. Dilute with water to obtain a concentration of 12.5 mg of digested bovine collagen per mL .
Procedure (see Spectrophotometry and Light-Scattering $\langle 851\rangle$ )-To triplicate $100-\mu \mathrm{L}$ aliquots each of Heparin standard curve solutions, Blank solution, Test solution, and Collagen control solution, add 2.5 mL of 1,9-Dimethylmethylene blue solution. Mix on a vortex mixer for 1 second and immediately read the absorbance at 525 nm . Generate a standard curve of absorbance versus concentration using the averages of each Heparin standard curve solution, correcting for the blank, and calculate the regression line and regression coefficient. The concentration of glycosaminoglycan in the Test solution and Collagen control solution is determined directly from the regression line. If the absorbance of the Test solution is greater than the highest Heparin standard curve solution, then dilute the Test solution appropriately, and repeat the Procedure beginning with "To trip-
licate $100-\mu \mathrm{L}$ aliquots." The test is considered valid if the regression curve has a square of the correlation coefficient ( $r^{2}$ ) not less than 0.95 ; the triplicate aliquots of the Test solution and Collagen control solution yield results that are within $20 \%$ of each other, respectively; and the average glycosaminoglycan content of the Test solution is statistically greater than the Collagen control solution using one-tailed, unequal variances, $t$-test at $\alpha=0.05$. The average glycosaminoglycan content of the Test solution is not less than $2 \mu \mathrm{~g}$ per mg.

## Metabolic activity assessment-

Dulbecco's modified Eagle's tissue culture medium-Prepare a solution that contains the components included in the following Table 1:

Table 1

|  | Content |
| :--- | :---: |
| Component | (mg per L) |.

Table 1 (Continued)

\left.| Component |  |
| :--- | :---: |
|  | Content |
| (mg per L) |  |$\right]$

Procedure-Remove three $12-\mathrm{mm}$ diameter circular sections of Small Intestinal Submucosa Wound Matrix, using the appropriate size biopsy punch. Immerse each section into individual wells of a 12-well cell culture plate (dimension of each well is about 22 to 23 mm in diameter and about 17 to 18 mm in depth), each containing 1 mL of Dulbecco's modified Eagle's tissue culture medium. Prepare a positive control by harvesting a full-thickness section of porcine jejunum immediately following slaughter. Rinse the section of jejunum in $37^{\circ}$ isotonic sodium chloride solution for 5 min utes to remove intestinal debris. Using scissors, split open the section of jejunum to form a sheet. Remove three 12mm diameter circular sections of jejunum, using the appropriate size biopsy punch. Immerse each section into individual wells of a 12-well cell culture plate, each well containing 1 mL of Dulbecco's modified Eagle's tissue culture medium. Treat these positive control wells in the same manner as the test wells. Prepare a blank solution using 1 mL of Dulbecco's modified Eagle's tissue culture medium. Allow sections to hydrate for 5 minutes, add $50 \mu \mathrm{~L}$ of MTT reagent to each of the sections and the blank, and mix. Incubate for 3 hours at $37^{\circ}$ in an atmosphere containing $5 \%$ carbon dioxide. Add $100 \mu \mathrm{~L}$ of Detergent reagent to each well, and mix. Leave the samples at ambient temperature in the dark for 2 hours. Measure the absorbance of the resulting solution at 570 nm , adjusting for the blank. For the test to be valid, the average absorbance in the positive control wells is greater than 0.100 . The average absorbance reading for the Small Intestinal Submucosa Wound Matrix wells is less than 0.100 . Bioactivity-
NOTE—Aseptic cell culture techniques should be employed throughout the performance of this test.

Modified RPMI-1640 culture medium-Prepare a sterile solution that contains the components included in the following Table 2:

Table 2

| Component | Content <br> $(\mathrm{mg}$ per L) |
| :--- | :---: |
| Calcium chloride | 264.9 |
| Ferric nitrate, nonahydrate | 0.10 |
| Potassium chloride | 400.0 |
| Magnesium sulfate, heptahydrate | 200.0 |
| Sodium chloride | $6,400.0$ |
| Sodium bicarbonate | $3,700.0$ |
| Sodium phosphate, monobasic, | 125.0 |
| monohydrate |  |
| Glucose | $4,500.0$ |
| Phenol red | 15.0 |
| Sodium pyruvate | 110.0 |
| L-Arginine hydrochloride | 84.0 |
| L-Cystine | 48.0 |
| Aminoacetic acid | 30.0 |
| L-Histidine hydrochloride, | 42.0 |
| monohydrate |  |
| L-Isoleucine | 104.8 |
| L-Leucine | 104.8 |
| L-Lysine hydrochloride | 146.2 |
| L-Methionine | 30.0 |
| L-Phenylalanine | 66.0 |
| L-Serine | 42.0 |
| L-Threonine | 95.2 |
| L-Tryptophan | 16.0 |
| L-Tyrosine | 72.0 |
| L-Valine | 93.6 |
| L-Calcium pantothenate | 4.0 |
| Choline chloride | 4.0 |
| Folic acid | 4.0 |

Table 2 (Continued)

|  | Content <br> (mg per L) |
| :--- | :---: |
| Component | 7.0 |
| Inositol | 4.0 |
| Nicotinamide | 4.0 |
| Pyridoxine hydrochloride | 0.40 |
| Riboflavin | 4.0 |
| Thiamine hydrochloride | 2383.0 |
| Sodium 1-heptanesulfonic acid |  |

Penicillin-streptomycin solution-Prepare a suitable buffered solution containing 10,000 USP Penicillin Units of penicillin per mL and 10 mg of streptomycin per $\mathrm{mL} .{ }^{4}$
PC12 cell line culture medium-Mix 420 mL of Modified RPMI-1640 culture medium, 50 mL of horse serum, ${ }^{5} 25 \mathrm{~mL}$ of fetal bovine serum, ${ }^{6}$ and 5 mL of Penicillin-streptomycin solution. Sterilize by passing through a $0.22-\mu \mathrm{m}$ filter.
Sterile PBS solution-Prepare as directed under Gly Fibroblast growth factor-2 content.
Rat tail collagen solution-Prepare a suspension containing 0.2 mg of rat tail collagen, type I, in sterile water.

Cell culture apparatus-Prepare by adding a sufficient volume of Rat tail collagen solution to completely cover the bottom of each well of a 12 -well cell culture plate (dimension of each well is about 22 to 23 mm in diameter and about 17 to 18 mm in depth). Incubate under sterile condi-

[^245]tions for 2 hours at $37^{\circ}$ or overnight at room temperature. Remove the Rat tail collagen solution by aspiration. Rinse with Sterile PBS solution that has been preheated to $37^{\circ}$.

PC12 cells-Use cultured rat pheochromocytoma cells (ATCC CRL-1721).

Cultivation of PC12 cells-Starting from a frozen culture, prewarm PC12 cell line culture medium to $37^{\circ}$. Add 15 mL of prewarmed PC12 cell line culture medium to a T-75 culture flask. Place a single vial containing the frozen PC12 cells in a $37^{\circ}$ water bath with gentle agitation until they start to thaw (about 1 minute). Complete the thawing procedure by slowly rotating the vial between the hands. Rinse the outside of the vial with 70 percent alcohol. Transfer the contents of the vial to the T-75 flask, and mix. Incubate the cells overnight at $37^{\circ}$ in a $5 \%$ carbon dioxide atmosphere. Transfer the contents of the T-75 culture flask to a sterile centrifuge tube, centrifuge at $200 \times g$ for 5 minutes at $37^{\circ}$, and discard the supernatant. Resuspend the cells in 15 mL of PC12 cell line culture medium, and transfer the contents back into the T-75 culture flask. Incubate the cells at $37^{\circ}$ in a $5 \%$ carbon dioxide atmosphere for 3 days.

Cell feeding-At the end of 3 days, the cells will need to be fed for optimal growth. To feed the cells, remove a flask of cells from the incubator, tightening the cap in the process. Examine the T-75 flask under the microscope and check for microbial contamination and confluency. If there is microbial contamination, then discard the flask. If the cells appear confluent, follow the instructions below for perpetuating the PC12 cell line (see Culture perpetuation). Otherwise, harvest the cells from the flask by pipeting the contents of the flask across the bottom of the flask several times. Transfer the cell suspension to a sterile $50-\mathrm{mL}$ centrifuge tube. Centrifuge the cells at $200 \times g$ for 5 minutes at $37^{\circ}$, and discard the supernatant. Resuspend the cells in 13 mL of PC12 cell line culture medium, prewarmed to $37^{\circ}$. Transfer
the cell suspension back to the T-75 flask, and mix. Loosen the cap of the flask, and return to the incubator; incubate the cells at $37^{\circ}$ in a $5 \%$ carbon dioxide atmosphere for another 3 to 7 days.

Culture perpetuation-To perpetuate a line of PC12 cells for culture, examine under the microscope a T-75 flask containing cells and check for microbial contamination and confluency. If there is microbial contamination, discard the flask and use another. If the cells do not appear confluent, then follow the instructions above for feeding the PC12 cell line (see Cell feeding), beginning with "Otherwise, harvest the cells from the flask by pipeting the contents of the flask across the bottom of the flask several times." If the cells are confluent and there is no contamination, harvest the cells from the flask by pipeting the contents of the flask across the bottom of the flask several times to loosen up the cells from their attachment to the bottom of the flask and to break up cell clusters. Check under the microscope prior to proceeding to ensure that most of the cells have detached from the plastic. Transfer the cell suspension to a sterile $50-\mathrm{mL}$ centrifuge tube, and centrifuge the cells at $200 \times$ $g$ for 5 minutes at $37^{\circ}$. Discard the supernatant and resuspend the cells with 10 mL of PC12 cell line culture medium, prewarmed to $37^{\circ}$. Dispense an equal amount of the cell suspension into each of three to five T-75 flasks, each flask containing 10 mL of PC12 cell line culture medium, prewarmed to $37^{\circ}$, and mix. Return the passed cells to the incubator, being sure to loosen the cap of the flasks. Incubate the cells at $37^{\circ}$ in a $5 \%$ carbon dioxide atmosphere. Feed the cells after 3 days as directed above, beginning with "To feed the cells, remove a flask of cells from the incubator, tightening the cap in the process." [NOTE-To perform the test for Bioactivity, cells that have undergone more than 15 passages after obtaining them from ATCC should not be used.]

Positive control solution-Prepare a solution containing about 10 ng of fibroblast growth factor-2 per mL of PC12 cell line culture medium.

Negative control solution-Use PC12 cell line culture medium.
Test solution-Immerse $70 \mathrm{~cm}^{2}$ of Small Intestinal Submucosa Wound Matrix in sterile water for 5 minutes. Remove the Small Intestinal Submucosa Wound Matrix, and blot excess water using sterile gauze. Weigh the rehydrated Small Intestinal Submucosa Wound Matrix to the nearest 0.1 g and add Modified RPMI-1640 culture medium at a ratio of 7.5 mL of Modified RPMI-1640 culture medium for each 1.0 g of Small Intestinal Submucosa Wound Matrix. Incubate for 24 hours at $37^{\circ}$ with constant shaking. Remove the Small Intestinal Submucosa Wound Matrix, and pass the solution through a $0.22-\mu \mathrm{m}$ filter. Add sufficient quantities of sterile horse serum and sterile fetal bovine serum to concentrations of $10 \%$ and $5 \%$, respectively, and add a sufficient quantity of Penicillin-streptomycin solution such that there are 100 USP Penicillin Units and 0.1 mg of streptomycin per mL. Adjust the pH of the Test solution to 7.4, using a sterile solution of either 1.0 M sodium hydroxide or 1.0 M hydrochloric acid.

Procedure-Harvest a flask of confluent PC12 cells by centrifuging at $200 \times g$ for 5 minutes. Remove the supernatant by aspiration, and resuspend the pellet to obtain a concentration of about $1 \times 10^{6}$ cells per mL of PC12 cell line culture medium. Add to each of three wells of the Cell culture apparatus 1.0 mL of Negative control solution. To a second set of three wells add to each 1.0 mL of Positive control solution, and to a third set of three wells add to each 1.0 mL of Test solution. Add to each well about 20,000 cells, mix by gentle rocking, and incubate for 48 hours at $37^{\circ}$. For each well, count three random microscopic fields of cells using a microscope with a $10 \times$ ocular lens and a
$20 \times$ objective lens. Each field should have at least 20 cells; avoid large clumps of cells where individual cell bodies cannot be ascertained. Determine the total number of cells in the field and, using USP Cultured Rat Pheochromocytoma Reference Photomicrographs of normal and differentiated rat pheochromocytoma cells for comparison, determine the total number of cells that have formed at least one neurite-like extension at least twice the diameter of a normal, undifferentiated cell body. For each experimental group, record the total number of cells counted and the total number of cells differentiated across all three wells, and calculate the total percentage of cells that have differentiated. For a test to be valid, the following criteria must be met: (1) none of the wells are microbially contaminated; (2) the weighted percentage of differentiated cells across the Negative control solution wells is less than $5 \%$; (3) the weighted percentage of differentiated cells across the Positive control solution wells is greater than $6 \%$; and (4) the weighted percentage of differentiated cells across the Negative control solution wells is statistically less than the weighted percentage of differentiated cells across the Positive control solution wells, using a one-sided, two-sample test for proportions at $\alpha=0.05$. The weighted percentage of differentiated cells incubated in the Test solution wells is statistically greater than those incubated in the Negative control solution wells, using a one-sided, two-sample test for proportions at $\alpha=0.05 \cdot \mathbf{@ L S}^{\text {(USP28) }}$

## Briefing

Excipients, USP and NF Excipients, Listed by Category, $N F$ 22 page 2809, page 3355 of the Second Supplement, and page 1317 of PF 30(4) [July-Aug. 2004]. The proposed revision complements the proposed new monograph, Myristic Acid, that appears elsewhere in this number of PF.

## DIETARY SUPPLEMENTS— MONOGRAPHS

## BRIEFING

> Chromium Picolinate Tablets. Because there is no existing $U S P$ monograph for this dietary supplement, a new monograph, based on validation data received, is being proposed.
(DSN: L. Evans; PSD: C. Okeke; NL: C. Barnstein) RTS-40078-1; 40078-2; 40078-3; 41479-1

## Add the following:

## ■Chromium Picolinate Tablets

## » Chromium Picolinate Tablets contain not less

 than 95.0 percent and not more than 125.0 percent of the labeled amount of chromium $(\mathrm{Cr})$.Packaging and storage-Preserve in well-closed containers, and store at controlled room temperature.

## Identification-

Test solution-Use the Assay preparation.
Procedure-The Test solution gives a positive test for chromium, determined at 357.9 nm using an atomic absorption spectrophotometer as directed for Procedure in the $A s$ say.

Disintegration and dissolution $\langle 2040\rangle$ : meet the requirements for Disintegration only.

Weight variation $\langle 2091\rangle$ : meet the requirements.

Assay-
Standard stock preparation 1-Transfer about 2.829 g of potassium dichromate, previously dried at $120^{\circ}$ for 4 hours and accurately weighed, to a $1000-\mathrm{mL}$ volumetric flask, dissolve in and dilute with water to volume, and mix to obtain a solution having a known concentration of about $1000 \mu \mathrm{~g}$ of chromium per mL . Store in a polyethylene bottle.

Standard stock preparation 2-Transfer 10.0 mL of Standard stock preparation 1 to a $1000-\mathrm{mL}$ volumetric flask, add 50.0 mL of 6 N hydrochloric acid, dilute with water to volume, and mix to obtain a solution having a known concentration of about $10 \mu \mathrm{~g}$ of chromium per mL .

Standard preparations-Transfer 10.0 mL and 20.0 mL of Standard stock preparation 2 to separate $100-\mathrm{mL}$ volumetric flasks, and transfer 15.0 mL and 20.0 mL of Standard stock preparation 2 to separate $50-\mathrm{mL}$ volumetric flasks. Dilute the contents of each of the four flasks with 0.125 N hydrochloric acid to volume, and mix to obtain solutions having known concentrations of about 1.0, 2.0, 3.0, and $4.0 \mu \mathrm{~g}$ of chromium per mL .
Assay preparation-Weigh and finely powder not fewer than 20 Tablets. Transfer an accurately weighed portion of the powder, equivalent to about 5 Tablets, to a porcelain crucible, heat the crucible in a muffle furnace maintained at about $550^{\circ}$ for 6 to 12 hours, and cool. Add about 60 mL of hydrochloric acid, and boil gently on a hot plate or steam bath for 30 minutes, intermittently rinsing the inner surface of the crucible with 6 N hydrochloric acid. Cool, and quantitatively transfer the contents of the crucible to a $100-\mathrm{mL}$ volumetric flask. Rinse the crucible with small portions of 6 N hydrochloric acid, and add the rinsings to the flask. Dilute with water to volume, mix, and filter, discarding the first 5 mL of the filtrate. Dilute this solution quantitatively, and
stepwise if necessary, with 0.125 N hydrochloric acid to obtain a solution having a concentration of about $1 \mu \mathrm{~g}$ of chromium per mL .

Procedure-Concomitantly determine the absorbances of the Standard preparations and the Assay preparation at the chromium emission line at 357.9 nm with an atomic absorption spectrophotometer (see Spectrophotometry and LightScattering $\langle 851\rangle$ ) equipped with a chromium hollow-cathode lamp and an air-acetylene flame, using 0.125 N hydrochloric acid as the blank. Plot the absorbances of the Standard preparations versus concentration, in $\mu \mathrm{g}$ per mL , of chromium, and draw the straight line best fitting the four plotted points. From the graph so obtained, determine the concentration, $C$, in $\mu \mathrm{g}$ per mL , of chromium in the Assay preparation. Calculate the quantity, in $\mu \mathrm{g}$, of chromium $(\mathrm{Cr})$ in the portion of Tablets taken by the formula:

## $C D$,

in which $C$ is as defined above; and $D$ is the dilution factor used to prepare the Assay preparation.■2S (USP28)

## BRIEFING

Lysine Hydrochloride Tablets. Because there is no existing USP monograph for this dietary supplement, a new monograph, based on validation data received, is being proposed.
(DSN: L. Evans; PSD: C. Okeke; NL: C. Barnstein) RTS-41480-1

## Add the following:

## ■ Lysine Hydrochloride Tablets

## » Lysine Hydrochloride Tablets contain not less

 than 90.0 percent and not more than 120.0 percent of the labeled amount of $\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{~N}_{2} \mathrm{O}_{2} \cdot \mathrm{HCl}$, as Llysine hydrochloride.Packaging and storage-Preserve in well-closed containers, and store at controlled room temperature.

USP Reference standards $\langle 11\rangle$ —USP L-Lysine Hydrochloride RS.

Thin-layer chromatographic identification test $\langle 201\rangle$ -
Test solution-Powder and transfer a portion of Tablets equivalent to about 40 mg of lysine hydrochloride to a $100-\mathrm{mL}$ volumetric flask. Dilute with water to volume, mix, and filter. Use the filtrate.

Standard solution-Dissolve an accurately weighed quantity of USP L-Lysine Hydrochloride RS in water to obtain a solution having a known concentration of about 0.4 mg per mL .
Developing solvent system-Prepare a mixture of isopropyl alcohol and ammonium hydroxide ( $70: 30$ ).

Spray reagent-Dissolve 0.2 g of ninhydrin in 100 mL of a mixture of butyl alcohol and 2 N acetic acid ( $95: 5$ ).
Procedure-Proceed as directed in the chapter. Dry the plate between $100^{\circ}$ and $105^{\circ}$ until the ammonia disappears completely. Spray with Spray reagent, and heat between $100^{\circ}$ and $105^{\circ}$ for about 15 minutes. Examine the plate under white light.

## Disintegration and dissolution of dietary supplements

$\langle 2040\rangle$ : meet the requirements for Disintegration only, 20 minutes.

Weight variation of dietary supplements $\langle 2091\rangle$ : meet the requirements.

Assay-Weigh and finely powder not fewer than 20 Tablets. Transfer about 75 mg of Lysine Hydrochloride, accurately weighed, to a $125-\mathrm{mL}$ flask, and dissolve in 5 mL of mercuric acetate TS with gentle heating. Cool, then add 50 mL of glacial acetic acid and 3 drops of crystal violets TS, and titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 9.133 mg of $\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{~N}_{2} \mathrm{O}_{2} \cdot \mathrm{HCl}_{\text {. }}{ }^{2 S}$ (USP28)

## MONOGRAPHS (NF)

[^247]
## Briefing

Myristic Acid. Because there is no existing $N F$ monograph for this excipient, a new monograph based on the Myristic Acid monograph in the Food Chemical Codex, 5th Edition, page 297, is being proposed.
(EMC: D. Bempong) RTS-41326-1

## Add the following:

## ■Myristic Acid

$\mathrm{C}_{14} \mathrm{H}_{28} \mathrm{O}_{2} \quad 228.37$
Tetradecanoic acid [544-63-8].
» Myristic Acid is obtained from coconut oil and other fats. It contains not less than 97.0 percent of $\mathrm{C}_{14} \mathrm{H}_{28} \mathrm{O}_{2}$.

Packaging and storage-Preserve in well-closed containers. No storage requirements specified.

USP Reference standards $\langle 11\rangle$ —USP Myristic Acid RS.
Congealing temperature $\langle 651\rangle$ : between $48^{\circ}$ and $55.5^{\circ}$.
Acid value $\langle 401\rangle$ : between 242 and 249.
Iodine value $\langle 401\rangle$ : not more than 1.0.
Saponification value $\langle 401\rangle$ : between 242 and 251.
Unsaponifiable matter $\langle 401\rangle$ : not more than $1 \%$.
Water, Method $I\langle 921\rangle$ : not more than $0.2 \%$.
Residue on ignition $\langle 281\rangle$ : not more than $0.1 \%$.

Limit of lead- [NOTE-Select reagents having as low a lead content as practicable, and store all solutions in high-density polyethylene containers. Rinse all plastic and glassware thoroughly with warm, 8 N nitric acid followed by deionized water.]

Standard stock solution-Dissolve about 160 mg of lead nitrate, accurately weighed, in 100 mL of water containing 1 mL of nitric acid. Dilute with water to 1000 mL , and mix.

Standard solutions-[NOTE-Prepare these solutions on the day of use.] Transfer 10.0 mL of Standard stock solution to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. Each mL of this solution contains the equivalent of about $10 \mu \mathrm{~g}$ of lead. Dilute accurately measured volumes of the diluted Standard stock solution with water to obtain solutions having known concentrations of about $1 \mu \mathrm{~g}, 2 \mu \mathrm{~g}$, and $5 \mu \mathrm{~g}$ of lead per mL .

Test solution-Transfer about 5 g of Myristic Acid, accurately weighed, to an evaporating dish. Add 5 mL of a $25 \%$ sulfuric acid solution, and distribute the sulfuric acid uniformly through the sample. Within a hood, place the dish on a steam bath to evaporate most of the water. Place the dish on a burner, and slowly pre-ash the sample by expelling most of the sulfuric acid. Place the dish in a muffle furnace that has been set at $525^{\circ}$, and ash the sample until the residue appears free from carbon. Prepare a blank by ashing 5 mL of a $25 \%$ sulfuric acid solution. Cool, and cautiously wash down the inside of each evaporation dish with water. Treat both the sample and the blank as follows. Add 5 mL of 1 N hydrochloric acid. Place each dish on a steam bath, and evaporate to dryness. To each dish add 1.0 mL of 3 N hydrochloric acid and approximately 5 mL of water, and heat briefly on a steam bath to dissolve any residue. Transfer each solution quantitatively to a $10-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix.

Procedure-Using a suitable atomic absorption spectrophotometer (see Spectrophotometry and Light-Scattering $\langle 851\rangle$ ) equipped with a lead electrodeless discharge lamp, an air-acetylene flame, and a suitable burner head, perform a blank determination with water, following the manufacturer's operating instructions. Concomitantly determine the absorbances of the blank, the Standard solutions, and the Test solution at the lead emission line of 283.3 nm , using a slit-width of 0.7 nm . Determine the corrected absorbance values by subtracting the absorbance of the blank from the absorbance of each of the Standard solutions and from the absorbance of the Test solution. Prepare a standard curve by plotting the corrected absorbance values of the Standard solutions versus their corresponding concentration, in $\mu \mathrm{g}$ per mL . From the calibration curve, determine the lead concentration in the Test solution. Calculate the lead content, in $\mu \mathrm{g}$ per g , in the portion of Myristic Acid taken by the formula:

$$
10 C / W_{s}
$$

in which $C$ is the concentration, in $\mu \mathrm{g}$ per mL , of lead from the standard curve; and $W_{S}$ is the weight, in g , of Myristic Acid taken: not more than $2 \mu \mathrm{~g}$ per g is found.

## Assay-

Resolution solution-Proceed as directed for the System Suitability Solution in Fatty Acid Composition under Fats and Fixed Oils $\langle 401\rangle$, except that only stearic acid and palmitic acid are used.

Standard preparation-Prepare as directed for the Assay preparation using 100 mg of USP Myristic Acid RS instead of the substance to be examined.

Assay preparation-Proceed as directed for the Test Solution in Fatty Acid Composition under Fats and Fixed Oils $\langle 401\rangle$.

Chromatographic system (see Chromatography $\langle 621\rangle$ )-
Prepare as directed for Fatty Acid Composition under Fats and Fixed Oils $\langle 401\rangle$. Chromatograph the Resolution solution, and record the peak responses as directed for Procedure: the resolution, $R$, between methyl stearate and methyl palmitate is not less than 1.5.

Procedure-Separately inject equal volumes (about $1 \mu \mathrm{~L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and identify the methyl myristate peak in the chromatogram obtained from the Assay preparation by comparing the retention times of the peaks in that chromatogram with those in the chromatogram obtained from the Standard preparation. Measure the responses for all of the peaks in the chromatogram obtained from the Assay preparation, excluding the solvent peak, and calculate the percentage of $\mathrm{C}_{14} \mathrm{H}_{28} \mathrm{O}_{2}$ in the portion of Myristic Acid taken by the formula:

## 100A/B,

in which $A$ is the the methyl myristate peak response; and $B$ is the sum of the responses of all the peaks in the chromatogram, except the solvent peak. $\mathbf{D S S}_{\text {2 (NF23) }}$

## Add the following:

-USP Reference standards $\langle 11\rangle$ —USP Polyoxyl 35 Castor Oil RS. $\mathbf{■ S ~}_{\text {2S (NF23) }}$

## Change to read:

## Identification-

A: Bissolve about 0.1 g in 1 mL of water, add 9 mL of sodium ehloride-solation (1-in 20), and heat in a water bath: the-selution becomes turbid at a temperature between $65^{\circ}$ and $85^{\circ}$ and becomes elear on cooling to $40^{\circ}$.

- Infrared Absorption $\langle 197 \mathrm{~F}\rangle$. ${ }^{2 S}$ (NF23

B: Dissolve about 0.1 g in 10 mL of alcoholic potassium hydroxide TS, boil for about 3 minutes, and evaporate to dryness. Mix the residue with 5 mL of water: it dissolves, yielding a clear solution. Add a few drops of glacial acetic acid: a white precipitate is formed.
C: To a solution (1 in 20) add bromine TS, dropwise: the bromine is decolorized.

Briefing

Sesame Oil, NF 22 page 2926 and page 608 of PF 30(2) [Mar.Apr. 2004]-See briefing under Soybean Oil.
(EMC: C. Sheehan; NL: W. Paul) RTS-41628-2

## Change to read:

» Sesame Oil is the refined fixed oil obtained from the seed of one or more cultivated varieties of Sesamum indicum Linné (Fam. Pedaliaceae).
-It may contain suitable antioxidants.■2S (NF23)

## Add the following:

-USP Reference standards $\langle 11\rangle$ —USP Sesame Oil Related Compound A RS. USP Sesame Oil Related Compound B RS.■1S (NF23)

## Add the following:

-Labeling-Label it to indicate the name and quantity of any added antioxidant. $\quad$ 2S (NF23)

## Change to read:

Triglyceride composition-
Mobile phase-Prepare a filtered and degassed mixture of acetonitrile and methylene chloride ( $60: 40$ ). Make adjustments if necessary (see System Suitability under Chromatography $\langle 621\rangle$ ).

NOTE-The fatty acid radicals are designated as linoleic (L), oleic $(\mathrm{O})$, palmitic $(\mathrm{P})$, and stearic (S), and the common abbreviations for triglycerides used are as follows: trilinolein (LLL), 1,2-dilino-leoyl-3-oleoyl-rac-glycerol (OLL), 1,2-dilinoleoyl-3-palmitoyl-rac-glycerol (PLL), 1,2-dioleoyl-3-linoleoyl-rac-glycerol (OOL), 1-palmitoyl-2-oleoyl-3-linoleoyl-rac-glycerol (POL), triolein (OOO), 1-linoleoyl-2-oleoyl-3-stearoyl-rac-glycerol (SOL), and 1,2-dioleoyl-3-palmitoyl-rac-glycerol (POO).

System suitability solution - Transfer abut 30 mg each of OLL and PLL, aceurately weighed, to a 10 mL volumetric flask, dissolve in and dilute with Mobile phase to volume, and mix.
-Dissolve an accurately weighed quantity of USP Sesame
Oil Related Compound A RS and USP Sesame Oil Related
Compound B RS in Mobile phase to obtain a solution having a known concentration of about 3 mg of each per mL . [nOTE--USP Sesame Oil Related Compound A RS is OLL and USP Sesame Oil Related Compound B RS is PLL]. ${ }^{1 S}$ (NF23)

Test solution-Transfer about 200 mg of Oil, accurately weighed, to a $10-\mathrm{mL}$ volumetric flask, dilute with Mobile phase to volume, and mix.

Chromatographic system (see Chromatography $\langle 621\rangle$ )—The chromatograph is equipped with a refractive index detector and two $4.6-\mathrm{mm} \times 25-\mathrm{cm}$ columns in series that contain packings L1 and are maintained at a constant temperature of about $30^{\circ}$. The flow rate is about 1.0 mL per minute. Chromatograph the System suitability solution, and record the peak areas as directed for Procedure: the relative retention times are about 0.93 for OLL and 1.0 for PLL; the resolution, $R$, between OLL and PLL is not less than 1.8; the relative standard deviation for replicate injections, determined from peak areas, is not more than $1.5 \%$; and the relative standard deviation for replicate injections, determined from peak area ratios of OLL to PLL, is not more than $2.2 \%$.

Procedure-Inject about $20 \mu \mathrm{~L}$ of the Test solution into the chromatograph, record the chromatogram, and measure the areas for the eight major triglyceride peaks, eluting from 0 to about $40 \mathrm{~min}-$ utes, with relative retention times stated in the table below and in the order specified. Calculate the percentage of each of these triglycerides in the portion of Oil taken by the formula:

$$
100(A / B)
$$

in which $A$ is the peak area for each individual triglyceride; and $B$ is the sum of the areas of all the peaks, excluding the solvent peak.

| Triglyceride | Relative Retention Time | Composition (\%) |
| :---: | :---: | :---: |
| LLL | 0.55 | 7.0 to 19.0 |
| OLL | 0.65 | 13.0 to 30.0 |
| PLL | 0.69 | 5.0 to 9.0 |
| OOL | 0.77 | 14.0 to 25.0 |
| POL | 0.82 | 8.0 to 16.0 |
| OOO | 0.93 | 5.0 to 14.0 |
| SOL | 0.97 | 2.0 to 8.0 |
| POO | 1.0 | 2.0 to 8.0 |

## Briefing

Anhydrized Liquid Sorbitol, page 993 of $P F$ 30(3) [May-June 2004]. It is proposed to adopt Sorbitol Sorbitan Solution as the title of this proposed new monograph, which first appeared with the name Anhydrized Liquid Sorbitol in a Pharmacopeial Preview in PF 28(3) [May-June 2002] and under In-Process Revision in PF 29(1) [Jan.-Feb. 2003] and subsequently, under In-Process Revision in PF 29(4) [July.-Aug. 2003]. The Expert Committee on Nomenclature and Labeling has proposed Sorbitol Sorbitan Solution as the title of the monograph for this excipient, which is proposed for inclusion in the Second Supplement to USP 28-NF 23, but with an official date of August 1,2010, which is sixty months later than the August 1, 2005, official date of the Second Supplement. The sixty month extension will provide the time deemed necessary for labeling changes to be made for the article and the numerous preparations in which it is an ingredient, and for practitioners, consumers, and regulatory agencies to become familiar with the terminology.
(EMC: C. Sheehan; NL: C. Barnstein) RTS-41545-1

## Add the following:

## ■Anhydrized Liquid-Sorbitol Sorbitol Sorbitan Solution

(Monograph under this new title - to become official August 1, 2010)
(Currently there is no official monograph for this article)

## " Anhydrized Liquid Sorbitel Sorbitol Sorbitan

Solution is a water solution containing, on the anhydrous basis, not less than 25.0 percent of D-sorbitol $\left(\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{O}_{6}\right)$ and not less than 15.0 percent of 1,4-sorbitan $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{5}\right)$. The amounts of total sugars, other polyhydric alcohols, and any other hexitol anhydrides, if detected, are not included in the requirements or in the calculated amount under Other Impurities.

Packaging and storage-Prese in tightentrens. Preserve in well-closed containers. Po nore $20^{\circ}$. No storage requirements specified.

Labeling-The labeling indicates the percentage content, on the anhydrous basis, of D-sorbitol and 1,4-sorbitan.

USP Reference standards $\langle 11\rangle — U S P$ Sorbitol RS. USP

## 1,4-Sorbitan RS.

## Identification-

A: Dissolve Prepare a solution containing 1.4 g of Ant hydrized Liquid Sorbitel Sorbitol Sorbitan Solution in 75 mL of water. Transfer 3 mL of this solution to a $15-\mathrm{cm}$ test tube, add 3 mL of freshly prepared catechol solution (1 in 10 ), and mix. Add 6 mL of sulfuric acid, mix again, then gently heat the tube in a flame for about 30 seconds: a deep pink or wine-red color appears.
B: The retention times of the major peaks in the chromatogram of the Assay preparation correspond to those in the chromatogram of the Standard preparation, as obtained in the Assay.

Microbial limits $\langle 61\rangle$ —The total aerobic microbial count using the Plate Method is not more than 1000 cfu per mL. The total combined molds and yeasts count is not more than 100 cfu per mL.
$\mathbf{p H}\langle 791\rangle$ : between 4.0 and 7.0 , in a $14 \%(\mathrm{w} / \mathrm{w})$ solution of Anhydrized Liquid Sorbitel Sorbitol Sorbitan Solution in carbon dioxide-free water.

Water, Method I $\langle 921\rangle$ : not more than 31.5\%.
Residue on ignition $\langle 281\rangle$ : not more than $0.20 \%$, calculated on the anhydrous basis. Determine on a $2-\mathrm{g}$ portion, accurately weighed.

Reducing sugars-To an amount of Anhydrized Liquid Serbitel Sorbitol Sorbitan Solution, equivalent to 3.3 g , on the anhydrous basis, add 3 mL of water, 20.0 mL of cupric citrate TS, and a few glass beads. Proce in the test for Reducing sugats under Mannitol, beginning with "Heat that beiling begins." Heat so that boiling begins after 4 minutes, and maintain boiling for 3 minutes. Cool
rapidly, and add 40 mL of diluted acetic acid, 60 mL of water, and 20.0 mL of 0.05 N iodine VS. With continuous shaking, add 25 mL of a mixture of 6 mL of hydrochloric acid and 94 mL of water. When the precipitate has dissolved, titrate the excess of iodine with 0.05 N sodium thiosulfate VS using 2 mL of starch TS, added towards the end of the titration, as an indicator. Not less than 12.8 mL of 0.05 N sodium thiosulfate VS is required, corresponding to not more than $0.3 \%$ of reducing sugars, on the anhydrous basis, as glucose. The amount determined in this test is not included in the calculated amount under

## Other Impurities.

## Limit of nickel-

Test solution-Dissolve 20.0 g of Anhydrized Liquid Sor bitol Sorbitol Sorbitan Solution in diluted acetic acid, and dilute with diluted acetic acid to 100.0 mL . Add 2.0 mL of a saturated solution of ammonium pyrrolidine dithiocarbamate (about 10 g of ammonium pyrrolidine dithiocarbamate per L ) and 10.0 mL of methyl isobutyl ketone, and shake for 30 seconds. Protect from bright light. Allow the two layers to separate, and use the methyl isobutyl ketone layer.

Blank solution-Prepare as directed for the Test solution, except to omit the use of Anhydrize Liquid Sorbited Sorbitol Sorbitan Solution. Quantities should be increased five fold to ensure that a sufficient volume of Blank solution is available.
Standard solutions-Prepare as directed for the Test solution, except to prepare three solutions by adding $0.5 \mathrm{~mL}, 1.0$ mL , and 1.5 mL of nickel standard solution TS.

Procedure-Procee as directed in the test for Nickel under Mat Set the instrument to zero using the Blank solution. Concomitantly determine the absorbances of the Standard solutions and the Test solution at least three times each, at the wavelength of maximum absorbance at 232.0
nm , with a suitable atomic absorption spectrophotometer (see Spectrophotometry and Light-Scattering $\langle 851\rangle$ ) equipped with a nickel hollow-cathode lamp and an air-acetylene flame. Record the average of the steady readings for each of the Standard solutions and the Test solution. Between each measurement, aspirate the Blank solution, and ascertain that the reading returns to zero. Plot the absorbances of the Standard solutions and the Test solution versus the added quantity of nickel. Extrapolate the line joining the points on the graph until it meets the concentration axis. The distance between this point and the intersection of the axes represents the concentration of nickel in the Test solution. Not more than $1 \mu \mathrm{~g}$ per g, calculated on the anhydrous basis, is found.

Assay-
Mobile phase-Use degassed water.
Resolution solution-Dissolve sorbitol, 1,4-sorbitan, isosorbide, and mannitol in water to obtain a solution having concentrations of about 10 mg per $\mathrm{g}, 4 \mathrm{mg}$ per $\mathrm{g}, 4 \mathrm{mg}$ per g , and 1 mg per g , respectively.
Standard preparation-Dissolve accurately weighed quantities of USP Sorbitol RS and USP 1,4-Sorbitan RS in water to obtain a solution having concentrations of about 10 mg per g and 4 mg per g , respectively.
Assay preparation-Dissolve about 0.40 g of Anhydrized Liquid Sorbitel Sorbitol Sorbitan Solution, accurately weighed, in water, and dilute with water to about 20 g . Accurately record the final solution weight, and mix thoroughly.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a refractive index detector that is maintained at a constant temperature of
about $35^{\circ}$, and a $7.8-\mathrm{mm} \times 10-\mathrm{cm}$ column that contains packing L34. The column temperature is maintained at about $50^{\circ}$, controlled within $\pm 2^{\circ}$, and the flow rate is about 0.6 mL per minute. Chromatograph the Resolution solution, and record the peak responses as directed for Procedure: the resolution, $R$, between the 1,4 -sorbitan and isosorbide is not less than 2.0. Chromatograph the Standard preparation, and record the peak responses for 1,4 -sorbitan and sorbitol as directed for Procedure: the relative retention times are about 0.35 for 1,4 -sorbitan, 0.43 for isosorbide, 0.7 for mannitol, and 1.0 for sorbitol; and the relative standard deviation for replicate injections is not more than $2.0 \%$ for each analyte.
Procedure-Separately inject equal volumes (about 10 $\mu \mathrm{L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Separately calculate the percentages, on the anhydrous basis, of 1,4-sorbi$\tan$ and sorbitol in the portion of Anhydrized Liquid Sorbitel Sorbitol Sorbitan Solution taken by the formula:

$$
\left[10,000\left(C_{S} / C_{U}\right)\left(r_{U} / r_{s}\right)\right] /(100-W)
$$

in which $C_{S}$ is the concentration, in mg per g , of the appropriate USP Reference Standard in the Standard preparation; $C_{U}$ is the concentration, in mg per g , of the Ambydrized Liq wid Sorbital Sorbitol Sorbitan Solution in the Assay preparation; $r_{U}$ and $r_{S}$ are the peak responses of the corresponding analyte obtained from the Assay preparation and the Standard preparation, respectively; and $W$ is the percentage obtained in the test for Water: $\quad$ 2S (NF23)

## Briefing

Tapioca Starch, NF 22 page 2940, page 3181 of the First Supplement, and page 1336 of PF 30(4) [July-Aug. 2004]. On the basis of comments received, it is proposed to revise the sample size in the test for Iron $\langle 241\rangle$.
(EMC: C. Sheehan) RTS-41473-1

$-0.75 \mathrm{~g}_{\mathrm{m} 2 \mathrm{~S}}{ }_{\text {(NF23) }}$
of Tapioca Starch with 15 mL of 0.1 N hydrochloric acid, and filter. Use 10 mL of this solution as the Test Preparation.

#### Abstract

\section*{BRIEFING}

Tagatose. Because there is no existing $N F$ monograph for this excipient, a new monograph is proposed based on a manufacturer's tests and acceptance criteria. The liquid chromatographic procedure in the Assay was validated using a Biorad Aminex HPX87 C brand of L19 column; tagatose peak elutes at approximately 32 minutes. (EMC: E. Gonikberg; AMB: D. Porter) RTS-41251-1

## Add the following:

## ©Tagatose

$\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} \quad 180.16$ [87-81-0].
d-Tagatose.
D-lyxo-Hexulose.
» Tagatose is a ketohexose, an epimer of D-fructose inverted at $\mathrm{C}-4$. It is obtained from D-galactose by isomerization under alkaline conditions in the presence of calcium. It contains not less than 98.0 percent of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$, calculated on the dried basis.

Packaging and storage-Preserve in well-closed containers, and store at room temperature.

USP Reference standards $\langle 11\rangle$ —USP Tagatose RS.

## Identification-

A: The retention time of the major peak in the chromatogram of the Assay preparation corresponds to that in the chromatogram of the Standard preparation, as obtained in the Assay.
B: It meets the requirements of the test for Specific rotation $\langle 781 \mathrm{~S}\rangle$.

C: Add 3 mL of a solution ( 1 in 5 ) to 5 mL of hot alkaline cupric tartrate TS: a copious red precipitate of cuprous oxide is formed.

Melting range, Class $1\langle 741\rangle$ : between $133^{\circ}$ and $144^{\circ}$.
Specific rotation $\langle 781 \mathrm{~S}\rangle$ : between $-4^{\circ}$ and $-5.6^{\circ}$.
Test solution: 10 mg per mL , in water.
Microbial limits $\langle 61\rangle$-It meets the requirements of the tests for absence of Salmonella species and Escherichia coli. The total aerobic microbial count does not exceed 1000 cfu per g , and the total combined molds and yeasts count does not exceed 100 cfu per g.

Loss on drying $\langle 731\rangle$ —Dry it at $102^{\circ}$ for 2 hours: it loses not more than $0.5 \%$ of its weight.

Total ash $\langle 561\rangle$ : not more than $0.1 \%$, determined on a $1.0-\mathrm{g}$ specimen.

## Limit of lead-

Test solution-Accurately weigh about 2.5 g of Tagatose, and dissolve in a mixture of 4 mL of sulfuric acid and 5 mL of hydrochloric acid. Transfer the solution to a $50-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix.

Standard lead solution-Dissolve 1.60 g of lead nitrate in diluted nitric acid ( 10 mL of nitric acid diluted with 20 mL water, boiled to remove nitrous fumes, and cooled), and di-
lute with water to 1000 mL . Dilute 10.0 mL of this solution with water to 500 mL . This solution contains the equivalent of $20 \mu \mathrm{~g}$ of lead per mL .
Calibration solutions-To a series of $100-\mathrm{mL}$ volumetric flasks, pipet $0,1,2,3,4$ and 5 mL of the Standard lead solution, and dilute to about 50 mL . Add 8 mL of sulfuric acid and 10 mL of hydrochloric acid to each flask, shake to dissolve, and dilute with water to volume. These solutions contain $0,0.2,0.4,0.6,0.8$ and $1.0 \mu \mathrm{~g}$ of lead per mL .

Procedure-Concomitantly determine the absorbances of the Calibration solutions and the Test solution at the wavelength of maximum absorbance at 283.3 nm , with a suitable atomic absorption spectrophotometer (see Spectrophotometry and Light-Scattering $\langle 851\rangle$ ) using an air-acetylene flame. Plot the absorbances of the Calibration solutions versus the concentration of lead. Using this graph, determine the concentration of lead in the Test solution. Not more than $1 \mu \mathrm{~g}$ per g is found.

## Assay-

Mobile phase-Prepare a solution in water containing 50 mg of calcium acetate per L .

Standard preparation-Dissolve an accurately weighed quantity of USP Tagatose RS in water to obtain a solution having a known concentration of about 5 mg per mL . Pass through a $0.2-\mu \mathrm{m}$ filter.

Assay preparation-Transfer about 50 mg of Tagatose, previously dried, to a $10-\mathrm{mL}$ volumetric flask, and dissolve in about 8 mL of water. Dilute with water to volume, and pass through a $0.2-\mu \mathrm{m}$ filter.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The liquid chromatograph is equipped with a refractive index detector and a $7.8-\mathrm{mm} \times 30-\mathrm{cm}$ column that contains $9-\mu \mathrm{m}$ packing L19. The column temperature is maintained at $85^{\circ}$. The flow rate is about 0.6 mL per minute. Chromat-
ograph the Standard preparation, and record the peak responses as directed for Procedure: the relative standard deviation for replicate injections is not more than $2.0 \%$.

Procedure-Separately inject equal volumes (about 20 $\mu \mathrm{L}$ ) of the Standard preparation and the Assay preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the quantity, in mg , of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ in the portion of Tagatose taken by the formula:

$$
10 C\left(r_{U} / r_{s}\right)
$$

in which $C$ is the concentration, in mg per mL , of USP Tagatose RS in the Standard preparation; and $r_{U}$ and $r_{S}$ are the peak responses obtained from the Assay preparation and the Standard preparation, respectively.n2S (NF23)

$\langle\mathbf{1 2 1}\rangle$ Insulin Assays, USP 27 page 2193. On the basis of information received, it is proposed to modify the calculation for potency and the statistics used to calculate the confidence interval. Several other changes have been made to clarify the procedure.
(BNT: L. Callahan) RTS—32750-1; 41659-1

## Change to read:

The most prominent manifestation of insulin activity, an abrupt decrease in blood glucose, was the basis for biologic assay from the time of the
$\boldsymbol{m}_{\text {its }}^{\boldsymbol{m 2 S}}$
first clinical use. of insulim
-2S (USP28)
The procedure, although relatively cumbersome, has the great merit of accurately reflecting the effect on the diabetic patient. The advent of practical yet sophisticated physicochemical methods (e.g., liquid chromatography) to measure insulin potency quantitatively has resulted in a more accurate and precise compendial test for insulin and insulin products. However, the bioidentity of insulin and insulin products cannot be assessed by these methods. Thus, a qualitative test in rabbits is included in this chapter, and its use is called for in the appropriate monographs.

The Rabbit Blood Sugar Method-Quantitative is used to determine the potency of Insulin Reference Standards, for the validation of the stability of new insulin preparations, and to determine the specific activities of insulin analogs.

## RABBIT BLOOD SUGAR METHODQUANTITATIVE

USP Reference Standards $\langle 11\rangle$ —USP Dextrose RS. USP Insulin RS. USP Insulin (Beef) RS. USP Insulin Human RS. USP Insulin (Pork) RS.
-Diluent-Prepare an aqueous solution containing $0.1 \%$ to $0.25 \%(\mathrm{w} / \mathrm{v})$ of either cresol or phenol, $1.4 \%$ to $1.8 \%$ $(\mathrm{w} / \mathrm{v})$ of glycerin, and sufficient hydrochloric acid to produce a pH between 2.5 and 3.5, unless otherwise directed in the individual monograph.■2S (USP28)

Standard Stock Solution-Dissolve either a suitable quantity of accurately weighed USP Insulin RS or a vial of lyophilized USP Insulin RS of the appropriate species in suffienter timing $0.1 \%$ 0- $0.25 \%$ (w) of either phenol or cresel, $1.4 \%$ to . $8 \%$ (w/v) of glyeerin, and sufficient hydrochloric acid

- Diluent ${ }_{\text {■2S }}$ (USP28)
to make a Standard Stock Solution containing 40 USP Insulin Units per mL and having a pH between 2.5 and 3.5 , unless otherwise directed in the individual monograph. Store in a cold place, protected from freezing, and use within 6 months.

Standard Solutions-Dilute portions of the Standard Stock Solution
$\mathbf{■}_{\text {With }}$ Diluent ${ }_{\text {■2S }}{ }_{\text {(USP28) }}$
to make two solutions, one to contain 1.0 USP Insulin Unit per mL (Standard Solution 1), and the other to contain 2.0 USP Insulin Units per mL (Standard Solution 2). Use as diluent a solution entaining $0.1 \%$ to $0.25 \%$ (w/v) of either eresolor phend, $1.4 \%$ to $1.8 \%$ (w/v) of glyeerin, and sufficient hydrochloric acid to produre a pH between 2.5 and 3.5 , unless otherwise directed in the individual monegraph.

■ ${ }^{\text {2S }}$ (USP28)
-Assay Stock Solution-Proceed as directed under Standard Stock Solution except use a suitable quantity of the preparation under test in place of USP Insulin RS. The $A s-$ say Stock Solution contains about 40 USP Insulin Units per mL.■2S (USP28)

Assay Solutions- Dilute volumes of the preparation under test with Stal Stock Solution to obtain a solution containing 1.0 USP Insulin Unit per mL (Assay Solution 1), and a second solution containing 2.0USP Insulin Units per mL (Assay Solution 2). th the ease of neutral insulin injection, adjust to a pH of 2.5 to 3.5 prior to making the dilutions.
-Dilute portions of the Assay Stock Solution with Diluent to make two dilutions of the preparation under test, one of which may be expected, on the basis of the assumed poten-
cy, to contain 1.0 USP Insulin Unit per mL (Assay Solution 1), and the other to contain 2.0 USP Insulin Units per mL (Assay Solution 2). In the case of neutral insulin injection, adjust to a pH of 2.5 to 3.5 prior to making the dilutions. $\mathbf{m}^{2 S}$ (USP28)

Doses of the Solutions To Be Injected-Select on the basis of trial or experience the dose of the dilutions to be injected, the volume of which usually will be between 0.30 mL and 0.50 mL . For each animal the volume of the Standard Solution is the same as that of the Assay Solution.

Preparation of Animal-Select suitable, healthy rabbits each weighing not less than 1.8 kg . Keep the rabbits in the laboratory for not less than 1 week before use in the assay, maintaining them on an adequate uniform diet, with water available at all times.
Procedure-Divide the rabbits into four equal groups of preferably not less than six rabbits each. On the preceding day, approximately 20 hours before the assay, provide each rabbit with an amount of food that will be consumed within 6 hours. Follow the same feeding schedule before each test day. During the assay, withhold all food until after the final blood specimen is taken. Handle the rabbits with care in order to avoid undue excitement, and inject subcutaneously the doses indicated in the following design
-(see Table 1), ${ }_{\text {\#2S }}$ (USP28)
the second injection being made on the day after the first injection, or not more than 1 week later.
-The time between the first and second injection is the same for all rabbits.

Table 1

| Group | First Injection |
| :--- | :--- | Second Injection

Anticoagulant Solution-Dissolve 1 g of edetate sodium and 200 mg of sodium fluoride in 1 L of water, and mix.
Dextrose Standard Preparations-Transfer known concentrations of USP Dextrose RS to suitable vessels, and dilute quantitatively and stepwise with Anticoagulant Solution (1:9) to obtain a range of Dextrose Standard Solutions containing between 20 and 100 mg per 100 mL , having known concentrations similar to the concentrations in the rabbit blood samples.
Test Preparations-Pipet into separate, suitable vessels 0.1 mL of each Blood Sample and 0.9 mL of Anticoagulant Solution.
Procedure-Subject the Test Preparations to dialysis across a semipermeable membrane for a sufficient time so that the dextrose passes through the membrane into a saline TS solution containing glucose oxidase, horseradish peroxidase, 3-methyl-2-benzothiazolinone hydrazone hydrochloride TS, and $N, N$-dimethylaniline. The absorbances of the Test Preparations are determined at 600 nm in a recording colorimeter. The absorbances of the Dextrose Standard Preparations are similarly determined at the start and the end of each run.

Calculation-Calculate the response of each rabbit to each injection from the sum of the two blood-sugar values, and subtract
 2,

■ 2 S (USP28)
disregarding the chronological order in which the responses were observed, to obtain the individual differences, $y$, as shown in the acempanying table
-Table 2.n2S (USP28)
When the data for one or more rabbits are missing in an assay, allow for differences in the sizes of the groups by suitable means (see Replacement of Missing Values under Design and Analysis of Biologieal Assay: $\langle(14\rangle$ ).
-do not use the confidence interval formulas given here, but seek statistical help. The data can still be analyzed with proper analysis of variance. $\quad$ 2S (USP28)

When the number of rabbits, $f$, carried through the assay is the same in each group, total the $y$ 's in each group and compute $T_{a}=-$ $T_{1}+T_{2}+T_{3}-T_{4}$ and $T_{b}=T_{1}+T_{2}+T_{3}+T_{4}$. The logarithm of the relative potency of the test dilutions is $M^{4}=0.301 T_{a} / T_{b}$. The potency of the injection in USP Units per mE
$\mathbf{- m g}_{\text {. } 2 \mathrm{~S}}$ (USP28)
equals the antilog $\left(\log R+M^{\prime}\right)$, where $R=v_{S} / v_{U}$, in which $v_{S}$ is the number of USP Units per mL of the Standard dilution and $v_{U}$ ithe number of of injection per mL of the Assay dilution.
$\boldsymbol{\square}_{\text {is }}$ the number of mg of insulin per mL of the corresponding

-Determine the $95 \%$ confidence interval for the log-relative potency using Fieller's Theorem (see Appendix and Design
and Analysis of Biological Assays (111〉). ${ }^{2}$ 2S (USP28)
If the confidence interval is more than 0.082 , which corresponds at $P=0.95$ to confidence limits of about $\pm 10 \%$ of the computed potency, repeat the assay until the combined data of the two or more assays, redetermined as described in Combination of Independent Assays under Design and Analysis of Biological Assays $\langle 111\rangle$, meet this acceptable limit.

Table 2

| Group | Differences | Individual <br> Response (y) | Total <br> Response ( $T$ ) | -Standard Deviations of <br> Differences $(S)_{\text {2S (USP28) }}$ |
| :---: | :---: | :---: | :---: | :---: |

## Add the following:

-Appendix—Fieller's Theorem for Determining the

## Confidence Interval for a Ratio

This version of Fieller's Theorem is for the case where the numerator and denominator are uncorrelated. The equation assumes the numerator and denominator are normally distributed and the groups of rabbits are equal-sized.

Then, the $95 \%$ confidence interval for the ratio is:

$$
(L, U)=\frac{M^{\prime} \pm \frac{t}{T_{B}} \sqrt{(1-g) S_{N}^{2}+\left(M^{\prime}\right) S_{D}^{2}}}{1-g}, \quad S_{N}=0.301 \sqrt{k} \sqrt{S_{1}^{2}+S_{2}^{2}+S_{3}^{2}+S_{4}^{2}},
$$

where $f$ (degrees of freedom in the standard errors) $=4(k-$ 1 ), where $k$ is the number of rabbits in a group, $t$ is the upper 97.5 percentile of the $t$-distribution with $f$ degrees of freedom, and

$$
g=\frac{t^{2} S_{D}^{2}}{T_{B}^{2}}
$$

If $g \geq 1$, the denominator is not significantly different from 0 and the formula does not work.

$$
S_{D}=\sqrt{k} \sqrt{S_{1}^{2}+S_{2}^{2}+S_{3}^{2}+S_{4}^{2}} \cdot \mathbf{m S}_{(U S P 28)}
$$

## GENERAL GAS CHROMATOGRAPHIC METHOD

The general procedures set forth in the following paragraphs are applicable to the quantitative determination of benzyl alcohol, chlorobutanol, phenol, and the methyl, ethyl, propyl, and butyl esters of $p$-hydroxybenzoic acid, the latter being treated as a group, the individual members of which, if present, are capable of separate determination. Prepare the Internal Standard Solution and the Standard Preparation for each agent as directed individually below. Unless otherwise directed below, prepare the Test Preparation from accurately measured portions of the Internal Standard Solution and the sample under test, of such size that the concentration of the agent and the composition of the solvent correspond closely to the concentration and composition of the Standard Preparation. Suggested operating parameters of the gas chromatograph apparatus are given in the accompanying table, the carrier gas being helium or nitrogen, and the detector being the flame-ionization type.

## Benzyl Alcohol

Internal Standard Solution-Dissolve about 380 mg of phenol in 10 mL of methanol contained in a $200-\mathrm{mL}$ volumetric flask. Add water to volume, and mix.

Standard Preparation-Dissolve about 180 mg of ©USP Benzyl Alcohol RS, ${ }^{1 S}$ (USP27) accurately weighed, in 20.0 mL of methanol contained in a $100-\mathrm{mL}$ volumetric flask. Add Internal Standard Solution to volume, and mix.

Procedure-Separately inject equal volumes (about $5 \mu \mathrm{~L}$ ) of the Standard Preparation and the Test Preparation into the chromatograph, record the chromatograms with the apparatus adjusted to the parameters set forth in the accompanying table, and measure the areas under the peaks for benzyl alcohol and phenol. Calculate the content, in mg per mL , of benzyl alcohol $\left(\mathrm{C}_{7} \mathrm{H}_{8} \mathrm{O}\right)$ in the specimen taken by the formula:

$$
100(C / V)\left(p_{1} / p_{2}\right)\left(P_{2} / P_{1}\right),
$$

in which $C$ is the concentration, in mg per mL , of benzyl alcohol in the Standard Preparation; $V$ is the volume, in mL , of the specimen under test used in preparing each 100 mL of the Test Preparation; $p_{1}$ and $p_{2}$ are the peak areas for benzyl alcohol and phenol, respectively, obtained from the Test Preparation; and $P_{1}$ and $P_{2}$ are the peak areas of benzyl alcohol and phenol, respectively, obtained from the Standard Preparation.

## Chlorobutanol

Internal Standard Solution-Transfer about 140 mg of benzaldehyde to a $100-\mathrm{mL}$ volumetric flask, add 10 mL of methanol, and swirl to dissolve. Dilute with water to volume, and mix.

Standard Preparation-Transfer about 125 mg of ehlorebuta n@l,
-USP Chlorobutanol RS, ${ }_{\text {W2S (USP28) }}$
accurately weighed, to a $25-\mathrm{mL}$ volumetric flask. Add 2 mL of methanol, swirl to dissolve, dilute with water to volume, and mix. Transfer 5.0 mL of this solution and 5.0 mL of Internal Standard Solution to a $25-\mathrm{mL}$ flask, and mix to obtain a solution having a known concentration of about 2.5 mg of chlorobutanol per mL .

Test Preparation-Quantitatively dilute, if necessary, an accurately measured volume of the specimen under test with methanol to obtain a solution containing not more than about 5.0 mg of chlorobutanol per mL. Combine 3.0 mL of this solution with 3.0 mL of Internal Standard Solution, and mix.

Chromatographic System (see Chromatography $\langle 621\rangle$ ) -[NOTE-See accompanying table for column dimensions, column packing phase and support, flow rate, and column temperature.] The injection port temperature is maintained at $180^{\circ}$, and the detector is maintained at $220^{\circ}$. Chromatograph the Standard Preparation, and record the peak responses as directed for Procedure: the relative retention times are about 0.8 for benzaldehyde and
1.0 for chlorobutanol; the resolution, $R$, between benzaldehyde and the chlorobutanol is not less than 2.0 ; and the relative standard deviation for replicate injections is not more than $2.0 \%$.

Procedure-Separately inject equal volumes (about $1 \mu \mathrm{~L}$ ) of the Standard Preparation and the Test Preparation into the chromatograph, record the chromatograms, and measure the areas for the major peaks. Calculate the quantity, in mg , of chlorobutanol $\left(\mathrm{C}_{4} \mathrm{H}_{7} \mathrm{Cl}_{3} \mathrm{O}\right)$ in each mL of the specimen under test by the formula:

$$
C(L / D)\left(R_{U} / R_{S}\right)
$$

in which $C$ is the concentration, in mg per mL , of chlorobutanol, calculated on the anhydrous basis, in the Standard Preparation; $L$ is the labeled quantity, in mg , of chlorobutanol in each mL of the specimen under test; $D$ is the concentration, in mg per mL , of chlorobutanol in the Test Preparation, based on the volume of specimen under test taken and the extent of dilution; and $R_{U}$ and $R_{S}$ are the ratios of the chlorobutanol peak to the benzaldehyde peak obtained from the Test Preparation and the Standard Preparation, respectively.

## Phenol

Internal Standard Solution-Pipet 1 mL of
■USP Benzyl Alcohol RS ${ }_{\text {n2S }}$ (USP28)
into a $500-\mathrm{mL}$ volumetric flask, add methanol to volume, and mix.
Standard Preparation-Dissolve about 75 mg of phenel,
-USP Phenol RS, ${ }_{\text {■ }}$ 2S (USP28)
accurately weighed, in 7.5 mL of methanol contained in a $100-\mathrm{mL}$ volumetric flask. Add 20.0 mL of Internal Standard Solution, then add water to volume, and mix.

Procedure-Separately inject equal volumes (about $3 \mu \mathrm{~L}$ ) of the Standard Preparation and the Test Preparation into the chromatograph, record the chromatograms with the apparatus adjusted to the parameters set forth in the accompanying table, and measure the areas under the peaks for phenol and benzyl alcohol Calculate the content, in mg per mL , of phenol $\left(\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}\right)$ in each mL of the specimen taken by the formula:

$$
100(C / V)\left(p_{1} / p_{2}\right)\left(P_{2} / P_{1}\right)
$$

in which $C$ is the concentration, in mg per mL , of phenol in the Standard Preparation; $V$ is the volume, in mL , of the specimen under test used in preparing each 100 mL of the Test Preparation; $p_{1}$ and $p_{2}$ are the peak areas for phenol and benzyl alcohol, respectively, obtained from the Test Preparation; and $P_{1}$ and $P_{2}$ are the peak areas of phenol and benzyl alcohol, respectively, obtained from the Standard Preparation.

## Methylparaben and Propylparaben

Internal Standard Solution-Place about 200 mg of benzophenone in a $250-\mathrm{mL}$ volumetric flask, dilute with ether to volume, and mix.

Standard Preparation-Place 100 mg of -USP Methylpara-
 each accurately weighed, in a $200-\mathrm{mL}$ volumetric flask, dilute with Internal Standard Solution to volume, and mix. Place 10 mL of this solution in a $25-\mathrm{mL}$ conical flask, and proceed as directed for Test Preparation, beginning with "Add 3 mL of pyridine."

Test Preparation-Pipet 10 mL of the specimen under test and 10 mL of the Internal Standard Solution into a small separator. Shake vigorously, allow the layers to separate, draw off the aqueous layer into a second separator, and transfer the ether layer into a small flask through a funnel containing anhydrous sodium sulfate. Extract the aqueous layer with two $10-\mathrm{mL}$ portions of ether, also
filtering the extracts through the anhydrous sodium sulfate. Evaporate the combined extracts under a current of dry air until the volume is reduced to about 10 mL , then transfer the residue to a 25 mL conical flask. Add 3 mL of pyridine, complete the evaporation of the ether, and boil on a hot plate until the volume is reduced to about 1 mL . Cool, and add 1 mL of a suitable silylation agent, such as bis(trimethylsilyl)trifluoroacetamide, bis(trimethylsilyl)acetamide, or a mixture of hexamethyldisilazane and trimethylchlorosilane [2:1 or $3: 1(\mathrm{v} / \mathrm{v})]$. Mix, and allow to stand for not less than 15 minutes.

Procedure-Separately inject equal volumes $(2 \mu \mathrm{~L})$ of the silanized solution from the Standard Preparation and the Test Preparation into the chromatograph, record the chromatograms with the apparatus adjusted to the parameters set forth in the accompanying table, and measure the areas under the peaks for methylparaben, propylparaben, and benzophenone. Calculate the content, in $\mu \mathrm{g}$ per mL , of methylparaben $\left(\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{O}_{3}\right)$ in the sample under test by the formula:

$$
10\left(C_{M} / V\right)\left(p_{1} / p_{3}\right)\left(P_{3} / P_{1}\right)
$$

in which $C_{M}$ is the concentration, in $\mu \mathrm{g}$ per mL , of methylparaben in the Standard Preparation; $V$ is the volume, in mL , of the specimen taken; $p_{1}$ and $p_{3}$ are the peak areas for methylparaben and benzophenone, respectively, obtained from the Test Preparation; and $P_{1}$ and $P_{3}$ are the peak areas of methylparaben and benzophenone, respectively, obtained from the Standard Preparation. Similarly, calculate the content, in $\mu$ g per mL , of propylparaben $\left(\mathrm{C}_{10} \mathrm{H}_{12} \mathrm{O}_{3}\right)$ in the specimen under test by the formula:

$$
10\left(C_{P} / V\right)\left(p_{2} / p_{3}\right)\left(P_{3} / P_{2}\right)
$$

in which $C_{P}$ is the concentration, in $\mu \mathrm{g}$ per mL , of propylparaben in the Standard Preparation; $V$ is the volume, in mL , of the specimen taken; $p_{2}$ and $p_{3}$ are the peak areas for propylparaben and benzophenone, respectively, obtained from the Test Preparation; and $P_{2}$ and $P_{3}$ are the peak areas of propylparaben and benzophenone, respectively, obtained from the Standard Preparation.

Ethylparaben and butylparaben may be determined in a similar manner.

## Change to read:

## POLAROGRAPHIC METHOD

## Phenylmercuric Nitrate

Standard Preparation-Dissolve about 100 mg of phenylmercuric nitrate, accurately weighed, in sodium hydroxide solution (1 in 250 ) contained in a $1000-\mathrm{mL}$ volumetric flask, warming if necessary to effect solution, add the sodium hydroxide solution to volume, and mix. Pipet 10 mL of this solution into a $25-\mathrm{mL}$ volumetric flask, and proceed as directed under Test Preparation, beginning with "add 2 mL of potassium nitrate solution (1 in 100)."

Test Preparation-Pipet 10 mL of the specimen under test into a $25-\mathrm{mL}$ volumetric flask, add 2 mL of potassium nitrate solution ( 1 in 100) and 10 mL of pH 9.2 alkaline borate buffer (see under Buffer Solutions in the section Reagents, Indicators, and Solutions), and adjust to a pH of 9.2, if necessary, by the addition of 2 N nitric acid. Add 1.5 mL of freshly prepared gelatin solution ( 1 in 1000), then add the pH 9.2 alkaline borate buffer to volume, and mix.

Procedure-Pipet a portion of the Test Preparation into the polarographic cell, and deaerate by bubbling nitrogen through the solution for 15 minutes. Insert the dropping mercury electrode of a suitable polarograph (see Polarography $\langle 801\rangle$ ), and record the polarogram from -0.6 to -1.5 volts versus the saturated calomel elec-
trode. Determine the diffusion current of the Test Preparation, $\left(i_{d}\right)_{U}$, as the difference between the residual current and the limiting current. Similarly and concomitantly determine the diffusion current, $\left(i_{d}\right)_{s}$, of the Standard Preparation. Calculate the quantity, in $\mu \mathrm{g}$, of phenylmercuric nitrate $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{HgNO}_{3}\right)$ in each mL of the specimen taken by the formula:

$$
2.5 C\left[\left(i_{d}\right)_{U} /\left(i_{d}\right)_{S}\right]
$$

in which $C$ is the concentration, in $\mu \mathrm{g}$ per mL , of phenylmercuric nitrate in the Standard Preparation.

## Thimerosal

Standard Preparation-On the day of use, place about 25 mg of thimeroset,

■USP Thimerosal RS, ${ }_{\square 2 S}$ (USP28)
accurately weighed, in a $250-\mathrm{mL}$ volumetric flask, add water to volume, and mix. Protect from light. Pipet 15 mL of this solution into a $25-\mathrm{mL}$ volumetric flask, add 1.5 mL of gelatin solution ( 1 in 1000), then add potassium nitrate solution ( 1 in 100) to volume, and mix.

Test Preparation-Pipet 15 mL of the test specimen into a 25 mL volumetric flask, add 1.5 mL of gelatin solution (1 in 1000), add potassium nitrate solution (1 in 100) to volume, and mix.

Procedure-Transfer a portion of the Test Preparation to a polarographic cell, and deaerate by bubbling nitrogen through the solution for 15 minutes. Insert the dropping mercury electrode of a suitable polarograph (see Polarography $\langle 801\rangle$ ), and record the polarogram from -0.2 to -1.4 volts versus the saturated calomel electrode. Determine the diffusion current, $\left(i_{d}\right)_{U}$, as the difference between the residual current and the limiting current. Similarly and concomitantly determine the diffusion current, $\left(i_{d}\right)_{S}$, of the Standard Preparation. Calculate the quantity, in $\mu \mathrm{g}$, of thimerosal $\left(\mathrm{C}_{6} \mathrm{H}_{9} \mathrm{HgNaO}_{2} \mathrm{~S}\right)$ in each mL of the test specimen taken by the formula:

$$
1.667 C\left[\left(i_{d}\right)_{U} /\left(i_{d}\right)_{S}\right],
$$

in which $C$ is the concentration, in $\mu \mathrm{g}$ per mL , of thimerosal in the Standard Preparation; and the other terms are as defined therein.

## Briefing

〈386〉 Environmentally Sensitive Preparations, page 1143 of PF 29(4) [July-Aug. 2003]. Following the PSD Open Conference held October 12-15, 2003, this chapter was revised to incorporate comments received. The revised version was further discussed with FDA representatives, and based on the comments presented by FDA, additional revisions were made. Listed below are highlights of the revisions made to the chapter:

1. Emphasis on packaging selection.
2. Definition of repackager(s)-contract and wholesale.
3. Deletion of $37^{\circ} \mathrm{C}$, in item 2 b , under Criteria to Determine if a Product is an Environmentally Sensitive Preparation.
4. Deletion of $65 \pm 5 \%$ relative humidity, item 2 c under the same section.
5. Removal of all references to data and replacing it with stability and packaging information.
6. Introduction of icons in appropriate sections of the text.

The PSD Committee believes that these changes address FDA's and manufacturers' concerns, as well as defining, more precisely, information required from the manufacturers.
(PSD: C. Okeke) RTS-40548-7; 40622-1; 40657-1

## Add the following:

## - 386$\rangle$ ENVIRONMENTALLY SENSITIVE PREPARATIONS

## In the interest of enstring the integrity of a pharmaceuti-

eal article as it reaches the patient for acourse of treatment, this chapter foeuses on preparations that may be repackaged or dispensed in other than the market package so that proper storage and shipment instructions can be ineluded with the efficial preparation. It is assumed that, as long as these pack aged preparations are transported aceording to the directions in the packuge insert, the original manufacturer's packages are-sufficient for assuring that these requirements are met.

An individual preparation is an Envirommentally Sensi-
tive Preparation if data indicate the failure of that preparation to conform to a monograph requirement after expesure tone of the following sets of criteria.

## СRझТЕRझА ТО-DETERMझNE IF A PRODUCT IS AN

## ENVHRONMENTALLY SENSHTHVE PREPARATION

NOTE-The desage form may be protected from light dur ing the studies.

1. Use pertinent stability data available on file, or
2. Betermine if a preparation meets the test requirements (a-d) listed below. If a preparation does not meet a menegraph requirement after expestre-to-enditions speciffed for requirement $a$, retest as-directed for $b, c$, or $d$, as apprepriate.
a. For any dosage form: 3-menths at a temperature-of $40 \pm 2^{\circ}$ and $75 \pm 5 \%$ relative humidity in the market container, or $30 \pm 2^{\circ}$ and $60 \pm 5 \%$ relative hemidity for 6 menths.
b. For solutions: 3-months at a temperature of $37^{\circ}$ to $40 \pm 2^{\circ}$ and ambient humidity in the market container.
e. For semisolids and heterogeneous liquids, such as ereams, transdermal systems, gels, emulsions, and-suspensions; and for sterile solids for injection: 6 months at atemperature of $30 \pm 2^{\circ}$ and $60 \pm 5 \%$ relative hemid ity in the market container.
3. For solid oral dosage form: 30 days at a temperature of $25 \pm 2^{\circ}$ and $60 \pm 5 \%$ relative humidity in an open dish (i.e., the container without closure, coil, desiecant, or tusealed blisters).

## Definitions

For the purpose of this chapter, a packager is deffned as ene whe puts a drug product inte a primary container for distribution to patients. A packager may be a repackager, a pharmacist, or a manufacturer.

## Labeling, Storage, and Shipping

Pecisions regarding the labeling of a product as an Envirammentally Sensitive Preparation are the respensibility of the packager and are based on the product's characteristies and stability history.

Where data establish that a preparation is an Enviremment tally-Sensitive Preparation, any of the following labeling and shipping arrangements are employed, as appropriate, teensure menegraph conformity.
a. The artiele is shipped in a manner that (1) ensures that its integrity is maintained, and (2) is based on product int formation, packaging data, and the distribution system theed.
b. The article-is shipped in suitable appropriate protective packaging insulated package that could include feillaminated polyethylene bags, desiceant containers, or packages of sufficient desiceant capacity.
e. The article is shipped with a validated time temperature monitoring device (see Monitoring Devices Tine, Femperature, and Humidity $\langle 1418\rangle$ andether goodstor age and shipping practice documents). The menitoring device is affixed either to the outer shipping package or to the packuging of individual containers (for example, for mixed shipments).
4. Unepened packages shall be moved through the distribution chain with the menitoring device intact.
e. Where-shipping is expected to extend beyond 48 heurs, instructions are included, specifying that the article is not to be used if the menitoring device discloses a ent mulative history of exposure equivalent to mere than-48 hours at or above a temperature of $40^{\circ}$. A manufacturer may make other assurances about packaging and distri bution arrangements based on product data and infor mation.

## Instructions to the Pharmacist or Repackager

Suitable information must be available to identify an Envirommentally Sensitive Preparation to the pharmacist or repackager along with appropriate instructions for handling the preparation. For example, the labeling of a mantafac
farer's maltiple-unit package (or market repackage) of a hut midity sensitive preparation may include one or more of the following statements:
at Be net dispense mere than a 30-day supply of the preseription in one multiple-unit container.
b. Dispense it in a desiccant container of sufficient desiceant capacity.
e. Pispense it in a tight or Class $A$ container (see Con tainers Permeation- 674$\rangle$ ) if it is net dispensed in a market package.
4. "Do net repackage", if the medieation is net to be repackaged.
e. Dispense it in a unit of use container (see Packaging Unit of Use $\langle 1136\rangle$-.
f. Label the patient's-containers to-state "use the contents within 30 days frem the first day that individual eontainer is opened".

## Instructions-to-Institutional-Settings

In an institutional setting, store packages of an Environmentally Sensitive Preparation at controlled room temperature or aceording to labeled requirements in the market package. Packages dispensed for use by a partieular patient should bear a beyond use date of 3 months or 90 days and a statement "Store at $20^{\circ}$ to $25^{\circ}\left(68^{\circ} \mathrm{F}\right.$ to $\left.77^{\circ} \mathrm{F}\right)$ ", unless (1) dat suppert other labeling or (2) other manafacturer's ree emmendations are applieable-

## Instruetions to the Mantafacturer

For an Environnentally Sensitive Preparation for which data-suppert other labeling, beyond-use dates, or expestre equivalents, the manufacturer must inelude labeling and in-
formation suitable for optimal handling by the practitioner Or pharmacist, by the repackager, and by the patient. Product development or stability datacan be used to determine appropriate labeling and shipping statements that will properly inform patients and practitioners.

When repackagers and pharmacists, ineluding hespitat, emergency medical services, mail service, Internet based services, and other practitioners, request information about product behavior upon expesure to various temperature and humidity conditions, pharmaceutieal manufacturers are-encouraged to provide such information if available.

## Exemptions

4. The following preparations are-exempt frem the above eonsiderations: these labeled that they must be stored and transperted refrigerated or frozen; labeled radiopharmaceuticals; and these-shipped and received-in net more than the time period specified on the outer package, provided data are available to show that the stability of the article is not compromised dering that period under the expected conditions of temperature and/or htmidity.
5. For classifying a preparation as an Enviromnentally Sensitive Prepatation, the general chapter Uniformity Of Desage Units $\langle 905\rangle$-does not apply.

In the interest of ensuring that a pharmaceutical article meets monograph requirements when it reaches the patient for a course of treatment, this chapter focuses on preparations that may be repackaged or dispensed in other than the market package so that proper packaging selection, storage, and shipment instructions can be included with the official preparation. Most articles when shipped or stored in the manufacturer's original container-closure system, or that of an appropriate contract repackager (see below), are
not compromised under stressful environmental conditions in the expected distribution system. However, there is uncertainty about the preparation's stability if it has been repackaged into another container. This chapter is intended to focus on these repackaging and distribution processes to ensure that proper communication and requirements are established to protect the preparation until it reaches the patient.

An individual preparation is an Environmentally (Humidity and/or Temperature) Sensitive Preparation if stability information demonstrates the failure of that preparation to conform to a monograph requirement under conditions described in either of the two criteria described below.

## CRITERIA TO DETERMINE IF A PRODUCT IS AN ENVIRONMENTALLY SENSITIVE PREPARATION

NOTE-The dosage form may be protected from light during the studies.

1. Use pertinent stability information available on file, or
2. Determine if a preparation meets the test requirements ( $a-d$ ) listed below. If a preparation does not meet a monograph requirement after exposure to conditions specified for requirement $a$, retest for conformance as directed for $b, c$, or $d$, as appropriate.
a. For any dosage form in the market container: 3 months at a temperature of $40 \pm 2^{\circ}$ and $75 \pm 5 \%$ relative humidity, or 6 months at $30 \pm 2^{\circ}$ and $65 \pm 5 \%$ relative humidity or other appropriate storage condition.
b. For solutions in the market container: 3 months at a temperature of $40 \pm 2^{\circ}$ and ambient humidity.
c. For semisolids and heterogeneous liquids, such as creams, transdermal systems, gels, emulsions, and suspensions; and for sterile solids for injection in the market container: 6 months at a temperature of $30 \pm 2^{\circ}$.
d. For solid oral dosage forms that are not Temperature Sensitive Preparations: 30 days at a temperature of $30 \pm 2^{\circ}$ and $65 \pm 5 \%$ relative humidity in an open dish (or the market container without closure, seal, coil, desiccant; or unsealed blisters).

## DEFINITIONS

For the purpose of this chapter, a packager is defined as one who puts a drug product into a primary container for distribution to patients. A packager may be a repackager, a pharmacist, or a manufacturer.
A repackager is an establishment that removes the preparation from its original container and places it into another suitable container or container closure system, usually of smaller size, and sends it to a second location in anticipation of a need (see Packaging Practice-Repackaging a Single Solid Oral Drug Product into a Unit-Dose Container $\langle 1146\rangle)$. A contract repackager is a repackager that acts on an article owned by the manufacturer. Repackagers are regulated under the FD\&C Act (see 21 CFR 210 and 211).
A pharmacy or pharmacist dispenser or pharmacy repackager is regulated by the various states. A wholesaler repackager is a repackager that acts on a product owned by the wholesaler and is regulated by the various states.

## LABELING, STORAGE, AND SHIPPING

Decisions regarding the labeling, storage, and shipping of an article as an Environmentally Sensitive Preparation are the responsibility of the packager or intermediary (e.g., wholesaler) initiating that phase of distribution and are based on the manufacturer's suggested storage conditions. For an Environmentally Sensitive Preparation, employ any of the following labeling and shipping arrangements, as appropriate, to ensure continued conformity with the monograph.
a. Consider using one or more icons or other symbols on the label to notify all recipients of the environmentally sensitive nature of the preparations (see Figures 1-4 below).
b. Ship the article in a manner that: (1) ensures that its attributes are maintained, and (2) is based on product and packaging information and the distribution system used.
c. Ship the article in suitable protective packaging that could include insulated packaging, foil-laminated polyethylene bags, desiccant containers, or packages of sufficient desiccant capacity for the distribution system used.
d. Ship the article with a Time-temperature monitoring device (see Monitoring Devices-Time, Temperature, and Humidity $\langle 1118\rangle$ and the monograph). The monitoring device is affixed either to the outer shipping package or to the packaging of individual containers,
for example, for mixed shipments. Alternatively, ship it in a suitably monitored vehicle compartment. Unopened packages shall be moved through the distribution chain with the monitoring device intact.
e. A manufacturer may make specific recommendations about packaging and distribution arrangements based on product and packaging information. In absence of such recommendations, where shipping is expected to extend beyond 48 hours, include instructions specifying that the article is not to be used if the monitoring device discloses a cumulative history of exposure equivalent to more than 48 hours at or above a temperature of $40^{\circ}$.
f. The Poison Prevention Packaging Act of 1970 (see the General Notices) requires in certain cases the use of special packaging-child-resistant or senior friendly. The packaging of Environmentally Sensitive Preparations should conform to these regulations.

## INSTRUCTIONS TO THE PHARMACIST OR REPACKAGER

Suitable information must be available to identify an Environmentally Sensitive Preparation to the pharmacist or repackager along with appropriate instructions for handling the preparation. For example, the labeling of a manufacturer's multiple-unit package (or contract repackage) of a Humidity Sensitive Preparation may include one or more of the following statements:
a. Do not dispense more than a 30-day supply of the Preparation in one multiple-unit container. Label the patient's containers to state "use the contents within 30 days from the first day that the individual container is opened."
b．Do not repackage in single－unit containers．
c．Dispense in a desiccant container of sufficient desiccant capacity．
d．Dispense in a tight or Class A container（see Con－ tainers－Permeation $\langle 671\rangle$ ）if it is not dispensed in a market package．
e．Dispense in a unit－of－use container（see Packaging－ Unit of Use 〈1136〉）．
f．Do not repackage if the medication is labeled not to be repackaged．

## INSTRUCTIONS TO INSTITUTIONAL

## PRACTITIONERS

In a pharmacy or an institutional setting，store packages of an Environmentally Sensitive Preparation at controlled room temperature or according to other labeled conditions in the market package．Packages dispensed for use by a par－ ticular patient should bear a discard－after date of 3 months or 90 days and a statement＂Store at $20^{\circ}$ to $25^{\circ}\left(68^{\circ} \mathrm{F}\right.$ to $77^{\circ}$ F）＂，unless（1）stability information supports other labeling， or（2）other recommendations of the manufacturer are applicable．

## INSTRUCTIONS TO THE MANUFACTURER

For an Environmentally Sensitive Preparation for which stability information supports other labeling，discard－after dates，or exposure equivalents，the manufacturer must in－ clude labeling and information suitable to enable optimal handling by the practitioner or pharmacist，by the repack－
ager，and by the patient．Product development or stability information can be used by the manufacturer to determine appropriate labeling and shipping statements，or icons or symbols（see Figures 1－4 below），that will properly inform repackagers，patients，and practitioners．See Instructions to the Pharmacist or Repackager，above．

When repackagers and pharmacists，including hospital， emergency medical services，mail service，Internet－based services，and other practitioners，request information about product behavior upon exposure to various temperature and humidity conditions，pharmaceutical manufacturers are en－ couraged to provide such information，if available．

## EXEMPTIONS

1．The following preparations are exempt from the above considerations：those labeled that they must be stored and transported refrigerated or frozen；and those shipped and received in not more than the time period specified on the outer package，provided stability infor－ mation is available to show that the stability of the ar－ ticle is not compromised during that period under the conditions of temperature and／or humidity expected for the distribution system used．

2．For classifying a preparation as an Environmentally Sensitive Preparation，Uniformity of Dosage Units〈905〉 does not apply．■2S（USP28）

# Physical Tests and Determinations 

## BRIEFING

〈621〉Chromatography, USP 27 page 2272, page 3325 of the Second Supplement, and page 1007 of $P F 30$ (3) [May-June 2004]. A reference to TLC plates with a preadsorbent zone is included in the Thin-Layer Chromatography section. The PA2 Expert Committee agreed to include a Quantitation Limit Solution as part of the system suitability test for the Chromatographic purity or Related compounds tests. The objective of this procedure is to ensure that under the test conditions, the system is able to detect impurities in low concentration. A paragraph introduced in the System suitability section suggests that changes in the chromatographic system can produce unexpected changes in the performance of the test. The analyst must ensure that the changes introduced in the chromatographic system do not have a negative impact on the test performance. Changes in the allowable adjustments are also included.

## Change to read:

## INTRODUCTION

This chapter defines the terms and procedures used in chromatography and provides general information. Specific requirements for chromatographic tests and assays of

■procedures for $_{\text {■2S (USP28) }}$
drug substances and dosage forms, including adsorbent and developing solvents, are given in the individual monographs.

Chromatography is defined as a procedure by which solutes are separated by a dynamic differential migration process in a system consisting of two or more phases, one of which moves continuously in a given direction and in which the individual substances exhibit different mobilities by reason of differences in adsorption, partition, solubility, vapor pressure, molecular size, or ionic charge density. The individual substances thus ebtined
$\square_{\text {separated }}{ }_{\text {■2S (USP28) }}$
can be identified or determined by analytical metheds.
■procedures
S. 12 S (USP28)

The general chromatographic technique requires that a solute undergo distribution between two phases, one of them fixed (stationary phase), the other moving (mobile phase). It is the mobile phase that transfers the solute through the medium until it eventually emerges separated from other solutes that are eluted earlier or later. Generally, the solute is transported through the separation medium by means of a flowing stream of a liquid or a gaseous solvent known as the "eluant." The stationary phase may act through adsorption, as in the case of adsorbents such as activated alumina; silien gel, and ion exchange resins,

or it may act by dissolving the solute, thus partitioning the latter between the stationary and mobile phases. In the latter process, a tiquid coating held on an inert support serves as the stationary phase.
-In the latter process, a liquid coated onto an inert support, or chemically bonded onto silica gel, or directly onto the wall of a fused silica capillary, serves as the stationary phase. $\mathbf{m}_{2 S}$ (USP28)
Partitioning is the predominant mechanism of separation in gas-liquid chromatography, paper chromatography, and forms of column chromatography
$\boldsymbol{m}_{\text {and thin-layer chromatography }}^{\mathbf{m}_{2 S} \text { (USP28) }}$
designated as liquid-liquid ehremagraphy.

- $_{\text {separation. }}^{\text {■2S (USP28) }}$

In practice, separations frequently result from a combination of adsorption and partitioning effects.
-Other separation principles include ion exchange, ion pair formation, size exclusion, hydrophobic interaction, and chi-
ral recognition. $\mathbf{m}_{2 S}$ (USP28)
The types of chromatography useful in qualitative and quantitative analysis that are employed in the $U S P$ ests assays

■procedures $_{\text {■2S }}$ (USP28)
are column, gas, paper, thin-layer,

- (including high-performance thin-layer chromatogra-

## phy), ${ }^{2 S}$ (USP28)

and pressurized liquid chromatography (commonly called highpressure or high-performance liquid chromatography). Paper and thin-layer chromatography are ordinarily more useful for purposes of identification, because of their convenience and simplicity. Column chromatography offers a wider choice of stationary phases and is useful for the separation of individual compounds, in quantity, from mixtures. Both ehromatography and pressurized lif rid chromatography require more elaborate apparatus and usually provide high resolution metheds hat will identify and quantitate very small amounts of material.

- Modern high-performance thin-layer chromatography, gas chromatography, and pressurized liquid chromatography require more elaborate apparatus but usually provide high resolution and identify and quantitate very small amounts of material. ${ }^{\text {2S }}$ (USP28)

Use of Reference Substances in Identity Tests-In paper and thin-layer chromatography, the ratio of the distance (this distance being measured to the point of maximum intensity of the spot
$■_{\text {or zone) }}^{\text {■2S (USP28) }}$
traveled on the medium by a given compound to the distance traveled by the front of the mobile phase, from the point of application of the test substance, is designated as the $R_{F}$ value of the compound. The ratio between the distances traveled by a given compound and a reference substance is the $R_{R}$ value. $R_{F}$ values vary with the experimental conditions, and thus identification is best accomplished where an authentic specimen of the compound in question is used as a reference substance on the same chromatogram.

For this purpose, chromatograms are prepared by applying on the thin-layer adsorbent or on the paper in a straight line, parallel to the edge of the chromatographic plate or paper, solutions of the substance to be identified, the authentic specimen, and a mixture of nearly equal amounts of the substance to be identified and the authentic specimen. Each sample application contains approximately the same quantity by weight of material to be chromatographed. If the substance to be identified and the authentic specimen are identical, all chromatograms agree in color and $R_{F}$ value and the mixed chromatogram yields a single spot; i.e., $R_{R}$ is 1.0 .

## Change to read:

## THIN-LAYER CHROMATOGRAPHY

In thin-layer chromatography, the adsorbent is a relatively thin, uniform layer of dry, finely powdered material applied to a glass, plastic, or metal sheet or plate, glass plates being most commonly employed. The coated plate can be considered an "open chromatographic column" and the separations achieved may be based upon adsorption, partition, or a combination of both effects, depending on the particular type of suppert,

its preparation, and its use with different solvents. Thin-layer chromatography on ion-exchange flms

- layers $_{\text {2S (USP28) }}$
can be used for the fractionation of polar compounds. Presumptive identification can be effected by observation of spots
- or zones $_{\mathbf{m 2 S}}$ (USP28)
of identical $R_{F}$ value and about equal magnitude obtained, respectively, with an unknown and a reference sample chromatographed on the same plate. A visual comparison of the size of the spets
- or intensity of the spots or zones $_{\text {m2S (USP28) }}$
may serve for semiquantitative estimation. Quantitative measurements are possible by means of densitometry, fluoresenee, and flurescence quenehing;
-(absorbance or fluorescence measurements), $\mathbf{\square} 2$ (USP28) or the spots may be carefully removed from the plate, followed by elution with a suitable solvent and spectrophotometric measurement. For two-dimensional thin-layer chromatography, the chromatographed plate is turned at a right angle and again chromatographed, usually in another chamber equilibrated with a different solvent system.

Apparatus-Acceptable apparatus and materials for thin-layer chromatography consist of the following.

Flat glass plates of convenient size, typieally $20 \mathrm{~cm} \times 20 \mathrm{~cm} .{ }^{+}$
Analigning tray or a flat surface upen whieh to align and rest the plates during the applieation of the adsorbent.

A storage rack to hold the prepared plate during drying and tramspertation. The rack holding the plates should be kept in a desiccutor or be capable of being sealed in order to protect the plater from the environment after removal from the drying oven. The adsorbent consists of finely divided adsorbent materials, nermally 5 to $-40 \mu \mathrm{~m}$ in diameter, suitable for chrematography. It ean be applied direetly to the glass plate or can be bended to the plate by means of plaster of paris (hydrated calcium sulfate) [at a ratio of $5 \%$ to $15 \%$ ] or with stareh paste or other binders. The for mer will not yield as hard a surface as will the stareh, but it is net
affected by strongly oxidizing spray reagents. The adsorbent may centain fluorescing material to aid in the visualization of spots that absorb ultraviolet light.

A spreader, which, when moved over the glass plate, will apply a uniform layer of adsorbent of desired thickness over the entire sufface of the plate.

A developing ehember that can aceommodate one or more plates and ean be properly elesed and sealed as deseribed under Aseend ing Chromatography. The chamber is fitted with a plate support rack that supports the plates, back to back, with the lid of the chamber in place.

A template (generally made of plastic) to aid in placing the eest spots at definite intervals, to mark distanees as needed, and to aid im tabeling the plates.

A graduated mieropipet eapable of delivering $10 \mu \mathrm{~L}$ volumes. Total volumes of test and standard solutions are specified in the individual menegraph.
Aredgent spratyer that will emit a finespray and will not itself be attacked by the reagent.
An ultraviolet light souree suitable for observations with shert $(254 \mathrm{~nm})$ and long ( 360 nm ) UV wavelengths.

- A TLC or HPTLC plate. The chromatography is generally carried out using precoated plates or sheets (on glass, aluminum, or polyester support) of suitable size. It may be necessary to clean the plates prior to separation. This can be done by migration of, or immersion in, an appropriate solvent. The plates may also be impregnated by procedures such as development, immersion, or spraying. At the time of use, the plates may be activated, if necessary, by heating in an oven at $120^{\circ}$ for 20 minutes. The stationary phase of TLC plates has an average particle size of $10-15 \mu \mathrm{~m}$, and that of HPTLC plates an average particle size of $5 \mu \mathrm{~m}$. Commercial plates with a preadsorbant zone can be used if they are specified in a monograph. Sample applied to the preabsorbant region develops into sharp, narrow bands at the pre-absorbant-sorbent interface. Alternatively, flat glass plates of convenient size, typically $20 \mathrm{~cm} \times 20 \mathrm{~cm}$ can be coated as described under Preparation of Chromatographic Plates.

A suitable manual, semiautomatic, or automatic application device can be used to ensure proper positioning of the plate and proper transfer of the sample, with respect to volume and position, onto the plate. Alternatively, a template can be used to guide in manually placing the test spots at definite intervals, to mark distances as needed, and to aid

[^248]in labeling the plates. For the proper application of the solutions, micropipets, microsyringes, or calibrated disposable capillaries are recommended.

For ascending development, a chromatographic chamber made of inert, transparent material and having the following specifications is used: a flat bottom or twin trough, a tightly fitted lid, and a size suitable for the plates. For horizontal development, the chamber is provided with a reservoir for the mobile phase, and it also contains a device for directing the mobile phase to the stationary phase.

Devices for transfer of reagents onto the plate by spraying, immersion, or exposure to vapor and devices to facilitate any necessary heating for visualization of the separated spots or zones.

A UV light source suitable for observations under short ( 254 nm ) and long ( 365 nm ) wavelength UV light.

A suitable device for documentation of the visualized chromatographic result.

Procedure-Apply the prescribed volume of the test solution and the standard solution in sufficiently small portions to obtain circular spots of 2 to 5 mm in diameter ( 1 to 2 mm on HPTLC plates) or bands of 10 to 20 mm by 1 to 2 mm ( 5 to 10 mm by 0.5 to 1 mm on HPTLC plates) at an appropriate distance from the lower edge-during chromatography the application position must be 3 mm (HPTLC) to 5 mm (TLC) above the level of the developing solvent-and from the sides of the plate. Apply the solutions on a line parallel to the lower edge of the plate with an interval of at least 10 mm ( 5 mm on HPTLC plates) between the centers of spots or 4 mm ( 2 mm on HPTLC plates) between the edges of bands, and allow to dry.

Ascending Development-Line at least one wall of the chromatographic chamber with filter paper. Pour into the chromatographic chamber a quantity of the mobile phase sufficient for the size of the chamber to give, after impreg-
nation of the filter paper, a level of depth appropriate to the dimension of the plate used. For saturation of the chromatographic chamber, close the lid, and allow the system to equilibrate. Unless otherwise indicated, the chromatographic separation is performed in a saturated chamber.

Place the plate in the chamber, ensuring that the plate is as vertical as possible and that the spots or bands are above the surface of the mobile phase, and close the chamber. The stationary phase faces the inside of the chamber. Remove the plate when the mobile phase has moved over the prescribed distance. Dry the plate, and visualize the chromatograms as prescribed. For two-dimensional chromatography, dry the plates after the first development, and carry out a second development in a direction perpendicular to that of the first development.

## Horizontal Development-Introduce a sufficient quantity

 of the developing solvent into the reservoir of the chamber using a syringe or pipet. Place the plate horizontally in the chamber, connect the mobile phase direction device according to the manufacturer's instructions, and close the chamber. If prescribed, develop the plate starting simultaneously at both ends. Remove the plate when the mobile phase has moved over the distance prescribed in the monograph. Dry the plate, and visualize the chromatograms as prescribed.For two-dimensional chromatography, dry the plates after the first development, and carry out a second development in a direction perpendicular to that of the first development.

Detection-Observe the dry plate first under short-wavelength UV light ( 254 nm ) and then under long-wavelength UV light ( 365 nm ) or as stated in the monograph. If further directed, spray, immerse, or expose the plate to vapors of the specified reagent, heat the plate when required, observe, and compare the test chromatogram with the standard chromatogram. Document the plate after each observation. Measure and record the distance of each spot or zone from the point
of origin, and indicate for each spot or zone the wavelength under which it was observed. Determine the $R_{F}$ values for the principal spots or zones (see Glossary of Symbols).

Quantitative Measurement-Using appropriate instrumentation, substances separated by TLC and responding to ultraviolet-visible (UV-Vis) irradiation prior to or after derivatization can be determined directly on the plate. While moving the plate or the measuring device, the plate is examined by measuring the reflectance of the incident light. Similarly, fluorescence may be measured using an appropriate optical system. Substances containing radionuclides can be quantified in three ways: (1) directly by moving the plate alongside a suitable counter or vice versa; (2) by cutting the plates into strips and measuring the radioactivity on each individual strip using a suitable counter; or (3) by scraping off the stationary phase, dissolving it in a suitable scintillation cocktail, and measuring the radioactivity using a liquid scintillation counter (see Radioactivity $\langle 821\rangle$ ).

The apparatus for direct quantitative measurement on the plate is a densitometer that is composed of a mechanical device to move the plate or the measuring device along the x axis and the $y$-axis, a recorder, a suitable integrator or a computer; and, for substances responding to UV-Vis irradiation, a photometer with a source of light, an optical device capable of generating monochromatic light, and a photo cell of adequate sensitivity, all of which are used for the measurement of reflectance. In the case where fluorescence is measured, a suitable filter is also required to prevent the light used for excitation from reaching the photo cell while permitting the emitted light or specific portions thereof to pass. The linearity range of the counting device must be verified.

For quantitative tests, it is necessary to apply to the plate not fewer than three standard solutions of the substance to be examined, the concentrations of which span the expected
value in the test solution (e.g., $80 \%, 100 \%$, and $120 \%$ ). Derivatize with the prescribed reagent, if necessary, and record the reflectance or fluorescence in the chromatograms obtained. Use the measured results for the calculation of the amount of substance in the test solution.

Preparation of Chromatographic Plates-
Apparatus-
Flat glass plates of convenient size, typically $20 \mathrm{~cm} \times 20$ cm .

An aligning tray or a flat surface upon which to align and rest the plates during the application of the adsorbent.

A storage rack to hold the prepared plates during drying and transportation. The rack holding the plates should be kept in a desiccator or be capable of being sealed in order to protect the plates from the environment after removal from the drying oven.
The adsorbent consists of finely divided adsorbent materials, normally 5 to $40 \mu \mathrm{~m}$ in diameter, suitable for chromatography. It can be applied directly to the glass plate or can be bonded to the plate by means of plaster of Paris (calcium sulfate hemihydrate [at a ratio of $5 \%$ to $15 \%$ ]) or with starch paste or other binders. The plaster of Paris will not yield as hard a surface as will the starch, but it is not affected by strongly oxidizing spray reagents. The adsorbent may contain fluorescing material to aid in the visualization of spots that absorb UV light.

A spreader, which, when moved over the glass plate, will apply a uniform layer of adsorbent of desired thickness over the entire surface of the plate. $\quad$ 2S (USP28)

Procedure-[NOTE-In this procedure, use purified water that is obtained by distillation.] Clean the

- $^{\text {glass }}{ }_{\text {■2S (USP28) }}$
plates scrupulously, as by immersion in chromic acid cleansing mixture,
-using an appropriate cleaning solution (see Cleaning Glass Apparatus $\langle 1051\rangle$ ), ■ $^{2 S}$ (USP28)
rinsing them with copious quantities of water until the water runs off the plates without leaving any visible water or oily spots, then dry. It is important that the plates be completely free from lint and dust when the adsorbent is applied.

Arrange the plate or plates on the aligning tray, place a $5-\times 20-$ cm plate adjacent to the front edge of the first square plate and another $5-\times 20-\mathrm{cm}$ plate adjacent to the rear edge of the last square, and secure all of the plates so that they will not slip during the application of the adsorbent. Position the spreader on the end plate opposite the raised end of the aligning tray. Mix 1 part of adsorbent with 2 parts of water (or in the ratio suggested by the supplier) by shaking vigorously for 30 seconds in a glass-stoppered conical flask, and transfer the slurry to the spreader. Usually 30 g of adsorbent and 60 mL of water are sufficient for five $20-\times 20-\mathrm{cm}$ plates. Complete the application of adsorbents using plaster of Paris binder within 2 minutes of the addition of the water, because thereafter the mixture begins to harden. Draw the spreader smoothly over the plates toward the raised end of the aligning tray, and remove the spreader when it is on the end plate next to the raised end of the aligning tray. (Wash away all traces of adsorbent from the spreader immediately after use.) Allow the plates to remain undisturbed for 5 minutes, then transfer the square plates, layer side up, to the storage rack, and dry at $105^{\circ}$ for 30 minutes. Preferably place the rack at an angle in the drying oven to prevent the condensation of moisture on the back sides of plates in the rack. When the plates are dry, allow them to cool to room temperature, and inspect the uniformity of the distribution and the texture of the adsorbent layer; transmitted light will show uniformity of distribution, and reflected light will show uniformity of texture. Store the satisfactory plates over silica gel in a suitable chamber.

Place fwe filter paper wicks, 18 cm in height and ws wide as the length of the developing chamber, into the chamber, add about 100 mL of the solvent (sufficient to have depth of 5 to 10 mm at the bettom of the chamber), seal the eover to the top of the chamber, and allow the system to equilibrate; it is essential that the wieks become completely wet. Altematively, the chamber may be completely lined with filter paper. In either ease, assure that the fllter paper dips into the solvent at the bettom of the chamber. Where vapor saturation of the chamber by these methods is undesirable, it is so indicated in the individual menegraph.

Apply the test solution and the standard solution, as directed in the individual menegraph, at peints about 1.5 cm apart and about 2 em from the lower edge of the plate (the lower edge is the first part over which the-spreader moved in the applieation of the adsorbent tayer), and allow to dry. Avoid physieal distubanee of the adsor bent during the spoting procedure (by the pipet or other applientor) or when handling the plates. The template will aid in determining the spot points and the 10 to 15 cm distance through which the solvent from should pass.

Place a mark 10 to 15 cm above the spet point. Arrange the plate en the supperting rack (test spets toward the bottom), and introduce the rack into the developing chamber. Allow the solvent in the chamber to reach the lower edge of the adsorbent, but do not allow the spot points to be immersed. Put the cover in place, and maintain the systemuntil the solvent aseends to a peint 10.015 cm above the initial spots, this usually requires about 15 minntes to 1 hour. Remove the plate from the developing chamber, mark the solvent frent, air dry the plates, and observe first mender shert wavelength UV light ( 254 mm ) and then under long wavelength UV light ( 360 nm ). Measure and record the distance of each spot from the peint of origin, and indiente for each spet the wavelength under which it was observed. Determine the $R_{t}$ values for the principat spots (see Glossaty of Symbels). If further directed, spray the spots with the reagent speciffed, observe, and compare the test chromat egram with the standard chrematogram.

## Contintous Development Thin-Layyr Chromatography

In centrast to conventional thin layer chremategraphy, which is earried out in clesed tank, the eontinnous development or continHous flow technigue allows the upper end of the plate to project threugh a slot in the cover of the developing chamber. When the developing solvent reaches the slot, contintrous-vaporation or eurs, producing a steady flow of solvent over the plate. In conventional thin layer ehromatography, spot migration ceases when the solvent reaches the top of the plate, after which the spots simply enlarge by diffusion. In the continueus flow process, spet migration contintes as long as the plate remains in the tank and the developing solvent is not exhatusted.

Development may be continued for several heurs after the sol tent reaches the top of the plate, to provide adequate migration of the spots. Usually spot of a standard solution, a test solution, anda mixture of equal amounts of test and standard solutions, are initial y y applied at a standard distanee frem the base of the plate. Identity of the standard and test substances is confirmed by their migrating equal distances from the origin and by the observation that the two substances applied as mixture-show ne tendeney to-separate.
A major advantage of continuous development thin layer chromatography stems from the greater solvent selectivity for solvents of low solvent strength. Solvent strength refers to the property of a developing solvent that eauses solutes to migrate, and it is strengly influeneed by the polarity of the-solvent. Inereasing the solvent strength by adding a more polar solvent causes the $R_{\text {, value }}$ to in rease. Solvent selectivity refers to the ability of a solvent system to produce different $R_{L}$ values for closely related substances. In eonventional thin layer chromatography, a solvent system giving an $R_{f}$ value in the range of 0.3 to 0.7 , but with adequate selectivity to permit separation of the substances being examined is usually selected. It is muth easier to find solvent systems producing adequate migration than to find these affording adequate-selectivity.

Solvent systems of lower strength generally exhibit higher selec tivity, but are diffieult to employ in conventional thin layer chromatography beeause they result in very little migration before the solvent reaches the top-of the plate. Migration may be increased, however, by repeated drying and redevelopment of the plate-or, more conveniently, by providing means for evaporation of solvent at the top of the plate, which results in continueus development. Two-echniques are used: contintrous development and short bed eontinuous development thin layer chromatography.

An $R_{L}$ value cannot be measured in continurus development thin layer chrematography. Substances may be compared either by their migration distance over a fixed period of time or by comparisen with the migration of a standard- substance applied to the plate.

## GONTINUOUS DEVELOPMENT

Apparatus Aeceptable apparatus and materials for continteres development thin layer chromatography are the same as these de scribed under conventional Thin Layer Chrematography, exeeptas follows.

Adeveloping chamber is used that consists of a rectangular tank, approximately $23 \mathrm{~cm} \times 23 \mathrm{~cm} \times 9 \mathrm{~cm}$, equipped with a glass solvent treugh and a platform about 3.75 cm high to elevate the solvent treugh above the base of the tank. The chamber is fitted with a cover having a $21 \times 6 \mathrm{em}$ slot in the front edge.

Proeedure- Apply the standard solution, the test solution, and a mix of equal amounts of the standard solution and the test solution to a line about 2 cm from the base of the plate. Place the plate in the elevated emply solvent trough with the adsorbent on the underside of the leaning plate. The adsorbent rests against a piece of heary (about 1 mm thick) ${ }^{2}$ filter paper measuring $20 \mathrm{em}-x$

[^249]3 cm , folded lengthwise and placed over the from edge of the tank. Place the developing solvent in the trough; set the cover in place, and seal all openings except where the adsorbent contacts the paper wick. The plate extends about 1 em beyond the top of the tank. After the solvent reaches the top of the plate, allow development to continue for an appropriate time. Then remove and dry the plate, and deteet the spets by suitable means.

## SHORT BED CONTINUOUS DEVELOPMENT

A major advantage of the short bed teehnique derives from the fact that solvent velocity is inversely related to bed length. Since spet migration depends upen the total amount of solvent passing over the plate, the short bed permits usefull migration to be ob fained in a reasonable time with solvent having very low solvent strength. Lower diffusion in solvents of low solvent strength produres smaller and more dense spots, which enhances both detect ability and discernment of small differences in migration distance.

Apparatus Acceptable apparatts and materials for shert bed eontinuous development thin layer chromatography are the same as those described under conventional Thin Layer Chromatograt phy, exeept as follows.

A shallow developing ehamber ${ }^{2}$ approximately $22 \mathrm{~cm} \times-9 \mathrm{~cm}$ $* 3 \mathrm{~cm}$, equipped with a eover plate and tight fitting polytef wings that enable the chamber to be sealed against the plate, is used. The
inside bottom of the chamber contains ridges that suppert the plate and allow it to be inserted at different angles, thereby varying the length of the plate contained within the tank.

Procedure-Apply the standard solution, the test solution, and a mixture of equal parts of the standard solution and the test solut tion to a line about 2 cm from the base of the plate. Place the plate in the developing chamber (adsorbent side up), and add the devel eping solvent to the chamber. No paper wick is employed. After the solvent reaches the top of the plate, allow development to eontime for an appropriate time. Then remove and dry the plate, and detect the spets by suitable means.

- ${ }^{\text {nS }}$ (USP28)

## Change to read:

## INTERPRETATION OF CHROMATOGRAMS

Figure 1 represents a typical chromatographic separation of two substances, 1 and 2 , where $t_{1}$ and $t_{2}$ are the respective retention times; and $h, h / 2$, and $W_{h / 2}$ are the height, the half-height, and the width at half-height, respectively, for peak 1. $W_{1}$ and $W_{2}$ are the respective widths of peaks 1 and 2 at the baseline. Air peaks are a feature of gas chromatograms and correspond to the solvent front in liquid chromatography.

Fig. 1. Chromatographic separation of two substances

Chromatographic retention times are characteristic of the compounds they represent but are not unique. Coincidence of retention times of a test and a reference substance can be used as a feature in construction of an identity profile but is insufficient on its own to establish identity. Absolute retention times of a given compound vary from one chromatogram to the next. Comparisons are normally made in terms of relative retention, $*$,
$\square_{r,}$ ■1S (USP28)
which is calculated by the equation:

$$
r=\frac{t_{2}-t_{a}}{t_{1}-t_{a}},
$$

where $t_{2}$ and $t_{1}$ are the retention times, measured from the point of injection, of the test and reference substances, respectively, determined under identical experimental conditions on the same column, and $t_{a}$ is the retention time of a nonretained substance, such as methane in the case of gas chromatography.

In this and the following expressions, the corresponding retention volumes or linear separations on the chromatogram, both of which are directly proportional to retention time, may be substituted in the equations. Where the value of $t_{a}$ is small, $R_{R_{R}}$
$\boldsymbol{■}_{\mathbf{m}_{1 S}}$ (USP28)
may be estimated from the retention times measured from the point of injection $\left(t_{2} t_{+}\right)$.

- $R_{R}$.■1S (USP28)

[^250]The number of theoretical plates, $N$, is a measure of column efficiency. For Gaussian peaks, it is calculated by the equation:

$$
N=16\left(\frac{t}{W}\right)^{2}, \square_{1 \mathrm{~S}(U S P 28)}
$$

where $t$ is the retention time of the substance and $W$ is the width of the peak at its base, obtained by extrapolating the relatively straight sides of the peak to the baseline. $W_{\text {Hs }}$ is the peak width at half height, obtained direetly by electronic integrators.
-1S (USP28)
The value of $N$ depends upon the substance being chromatographed as well as the operating conditions such as mobile phase or carrier gas flow rates and temperature, the quality of the packing, the uniformity of the packing within the column and, for capillary columns, the thickness of the stationary phase film, and the internal diameter and length of the column.

The separation of two components in a mixture, the resolution, $R$, is determined by the equation:

$$
R=\frac{2\left(t_{2}-t_{1}\right)}{W_{2}+W_{1}}
$$

in which $t_{2}$ and $t_{1}$ are the retention times of the two components, and $W_{2}$ and $W_{1}$ are the corresponding widths at the bases of the peaks obtained by extrapolating the relatively straight sides of the peaks to the baseline.

Where electronic integrators are used, it may be convenient to determine the resolution, $R$, by the equation:

$$
R=\frac{2\left(t_{2}-t_{1}\right)}{1.70\left(W_{1, h} / 2+\mathrm{W}_{2, h / 2}\right)}
$$

and to determine the number of theoretical plates, $N$, by the equation:

$$
N=5.54\left(t / W_{h / 2}\right)^{2}
$$

$\square_{\text {where }} W_{h / 2}$ is the peak width at half-height, obtained directly by electronic integrators.■1S (USP28)
However, in the event of dispute, only equations based on peak width at baseline are to be used.

Peak areas and peak heights are usually proportional to the quantity of compound eluting. These are commonly measured by electronic integrators but may be determined by more classical approaches. Peak areas are generally used but may be less accurate if peak interference occurs. For manual measurements, the chart should be run faster than usual, or a comparator should be used to measure the width at half-height and the width at the base of the peak, to minimize error in these measurements. For accurate quantitative work, the components to be measured should be separated from any interfering components. Peak tailing and fronting and the measurement of peaks on solvent tails are to be avoided.

Chromatographic purity tests for drug raw materials are sometimes based on the determination of peaks due to impurities, expressed as a percentage of the area due to the drug peak. It is preferable, however, to compare impurity peaks with those in the chromatogram of a standard at a similar concentration. The standard may be the drug itself at a level corresponding to, for example, $0.5 \%$ impurity, or in the case of toxic or signal impurities, a standard of the impurity itself.

## Change to read:

## SYSTEM SUITABILITY

System suitability tests are an integral part of gas and liquid chromatographic methods. They are used to verify that the

- detection sensitivity, ${ }^{\text {mS }}$ (USP28)
resolution, and reproducibility of the chromatographic system are adequate for the analysis to be done. The tests are based on the concept that the equipment, electronics, analytical operations, and samples to be analyzed constitute an integral system that can be evaluated as such.
-The detection sensitivity is a measure used to ensure the suitability of a given chromatographic procedure for the complete detection of the impurities in the Chromatographic purity or Related compounds tests by injecting a volume of a Quantitation Limit Solution equal to that of the Test solution. Unless otherwise specified in the individual monograph, the Quantitation Limit Solution may be prepared by dissolving the drug substance Reference Standard in the same solvent as that used for the Test preparation at a $0.05 \%$ concentration level relative to the amount of drug substance in the Test Preparation for drug substances, and a $0.1 \%$ level relative to the amount of drug substance in the Test Preparation for drug products. The signal-to-noise ratio for the drug substance peak obtained with the Quantitation

Limit Solution should be not less than 10. n2s (USP28)
The resolution, $R$, [NOTE-All terms and symbols are defined in the Glossary of Symbols] is a function of the column efficiency, $N$, and is specified to ensure that closely eluting compounds are resolved from each other, to establish the general resolving power of the system, and to ensure that internal standards are resolved
from the drug. Column efficiency may be specified also as a system suitability requirement, especially if there is only one peak of interest in the chromatogram; however, it is a less reliable means to ensure resolution than direct measurement. Column efficiency is a measure of peak sharpness, which is important for the detection of trace components.

Replicate injections of a Standard preparation used in the assay or other standard solution are compared to ascertain whether requirements for precision are met. Unless otherwise specified in the individual monograph, data from five replicate injections of the analyte are used to calculate the relative standard deviation, $S_{R}$, if the requirement is $2.0 \%$ or less; data from six replicate injections are used if the relative standard deviation requirement is more than $2.0 \%$.

The tailing factor, $T$, a measure of peak symmetry, is unity for perfectly symmetrical peaks and its value increases as tailing becomes more pronounced (see Fig. 2). In some cases, values less than unity may be observed. As peak asymmetry increases, integration, and hence precision, becomes less reliable.

Fig. 2. Asymmetrical chromatographic peak
These tests are performed by collecting data from replicate injections of standard or other solutions as specified in the individual monograph. The specification of definitive parameters in a monograph does not preclude the use of other suitable operating conditions (see Procedures under Tests and Assays in the General Notices). Adjustments of operating eonditions to meet system suit ability requirements may be neeessary.
-If adjustments of operating conditions to meet system suitability requirements are necessary, each of the following is the maximum specifieatienvariation that can be considered, unless otherwise directed in the monograph. Adjustments are permitted only when Reference Standards suitable standards (including Reference Standards) are available for all amalytes compounds used in the suitability test and are used to show that the adjustments have improved the quality of the chromatography in meeting system suitability requirements. Adjustments to chromatographic systems performed in order to comply with system suitability requirements are not to be made to compensate for column failure or to circumvent replacing a deteriorated column. The changes described below may require additional validation data unless
the user can verify the suitability of the method under the new conditions. This verification consists of assessing the analytical performance characteristics that can be affected by the change (e.g., specificity, linearity, precision, accuracy) to ensure the adequacy of the method. Multiple adjustments that may have a cumulative effect in the performance of the system are to be avoided.
pH of Mobile Phase (HPLC)-The pH of the aqueous buffer used in the preparation of the mobile phase can be adjusted to within 0.2 units of the value or range specified.

Concentration of Salts in Buffer (HPLC)—The concentration of the salts used in the preparation of the aqueous buffer used in the mobile phase can be adjusted to within $\pm 10 \%$, provided the permitted pH variation (see above) is met.

## Ratio of Components in Mobile Phase (HPLC) - The

 amount of the miner The following adjustment limits apply to minor components of the mobile phase (specified at $50 \%$ or less). The amount(s) of these component(s) can be adjusted by $\pm 30 \%$ relative or $\pm 2 \%$ absolute (i.e., in relation to the mobile phase), whichever is latger. However, the change in any component cannot exceed $\pm 10 \%$ absolute (i.e., in relation to the total mobile phase), nor can the final concentration of any component be reduced to zero. Adjustment can be made to one minor component in a ternary mixture. Examples of adjustments for binary and ternary mixtures are given below.
## Binary Mixtures-

SPECIFIED RATIO OF $50: 50$ - Thirty percent of 50 is $15 \%$ absolute, but this exceeds the maximum permitted change of $\pm 10 \%$ absolute in either component. Therefore, the mobile phase ratio may be adjusted only within the range of $40: 60$ to $60: 40$.

SPECIFIED-PATIO-OF-95:5_Thirty percent of 5 is $1.5 \%$ absolute. However, because adjustments up to $\pm 2 \%$ abse lete are allowed, the ratio may be adjusted within the range of $93: 7$ to $97: 3$.

SPECIFIED RATIO OF 2:98-Thirty percent of 2 is $0.6 \%$ absolute. In this ease an absolute adjustment of $\pm 2 \%$ is not at fowe because it would reduce the amount of the first empore. Therefore the maximum allowed adjustment is within the range of $1.4: 98.6$ to $2.6: 97.4$.

## Ternary Mixtures-

SPECIFIED RATIO OF $60: 35: 5$-For the second component, $30 \%$ of 35 is $10.5 \%$ absolute, which exceeds the maximum permitted change of $\pm 10 \%$ absolute in any component. Therefore the second component may be adjusted only within the range of $25 \%$ to $45 \%$ absolute. For the third component, $30 \%$ of 5 is $1.5 \%$ absolute. sinee $\pm 2 \%$ is permit ted and provides more flexibility, the third compenent may be adjusted within the range of $3 \%$ to $7 \%$ absolute. In all cases, a sufficient quantity of the first component is used to give a total of $100 \%$. Therefore, mixture ranges of $50: 45: 5$ to $70: 25: 5$ or $58: 35: 7-62: 35: 3$ $58.5: 35: 6.5$ to $61.5: 35: 3.5$ would meet the requirement.

## Detar Wavelength of UV-Visible Detector

 (HPLC)—Deviations from the wavelengths specified in the method are not permitted. The procedure specified by the detector manufacturer, or another validated procedure, is to be used to verify that error in the detector wavelength is, at most, $\pm 3 \mathrm{~nm}$.Column Length (GC, HPLC): can be adjusted by as much as $70 \%$.

Column Inner Diameter (GC, HPLC): can be adjusted by as much as $\pm 25 \% 50 \%$. $\pm 25 \%$ for HPLC and $\pm$ $50 \%$ for GC.

Film Thickness (Capillary GC): can be adjusted by as much as $-50 \%$ to $100 \%$.

Particle Size (HPLC): can be reduced by as much as 50\%.

Particle Size (GC): going from a larger to a smaller or a smaller to a larger (if it is the same "Range Ratio", which is the diameter of the largest particle divided by the diameter of the smallest particle) particle size GC mesh support is acceptable, provided the chromatography meets the requirements of the system suitability.

Flow Rate (GC, HPLC): can be adjusted by as much as $\pm 50 \%$.

Injection Volume (GC, HPLC): can be reduced as far as is consistent with accepted precision and detection limits.

It may be-inereased to as mueh as wiee the volume-specifled, provided there are ne adverse-effects-on factors sueh as baseline, peak shapes, reselutien, linearity, and retention times.

Column Temperature (HPLC): can be adjusted by as much as $\pm 20^{\circ} . \pm 10^{\circ}$. Column thermostating is recommended to improve control and reproducibility of retention time.

Column Oven Temperature (GC): can be adjusted by as much as $\pm 2 \%$, in terms of $\pm 10 \%$.

Oven Temperature Program (GC)—Adjustment of temperatures is permitted as stated above. For the times specified for the temperature to be maintained or for the temperature to be changed from one value to another, an adjustment of up to $\pm 20 \%$ is permitted.

Gradient Elution-(HPLC) The configuration of the equipment employed may significantly alter the resolution, retention time, and relative retentions deseribed in the meth-

## ed. Should this oceur, it may be due to excess dwell time,

which is the volume between the point at whieh the et
thants meet and the top-of the eolumat.as (USP28)
Unless otherwise directed in the monograph, system suitability parameters are determined from the analyte peak.

To ascertain the effectiveness of the final operating system, it should be subjected to suitability testing. Replicate injections of the standard preparation required to demonstrate adequate system precision may be made before the injection of samples or may be interspersed among sample injections. System suitability must be demonstrated throughout the run by injection of an appropriate control preparation at appropriate intervals.

The control preparation can be a standard preparation or a solution containing a known amount of analyte and any additional materials useful in the control of the analytical system, such as excipients or impurities. Whenever there is a significant change in equipment or in a critical reagent, suitability testing should be performed before the injection of samples. No sample analysis is acceptable unless the requirements of system suitability have been met. Sample analyses obtained while the system fails
$\square_{\text {System suitability }} \mathbf{m}^{2 S}$ (USP28)
requirements are unacceptable.

## CHROMATOGRAPHIC REAGENTS

The following list of packings (L), phases (G), and supports (S) is intended to be a convenient reference for the chromatographer. [NOTE-Particle sizes given in this listing are those generally provided. Where other, usually finer, sizes are required, the individual monograph specifies the desired particle size. Within any category of packings or phases listed below, there may be a wide range of columns available. Where it is necessary to define more specifically the chromatographic conditions, the individual monograph so indicates.]

## Packings

L1-Octadecyl silane chemically bonded to porous silica or ceramic micro-particles, 3 to $10 \mu \mathrm{~m}$ in diameter.

L2-Octadecyl silane chemically bonded to silica gel of a controlled surface porosity that has been bonded to a solid spherical core, 30 to $50 \mu \mathrm{~m}$ in diameter.

L3-Porous silica particles, 5 to $10 \mu \mathrm{~m}$ in diameter.
L4-Silica gel of controlled surface porosity bonded to a solid spherical core, 30 to $50 \mu \mathrm{~m}$ in diameter.

L5-Alumina of controlled surface porosity bonded to a solid spherical core, 30 to $50 \mu \mathrm{~m}$ in diameter.

L6-Strong cation-exchange packing-sulfonated fluorocarbon polymer coated on a solid spherical core, 30 to $50 \mu \mathrm{~m}$ in diameter.
L7-Octylsilane chemically bonded to totally porous silica particles, 3 to $10 \mu \mathrm{~m}$ in diameter.
L8-An essentially monomolecular layer of aminopropylsilane chemically bonded to totally porous silica gel support,
-3 to $\quad$ IS (USP28)
$10 \mu \mathrm{~m}$ in diameter.
L9- $10-\mu \mathrm{m}$ irregular or spherical, totally porous silica gel having a chemically bonded, strongly acidic cation-exchange coating.

L10-Nitrile groups chemically bonded to porous silica particles, 3 to $10 \mu \mathrm{~m}$ in diameter.

L11-Phenyl groups chemically bonded to porous silica particles, 5 to $10 \mu \mathrm{~m}$ in diameter.

L12-A strong anion-exchange packing made by chemically bonding a quaternary amine to a solid silica spherical core, 30 to $50 \mu \mathrm{~m}$ in diameter.

L13-Trimethylsilane chemically bonded to porous silica particles, 3 to $10 \mu \mathrm{~m}$ in diameter.

L14-Silica gel $10 \mu \mathrm{~m}$ in diameter

- 1 IS (USP28)
having a chemically bonded, strongly basic quaternary ammonium anion-exchange coating,
-5 to $10 \mu \mathrm{~m}$ in diameter. $\quad$ 1s (USP28)
L15-Hexylsilane chemically bonded to totally porous silica particles, 3 to $10 \mu \mathrm{~m}$ in diameter.
L16-Dimethylsilane chemically bonded to porous silica particles, 5 to $10 \mu \mathrm{~m}$ in diameter.

L17-Strong cation-exchange resin consisting of sulfonated cross-linked styrene-divinylbenzene copolymer in the hydrogen form, 7 to $11 \mu \mathrm{~m}$ in diameter.

L18-Amino and cyano groups chemically bonded to porous silica particles, 3 to $10 \mu \mathrm{~m}$ in diameter.

L19-Strong cation-exchange resin consisting of sulfonated cross-linked styrene-divinylbenzene copolymer in the calcium form, about $9 \mu \mathrm{~m}$ in diameter.
L20-Dihydroxypropane groups chemically bonded to porous silica particles, 5 to $10 \mu \mathrm{~m}$ in diameter.

L21-A rigid, spherical styrene-divinylbenzene copolymer, 5 to $10 \mu \mathrm{~m}$ in diameter.

L22-A cation-exchange resin made of porous polystyrene gel with sulfonic acid groups, about $10 \mu \mathrm{~m}$ in size.

L23-An anion-exchange resin made of porous polymethacrylate or polyacrylate gel with quaternary ammonium groups, about $10 \mu \mathrm{~m}$ in size.

L24-A semi-rigid hydrophilic gel consisting of vinyl polymers with numerous hydroxyl groups on the matrix surface, 32 to $63 \mu \mathrm{~m}$ in diameter. ${ }^{5}$

L25-Packing having the capacity to separate compounds with a molecular weight range from 100-5000 (as determined by polyethylene oxide), applied to neutral, anionic, and cationic water-soluble polymers. A polymethacrylate resin base, cross-linked with polyhydroxylated ether (surface contained some residual carboxyl functional groups) was found suitable.

L26-Butyl silane chemically bonded to totally porous silica particles, 5 to $10 \mu \mathrm{~m}$ in diameter.

L27-Porous silica particles, 30 to $50 \mu \mathrm{~m}$ in diameter.
L28-A multifunctional support, which consists of a high purity, $100 \AA$, spherical silica substrate that has been bonded with anionic exchanger, amine functionality in addition to a conventional reversed phase C 8 functionality.

L29-Gamma alumina, reverse-phase, low carbon percentage by weight, alumina-based polybutadiene spherical particles, $5 \mu \mathrm{~m}$ in diameter with a pore volume of $80 \AA$.

L30-Ethyl silane chemically bonded to totally porous silica particles, 3 to $10 \mu \mathrm{~m}$ in diameter.

L31-A strong anion-exchange resin-quaternary amine bonded on latex particles attached to a core of $8.5-\mu \mathrm{m}$ macroporous particles having a pore size of $2000 \AA$ and consisting of ethylvinylbenzene cross-linked with $55 \%$ divinylbenzene.

L32-A chiral ligand-exchange packing-L-proline copper complex covalently bonded to irregularly shaped silica particles, 5 to $10 \mu \mathrm{~m}$ in diameter.

[^251]L33-Packing having the capacity to separate dextrans by molecular size over a range of 4000 to $500,000 \mathrm{Da}$. It is spherical, silica-based, and processed to provide pH stability. ${ }^{6}$
L34-Strong cation-exchange resin consisting of sulfonated cross-linked styrene-divinylbenzene copolymer in the lead form, about $9 \mu \mathrm{~m}$ in diameter.

L35-A zirconium-stabilized spherical silica packing with a hydrophilic (diol-type) molecular monolayer bonded phase having a pore size of $150 \AA$.

L36-A 3,5-dinitrobenzoyl derivative of L-phenylglycine covalently bonded to $5-\mu \mathrm{m}$ aminopropyl silica.

L37-Packing having the capacity to separate proteins by molecular size over a range of 2,000 to $40,000 \mathrm{Da}$. It is a polymethacrylate gel.
L38-A methacrylate-based size-exclusion packing for watersoluble samples.

L39-A hydrophilic polyhydroxymethacrylate gel of totally porous spherical resin.

L40-Cellulose tris-3,5-dimethylphenylcarbamate coated porous silica particles, 5 to $20 \mu \mathrm{~m}$ in diameter.

L41-Immobilized $\alpha_{1}$-acid glycoprotein on spherical silica particles, $5 \mu \mathrm{~m}$ in diameter.

L42-Octylsilane and octadecylsilane groups chemically bonded to porous silica particles, $5 \mu \mathrm{~m}$ in diameter.

L43-Pentafluorophenyl groups chemically bonded to silica particles $\square_{\text {by }}$ a propyl spacer, $\mathbf{m S}_{\text {(USP27) }} 5$ to $10 \mu \mathrm{~m}$ in diameter.
L44-A multifunctional support, which consists of a high purity, $60 \AA$, spherical silica substrate that has been bonded with a cationic exchanger, sulfonic acid functionality in addition to a conventional reversed phase C8 functionality.

L45-Beta cyclodextrin bonded to porous silica particles, 5 to $10 \mu \mathrm{~m}$ in diameter.

L46-Polystyrene/divinylbenzene substrate agglomerated with quaternary amine functionalized latex beads,
-about.IS (USP28)
$10 \mu \mathrm{~m}$ in diameter.
L47-High-capacity anion-exchange microporous substrate, fully functionalized with trimethlyamine groups, $8 \mu \mathrm{~m}$ in diameter. ${ }^{7}$

L48-Sulfonated, cross-linked polystyrene with an outer layer of submicron, porous, anion-exchange microbeads, $15 \mu \mathrm{~m}$ in diameter.

L49-A reversed-phase packing made by coating a thin layer of polybutadiene onto spherical porous zirconia particles, 3 to $10 \mu \mathrm{~m}$ in diameter. ${ }^{8}$

L50-Multifunction resin with reversed-phase retention and strong anion-exchange functionalities. The resin consists of ethylvinylbenzene, $55 \%$ cross-linked with divinylbenzene copolymer, 3 to $15 \mu \mathrm{~m}$ in diameter, and a surface area not less than $350 \mathrm{~m}^{2}$ per g . Substrate is coated with quaternary ammonium functionalized latex particles consisting of styrene cross-linked with divinylbenzene. ${ }^{9}$

L51-Amylose tris-3,5-dimethylphenylcarbamate-coated, porous, spherical, silica particles, 5 to $10 \mu \mathrm{~m}$ in diameter. ${ }^{10}$

[^252]L52-A strong cation exchange resin made of porous silica with sulfopropyl groups, 5 to $10 \mu \mathrm{~m}$ in diameter. ${ }^{11}$

L53-Weak cation-exchange resin consisting of ethylvinylbenzene, $55 \%$ cross-linked with divinylbenzene copolymer, 3 to 15 $\mu \mathrm{m}$ diameter. Substrate is surface grafted with carboxylic acid and/or phosphoric acid functionalized monomers. Capacity not less than $500 \mu \mathrm{Eq} /$ column. ${ }^{12}$

L54-A size exclusion medium made of covalent bonding of dextran to highly cross-linked porous agarose beads, about 13 $\mu \mathrm{m}$ in diameter. ${ }^{13}$
${ }^{\mathbf{\Delta}}$ L55-A strong cation-exchange resin made of porous silica coated with polybutadiene-maleic acid copolymer, about $5 \mu \mathrm{~m}$ in diameter. ${ }^{14} \mathbf{\Delta U S P 2 7}$
${ }^{\mathbf{4}}$ L56-Propyl silane chemically bonded to totally porous silica particles, 3 to $10 \mu \mathrm{~m}$ in diameter. ${ }^{15} \mathbf{\Delta}$ USP27
-L57-A chiral-recognition protein, ovomucoid, chemically bonded to silica particles, about $5 \mu \mathrm{~m}$ in diameter, with a pore size of 120 À. $\mathbf{m}^{2 S}$ (USP27)
${ }^{\bullet}$ L58-Strong cation-exchange resin consisting of sulfonated cross-linked styrene-divinylbenzene copolymer in the sodium form, about 7 to $11 \mu \mathrm{~m}$ in diameter. ${ }^{16}$ 2S (USP27)
${ }^{\text {4}}$ L57 \#\# (Nevirapine, Supelcosil ABZ)——Spherical, porous silica gel, 3 or $5 \mu \mathrm{~m}$ in diameter, the surface of which has been covalently modified with palmitamidopropyl groups and endcapped with acetamidopropyl groups to a ligand density of about $6 \mu$ moles per $\mathrm{m}^{2}{ }^{\mathrm{a}} \mathbf{\Delta U S P 2 8}$
${ }^{\text {4 }}$ L58 \#\# (Albumin Human, Antithrombin III Human, TSKgel G3000 SW)_Packing having the capacity to separate proteins by molecular weight over the range of 10 to 500 kDa . It is spherical $(10 \mu \mathrm{~m})$, silica-based, and processed to provide hydrophilic characteristics and pH stability. ${ }^{\mathrm{b}}{ }_{\triangle U S P 28}$

## Phases

G1-Dimethylpolysiloxane oil.
G2-Dimethylpolysiloxane gum.
G3-50\% Phenyl-50\% methylpolysiloxane.
G4-Diethylene glycol succinate polyester.
G5-3-Cyanopropylpolysiloxane.
G6-Trifluoropropylmethylpolysiloxane.
G7-50\% 3-Cyanopropyl-50\% phenylmethylsilicone.
G8-80\% Bis(3-cyanopropyl)-20\% 3-cyanopropylphenylpoly-
siloxane (percentages refer to molar substitution).
G9-Methylvinylpolysiloxane.
G10-Polyamide formed by reacting a $\mathrm{C}_{36}$ dicarboxylic acid with 1,3-di-4-piperidylpropane and piperidine in the respective mole ratios of $1.00: 0.90: 0.20$.

G11—Bis(2-ethylhexyl) sebacate polyester.
G12-Phenyldiethanolamine succinate polyester.
G13-Sorbitol.
G14-Polyethylene glycol (av. mol. wt. of 950 to 1050).
G15-Polyethylene glycol (av. mol. wt. of 3000 to 3700 ).
G16-Polyethylene glycol compound (av. mol. wt. about 15,000 ). A high molecular weight compound of polyethylene glycol with a diepoxide linker. Available commercially as Polyethylene Glycol Compound 20M, or as Carbowax 20M, from suppliers of chromatographic reagents.

G17-75\% Phenyl-25\% methylpolysiloxane.
G18-Polyalkylene glycol.
G19-25\% Phenyl-25\% cyanopropyl-50\% methylsilicone.
G20-Polyethylene glycol (av. mol. wt. of 380 to 420).
G21-Neopentyl glycol succinate.
G22-Bis(2-ethylhexyl) phthalate.
G23-Polyethylene glycol adipate.
G24-Diisodecyl phthalate.
G25-Polyethylene glycol compound TPA. A high molecular weight compound of a polyethylene glycol and a diepoxide that is esterified with terephthalic acid. Available commercially as Carbowax $20 \mathrm{M}-\mathrm{TPA}$ from suppliers of chromatographic reagents.

G26-25\% 2-Cyanoethyl-75\% methylpolysiloxane.

G27-5\% Phenyl-95\% methylpolysiloxane.
G28-25\% Phenyl-75\% methylpolysiloxane.
G29-3,3'-Thiodipropionitrile.
G30-Tetraethylene glycol dimethyl ether.
G31-Nonylphenoxypoly(ethyleneoxy)ethanol (av. ethyleneoxy chain length is 30); Nonoxynol 30 .

G32-20\% Phenylmethyl-80\% dimethylpolysiloxane.
G33-20\% Carborane-80\% methylsilicone.
G34-Diethylene glycol succinate polyester stabilized with phosphoric acid.

G35-A high molecular weight compound of a polyethylene glycol and a diepoxide that is esterified with nitroterephthalic acid.

G36-1\% Vinyl-5\% phenylmethylpolysiloxane.
G37-Polyimide.
G38-Phase G1 containing a small percentage of a tailing inhibitor. ${ }^{17}$

G39—Polyethylene glycol (av. mol. wt. about 1500).
G40-Ethylene glycol adipate.
G41-Phenylmethyldimethylsilicone ( $10 \%$ phenyl-substituted).
G42-35\% phenyl-65\% dimethylpolysiloxane (percentages refer to molar substitution).

G43-6\% cyanopropylphenyl-94\% dimethylpolysiloxane (percentages refer to molar substitution).

G44-2\% low molecular weight petrolatum hydrocarbon grease and $1 \%$ solution of potassium hydroxide.

G45-Divinylbenzene-ethylene glycol-dimethylacrylate.
G46-14\% Cyanopropylphenyl-86\% methylpolysiloxane.
G47-Polyethylene glycol (av. mol. wt. of about 8000).
G48-Highly polar, partially cross-linked cyanopolysiloxane.
G49 Proprietary derivatized phenyl groups on a polysiloxane backbene. ${ }^{\text {º }}$
-G50 \#\# (Docosahexaenoic Acid)—Polyethylene glycol, cross-linked (av. mol. wt. of more than 20,000). ${ }^{\mathrm{c}_{1 S}}{ }_{\text {(USP28) }}$

## Supports

NOTE-Unless otherwise specified, mesh sizes of 80 to 100 or, alternatively, 100 to 120 are intended.

S1A-Siliceous earth for gas chromatography has been flux-calcined by mixing diatomite with $\mathrm{Na}_{2} \mathrm{CO}_{3}$ flux and calcining above $900^{\circ}$. The siliceous earth is acid-washed, then water-washed until neutral, but not base-washed. The siliceous earth may be silanized by treating with an agent such as dimethyldichlorosilane ${ }^{19}$ to mask surface silanol groups.
S1AB-The siliceous earth as described above is both acid- and base-washed. ${ }^{19}$

S1C-A support prepared from crushed firebrick and calcined or burned with a clay binder above $900^{\circ}$ with subsequent acidwash. It may be silanized.

S1NS-The siliceous earth is untreated.
S2-Styrene-divinylbenzene copolymer having a nominal surface area of less than $50 \mathrm{~m}^{2}$ per g and an average pore diameter of 0.3 to $0.4 \mu \mathrm{~m}$.

[^254]S3-Copolymer of ethylvinylbenzene and divinylbenzene having a nominal surface area of 500 to $600 \mathrm{~m}^{2}$ per $g$ and an average pore diameter of $0.0075 \mu \mathrm{~m}$.

S4-Styrene-divinylbenzene copolymer with aromatic -O and N groups, having a nominal surface area of 400 to $600 \mathrm{~m}^{2}$ per $g$ and an average pore diameter of $0.0076 \mu \mathrm{~m}$.

S5-40- to 60-mesh, high-molecular weight tetrafluorethylene polymer.

S6-Styrene-divinylbenzene copolymer having a nominal surface area of 250 to $350 \mathrm{~m}^{2}$ per g and an average pore diameter of $0.0091 \mu \mathrm{~m}$.

S7-Graphitized carbon having a nominal surface area of $12 \mathrm{~m}^{2}$ per g .

S8-Copolymer of 4-vinyl-pyridine and styrene-divinylbenzene.

S9-A porous polymer based on 2,6-diphenyl-p-phenylene oxide.
S10-A highly polar cross-linked copolymer of acrylonitrite and divinylbenzene.

S11-Graphitized carbon having a nominal surface area of 100 $\mathrm{m}^{2}$ per g modified with small amounts of petrolatum and polyethylene glycol compound. ${ }^{20}$

S12-Graphitized carbon having a nominal surface area of 100 $\mathrm{m}^{2}$ per g .

## BRIEFING

$\langle 643\rangle$ Total Organic Carbon, USP 27 page 2285. This is the third attempt by the Pharmaceutical Waters Expert Committee to revise this general test chapter. This revision incorporates most of the comments received since the publication of proposed revisions in PF 29(6) [Nov.-Dec. 2003], which have been cancelled. This current proposal adds quantitative values to the testing procedure that provide more flexibility in its application. Please address comments to Frank Barletta, liaison to the Pharmaceutical Waters Expert Committee.

$$
\text { (PW: F. Barletta) } \quad \text { RTS }-41409-1
$$

## Change to read:

Total organic carbon (TOC) is an indirect measure of organic molecules present in pharmaceutical waters measured as carbon. Organic molecules are introduced into the water from the source water, from purification and distribution system materials, and from biofilm growing in the system. TOC can also be used as a process control attribute to monitor the performance of unit operations comprising the purification and distribution system.

A number of acceptable methods exist for analyzing TOC. This chapter does not limit or prevent alternative technologies from being used, but provides guidance on how to qualify these analytical technologies for use as well as guidance on how to interpret instrument results for use as a limit test. The Solltan
$\mathbf{- S u c r o s e ~ S o l u t i o n}_{\text {■2S (USP28) }}$

[^255]is a theoretically easy-to-oxidize solution that gives an instrument response at the attribute limit. The analytical technology is qualified by challenging the capability of the instrument using a theoretically difficult to oxidize solution in the system suitability portion of the method.

Analytical technologies utilized to measure TOC share the objective of completely oxidizing the organic molecules in an aliquot of sample water to carbon dioxide $\left(\mathrm{CO}_{2}\right)$, measuring the resultant $\mathrm{CO}_{2}$ tevels,

- concentration, $\boldsymbol{m}_{2 S}$ (USP28)
and expressing this response as carbon concentration. All technologies must discriminate between the inorganic carbon, which may be present in the water from sources such as dissolved $\mathrm{CO}_{2}$ and bicarbonate, and the $\mathrm{CO}_{2}$ generated from the oxidation of organic molecules in the sample.

Two general approaches are used to measure TOC. One approach determines TOC by subtracting the measured inorganic carbon (IC) from the measured total carbon (TC), which is the sum of organic carbon and inorganic carbon:

$$
\mathrm{TOC}=\mathrm{TC}-\mathrm{IC}
$$

The other approach first purges the IC from the sample before any carbon measurement is performed. However, this IC purging step also purges some of the organic molecules, which can be retrapped, oxidized to $\mathrm{CO}_{2}$, and quantitated as purgeable organic carbon (POC). The remaining organic matter in the sample is also oxidized to $\mathrm{CO}_{2}$ and quantitated as nonpurgeable organic carbon (NPOC). In this approach, TOC is the sum of POC and NPOC:

$$
\mathrm{TOC}=\mathrm{POC}+\mathrm{NPOC}
$$

In pharmaceutical waters, the amount of POC is negligible and can be discounted. Therefore, for the purpose of this methodology, NPOC is equivalent to TOC.

## Change to read:

Reagent Water-Use water having a TOC level of not more than 0.10 mg per L. [NOTE-A conductivity requirement may be neeessary to enstre methed reliability.

in which $C_{s s}$ is the concentration of the System Suitability
Solution, in mg of carbon per L (ppm). $\mathbf{w}^{2 S}$ (USP28)
The system is suitable if the response efficiency

- of both the Sucrose Solution and the System Suitability So-
lution ${ }_{\text {2S }}$ (USP28)
is not less than $85 \%$ and not more than $115 \%$ of the theoretical response.

## Change to read:

Procedure-Perform the test on the Test Solution, and record the respense, $r_{4}$. The Test Solution meets the requirements if $\Psi_{\Perp}$ is not more than the limit response, $+r_{s}=$
-the TOC value: it contains not more than 0.5 mg of carbon

## per L (ppm). ${ }^{2 S}$ (USP28)

This method also can be performed alternatively using on-line instrumentation that has been appropriately calibrated, standardized, and has demonstrated acceptable system suitability. The acceptability of such on-line instrumentation for quality attribute testing is dependent on its location(s) in the water system. These instrument location(s) and responses must reflect the quality of the water used.

## BRIEFING

〈785〉 Osmolality and Osmolarity, USP 27 page 2335 and page 3331 of the Second Supplement. On the basis of comments received, it is proposed to revise the Measurement of Osmolality section to clarify that vapor pressure osmometers may be used for osmolality determinations. Although used less frequently than osmometers that measure freezing point depression, vapor pressure osmometers require a smaller volume of specimen and provide comparable results.
(PA4: H. Pappa) RTS-41268-1

## Change to read:

## MEASUREMENT OF OSMOLALITY

The osmolality of a solution is commonly determined by the measurement of the freezing point depression of the solution.
Apparatus-The apparatus, an osmometer for freezing point depression measurement, consists of the following: a means of cooling the container used for the measurement; a resistor sensitive to temperature (thermistor), with an appropriate current- or poten-tial-difference measurement device that may be graduated in temperature change or in osmolality; and a means of mixing the sample.
-Osmometers that measure the vapor pressures of solutions are less frequently employed. They require a smaller volume of specimen (generally about $5 \mu \mathrm{~L}$ ), but the accuracy and precision of the resulting osmolality determination are comparable to those obtained by the use of osmometers that depend upon the observed freezing points of solutions.■2S (USP28)

Standard Solutions-Prepare Standard Solutions as specified in Table 1, as necessary.

Table 1. Standard Solutions for Osmometer Calibration ${ }^{2}$

| Standard Solutions <br> (Weight in g of sodium chloride <br> per kg of water) | Osmolality <br> $(\mathrm{mOsmol} / \mathrm{kg})$ <br> $\left(\xi_{m}\right)$ | Molal Osmotic <br> Coefficient <br> $\left(\Phi_{m, \mathrm{NaCl}}\right)$ | Freezing Point <br> Depression $\left({ }^{\circ}\right)$ |
| :---: | :---: | :---: | :---: |
| 3.087 | 100 | 0.9463 | $\Delta T_{f}$ |

[^256]Test Solution-For a solid for injection, constitute with the appropriate diluent as specified in the instructions on the labeling. For solutions, use the sample as is. [NOTE-A solution can be diluted to bring it within the range of measurement of the osmometer, if necessary, but the results must be expressed as that of the diluted solution and must NOT be multiplied by a dilution factor to calculate the osmolality of the original solution. The molal osmotic coefficient is a function of concentration. Therefore, it changes with dilution.]

Procedure-Set the zero of the apparatus using water. To calibrate the apparatus, choose at least two solutions from Table 1 such that the osmolalities of the Standard Solutions span the expected range of osmolality of the Test Solution. Introduce an appropriate volume of each Standard Solution into the measurement cell as per the manufacturer's instructions, and start the cooling system. Usually, the mixing device is programmed to operate at a temperature below the lowest temperature expected from the freezing point depression. The apparatus indicates when the equilibrium is attained. Calibrate the osmometer using an appropriate adjustment device such that the reading corresponds to either the osmolality or freezing point depression value of the Standard Solution shown in Table 1. [NOTE-Some instruments indicate osmolality and some others show freezing point depression.] Before each measurement, rinse the measurement cell at least twice with the solution to be tested. Repeat the procedure with each Test Solution. Read the osmolality of the Test Solution directly, or calculate it from the measured freezing point depression.

Assuming that the value of the osmotic coefficient is essentially the same whether the concentration is expressed in molality or molarity, the experimentally determined osmolality of a solution can be converted to osmolarity in the same manner in which the concentration of a solution is converted from molality to molarity. Unless a solution is very concentrated, the osmolarity of a solution $\left(\xi_{c}\right)$ can be calculated from its experimentally determined osmolality $\left(\xi_{m}\right)$ :

$$
\xi_{c}=1000 \xi_{m} /\left(1000 / \rho+\Sigma w_{i} \nu_{i}\right)
$$

where $w_{i}$ is the weight in g ; and $\nu_{i}$ is the partial specific volume, in mL per g , of the $i^{\text {th }}$ solute. The partial specific volume of a solute is the change in volume of a solution when an additional 1 g of solute is dissolved in the solution. This volume can be determined by the measurement of densities of the solution before and after the addition of the solute. The partial specific volumes of salts are generally very small, around 0.1 mL per g . However, those of other solutes are generally higher. For example, the partial specific volumes of amino acids are in the range of $0.6-0.9 \mathrm{~mL}$ per $g$.

## PROCEDURE

## Absorption Spectrophotometry

Detailed instructions for operating spectrophotometers are supplied by the manufacturers. To achieve significant and valid results, the operator of a spectrophotometer should be aware of its limitations and of potential sources of error and variation. The instruction manual should be followed closely on such matters as care, cleaning, and calibration of the instrument, and techniques of handling absorption cells, as well as instructions for operation. The following points require special emphasis.

Check the instrument for accuracy of calibration. Where a continuous source of radiant energy is used, attention should be paid to both the wavelength and photometric scales; where a spectral line source is used, only the photometric scale need be checked. A number of sources of radiant energy have spectral lines of suitable intensity, adequately spaced throughout the spectral range selected. The best single source of UV and visible calibration spectra is the quartz-mercury arc, of which the lines at $253.7,302.25,313.16$, $334.15,365.48,404.66$, and 435.83 nm may be used. The glassmercury arc is equally useful above 300 nm . The $486.13-\mathrm{nm}$ and $656.28-\mathrm{nm}$ lines of a hydrogen discharge lamp may be used also. The wavelength scale may be calibrated also by means of suitable glass filters, which have useful absorption bands through the visible and UV regions. Standard glasses containing didymium (a mixture of praseodymium and neodymium) have been used widely, although glasses containing holmium were found to be superior. More recently, standard
${ }^{-}$Standard ${ }_{\text {ne2 }}$ (USP28)
holmium oxide solution has superseded the use of holmium glass. ${ }^{1}$ The wavelength scales of near-IR and IR spectrophotometers are readily checked by the use of absorption bands provided by polystyrene films, carbon dioxide, water vapor, or ammonia gas.

For checking the photometric scale, a number of standard inorganic glass filters as well as standard solutions of known transmittances such as orsium chremate or
-n2S (USP28)
potassium dichromate are available. ${ }^{2}$
Quantitative absorbance measurements usually are made on solutions of the substance in liquid-holding cells. Since both the solvent and the cell window absorb light, compensation must be made
${ }^{1}$ Gertified helmium oxide-selution, SPM H2034, (wavelength-standard frem 240 to 650 nm ) may be obtained frem the

photometric scales of a spectrophotometer, reference may be made to the following NIST publications: SRM \#93le "Liquid Absorbance Standard for UV and Vis Spectrophotometry," J. Res. Natl. Bur. Stds. 76A, 405 and 469 (1972); SRM \#930e "Glass Filters for Spectrophotometry-for verification of the transmittance and absorbance scales of spectrophotometry in the visible spectral domain ( $10 \%$ T, 20\%T, 30\%T)," NIST Spec. Publ. 260-116 (1994).
for their contribution to the measured absorbance. Matched cells are available commercially for UV and visible spectrophotometry for which no cell correction is necessary. In IR spectrophotometry, however, corrections for cell differences usually must be made. In such cases, pairs of cells are filled with the selected solvent and the difference in their absorbances at the chosen wavelength is determined. The cell exhibiting the greater absorbance is used for the solution of the test specimen and the measured absorbance is corrected by subtraction of the cell difference.

With the use of a computerized Fourier transform IR system, this correction need not be made, since the same cell can be used for both the solvent blank and the test solution. However, it must be ascertained that the transmission properties of the cell are constant.

Comparisons of a test specimen with a Reference Standard are best made at a peak of spectral absorption for the compound concerned. Assays prescribing spectrophotometry give the commonly accepted wavelength for peak spectral absorption of the substance in question. It is known that different spectrophotometers may show minor variation in the apparent wavelength of this peak. Good practice demands that comparisons be made at the wavelength at which peak absorption occurs. Should this differ by more than $\pm 1 \mathrm{~nm}$ from the wavelength specified in the individual monograph, recalibration of the instrument may be indicated.

## TEST PREPARATION

For determinations utilizing UV or visible spectrophotometry, the specimen generally is dissolved in a solvent. Unless otherwise directed in the monograph, determinations are made at room temperature using a path length of 1 cm . Many solvents are suitable for these ranges, including water, alcohols, chloroform, lower hydrocarbons, ethers, and dilute solutions of strong acids and alkalies. Precautions should be taken to utilize solvents free from contaminants absorbing in the spectral region being used. It is usually advisable to use water-free methanol or alcohol, or alcohol denatured by the addition of methanol but not containing benzene or other interfering impurities, as the solvent. Solvents of special spectrophotometric quality, guaranteed to be free from contaminants, are available commercially from several sources. Some other analytical reagent-grade organic solvents may contain traces of impurities that absorb strongly in the UV region. New lots of these solvents should be checked for their transparency, and care should be taken to use the same lot of solvent for preparation of the test solution and the standard solution and for the blank.

No solvent in appreciable thickness is completely transparent throughout the near-IR and IR spectrum. Carbon tetrachloride (up to 5 mm in thickness) is practically transparent to $6 \mu \mathrm{~m}$ ( $1666 \mathrm{~cm}^{-1}$ ). Carbon disulfide ( 1 mm in thickness) is suitable as a solvent to $40 \mu \mathrm{~m}\left(250 \mathrm{~cm}^{-1}\right)$ with the exception of the $4.2-\mu \mathrm{m}$ to $5.0-\mu \mathrm{m}\left(2381-\mathrm{cm}^{-1}\right.$ to $\left.2000-\mathrm{cm}^{-1}\right)$ and the $5.5-\mu \mathrm{m}$ to $7.5-\mu \mathrm{m}$ $\left(1819-\mathrm{cm}^{-1}\right.$ to $\left.1333-\mathrm{cm}^{-1}\right)$ regions, where it has strong absorption. Other solvents have relatively narrow regions of transparency. For IR spectrophotometry, an additional qualification for a suitable solvent is that it must not affect the material, usually sodium chloride, of which the cell is made. The test specimen may also be prepared by dispersing the finely ground solid specimen in mineral oil or by mixing it intimately with previously dried alkali halide salt (usually potassium bromide). Mixtures with alkali halide salts may be examined directly or as transparent disks or pellets obtained by pressing the mixture in a die. Typical drying conditions for potassium
bromide are $105^{\circ}$ in vacuum for 12 hours, although grades are commercially available that require no drying. ${ }^{\mathbf{m}}$ Infrared microscopy or $\mathrm{a}_{\mathbf{1}_{1 S}(U S P 27)}$ mineral oil dispersion is preferable where disproportionation between the alkali halide and the test specimen is encountered. For suitable materials the test specimen may be $\square_{\text {prepared neat as a thin sample for IR microscopy or }}^{1 S}$ (USP27) Suspended neat as a thin film ${ }^{\mathbf{-}}$ for mineral oil dispersion. 1 (USP27) For Raman spectrometry, most common solvents are suitable, and ordinary (nonfluorescing) glass specimen cells can be used. The IR region of the electromagnetic spectrum extends from 0.8 to 400 $\mu \mathrm{m}$. From 800 to $2500 \mathrm{~nm}(0.8$ to $2.5 \mu \mathrm{~m})$ is generally considered to be the near-IR (NIR) region; from 2.5 to $25 \mu \mathrm{~m}(4000$ to $400 \mathrm{~cm}^{-1}$ ) is generally considered to be the mid-range (mid-IR) region; and from 25 to $400 \mu \mathrm{~m}$ is generally considered to be the farIR (FIR) region. Unless otherwise specified in the individual monograph, the region from 3800 to $650 \mathrm{~cm}^{-1}$ ( 2.6 to $15 \mu \mathrm{~m}$ ) should be used to ascertain compliance with monograph specifications for IR absorption.

Where values for IR line spectra are given in an individual monograph, the letters $s, m$, and $w$ signify strong, medium, and weak absorption, respectively; $s h$ signifies a shoulder, $b d$ signifies a band, and $v$ means very. The values may vary as much as $0.1 \mu \mathrm{~m}$ or $10 \mathrm{~cm}^{-1}$, depending upon the particular instrument used. Polymorphism gives rise to variations in the IR spectra of many compounds in the solid state. Therefore, when conducting IR absorption tests, if a difference appears in the IR spectra of the analyte and the standard, dissolve equal portions of the test substance and the standard in equal volumes of a suitable solvent, evaporate the solutions to dryness in similar containers under identical conditions, and repeat the test on the residues.

In NIR spectroscopy much of the current interest centers around the ease of analysis. Samples can be analyzed in powder form or by means of reflectance techniques, with little or no preparation. Compliance with in-house specifications can be determined by computerized comparison of spectra with spectra previously obtained from reference materials. Many pharmaceutical materials exhibit low absorptivity in this spectral region, which allows incident nearIR radiation to penetrate samples more deeply than UV, visible, or IR radiation. NIR spectrophotometry may be used to observe matrix modifications and, with proper calibration, may be used in quantitative analysis.

In atomic absorption spectrophotometry, the nature of the solvent and the concentration of solids must be given special consideration. An ideal solvent is one that interferes to a minimal extent in the absorption or emission processes and one that produces neutral atoms in the flame. If there is a significant difference between the surface tension or viscosity of the test solution and standard solution, the solutions are aspirated or atomized at a different rate, causing significant differences in the signals generated. The acid concentration of the solutions also affects the absorption processes. Thus, the solvents used in preparing the test specimen and the standard should be the same or as much alike in these respects as possible, and should yield solutions that are easily aspirated via the specimen tube of the burner-aspirator. Since undissolved solids present in the solutions may give rise to matrix or bulk interferences, the total undissolved solids content in all solutions should be kept below $2 \%$ wherever possible.

## CALCULATIONS

The application of absorption spectrophotometry in an assay or a test generally requires the use of a Reference Standard. Where such a measurement is specified in an assay, a formula is provided in order to permit calculation of the desired result. A numerical constant is frequently included in the formula. The following derivation is provided to introduce a logical approach to the deduction of the constants appearing in formulas in the assays in many monographs.

The Beer's law relationship is valid for the solutions of both the Reference Standard ( $S$ ) and the test specimen ( $U$ ): in which $A_{S}$ is the absorbance of the Standard solution of concentration $C_{S}$; and $A_{U}$ is the absorbance of the test specimen solution of concentration $C_{U}$. If $C_{S}$ and $C_{U}$ are expressed in the same units and the absorbances of both solutions are measured in matching cells having the same dimensions, the absorptivity, $a$, and the cell thickness, $b$, are the same; consequently, the two equations may be combined and rewritten to solve for $C_{U}$ :
(3)

$$
C_{U}=C_{S}\left(A_{U} / A_{S}\right)
$$

Quantities of solid test specimens to be taken for analysis are generally specified in mg. Instructions for dilution are given in the assay and, since dilute solutions are used for absorbance measurements, concentrations are usually expressed for convenience in units of $\mu \mathrm{g}$ per mL . Taking a quantity, in mg , of a test specimen of a drug substance or solid dosage form for analysis, it therefore follows that a volume $\left(V_{U}\right)$, in L , of solution of concentration $C_{U}$ may be prepared from the amount of test specimen that contains a quantity $W_{U}$, in mg, of the drug substance [NOTE- $C_{U}$ is numerically the same whether expressed as $\mu \mathrm{g}$ per mL or mg per L], such that:
(4) $W_{U}=V_{U} C_{U}$.

The form in which the formula appears in the assay in a monograph for a solid article may be derived by substituting $C_{U}$ of equation (3) into equation (4). In summary, the use of equation (4), with due consideration for any unit conversions necessary to achieve equality in equation (5), permits the calculation of the constant factor $\left(V_{U}\right)$ occurring in the final formula:
(5) $\quad W_{U}=V_{U} C_{S}\left(A_{U} / A_{S}\right)$.

The same derivation is applicable to formulas that appear in monographs for liquid articles that are assayed by absorption spectrophotometry. For liquid dosage forms, results of calculations are generally expressed in terms of the quantity, in mg , of drug substance in each mL of the article. Thus it is necessary to include in the denominator an additional term, the volume $(V)$, in mL , of the test preparation taken.

Assays in the visible region usually call for comparing concomitantly the absorbance produced by the Assay preparation with that produced by a Standard preparation containing approximately an equal quantity of a USP Reference Standard. In some situations, it is permissible to omit the use of a Reference Standard. This is true where spectrophotometric assays are made with routine frequency, and where a suitable standard curve is available, prepared with the respective USP Reference Standard, and where the substance assayed conforms to Beer's law within the range of about $75 \%$ to $125 \%$ of the final concentration used in the assay. Under these circumstances, the absorbance found in the assay may be interpolated on the standard curve, and the assay result calculated therefrom.

Such standard curves should be confirmed frequently, and always when a new spectrophotometer or new lots of reagents are put into use.

In spectrophotometric assays that direct the preparation and use of a standard curve, it is permissible and preferable, when the assay is employed infrequently, not to use the standard curve but to make the comparison directly against a quantity of the Reference Standard approximately equal to that taken of the specimen, and similarly treated.

## Fluorescence Spectrophotometry

The measurement of fluorescence is a useful analytical tech nique. Fluorescence is light emitted from a substance in an excited state that has been reached by the absorption of radiant energy. A substance is said to be fluorescent if it can be made to fluoresce. Many compounds can be assayed by procedures utilizing either their inherent fluorescence or the fluorescence of suitable derivatives.

Test specimens prepared for fluorescence spectrophotometry are usually one-tenth to one-hundredth as concentrated as those used in absorption spectrophotometry, for the following reason. In analytical applications, it is preferable that the fluorescence signal be linearly related to the concentration; but if a test specimen is too concentrated, a significant part of the incoming light is absorbed by the specimen near the cell surface, and the light reaching the center is reduced. That is, the specimen itself acts as an "inner filter." However, fluorescence spectrophotometry is inherently a highly sensitive technique, and concentrations of $10^{-5} \mathrm{M}$ to $10^{-7}$ M frequently are used. It is necessary in any analytical procedure to make a working curve of fluorescence intensity versus concentration in order to establish a linear relationship. All readings should be corrected for a solvent blank.

Fluorescence measurements are sensitive to the presence of dust and other solid particles in the test specimen. Such impurities may reduce the intensity of the exciting beam or give misleading high readings because of multiple reflections in the specimen cell. It is, therefore, wise to eliminate solid particles by centrifugation; filtration also may be used, but some filter papers contain fluorescent impurities.

Temperature regulation is often important in fluorescence spectrophotometry. For some substances, fluorescence efficiency may be reduced by as much as $1 \%$ to $2 \%$ per degree of temperature rise. In such cases, if maximum precision is desired, temperature-controlled specimen cells are useful. For routine analysis, it may be sufficient to make measurements rapidly enough so that the specimen does not heat up appreciably from exposure to the intense light source. Many fluorescent compounds are light-sensitive. Exposed in a fluorometer, they may be photo-degraded into more or less fluorescent products. Such effects may be detected by observing the detector response in relationship to time, and may be reduced by attenuating the light source with filters or screens.

Change of solvent may markedly affect the intensity and spectral distribution of fluorescence. It is inadvisable, therefore, to alter the solvent specified in established methods without careful preliminary investigation. Many compounds are fluorescent in organic solvents but virtually nonfluorescent in water; thus, a number of solvents should be tried before it is decided whether or not a compound is fluorescent. In many organic solvents, the intensity of fluorescence is increased by elimination of dissolved oxygen, which has a strong quenching effect. Oxygen may be removed by bubbling an inert gas such as nitrogen or helium through the test specimen.

A semiquantitative measure of the strength of fluorescence is given by the ratio of the fluorescence intensity of a test specimen and that of a standard obtained with the same instrumental settings. Frequently, a solution of stated concentration of quinine in 0.1 N sulfuric acid or fluorescein in 0.1 N sodium hydroxide is used as a reference standard.

## Light-Scattering

Turbidity can be measured with a standard photoelectric filter photometer or spectrophotometer, preferably with illumination in the blue portion of the spectrum. Nephelometric measurements require an instrument with a photocell placed so as to receive scattered rather than transmitted light; this geometry applies also to fluorometers, so that, in general, fluorometers can be used as nephelometers, by proper selection of filters. A ratio turbidimeter combines the technology of $90^{\circ}$ nephelometry and turbidimetry: it contains photocells that receive and measure scattered light at a $90^{\circ}$ angle from the sample as well as receiving and measuring the forward scatter in front of the sample; it also measures light transmitted directly through the sample. Linearity is attained by calculating the ratio of the $90^{\circ}$ angle scattered light measurement to the sum of the forward scattered light measurement and the transmitted light measurement. The benefit of using a ratio turbidimetry system is that the measurement of stray light becomes negligible.

In practice, it is advisable to ensure that settling of the particles being measured is negligible. This is usually accomplished by including a protective colloid in the liquid suspending medium. It is important that results be interpreted by comparison of readings with those representing known concentrations of suspended matter, produced under precisely the same conditions.

Turbidimetry or nephelometry may be useful for the measurement of precipitates formed by the interaction of highly dilute solutions of reagents, or other particulate matter, such as suspensions of bacterial cells. In order that consistent results may be achieved, all variables must be carefully controlled. Where such control is possible, extremely dilute suspensions may be measured.

The specimen solute is dissolved in the solvent at several different accurately known concentrations, the choice of concentrations being dependent on the molecular weight of the solute and ranging from $1 \%$ for $M_{w}=10,000$ to $0.01 \%$ for $M_{w}=1,000,000$. Each solution must be very carefully cleaned before measurement by repeated filtration through fine filters. A dust particle in the solution vitiates the intensity of the scattered light measured. A criterion for a clear solution is that the dissymmetry, $45^{\circ} / 135^{\circ}$ scattered intensity ratio, has attained a minimum.

The turbidity and refractive index of the solutions are measured. From the general $90^{\circ}$ light-scattering equation, a plot of $H C / \tau$ versus $C$ is made and extrapolated to infinite dilution, and the weightaverage molecular weight, $M$, is calculated from the intercept, 1/ $M$.

## Visual Comparison

Where a color or a turbidity comparison is directed, color-comparison tubes that are matched as closely as possible in internal diameter and in all other respects should be used. For color comparison, the tubes should be viewed downward, against a white background, with the aid of a light source directed from beneath the bottoms of the tubes, while for turbidity comparison the tubes should be viewed horizontally, against a dark background, with the aid of a light source directed from the sides of the tubes.

In conducting limit tests that involve a comparison of colors in two like containers (e.g., matched color-comparison tubes), a suit able instrument, rather than the unaided eye, may be used.

# GENERAL CHAPTERS 

## General Information

## Briefing

$\langle\mathbf{1 0 7 0}\rangle$ Emergency Medical Services Vehicles and Ambu-lances-Storage of Preparations. Following the PSD Open Conference in October 2003, the PSD Expert Committee determined that the treatment of the handling and storage of medications in emergency medical services vehicles had to be on a separate, faster track from the rest of the content of the proposed general chapter Good Storage and Shipping Practices $\langle 1079\rangle$ (see page 1612 of PF 29(5) [Sept.-Oct. 2003]. As a result of the considerable discussion of this topic at the Open Conference, the text is revised extensively from that which appeared in the conference workbook. It is proposed here as an informational chapter. This proposed general chapter includes a list of the most commonly used articles in EMS vehicles. Readers are invited to submit any available stability data that will allow assignment of reasonable storage and handling limits for these preparations. Alternatively, typical residence time stability studies at elevated and reduced temperature conditions for the limited drugs in this list are invited. Because space is limited in an EMS vehicle, identification of just those preparations having more stringent storage requirements would have practical benefit. In preparing this text for public comment, the Expert Committee has drawn on input from several notable experts in this area.
(PSD: C. Okeke) RTS-41624-1

Add the following:
> - \{1070〉 EMERGENCY MEDICAL SERVICES VEHICLES AND AMBULANCES-STORAGE OF PREPARATIONS

The storage and handling of pharmaceuticals in emergency vehicles and ambulances should be done so that the attributes of the official articles are preserved. For examples, see the list below for typical articles. There are a number of
practices that need consideration when an effective plan is formulated, evaluated, put in place, and periodically re-evaluated. Those practices are listed here.

Monitoring devices should be in place to record weekly temperatures, and allow calculation of mean kinetic temperature for conformance to controlled room temperature storage for those vehicles utilized continuously. Measurement should also be made during a typical challenging 24-hour period, and the derived temperature should be used for calculation of MKT and storage temperature of the sample.

## PHARMACEUTICAL STORAGE CABINET MONITORING; LOCATION OF PARKED <br> VEHICLES

Ambulances and other emergency medical response vehicles that routinely carry Pharmacopeial articles should be monitored to verify that temperature profiles and on-board pharmaceutical storage cabinets or cold chests are within established limits. Suitable monitoring devices are to be placed in the pharmaceutical cabinet of each vehicle that records highest and lowest temperatures, at the least, of each hot summer and cold winter day. Ambulance personnel should consider parking in the shade or in air-conditioned garages in the summer or in heated garages in the winter to avoid temperature extremes.

## STOCK ROTATION

A program of regular stock rotation should be in place for articles with low rates of turnover. Rotation is understood as transfer of the articles with suitable marking of stock items to an appropriate climate controlled facility or storage cab-
inet such as in an ambulance bay. Off-vehicle storage of each article is subject to the storage requirement in the approved labeling or the pertinent USP monograph.

## PORTABLE CARRYING CASE STORAGE AND MONITORING

The portable bag or carrying case in which drugs are kept is to be insulated, and when not in use, should be kept in a pharmaceutical storage cabinet or at controlled room temperature within facilities. Storage in portable bags or cases only rather than in on-board cabinets should be considered to facilitate stock rotation where that is indicated. The use of time-temperature indicators is recommended to monitor cumulative insult to the contents of all compartments.

## ADDITIONAL REQUIREMENTS FOR SOME <br> ARTICLES

All articles are to be protected from excessive heat, $40^{\circ}$. If the article requires storage in a cold or dry place or at controlled room temperature, then suitable measures are to be taken to maintain it within the defined limits, see General Notices-Preservation, Packaging, Storage, and Labeling. Articles that have the most stringent storage requirements determine the storage of mixed loads.

## STORAGE AND HANDLING OF SENSITIVE PREPARATIONS

Environmentally Sensitive Preparations (see $\langle 386\rangle$ ) are not to be stored in emergency response vehicles unless the on-board cabinet in which the medications is stored is climate controlled or a time-temperature indicator is attached to each package. If Environmentally Sensitive Preparations
must be kept in the EMS vehicle, then medications supply should be rotated with reserve stock on a schedule based on local climate, but not longer than every 3 days.

## USE OF TIME-TEMPERATURE INDICATORS

Attach time-temperature indicators to individual Thermally Sensitive Preparations where time outside of the on-board cabinet can exceed 4 days total. On-board cabinets must be insulated and should use active heating/cooling devices in accord with the local climate and as specified for the preparations while medications are inside.

## COMPOSITE INVENTORY OF TYPICAL AMBULANCE SERVICE MEDICATIONS

NOTE-Each vehicle may carry only a portion of the articles herein, or others.

Adenosine Injection
Afrin
Albuterol Sulfate Injection
Amiodarone
Amyl Nitrite Inhalant
Aspirin Tablets
Atropine Sulfate Injection
Atropine and 2-PAM Antidote [Mark 1 Kits]
Atrovent
Bretylium Tosylate Injection
Calcium Chloride Injection
Calcium Gluconate Injection

## Activated Charcoal

Dextrose 50\%, Dextrose 25\% Injection
Diazepam Gel
Diazepam Injection
Diltiazem
Diphenhydramine Injection
Dopamine Injection
Epinephrine $1: 10000$, Epinephrine $1: 1000$ Injection Furosemide Injection
Glucagon for Injection
Lidocaine Hydrochloride Injection, Lidocaine 1\% Gel
Magnesium Sulfate
Methylprednisone
Metoprolol
Midazolam
Morphine Sulfate Injection
Nalbuphine
Naloxone Hydrochloride Injection
Nitroglycerin Spray, Nitroglycerin Tablets,
Nitroglycerin Ointment
Oxytocin Injection
Promethazine
Sodium Bicarbonate Injection
Sodium Nitrite Injection
Sodium Thiosulfate Injection
Terbutaline Injection
Tetracaine Ophthalmic Solution, Ointment
Thiamine Hydrochloride Injection
Toradol Injection $\mathbf{Q 2 S}^{\text {(USP28) }}$

## BRIEFING

$\langle\mathbf{1 1 1 2}\rangle$ Microbiological Attributes of Nonsterile Pharmaceutical Products-Application of Water Activity Determination, page 2009 of $P F 28(6)$ [Nov.-Dec. 2002]. This new chapter, which previously appeared in Pharmacopeial Previews, is now moved to In-Process Revision with the following changes on the basis of comments received:
(1) The title of the chapter has changed.
(2) The importance of container-closure integrity in maintaining the water activity level during the product shelf life is emphasized.
(3) Reduced microbial limits testing must be justified through risk assessment and not solely on water activity determinations.
(4) The ability of more resistant microorganisms to persist in drug products of low water activity is acknowledged.
(AMB: D. Porter) RTS-41476-1

## Add the following:

## 〈1112〉 MICROBIOLOGICAL ATTRIBUTES OF NONSTERIEE PHARMACEUTICAL PRODUCTSAPPLICATION OF WATER ACTIVITY DETERMINATION APPLICATION OF WATER ACTIVITY DETERMINATION TO NONSTERILE PHARMACEUTICAL PRODUCTS

The determination of the water activity of nonsterile pharmaceutical dosage forms aids in the decisions relating to the following:
(a) optimizing product formulations to improve antimicrobial effectiveness of preservative systems,
(b) reducing the degradation of active pharmaceutical ingredients within product formulations susceptible to chemical hydrolysis,
(c) reducing the susceptibility of formulations (especially liquids, ointments, lotions, and creams) to microbial contamination, and
(d) providing a tool for the rationale for reducing the frequency of microbial limit testing and screening for objectionable microorganisms for product release and stability testing using methods contained in the general test chapter Microbial Limit Tests $\langle 61\rangle$.

Reduced water activity ( $a_{W}$ ) will greatly assist in the prevention of microbial proliferation in pharmaceutical products; and the formulation, manufacturing steps, and testing of nonsterile dosage forms should reflect this parameter.

Low water activity has traditionally been used to control microbial deterioration of foodstuffs. Examples where the available moisture is reduced are dried fruit, syrups, and pickled meats and vegetables. Low water activities make these materials self-preserved. Low water activity will also prevent microbial growth within pharmaceutical drug products. Other product attributes, for example, low or high pH , absence of nutrients, presence of surfactants, and addition of antimicrobial agents, as well as low water activity, help to prevent microbial growth. However, it should be noted that more resistant microorganisms, including spore-forming

Clostridium spp., Bacillus spp., Salmonella spp. and filamentous fungi, although they may not proliferate in a drug product with a low water activity, may persist within the product.

When formulating an aqueous oral or topical dosage form, candidate formulations should be evaluated for water activity so that the drug product may be self-preserving, if possible. For example, small changes in the concentration of sodium chloride, sucrose, alcohol, propylene glycol, or glycerin in a formulation may result in the creation of a drug product with a lower water activity that can discourage the proliferation of microorganisms in the product. This is particularly valuable with a multiple-use product that may be contaminated by the user. Packaging studies should be conducted to test product stability and to determine that the con-tainer-closure system protects the product from moisture gains that would increase the water activity during storage.
Reduced microbial limits testing may be justified through risk assessment. This reduction in testing, when justified, may entail forgoing full microbial limits testing, implementing skip-lot testing, or eliminating routine testing.

Nonaqueous liquids or dry solid dosage forms will not support spore germination or microbial growth due to their low water activity. The frequency of their microbial monitoring can be determined by a review of the historic testing database of the product and the demonstrated effectiveness of microbial contamination control of the raw materials, ingredient water, and the manufacturing proess manufacturing process, formulation, and packaging system. The testing history would include microbial monitoring during product development, scale-up, process validation, and routine testing of sufficient marketed product lots (e.g., up to 20 lots) to ensure that the product has little or no potential for microbial contamination. Because the water activity requirements for different Gram-reactive bacteria, bacterial spores, yeasts, and molds are well described in the literature, ${ }^{1}$ the appropriate microbial limit testing program for products of differing water activities can be established. For example, Gram-negative bacteria including the specific objectionable microorganisms, Pseudomonas aeruginosa, Escherichia coli, and Salmonella species will not proliferate or survive in preserved products with water activities below 0.91 , while Gram-positive bacteria such as Staphylococcus aureus will not proliferate below 0.86, and Aspergillus niger will not proliferate below 0.77 . Furthermore, even the most osmophilic yeast and xerophilic fungi will not proliferate below 0.60 , and they cannot be isolated on compendial microbiological media. ${ }^{1}$ The water activity requirements measured at $25^{\circ}$ for the growth of a range of representative microorganisms are presented in Table 1.

[^257]Table 1. Water Activities $\left(a_{W}\right)$ Required to Support the Growth of Representative Microorganisms

| Bacteria | Water Activity $\left(a_{w}\right)$ | Molds and Yeast | Water Activity $\left(a_{w}\right)$ |
| :--- | :---: | :---: | :---: |
| Pseudomonas aeruginosa | 0.97 | Rhyzopus nigricans | 0.93 |
| Bacillus cereus | 0.95 | Mucor plumbeus | 0.92 |
| Clostridium botulinum, | 0.95 | Rhodotorula mucilaginosa | 0.92 |
| Type A |  |  |  |
| Escherichia coli | 0.95 | Saccharomyces cerevisiae | 0.90 |
| Clostridium perfringens | 0.95 | Paecilomyces variotti | 0.84 |
| Lactobacillus viridescens | 0.95 | Penicillium chrysogenum | 0.83 |
| Salmonella spp. | 0.95 | Aspergillus fumigatus | 0.82 |
| Enterobacter aerogenes | 0.94 | Penicillium glabrum | 0.81 |
| Bacillus subtilis | 0.90 | Aspergillus flavus | 0.78 |
| Micrococcus lysodekticus | 0.93 | Zygosachharomyces rouxii | 0.77 |
| Staphylococcus aureus | 0.86 | (osmophilic yeast) | 0.62 |
|  |  | Xeromyces bisporus |  |
| Halobacterium halobium | (xerophilic fungi) | 0.61 |  |
| (halophilic bacterium) |  |  |  |

Pharmaceutical drug products with water activities well below 0.75 (e.g., direct compression tablets, powder and liquid-filled capsules, nonaqueous liquid products, ointments, rectal suppositories, etc.) would be excellent candidates for reduced microbial limit testing for product release and stability evaluation. This is especially true when pharmaceutical products are made from ingredients of good microbial quality, when manufacturing environments do not foster microbial contamination, when there are processes that inherently reduce the microbial content, when the formulation of the drug product has antimicrobial activity, and when manufacturing sites have an established testing history of low bioburden associated with their products. Table 2 contains suggested microbial limit testing strategies
for typical pharmaceutical and over-the-counter (OTC) drug products based on water activity. Other considerations, as listed above, would be applied when setting up the microbial limits testing program for individual drug products because water activity measurements cannot solely be used to justify the elimination of microbial content testing for product release.

Similar arguments could be made for the microbial limits testing of pharmaceutical ingredients. However, this would require pharmaceutical manufacturers to have a comprehensive knowledge of the pharmaceutical ingredient manufacturer's manufacturing processes, quality programs, and testing record. This could be obtained through a supplier audit program.

Table 2. Microbial Limit Testing Strategy for Typieal Representative Pharmaceutical and OTC Drug Products Based on Water Activity

| Products | Water Activity $\left(a_{W}\right)$ | Greatest Potential <br> Contaminants | Testing Recommended |
| :---: | :---: | :---: | :---: |
| Nasal inhalant | 0.99 | Gram-negative bacteria | TAMC, ${ }^{*}$ TCYMC, absence of $S$. aureus and $P$. aeruginosa |
| Hair shampoo | 0.99 | Gram-negative bacteria | TAMC, TCYMC, absence of $S$. aureus and $P$. aeruginosa |
| Antacid | 0.99 | Gram-negative bacteria | TAMC, TCYMC, absence of $E$. coli and Salmonella spp. |
| Topical cream | 0.97 | Gram-positive bacteria | TAMC, TCYMC, absence of $S$. aureus and $P$. aeruginosa |
| Oral liquid | 0.90 | Gram-positive bacteria and fungi | TAMC and TCYMC |
| Oral suspension | 0.87 | Fungi | TAMC and TCYMC |
| Topical ointment | 0.55 | None | TCYMG Reduced testing |
| Lip balm | 0.36 | None | None Reduced testing |
| Vaginal and rectal suppositories | 0.30 | None | None Reduced testing |
| Compressed tablets | 0.36 | None | None Reduced testing |
| Liquid-filled capsule | 0.30 | None | None Reduced testing |

* TAMC $=$ Total aerobic microbial count; TCYMC $=$ Total combined yeast and mold count.
note-The water activities cited in Table 2 for the different dosage forms are representative, and companies are urged to test their individual products before developing a testing strategy.

Water activity, $a_{H}$, is the ratio of vapor pressure of $\mathrm{H}_{2} \mathrm{O}$ in product $(P)$ to vapor pressure of pure $\mathrm{H}_{2} \mathrm{O}(P o)$ at the same temperature. It is numerically equal to $1 / 100$ of the relative humidity ( RH ) generated by the product in a closed system. RH can be calculated from direct measurements of partial vapor pressure or dew point or indirect measurement by sensors whose physical or electric characteristics are altered by the RH to which they are exposed.

The relationship between $a_{W}$ and equilibrium relative humidity (ERH) are represented by the following equations:

$$
a_{W}=P / P o \text { and } \operatorname{ERH}(\%)=a_{W} \times 100
$$

The $a_{W}$ measurement may be conducted using the dew point/ chilled mirror method. ${ }^{2}$ A polished, chilled mirror is used as the condensing surface. The cooling system is electronically linked to a photoelectric cell into which light is reflected from the condensing mirror. An air stream, in equilibrium with the test sample, is directed at the mirror which cools until condensation occurs on the mirror. The temperature at which this condensation begins is the dew point from which the ERH is determined. Sample preparation should be considered as it may affect the water activity level of the material tested. Commercially available instruments using the dew point/chilled mirror method or other technologies need to be evaluated for suitability, validated, and calibrated when used to make water activity determinations. These instruments are typically calibrated using saturated salt solutions at $25^{\circ}$ as listed in Table 3.

Table 3. Standard Saturated Salt Solutions Used to Calibrate Water Activity Determination Instruments

| Saturated Salt Solutions | ERH (\%) | $a_{W}$ |
| :--- | :---: | :---: |
| Potassium sulfate $\left(\mathrm{K}_{2} \mathrm{SO}_{4}\right)$ | 97.3 | 0.973 |
| Barium chloride $\left(\mathrm{BaCl}_{2}\right)$ | 90.2 | 0.902 |
| Sodium chloride $(\mathrm{NaCl})$ | 75.3 | 0.753 |
| Magnesium nitrate $\left(\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}\right)$ | 52.9 | 0.529 |
| Magnesium chloride $\left(\mathrm{MgCl}_{2}\right)$ | 32.8 | 0.328 |

## BRIEFING

〈1117〉 Microbiological Best Laboratory Practices, page 842 of PF 29(3) [May-June 2003]. This proposed general information chapter, which previously appeared in Pharmacopeial Previews, has been revised in response to comments received and is now forwarded to In-Process Revision. Along with numerous editorial

[^258]changes, the sections on Media Preparation and Quality Control, Maintenance of Microbiological Cultures, and Interpretation of Laboratory Results underwent substantial revision.
(AMB: D. Porter)
RTS-41617-1

## Add the following:

## - 1117$\rangle$ MICROBIOLOGICAL GOOD BEST LABORATORY PRACTICES

## INTRODUCTION

Good laboratory practices in a microbiology laboratory consist of activities that depend on several principles: aseptic technique, control of media, control of test strains, control of equipment, diligent recording and evaluation of data, and training of the laboratory staff. Because of the known variability in microbiology data, reliability and reproducibility are dependent on the use of accepted methods and adherence to good laboratory practices.

## MEDIA PREPARATION AND QUALITY CONTROL

## Media Preparation

Culture media are the basis for most microbiological tests. While growth media can be prepared in a laboratory from individual components, many laboratories, for their easeef use, use dehydrated media or purchase commereially prepared media in plates of glass entainers. Manufacturers of media attempt to standardize raw materiats frem biologieat sourees, but must constantly deal with unavoidable differ ences in raw materials obtained from natural sources and with lot to lot variability of media. The performanee of media prepared in a laboratory or by a manufacturer is highly dependent on preparation. Improper media preparation can eatuse unsatisfactory conditions for microbial growth or re-
eovery and unreliable results. Safeguarding the quality of this media is therefore critical to the success of the microbiology laboratory. Media preparation, proper storage, and quality control testing can assure a consistent supply of high quality media.

It is important to choose the correct media or components in making media based on the use of accepted sources or references for formulas. The manufacturer's formula and instructions for preparation routinely accompany dehydrated media and ready-made media. Because different media types may have different preparation requirements (e.g., heating, additives, pH adjustment, etc.), it is important to follow these instructions to ensure preparation of acceptable media quality. A certificate of analysis describing expiry dating and recommended storage conditions accompanies ready-made media, as well as the quality control organisms used in growth-promotion and selectivity testing of that media.

Water is the universal diluent for microbiological media. Purified Water is most often used for media preparation, but in certain cases the use of deionized or distilled water may be appropriate. The volume of the water used should be recorded.
Consistent preparation of media requires accurate weighing of dehydrated media or media constituents. A calibrated balance with the appropriate weight range for the ingredients should be used, andelean. Clean weighing containers and tools (such as spatulas) should be used to prevent foreign substances that may alter the composition of the finished media from entering the formulation. The weight of the components should be recorded.

Dehydrated media should be thoroughly dissolved in water prior to dispensing and sterilization. If heating is necessary to help dissolve media, care should be taken not to overheat media as all culture media, to a greater or lesser
extent, are heat-sensitive. The of hot plate with mag netic stirrer is recemmended for consistent mixing and heat ing. Equipment used in the preparation of media should be appropriate to allow for controlled heating and constant agitation and mixing of the media. Darkening of media (Mail-lard-type reaction or nonenzymatic browning) is a general indication of overheating. When adding required supplements to media, adequate mixing of the medium after adding the supplement should be performed.

Preparation of media in phelean or undedicated poorly cleaned glassware can allow inhibitory substances to enter the media. Inhibitory substances can come from detergent residue after cleaning glassware or from prior materials used in the glassware. Be sure that the cleaning process removes debris and foreign matter, and that the detergent is thoroughly rinsed out with high Purified Water. See Cleaning Glass Apparatus $\langle 1051\rangle$ for additional guidance.
Sterilization of media should be performed within the parameters provided by the manufacturer or validated by the user. Commercially prepared media should provide documentation of the sterilization method that was used. Forex temperaneously prepared media, follow the manufacturer's instrutions for heating or sterilization. Ideally the manufacturer should provide the sterility assurance level (SAL) of the media against a recognized biological indicator. Autoclaving by moist heat is the preferred sterilization technique, except in instances when the manufacturer speifies the use ef boiling is required in order to avoid deterioration of heatlabile components of the media. Sterilization by filtration may also be appropriate for some formulations.

The effects of timperature the sterilization method and conditions on the media should be validated by sterility and growth-promotion testing of the media. In addition, if sterilized by moist heat, the autoclave cycle should be validated to ensure proper heat distribution for se-
lected loads and volumes. Typically, manufacturers recommend using an autoclave cycle of $121^{\circ}$ for 15 minutes using a validated autoclave cycle. These conditions apply to time at temperature of the media. As the load configuration of the autoclave will influence the rate of heating, longer cycles may be required for larger loads. However, the sterilization time will be dependent on the media volume and autoclave load. Sterilization cycles in which the autoclave is slow to come up to temperature may result in overheating of the media. In such eases it may be preferable to the attoclave to deliver a $F_{9}$ of 15 minutes to include the heating up and eooling down part of the cycle. The overkill validation up proach used in many production operations results in -ex treme sterilization conditions and may destroy the growthprometing qualities of most bacterial or myeologieal growth madia. Therefore, care must be taken to validate a sterilization cycle to deliver the minimum SAL required, balancing the need for a sterile media against the tendency of the media to degrade under excessive heating. Storage of the media in the autoclave after the liquid cycle is completed is not recommended after cooling, as it may damage the media. Improper heating or sterilizing conditions-for commercially prepared or internally prepared media-may result in a difference in color change, loss of clarity, altered gel strength, or pH drift from the manufacturer's recommended range.

Check the pH of each batch of medimm The pH of each batch of medium should be confirmed after it has cooled to room temperature $\left(25^{\circ}\right)$ by aseptically withdrawing a sample for testing. A flat pH probe is recommended for agar surfaces, and for liquids an immersion probe is recommended. The pH of media should be in a range of $\pm 0.2$ of the value indicated by the manufacturer, unless a wider range is acceptable by the validated method.

Prepared media should be checked by $100 \%$ inspection of
plates and tubes for the following: cracked containers, un equal filling of containers, dehydration resulting in cracks or dimpled surfaces on solid medium, hemolysis, crystal formation from possible freezing, excessive number of bub-

## bles, and mierebial contamination.

Prepared media should be checked by appropriate inspection of plates and tubes for:

- Cracked containers or lids
- Unequal filling of containers
- Dehydration resulting in cracks or dimpled surfaces on solid medium
- Hemolysis
- Excessive darkening or color change
- Crystal formation from possible freezing
- Excessive number of bubbles
- Microbial contamination
- Status of redox indicators (if appropriate)
- Lot number and expiry date checked and recorded
- Sterility of the media

## Media Storage

It is prudent to consider how the manufacturer or supplier transports and stores media prior to distribution to the end user. Manufacturers of media should use transport and storage conditions that minimize the loss of moisture, control the temperature, and provide mechanical protection to the prepared media.

Media should be labeled properly with batch or lot numbers, preparation and expiration dates, and media identification. Media should be stored according to manufacturer's instructions. Media prepared in-house should be stored under entrolled refrigeration in a seled container. validated conditions. Do not store agar at or below $0^{\circ}$ this eould destroy as freezing could damage the gel structure.

Protect stored media from exposure to light and excessive temperature. Before prolonged storage, agar plates should be placed into a sealed package or container to retard moisture loss.

Remelting of an original container of solid media should be performed only once to avoid media whose quality is compromised by overheating or potential contamination. It is recommended that remelting be performed in a heated water bath or by using free-flowing steam. The use of microwave ovens and heating plates is common, but result in overheating of the media as well as exposing the laboratory stantial care should be take to avoid damaging media by overheating, and to avoid the potential injury to laboratory personnel danger from glass breakage and burns. The molten agar medium should be held in a monitored water bath at a temperature of $45^{\circ}$ to $50^{\circ}$ for not more than 8 hours. Caution should be taken when pouring the media from a container immersed in a water bath to prevent water from the bath comingling with the poured sterile media. Wiping the exterior of the container dry prior to pouring may be advisable.

Disposal of used cultured media (as well as expired media) should follow local biological hazard safety procedures.

## Quality Control Testing

It is important to confim the quality of the media. While growth media can be prepared in a laboratory from individual components, many laboratories, for their ease-of-use, use dehydrated media or purchase commercially prepared media in plates or glass containers. Manufacturers of media attempt to standardize raw materials from biological sources, but must constantly deal with unavoidable differences in raw materials obtained from natural sources and therefore lot-to-lot variability of media must be considered. The performance of media prepared in a laboratory or by a
manufacturer is highly dependent on preparation. Improper media preparation can cause unsatisfactory conditions for microbial growth or recovery and unreliable results.

Quality control tests should be performed on all prepared media. Tests routinely performed on inhouse prepared media are pH , growth promotion, and periodic stability checks to confirm the expiry dating.

When ical media is properly prepared and sterilized using a validated method, then the growth-promotion testing may be limited to each incoming lot of dehydrated media unless otherwise instructed by the relevant compendial method. If the media preparation was not validated, then every batch of media would be subjected to growth-promotion testing. Test organisms may be selected from the appropriate compendial test chapter, based on the manufacturer's recommendation for a particular medium or may include representative environmental isolates.

Expiration dates on media should have supporting growth-promotion testing to indicate that the performance of the media still meets acceptance criteria up to and including the expiration date. All media may be used, i.e., ineet tate the the length of shelf life of a batch of media will depend on the stability of the ingredients and formulation under specified conditions, as well as the type of container and closure.
When a tet batch of media does not meet the requirements of growth-promotion testing, an investigation should be initiated to identify the cause of themeng let. This investigation should include a corrective action plan to prevent the recurrence of the problem. Any nonconforming lot should not be used if an assignable cause or corrective resolution relative to nongrowth support is undetermined.

Some reagents are used for diagnostic purposes to help support identification of microbial organisms, e.g., Gram stain, oxidase test reagents, etc. These may have attributes that can be quality control tested similar to microbiological media. Select the correct quality control standard microorganisms, following the manufacturer's instructions, and perform the testing prior to unknown sample diagnostic testing.

Special care should be taken with media that is used in environmental monitoring studies. It is practice to pre-ineubate prepared paekaged envirenmental monitoring media the relevant test temperature(s) in sealed containers Or plastic sleeves and to-imspect them for any nomsterile units. This will prevent extraneous contamination from be ing earrie int controlled environments and will prevent false pesitive results. Media used for environmental monitoring of critical areas should preferably be double-wrapped and terminally sterilized. If terminal sterilization is not performed, media should be subjected to pre-incubation and $100 \%$ inspection prior to use within a critical area. This will prevent extraneous contamination from being carried into controlled environments and will prevent false-positive results. A raised agar level for surface contact plates should be verified.

## MAINTENANCE OF MICROBIOLOGICAL CULTURES

Biological specimens can be the most delicate standards to handle because their viability and characteristics are dependent on adequate handling and storage. Refereneent fures from national eulture eollections sueh as the Ameriean Type Culture Collection (ATCC) should be han dled and stored with eare. Standardizing the handling and storage of cultures by the user laboratory should be done in a way that will minimize the opportunity for contamination or alteration of growth characteristics. Them-
tures are routinely used for quality control of media and for microbiologieal assays, in both industrial and clinieal mierobiology laboratories, and thus require consistent, aeet rate, and reproducible handling practices. The careful and consistent treatment of stock cultures is critically important to the consistency of microbiological test results. Cultures for use in compendial tests should be acquired from a national culture collection. They Gultures can be acquired frozen, freeze-dried, on slants, or in ready-to-use forms. Confirmation of the identity of standard eulture collection should be performed prior to using the culture in quality entrol testing. Confirmation of the purity of the culture and the identity of the culture should be performed prior to its use in quality control testing. Ready-to-use cultures may require confirmation of purity, identity, and inoculum size. This confirmation of identity for commonly used laboratory strains should ideally be done at the level of genotypic analysis (i.e., DNA fingerprinting, 16 S rRNA gene sequencing or PCR analysis using suitably validated probes).

Preparation and resuscitation of cultures should follow the instructions of the stepplier. The supplier may have to be contacted to determine how it performs quantitation and identifieation, so that the user laboratory can follow the predtres. supplier or a validated, established method. The "Seed-Lot" technique is recommended for storage of stock cultures.

Stock cultures can be matle by transferring a suspension of the original or reference eultures to cryoprotective medium in vials and freezing unted suspensions The original sample from the national culture collection is resuscitated and grown in an appropriate medium. Aliquots of this stock culture (the first transfer or passage) are suspended in cryoprotective medium, transferred to vials and frozen at $-30^{\circ}$ or below, until use. If stored at $-70^{\circ}$, or in lyophilized form,
strains may be kept indefinitely. These frozen stocks can then be used to inoculate monthly or weekly working cultures. Đe Once opened, do not refreeze unused cell suspensions after culturing a working suspension becuse there is an inered risk flos viability suspension. The unused portion should be discarded to minimize the risk of loss of viability and contamination of the stock.

The number of transfers of working control cultures should be tracked to prevent excessive subculturing that increases the risk of phenotypic alteration. The of establishing "Seed Cultures" is recommended, which should be ne mere than five passages from the original stock obtained from the oulture ollection. One passage is defined as the transfer of organisms from a viable culture to fresh medium with growth of the microorganisms. Any form of subculturing is considered to be a transfer/passage.

## MAINTENANCE OF LABORATORY EQUIPMENT

Most equipment (incubators, water baths, autoclaves, etc.) is subject to standard validation practices of incoming qualification, operational qualification, and performance qualification. Additionally, periodic calibration (generally annually) is commonly required. New equipment, critical to the operation of the laboratory, should be qualified according to a protocol approved by the quality assurance unit (QAU).

Equipment Instruments ( pH meters, spectrophotometers, etc.) used in a microbiology laboratory should be calibrated on a regular schedule and tested to verify performance on a routine basis. The frequency of calibration and performance verification will vary based on the type of equipment instrument and the importance of that equipment to the generation of data in the laboratory.

## LABORATORY LAYOUT AND OPERATIONS

Laboratory layout and design should carefully consider the requirements of good microbiological practices and laboratory safety. It is essential that cross-contamination of microbial cultures be minimized to the greatest extent possible, and it is also important that microbiological samples be handled in an environment that makes contamination highly unlikely. The reliability of mierebial laberatery oper-ations-an be enhanced by proper layout; and good separaもion of activities can enhance the reliability of mierobiologieal laboratory operations.

In general, a laboratory should be divided into clean or aseptic areas and live culture areas. These sections of the laboratory should be separated and sheuld have separate ens. Areas in which environmental or sterile product samples are handled and incubated should be maintained completely free of live cultures, if possible. If complete separation of live and clean culture zones cannot be accomplished, then other eountermeasures barriers and aseptic practices should be employed to reduce the likelihood of accidental contamination. These ers include protective clothing, sanitization and disinfection procedures, and biological safety cabinets designated for clean or aseptic operations only. Procedures for handling spills or mishaps with live cultures should be in place and all relevant technical personnel should be trained regarding these methods.

Some samples will demonstrate microbial growth and require further laboratory works the nature of analysis to identify the contaminants. When growth is detected, the sample should be taken from the clean section of the laboratory to the live culture section without undue delay. Subculturing, staining, microbial identification, or other investigational operations should be undertaken in the live culture section of the laboratory. If possible, any
sample found to contain growing colonies should not be opened in the clean zone of the laboratory. Careful segregation of contaminated samples and materials will reduce false-positive results.

Staff engaged in sampling activities should not enter or work in the live culture handling section of a laboratory unless special precautions are taken including protective clothing, gloves, and careful sanitization of hands upon exiting. Ideally, staff assigned to sampling activities, particularly those in support of aseptic processing, should not work in the vicinity of live culture laboratory operations. Also, all microbiological samples should be taken using aseptic techniques including those taken in support of nonsterile products. If possible, all microbiological samples should be taken under full aseptic conditions in specialized sampling areas.

It is important to consider that microbial contamination of samples, which lead to false-positive results, is always possible unless careful aseptic precautions are taken. Facilities should be designed so that raw material and excipient sampling can be done under controlled conditions, including proper gowning and sterilized sampling equipment. It may not always be possible to sample utility systems, such as water systems, under full aseptic conditions; however, it should be noted that when samples are not taken aseptically, their reliability is inevitably compromised.

Environmental sampling methods should require minimal aseptic handling in loading and unloading sampling instruments. Whenever possible, sampling equipment should be loaded with its microbiological recovery media in the environment that is to be sampled.

All testing in laboratories used for critical testing procedures, such as sterility testing of final dosage forms, bulk product, seed cultures for biological production, or cell cul-
tures used in biological production should be performed under fullape controlled conditions. Isolator technology is also appropriate for critical, sterile microbiological testing. Isolators have been shown to have lower levels of environmental contamination than manned clean rooms, and therefore, are generally less likely to produce false-positive results. The general information chapter, Sterility Test ing Validation fisolator Sistems- $\langle 1208$ ), provides gener al guidane on the validation of isolators for sterility testing. Proper validation of isolators is critical both to ensure environmental integrity and to prevent the possibility of falsenegative results as a result of chemical disinfection of materials brought into or used within isolators (see Sterility Testing—Validation of Isolator Systems $\langle 1208\rangle$ ).

## TRAINING OF PERSONNEL

Each person engaged in all phases of pharmaceutical manufacture should have the education, training, and experience to do their job. Mierobiologists in the pharmaceutical taboratory should have sufficient academic training in mi erobiology or allied life seience and should be adequately trained in laberatory procedures and testing doeumentation eonducted in the mierobiology laboratory. The demands of microbiological testing require that the core educational background of the staff, supervisors, and managers be in microbiology or a closely related biological science. They should be assigned responsibilities in keeping with their level of skill and experience.

A coherent system of operating procedures is necessary to run the microbiology laboratory. These procedures serve two purposes in a training program. Firstly, these SOPs describe the methodology that the microbiologist will follow to obtain accurate and reproducible results and so serve as the basis for training. Secondly, by tracking the procedures in which a particular microbiologist has demonstrated pro-
ficiency, the procedure number or title also serves to identify what training the microbiologist has received specific to his or her job function.

Training curricula should be established for each laboratory staff member specific for their job function. They should not independently conduct a microbial test until they are qualified to run the test. Training records should be current, documenting the microbiologist's training in the proper revision to the particular SOP.

Periodic performance assessment is a wise investment in data quality. This performance testing should provide evidence of competency in core activities of the microbiology laboratory such as hygiene, plating, aseptic technique, documentation, and others as suggested by the microbiologist's job function.

Microbiologists with supervisory or managerial responsibilities should have appropriate education and inhouse training in supervisory skills, laboratory safety, scheduling, laberatory investigations, technical report writing, phamaceutical products, and in mantifacturing relevant SOPs and other critical aspects of the company's processes as suggested in their role of directing a laboratory function.

The demands of mierobiologieal testing require that the evre educational background of the-staff, supervisors, and managers be in mierobiolegy or a clesely related biologicat seience.

## DOCUMENTATION

Documentation should be sufficient to demonstrate that the testing was performed in a laboratory and by methods that were under control. This includes but is not limited to documentation of the following:

- Microbiologist training and verification of proficiency
- Equipment validation, calibration, and maintenance
- Equipment performance during test (e.g., 24-hour /7day chart recorders)
- Media preparation, sterility checks, and growth-promotion eapability and selectivity capabilities
- Media inventory and control testing
- Critical components of test conducted as specified by a procedure
- Data and calculations verified
- Reports reviewed by QAU or a qualified responsible manager
- Investigation of of specification results data deviations (if needed).

## MAINTENANCE OF LABORATORY RECORDS

Proper recording of data and studies is critical to the success of the microbiology laboratory. The over-riding principle is that the test should be performed as written in the SOP, the SOP should be written to reflect how the test is actually performed, and the laboratory notebook should provide a record of all critical details needed to confirm the integrity of the data. At a minimum, the laboratory write-up should include the following:

- Date
- Material tested
- Microbiologist's name
- Procedure number
- Document test results
- Deviations (if any)
- Documented parameters (equipment used, microbial stock cultures used, media lots used)
- Management/Second review signature

Every critical piece of equipment should be noted in the write-up, and all should be on a calibration schedule documented by SOP and maintenance records. Where appropriate, logbooks or forms should be available and supportive of
the laboratory notebook records. Equipment temperatures (waterbaths, incubators, autoclaves) should be recorded and traceable.

Training currieula should be established for each labora fory staff member specific for their job fanction. They should not independently conduet a mierobial test until they are qualified to rum the test. Training records should be current, doeumenting the mierobiologist's training in the proper revision to the partieular SOP. This The governing SOP and revision should be clearly noted in the write-up. Changes in the data should be crossed off with a single line and initialed. Original data should not be erased or covered over.

Test results should include the original plate counts, allowing a reviewer to recreate the calculations used to derive the final test results. Methods for data analysis should be detailed in cited SOPs.

All laboratory records should be archived and protected against catastrophic loss. A formal record retention and retrieval program should be in place.

## INTERPRETATION OF ASSAY RESULTS

Analytical microbiological assay results can be difficult to interpret for several important reasons: (1) Microorganisms are both ubiquitous in nature and common environmental contaminants; particularly organisms associated with humans predominate in many types of microbiological analysis; (2) The analyst has the potential to introduce contaminating organisms during sample handling or processing in the laboratory; (3) Microorganisms may not be homogeneously distributed within a sample or an environment; and
(4) Growth and reeovery based mierobiologieat Microbiological assays are subject to considerable variability of out-
come. as ypieal variability may be on the order of $\pm 0.5$ togit. Therefore, minor differences from an expected outcome may not be significant.

Because of these characteristics of microbiological analysis, laboratory studies should be conducted with the utmost care to avoid exogenous contamination as previously discussed in this chapter. Equally important, results must be interpreted from a broad microbiological perspective considering not only the nature of the putative contaminant, but the likelihood of that organism(s) surviving in the pharmaceutical ingredient, excipient, or environment under test. In addition, the growth characteristics of the microorganism should be considered (especially in questions of the growth of filimentous fungi in liquid media).

When results are observed that do not conform to a compendium monograph or another established quantitative target, an investigation into the finding is required. There are generally two distinct reasons for the observation of microbial contamination that does not comply with a target or requirement: There may be either a laboratory error or laboratory environmental conditions that produced an invalid result, or the product contains a level of contamination or specific types of contaminants outside established levels or limits. In either case, laboratory management and, in most cases, general management should be notified immediately.

A full and comprehensive evaluation of the situation surrounding the result should be undertaken. All microbiological conditions or factors that could bring about the observed condition should be fully considered, including the magnitude of the excursion compared to established limits or levels. It is critical to know if the finding is statistically significant in light of assay variability.

The laboratory environment, the protective conditions in place for sampling, historical findings concerning the material under test, and the nature of the material particularly with regard to microbial survival or proliferation in contact with the material should be considered in the investigation.
Eaboratories should as a standard practice retain preparafions, difutions, and any other assay related materials or artieles that might be usefuliminvestigating a test outeome. In addition, interviews with the laboratory analyst(s) may provide information regarding the actual conduct of the assay that can be valuable in determining the reliability of the result and in determining an appropriate course of action. If laboratory operations are identified as the cause of the nonconforming test outcome, then a corrective action plan should be developed to address the problem(s). Following the approval and implementation of the corrective action plan, the situation should be carefully monitored and the adequacy of the corrective action determined.

If assay results are invalidated based upon the discovery of an attributable error, this action must be documented. Laboratories also should have approved procedures for confirmatory testing (retesting), and if necessary, resampling where specific regulatory or compendial guidance do not govern the conduct of an assay investigation. Mieraby taberatery investigations frequently do not reveal the sotree of contamination because miereorganisms are ubiquiteus. Pharmacopeial and regulatory ageney guidelines present instructions for handling mierobiological result failures for some tests, particularly for sterility and bacterial endotoxin testing (see Sterility Tests $\langle 77$ ) and Bueterial Endetoxin Fests (85) ). These instructions should be followed in addition to the laboratory investigation.u2S (USP28)

## Briefing

〈1136〉 Packaging—Unit of Use, page 1215 of $P F$ 29(4) [JulyAug. 2003]. This proposed general information chapter, which previously appeared in the In-Process Revision section, has been modified based on comments received at the PSD Open Conference held October 12-15, 2003, in Washington, DC. Changes were made to the definitions to make the chapter consistent with the definitions in the General Notices. Other changes were made to clarify the intent of the chapter.
(PSD: C. Okeke) RTS-40548-6; 40704-1; 41220-1

## Add the following:

## ■ $\langle 1136\rangle$ PACKAGING—UNIT OF USE

## INTROPUCTION

This chapter is intended to provide guidance in the applieation of unit of use packaging. Unit-of use packaging, when provided by the manufacturer, offers some of the following attractive advantages. (1) The ability to dispense a desage form to a patient in the manufacturer's original container ensures that the-suitability of the container has been established based on the manufacturer's stability studies. (2) Gounting and repackaging of dosage units in the pharmacy is eliminated, thereby reducing the pessibility of human erfor. (3) The pharmacist is able to affix the label for the patient onto the unit-of use package and is free to use the manufacturer's expiration date as the beyond use date (provided that the date is equivalent to one year or less, and that other factors were-considered that might cause a-different beyond use date to be necessary). (4) The number of dosage units in a single unit of use package may be determined on a ease by case basis.

## DEFINHTHA

GONTAINER CLOSURE SYSTEM-is equivalent to a packas ing system. It is the sum of the packaging components that, together, contain and protect the dosage form. UNTI OF USE PACKAGE-is a container elosure-system that is designed to hold a specifie quantity of a drug product for a specific use and that is to be dispensed to a patient without any modification exeept for the addition of apprepriate la beling (see General Notices and Requirements). The pack aging of a unit of use system may be a multiple unit eontainer or a unit dose single-unit container. A unit of use may be a drug product in either a liquid or solid dosage form (see also the FDA Guidance for Industry on Containex Closure Systems for Packaging Human Drags and Biolog ies). [NOTE-The terms unit-of use package and a unit-ofuse container may be used interchangeably.] PEBLISTERING is the process of removing medication from a blister type container.

MMMEDHATE CONTAINER-is acontainer that is in direct contact with the article or preparation.

MATERIALSOF CONSTRUCTION-include substances used to manufacture-or package components-such as glass, plasties Fincluding high-density polyethylene-(HDPE), low density polyethylene (LDPE), and polypropylene (PP)], resins, and other materials as listed in the general test chapter Con tainers $(664$ ) and in the FDA Guidance for Industry on Comainer Closure Syistems for Packaging Haman Drugs and Biologics.

## TYPE OF-CONTAHNER FOR UNHT OF-USE

## Single-Unit Container

A single-mit container is a minit doseor asingle-doseconminer intended for either oral or parenteral use. See-Generat Notices and Requirements.

## UNHT DOSE CONTAINER

A single unit container or a single dose container, unit dose container, intended for oral use, is a container that has been packaged in the desage regime for the-course-of the therapy appropriate for the drug that is to be adminis tered.

## SINGLE-DOSE CONTAINER

A single-dose container, intended for parenteral use, is a eontainer that has been packaged in the dosage regime for the course of the therapy appropriate-for the drug that is to be administered.

## Multiple-Unit Container

A multiple unit or a multiple dose container is prepack aged in bettles or containers for injections of the drug in appropriate quantities. A multiple-dose container is a multipleunit container for articles intended for parenteral administra-tien-only.

## MATERLALS-OF-CONSTRUCTHON

## Unit-of-Use-Container

The Peisen Prevention Packaging Act (PPPA) of 1970 att therizes the use of special packaging child-resistant and senior friendly packaging. Child resistant packaging protects children frem serious injury or illness from ingesting or handling hazardous household products ineluding drugs. Unit of use containers are required to be child resistant. Unit of use containers in child resistant single unit containers include-supported blisters, sueh as-separate, peet,
push, and tear noteh; and enelosed or in-card blisters, sueh as pull tabs, slide packs, ete. Unit-of use containers in mat tiple unit containers include glass and plastic containers.

## GLASS

The packaging material equivalent to the immediatecentainer that is glass meets the glass test requirements Any glass packaging material used in the immediate container should meet the glass test requirements for Limits for Glass Fypes and Chemical Resistance Glass-Comtainers: Pow dered Glass, Weter Attack at 121, and Arsenic under the general test chapter Containers- $\langle 664$ )=

## PLASTIE

The packaging material equivalent to the immediatecen tainer that is plastic meets the test requirements Any plastic packaging material used in the immediate container should meet the plastic test requirements for Plasties in the generat test chapters-Containers $\langle 664$ ) and Containeris Permeafien $\langle 674\rangle$. Depending on the type of plastic packaging mat terial used, the packaging material meets the requirements for Biologieal Tests Plasties and Other Polymers, Physierehemical Tests Plasties, Polyethylene Containers, Poly ethylene Terephthalate/Polyethylene Terephthatate $G$, and Polypropylene Containers.

The test for meisture vaper transmission may be carried out as described in the general test chapter Containers-Permeation-(674) for multiple unit and unit dose containers.

## PACKAGING-CLOSURE TYPES

Reclosables and nonreclosables may be used for both sol id and liquid dosage forms. Both must be packaged in compliance with the 16 CFR 1700.15-standards.

## Reclosables

Reclesables are containers with suitable clesures that may incorperate tamper evidence and child resistance capabilities. Reclosables may be used for glass or plastic containers.

#### Abstract

\section*{Nonreclosables}

Nenreclosables are containers with clesures that are nen-reclosable-such as blisters, sachets, strips, and other singleunit containers. Nenreclosables may include packs such as celd formed feil blisters, feil strip packs, and PVC/Aclar eembining multilayer materiats that are therme-formed or eold-formed foil blisters (see Packaging Practie Re packaging a Single Solid Oral Drag Product Into a Unit Pose Container $\langle 1446$ ). Nenreclesables may be child resis ant depending on the intended use and place of use. Heuseheld nenreelesables are subject to the PPPA as definedin-16 ERF 1700.14. However, because of some unit dose designs, not all unit dose packages comply with the PPPA.

\section*{士ABELING}

The unit of use entainers are labeled as such to include manufacturer's lot numbers, aceuracy or bar codes, andex piration dates expiration dates, and in some instances, the manufacturer's lot numbers and bar codes as provided in the Labeling section of the-General Notices and Require ments under Preservation, Packaging, Storage, and Label ing. Some of the advantages of having bar codes on the label include reduced medieationerrors, improved inventery con-

frol, and improved aceess to medieation identity. The labeling covers information placed in the pack by the manufac turer and the label added at the dispensing stage by the pharmacist. container by the manufacturer (see General Nofices and Requirenents). Acceptable labeling can range from the full labeling for multiple-unit containers to an abbreviated labeling when the container is too small to include all the text. Full labeling may atso be provided on the carton if it is net present on the immediate container.

## REPACKAGING AND-REPROCESSING

Unit-of use containers are reprocessed or repackaged as instructed by the manufacturer or as directed in the generat test chapter Containers $\langle 664$ ) or in the general information ehapter Packaging Practice Repackaging a Single Solid Oral Drug Product Into a Unit Dose Container- $\langle 1146\rangle$.-A unit of use package may not be reprocessed by a pharmacist ence it has been deblistered from a unit dose container (see General Notices and Requirements for application of the appropriate beyond use date for a multiple unit or unit dose eontainer). However, under eurrent Good Manufacturing Practices (eGMPs) and tight quality controls, the manufactarer or contract repackager may repackage and reprocess unit of use containers.

## RESPӨNS円ВЩНY OF THE DЏSPENSER

The unit of use packageshall contain such label informat tion as the following:

## Eabeling

The labeling on a unit of use container also ineludes a lat beladed at the dispensing stage by the pharmacist. Prior to dispensing the unit of use package, the-dispenser shall add tabel(s) that provide the following information:
(1) the name of the patient;
(2) the name and strength, the directions for use as preseribed by a doctor or health care provider, and the name of the preseriber, ant
(3) any storage instruction, appropriate package insert, length of days of use, beyond use date, and other infor mation as deemed appropriate by federal and state laws. In the pharmacy setting, pharmacists are encouraged to use bar codes, in conjunction with computerized prescription orders, to conflrm that the right drug is being dispensed to the right patient. Bar coding would minimize errors and ereate-opportanity for medieation fraceability and accountability.

## Information-to-Patient

Patients must be given information that applies to the speeifie brand of prodtret being dispensed.

## INFORMATION FROM MANUFACTURERS

The manufacturer should provide appropriate product de velopment or stability data information that can be used to determine appropriate labeling, storage, and shipping statements that will properly inform patients and practitioners. The manufacturer may make other assurances based on product information and data on packaging and distribution arfangements. In the event that a product is not to be repackaged, the manufacturer may state so-in the labeling. The manufacturer also includes labeling and information suitable for optimal handling by the practitioner and the patient. The labeling and information should be bar coded to eliminate medication errer and promete medieation tracenbility.

## QUАЦНТ CONTROL OF PACKAGHNG SYSTEM

The packaging system shall meet the general considera-
tions for system suitability, pretection, safety, and perfor
manee characteristies as deseribed in the FDA Guidtace
for Industry on Container Closure Systems for Packaging
Human Drugs and Biologies, in the general test chapter
Containers- $\langle 664$, and in the general information chapter
Packaging Practice Repackaging a Single Solid Orat
Prug Product Into a Unit Dose Container-(1146):

## INTRODUCTION

This chapter provides guidance in the use and application of unit-of-use packaging and is intended for use by drug manufacturers, repackagers, and pharmacists. Suppliers of packages and packaging components may find the information useful, as well.

The General Notices defines a unit-of-use container as one that contains a specific quantity of a drug product that is intended to be dispensed as such without further modification except for the addition of appropriate labeling.

Unit-of-use packaging, when provided by the manufacturer, offers some of the following attractive advantages. (1) The ability to dispense a dosage form to a patient in the manufacturer's original container, a practice that recognizes that the suitability of the container has been established on the basis of the manufacturer's stability studies. (2) The counting and repackaging of dosage units in the pharmacy is eliminated, thereby reducing the possibility of human error. (3) The pharmacist is able to affix the label for the patient onto the unit-of-use package and is free to use the manufacturer's expiration date as the beyond-use date. (4) The number of dosage units in a single unit-of-use package may be determined on a case-by-case basis. (5) Patient com-
pliance is improved. (6) The unit-of use package can protect against countertfeiting because traceability of product is ensured through bar coding techniques and NDC numbers.

Unit-of-use packaging, when provided by repackagers, offers the same attractive advantages as those offered by manufacturer. However, unit-of-use repackagers should conform to all requirements as presented in Good Repackaging Practices $\langle 1178\rangle$. There are a number of reasons as to why repackagers produce unit-of-use packaging; for example, (1) requests from institutions, (2) better inventory control, (3) reduced dispensing times, and (4) variations in some drug therapies.

The packaging of a unit-of-use system may be a multiple container or a single-unit container. A unit-of-use system may contain a drug product in a liquid, semi-solid, or solid dosage form (see also the FDA Guidance for Industry on Container Closure Systems for Packaging Human Drugs and Biologics). [NOTE-The terms unit-of-use package and unit-of-use container may be used interchangeably.]

The Poison Prevention Packaging Act (PPPA) of 1970 requires in certain cases the use of special packaging-child-resistant and senior-friendly. Child-resistant packaging protects children from serious injury or illness resulting from ingesting or handling hazardous products including drugs.

Since drugs packaged in unit-of-use packaging are intended to be dispensed to the consumer without repackaging by the pharmacist, the manufacturer or repackager is responsible for the special packaging of PPPA-regulated substances in unit-of-use containers (16 CFR 1701.1).

## TYPES OF CONTAINERS FOR UNIT-OF-USE

Unit-of-use containers are required to be child-resistant if they are intended to be dispensed directly to the patient pursuant to a prescription. Unit-of-use packaging intended for
institutional or hospital use may or may not be required to be child-resistant. Unit-of-use containers that are child-resistant single-unit containers include supported blisters, such as separate, peel, push, and tear notch and enclosed or incard blisters, such as pull tabs and slide packs. Blister packaging is discussed in the general chapter Packaging Practice—Repackaging a Single Solid Oral Drug Product Into a Unit-Dose Container $\langle 1146\rangle$. Unit-of-use containers that are multiple-unit containers include glass and plastic containers.

## Single-Unit Container

A single-unit container is one that is designed to hold a quantity of drug product intended for administration as a single-dose or a single finished device intended for use promptly after the container is opened. Preferably, the immediate container and/or the outer container or protective packaging shall be so designed as to show any evidence of tampering with the contents. Each single-unit container shall be labeled to indicate the identity, quantity, and/or strength, name of the manufacturer, lot number, and expiration date of the article.

## Unit-Dose Container

A unit-dose container is a single-unit container for articles intended for administration by other than the parenteral route as a single dose, directly from the container.

## Single-Dose Container

A single-dose container is a single-unit container for articles intended for parenteral administration only. It is labeled as such.

## Multiple-Unit Container

A multiple-unit container is a container that permits withdrawal of successive portions of the contents without changing the strength, quality, or purity of the remaining portion.

## PACKAGING FABRICATION MATERIALS

Packaging fabrication materials include substances used to manufacture packaging containers such as glass, plastics (including high-density polyethylene (HDPE), low-density polyethylene (LDPE), polyethylene terephthalate, polyethylene terephthalate G and polypropylene (PP), other resins, and other materials as listed in the general test chapter Containers $\langle 661\rangle$ and in the FDA Guidance for Industry on Container Closure Systems for Packaging Human Drugs and Biologics.

## Glass

Any glass packaging material used in the immediate container should meet the glass test requirements for Limits for Glass Types and Chemical Resistance-Glass Containers: Powdered Glass, Water Attack at $121^{\circ}$, and Arsenic under the general test chapter Containers $\langle 661\rangle$.

## Plastic

Any plastic packaging material used in the immediate container should meet the plastic test requirements for Plastics in the general test chapters Containers $\langle 661\rangle$ and Con-tainers-Permeation $\langle 671\rangle$. Depending on the type of plastic packaging material used, the packaging material meets the requirements for Biological Tests-Plastics and Other Polymers, Physicochemical Tests-Plastics, Polyethylene Containers, Polyethylene Terephthalate/Polyethylene Terephthalate G, and Polypropylene Containers.

The test for moisture vapor transmission may be carried out as described in the general test chapter ContainersPermeation $\langle 671\rangle$ for multiple-unit and unit-dose containers.

## PACKAGING CLOSURE TYPES

Reclosables and nonreclosables may be used for solid, semi-solid, and liquid dosage forms. Both must be packaged in compliance with the 16 CFR 1700.15 standards.

## Reclosables

Reclosables are containers with suitable closures that may incorporate tamper evidence and child-resistance capabilities. Reclosables may be used for glass or plastic containers.

## Nonreclosables

Nonreclosables are containers with closures that are nonreclosable such as blisters, sachets, strips, and other singleunit containers. Nonreclosables may include packs such as cold-formed foil blisters, foil strip packs, and PVC/Aclar combining multilayer materials that are thermo-formed or cold-formed foil blisters (see Packaging Practice-Repackaging a Single Solid Oral Drug Product Into a UnitDose Container $\langle 1146\rangle$ ). Nonreclosables may be child resistant depending on the intended use and place of use. Household nonreclosables are subject to the PPPA as defined in 16 CFR 1700.14. However, because of some unit-dose designs, not all unit-dose packages comply with the PPPA.

## LABELING

The unit-of-use containers are labeled to include expiration dates, the manufacturer's lot number, the NDC designation, and bar codes as provided in the Labeling section of the General Notices and Requirements under Preservation, Packaging, Storage, and Labeling and in Good Repackaging Practices $\langle 1178\rangle$. Some of the advantages of having bar codes on the label include reduced medication errors, improved inventory control, and improved access to medication identity. The labeling covers information placed in the container by the manufacturer (see General Notices and Requirements). Acceptable labeling can range from the full labeling as for multiple-unit containers to an abbreviated labeling when the container is too small to include all the text. Full labeling may also be provided on the carton if it is not present on the immediate container.

## REPACKAGING AND REPROCESSING

Unit-of-use containers are reprocessed or repackaged as instructed by the manufacturer or as directed in the general test chapter Containers $\langle 661\rangle$ or in the general information chapter Packaging Practice—Repackaging a Single Solid Oral Drug Product Into a Unit-Dose Container $\langle 1146\rangle$. A unit-of-use package that is a blister package may not be reprocessed by a pharmacist once it has been deblistered from a unit-dose container (see General Notices and Requirements for application of the appropriate beyond-use date for a multiple-unit or unit-dose container). Deblistering is the process of removing medication from a blister-type container. However, under current Good Manufacturing Practices (cGMPs) and tight quality controls, the manufacturer or contract repackager may repackage and reprocess unit-of-use containers.

## INFORMATION FROM MANUFACTURERS

The manufacturer should provide appropriate stability information that can be used to determine appropriate labeling, storage, and shipping statements that will properly inform patients and practitioners. The manufacturer may make other assurances based on product information on packaging and distribution arrangements. In the event that a product is not to be repackaged, the manufacturer may state so in the labeling. The manufacturer also includes labeling and information suitable for optimal handling by the practitioner and the patient. The labeling and information should be bar coded to eliminate medication error and promote medication traceability.

## RESPONSIBILITY OF THE DISPENSER

## Labeling

The labeling on a unit-of-use container also includes a label added at the dispensing stage by the pharmacist. Prior to dispensing the unit-of-use package, the dispenser shall add label(s) that provide the following information:
(1) the name of the patient;
(2) the name and strength, the directions for use as prescribed by a doctor or health-care provider, and the name of the prescriber; and
(3) any storage instruction, beyond-use date, and other information as deemed appropriate by federal and state laws.
In the pharmacy setting, pharmacists are encouraged to use bar codes, in conjunction with computerized prescription orders, to confirm that the right drug is being dispensed to the right patient. Bar coding would minimize errors and create opportunity for medication traceability and accountability.

## Information to Patient

Patients must be given information that applies to the specific prescription being dispensed.

## QUALITY CONTROL OF PACKAGING SYSTEM

The packaging system shall meet the general considerations for system suitability, protection, safety, and performance characteristics as described in the FDA Guidance for Industry on Container Closure Systems for Packaging Human Drugs and Biologics, in the general test chapters Containers $\langle 661\rangle$ and Containers-Permeation $\langle 671\rangle$, and in the general information chapter Packaging Practice—Repackaging a Single Solid Oral Drug Product Into a Unit-Dose Container $\langle 1146\rangle \cdot$.2S (USP28)

## Briefing

<1211〉Sterilization and Sterility Assurance of Compendial Articles, USP 27 page 2616. This proposed revision provides numerous updates to the chapter. Lethality value $\left(F_{0}\right)$ is discussed. New taxonomic terms for biological indicator species are used. Differences between biological indicator usage for moist-heat versus gas sterilization are discussed. The sections covering various modes of sterilization have been revised and updated. A section on vapor phase hydrogen peroxide sterilization has been added. The previous discussion pertaining to Stage 2 of sterilization testing has been deleted to reflect the currently official chapter Sterility Tests $\langle 71\rangle$.
(AMB: D. Porter) RTS-41616-1

## Change to read:

This informational chapter provides a general description of the concepts and principles involved in the quality control of articles that must be sterile. Any modifications or variations in sterility test procedures from those described under Sterility Tests $\langle 71\rangle$ should be validated in the context of the entire sterility assurance program and are not intended to be alternative methods to those described in that chapter.

Within the strictest definition of sterility, a specimen would be deemed sterile only when there is complete absence of viable mieroorgenisms from it.
-if it could be demonstrated that it was completely free of
viable microbial contamination. ${ }^{2 S}$ (USP28)
However, this absolute definition cannot currently be applied to an entire lot of finished
-aseptically produced 2S (USP28)
compendial articles because of limitations in testing. Absolute sterility cannot be practically demonstrated tion of erery finished article.

- in any sterility test because of the destructive nature of the test and the limited sensitivity of current methods. ${ }^{2 S}$ (USP28) The sterility of a lot purported to be sterile is therefore defined in probabilistic terms, where the likeliherninn artiele is neeptably remote.
-and provided the likelihood of contamination is sufficiently remote, the product is considered microbiologically safe. ${ }^{\text {m2S (USP28) }}$
Such a state of sterility assurance can be established only through the use of adequate sterilization cycles and subsequent aseptic proeescing, if any, under appropriate current goed manufacturing prac tice, and not by reliance solely on sterility testing.
- for final dosage forms or sterilization of components followed by aseptic processing, if any, under appropriate current good manufacturing practice, and not by reliance solely on sterility testing. ${ }^{\text {2S }}$ (USP28)
The basic principles for validation and certification of a sterilizing process are enumerated as follows:
(1) Establish that the preeess equipment has eapability of operat ing within the required parameters.
-Establish that the process equipment was properly installed, supplied with appropriate utilities, and has the capability of operating within the required parameters (Installation Qualification)..n2S (USP28)
(2) Demonstrate that the critical control equipment and instrumentation are capable of operating within the prescribed parameters for the process equipment
-(Operation Qualification). $\boldsymbol{\bullet}^{2 S}$ (USP28)
(3) Perform replicate cycles representing the required operational range of the equipment and employing actual or simulated product. Demonstrate that the processes have been carried out within the prescribed protocol limits and finally that the probability of microbial survival in the replicate processes completed is not greater than the prescribed limits
-(Performance Qualification). $\mathbf{\bullet 2 S}^{\text {(USP28) }}$
(4) Monitor the validated process during routine operation. Periodically as needed, requalify and recertify the equipment.
(5) Complete the protocols, and document steps (1) through (4) above.

The principles and implementation of a program to validate an aseptic processing procedure are simitar to the validation of a ster ilization process. In aseptic processing, the compenents of the finat dosage form are sterilized separately and the finished article is as sembled in an aseptic manner.
-parallel in some respects to the validation of a sterilization process. In aseptic processing, the components of the final dosage form (e.g., ampuls, vials, stoppers, and syringes) are sterilized separately and the finished article is assembled in an aseptic manner in an appropriately controlled environment.■2S (USP28)

Proper validation of the sterilization process or the aseptic process requires a high level of knowledge of the field of sterilization, andeleanroom technology.
-clean room design and operation, and aseptic manufacturing practice and technology. ${ }^{2 S}$ (USP28)
In order to comply with currently acceptable and achievable limits in sterilization parameters, it is necessary to employ appropriate instrumentation and equipment to control the critical parameters such as temperature, and time, humidity, and sterilizing sas eoneentration, or absorbed radiation.
-pressure and time (moist-heat sterilization), relative humidity, temperature and sterilizing gas concentration (gaseous sterilization), or absorbed radiation (irradiation sterilization). $\quad$ 2S (USP28)
An important aspect of the validation program in many sterilization procedures involves the mployment
$\mathbf{- s e l e c t i o n ~}$ and use ${ }_{\text {2S }}$ (USP28)
of biological indicators (see Biological Indicators for Sterilization $\langle 1035\rangle$ ). The validated and certified
$■_{\text {sterilization }}{ }_{\text {2S (USP28) }}$
process should be revalidated periodieally; however, the revalidat tion program need not neeessarily be as extensive as the originat program.

- evaluated annually to ensure that it is performing as validated; however, this so-called revalidation program need not be as extensive as the original program. ${ }^{2 S}$ (USP28)
A typical validation program, as outlined below, is one designed for the steam autoclave, but the principles are applicable to the other sterilization procedures discussed in this informational chapter. The program comprises several stages:
The Installation Qualification stag is in that eontrols and other instrumentan are properly designed and ealibrated.
-(IQ) stage is intended to establish that the equipment is correctly installed and serviced by appropriate utilities and controls and that other instrumentation are properly designed and calibrated. ${ }^{2 S}$ (USP28)
Documentation should be on file demonstrating the quality of the required utilities such as steam,
$\boldsymbol{■}_{\text {Vacuum, }}$ п2S (USP28)
water, and air. The Operational Qualification

## 

stage is intended to confirm that the empty chamber functions within the parameters of temperature at all of the key chamber locations prescribed in the protocol. It is usually appropriate to develop heat profile records, i.e., simultaneous temperatures in the chamber employing multiple temperature-sensing devices. A typical acceptable range of temperature in the empty chamber is $\pm 1^{\circ}$ when the cham ber temperattre is not less than $121^{\circ}$.

■at a temperature target appropriate to the process. ■2S (USP28) The Confirmatory stage of the validation program,

- or Performance Qualification (PQ) stage, $\mathbf{m}_{2}$ (USP28) is the actual sterilization of materials or articles

■using loading patterns to be employed.■2S (USP28) This determination requires the employment of temperature-sensing

■ and recording $_{\square 2 S}$ (USP28)
devices inserted into samples of the articles as ell as either samples of the articles to which appropriate concentrations of suitable test miervorganisms have been added, or separate biologieal indieators in operationally fully loaded autoclave ennfigurations. The effectiveness of he delivery or penetration into the actual articles and the time of the expesture are the wo main factors that deter mine the lethality of the sterilization process. The final stage of the validation program requires the documentation of the suppert ing data developed-in evecuting the program.
-to assess temperature penetration. The process parameters including heat-up and cool-down data can be used to select an appropriate exposure time for the required process lethality.

Once sterilization parameters of temperature and time are established, the physically measured lethality is assessed with biological indicators. The user should have a scientific rationale for the selection of a biological indicator organism.
The biological indicator system may consist of spores inoculated directly into or onto an article or a packaged biological indicator acquired from a vendor. A variety of strategies can be employed for sterilization cycle evaluation including bioburden based or overkill approaches (see Biological Indicators for Sterilization $\langle 1035\rangle$ and PDA Technical Monograph \#1 for a more detailed treatment of this subject). $\begin{aligned} & \text { 2S (USP28) }\end{aligned}$

It is generally accepted that terminally sterilized injectable articles or critical devices purporting to be sterile, when processed in the autoclave, attain a $10^{-6}$ microbial survivor probability, i.e., assurance of less than one chance in one million that viable microorganisms are present in the sterilized article or dosage form. With
heat-stable articles, the approach often is to considerably exceed the critieal time necessary to achieve the $10^{-4}$ mierobial surviver probability (overkill).
-an overkill approach is frequently chosen. (Overkill is defined in moist-heat sterilization as a process that delivers a
lethality value or $F_{0}$ of $\geq 12$ minutes.) $\mathbf{m}_{\text {2S }}$ (USP28)
However, with an article where extensive heat exposure may have a damaging effect
(i.e., loss of potency, physical attributes, or packaging integrity), $\mathbf{m}_{2 S}$ (USP28)
it may not be feasible to employ this overkill approach. In this latter instance, the development of the sterilization cycle depends heavily on knowledge of the microbial burden of the product based on examination, over a suitable time period, of a substantial number of lots of the presterilized product.
-Particular attention should be given to the number and resistance to moist heat of spore-forming bacteria within the
presterilization bioburden. п2S (USP28)
The D value is the time (in minutes) required to reduce the microbial population by $90 \%$ or $1 \log$ cycle (i.e., to a surviving fraction of $1 / 10$ ), at a specific temperature. Therefore, where the D value of a biological indicator preparation of, for example, Billus stear hermophilus

## -Geobacillus stearothermophilus (formally Bacillus stearo-

thermophilus) ATCC 7953.2S (USP28)
spores is 1.5 minutes under

- defined $_{\text {■2S (USP28) }}$
process parameters (e.g., at $121^{\circ}$, if it is treated for 12 minutes under the same conditions), it can be stated that the lethality input is 8
$\square_{\text {should }}$ result in a spore $\log$ reduction value (SLR) of

8. 12 S (USP28)

The effect of applying this input to the product would depend on the initial microbial burden. Assuming that its resistance to sterilization is equivalent to that of the biological indicator, if the microbial burden of the product in question is $10^{2}$ microorganisms, a lethality input of 2D yields a microbial burden of $1\left(10^{\circ}\right.$ theoretical) and a further 6D yields a calculated microbial survivor probability of $10^{-6}$. (Under the same conditions, a lethality imput of 12 D may be used in a ypieal "overkill"' approach.)
-n2S (USP28)
Generally, the survivor probability achieved for the article under the validated sterilization cycle is not completely correlated with what may occur with the biological indicator. For valid use, therefore, it is essential that the resistance of the biological indicator be greater than that of the natural microbial burden of the article sterilized. It is then apprepriate to make a worst ease assumption and treat the microbial burden as though its heat resistance were equiv alent to that of the biolegieal indieator, although it is not likely that the most resistan of a yypieal mierobial burden isolates will dem enstrate a heat resistance of the magnitude shown by this species, frequently employed as a biolegienl indientor for steam steriliza tion. In the above example, a 12 minute cyele-is considered ade quate for sterilization if the product had a mierobial burden of $10^{-3}$ mieroorganisms. However, if the indieator originally had $10^{6} \mathrm{mi}$ eroorganisms content, actully a-10-3 probability of survival could beexpect; i.e., 1 in 100 biologieal indientors may yield pesitive
results. This type of situation may be avoided by selection of the appropriate biological indieator. Altematively, high content indien tors may be used on the basis of a predetermined acceptable count reduction.
-The widely recognized biological indicators used to evaluate a sterilization process are generally more resistant than the mean resistance of process bioburden. The difference in resistance between moist-heat biological indicators and that of the bioflora can be enormous, although the difference in magnitude is much smaller for gas sterilization. Generally some margin of safety is built into the development and validation of sterilization processes. In moist heat the high resistance of the biological indicator may in and of itself result in worst-case conditions. $\quad$ 2S (USP28)

The D value for the Baeillus stearethemmphilus preparation- determined or verified for these conditions-should be reestablished when a specifie program of validation is changed. Determination ef survival eurves (see Biologieal Indieators-(1035)) -or what has been called the fractional cyele approach may be employed to determine the $D$ value of the biological indicator preferred for the specific sterilization procedure. The fractional cyele approach may also be used to waluate the resistance of the mierobial burden. Fractional cyeles are studied either for mierobial count reduction er for fraction negative achievement. These numbers may be used to determine the lethality of the process under production conditions. The data can be used in qualified production equipment to establish appropriate sterilization cyeles. A suitable biologieal in dientor such as the Bacillus stearothermophilus preparation may be employed also during routine sterilization. Any mierobial burden method for sterility assuranee requires adequate surveillanee of the mierobial resistance of the artiele to detect any changes, in addition to periodic surveillanee of other attributes.
-However, this is unlikely to be true in gas sterilization processes. When allowing for worst-case conditions to ensure safety, it is important to recognize that sterilization processes are always a trade off between microbiological safety and materials resistance to the sterilization process. Processes that deliver far more lethality than is necessary to achieve microbiological safety may damage product or components and actually reduce microbiological safety of the product by affecting container or package integrity.
The D value for the Geobacillus stearothermophilus preparation determined or verified for these conditions should be re-established when a specific program of validation is changed. Criteria for the selection and testing of biological
indicators are also given in ISO 14161 Sterilization of Health Care Products. $\quad$ 2S (USP28)

## Change to read:

## METHODS OF STERILIZATION

In this informational chapter, five methods of terminal sterilization, including removal of microorganisms by filtration, and guidelines for aseptic processing are described. Modern technological developments, however, have led to the use of additional procedures. These include blow-molding (at high temperatures), forms of moist heat other than saturated steam and UV irradiation, as well as on-line continuous filling in aseptic processing. The choice of the appropriate process for a given dosage form or component requires a high level of knowledge of sterilization techniques and information concerning any effects of the process on the material being sterilized. ${ }^{1}$

## Steam

## -Moist-Heat ${ }_{\text {2S }}^{\text {(USP28) }}$

 SterilizationThe process of thermal sterilization employing
$\boldsymbol{■}_{\text {moist }}$ heat $_{\text {n2S }}$ (USP28)
under pressure is carried out in a chamber called an autoclave,
$\square_{\text {or }}$ in process pipe work, or directly in a product container
using microwave, for example, as a heat source.m2S (USP28 It is probably the most widely employed sterilization process. ${ }^{2}$ The basic principle of operation is that the air in the sterilizing chamber is displaced by the saturated steam, achieved by employing vents or traps. In order to displace air more effectively from the chamber and from within artieles, the sterilization cyele may inelude air and steam-vaeution stages. The design or choiee of a cyele for given

[^259]products or compenents depends on a number of factors, including the heat lability of the material, knowledge of heat penetration inte the articles, and other factors described under the validation program (see abeve). Apat frem that description of sterilization cyele parameters, using a temperature of 121 , the $\mathrm{F}_{4}$ concept may be appropriate. The $\mathrm{F}_{4}$, at a particular temperature other than $121^{\circ}$, is the time (in minutes) required to provide the lethality equivalent to that provided at $121^{\circ}$ for a stated time. Modern attoclaves gen erally operate with a control system that is significantly more respensive than the steam reduction valve of older units that have been in serviee for many years. In order for these older whits to achieve the precision and level of enntrol of the eyele-diseussed in this chapter, it may be neeessay to upgrade or modify the con frol equipment and instrumentation on these units. This modifieation is warrantedonly if the chamber and steam jacket are intact for eontinned safe use and if depesits that interfere with heat distribu tion can be removed.
-In moist-heat sterilization employing steam in an autoclave chamber, the air within the chamber can be removed by either gravity or vacuum. In autoclaves, which rely on steam acting directly on articles, the removal of air and penetration of steam into materials may be critical when porous loads are being sterilized. The effectiveness of air removal and steam penetration can best be assessed using biological indicators. Ideally, there should be a relatively close match between physically measured lethality and biological lethality. Air removal is not critical in processes where the steam is used to heat the contents of a container; such loads are often called nonporous. Air and steam mixtures, or hot water under pressure, can also achieve moist-heat sterilization of product in containers. In this case the contents of containers (generally aqueous solutions) are heated in a manner that protects the container-closure system by attempting to equalize pressure on the inside and outside of the container. This type of process is applied only to nonporous loads, and, in this case, air removal is irrelevant. In line moist-heat sterilization on product containers can be accomplished using microwave to heat the contents of a sealed container that holds within it an aqueous solution.■2S (USP28)

## Dry-Heat Sterilization

The process of thermal sterilization of Pharmacopeial articles by dry heat is usually carried out by a batch process in an oven designed expressly for that purpose. A modern oven is supplied with heated, filtered air, distributed uniformly throughout the chamber
by convection or radiation and employing a blower system with devices for sensing, monitoring, and controlling the critical parameters.

- A modern oven is supplied with heated, HEPA-filtered air, distributed uniformly throughout the chamber by convection or radiation and employing a blower system with devices for sensing, monitoring, and controlling the critical
parameters of time and temperature. ${ }^{2 S}$ (USP28)
The validation of a dry-heat sterilization facility is carried out in a manner similar to that for a steam sterilizer described earlier. Where the unit is employed for sterilizing components such as containers intended for intravenous solutions, care should be taken to avoid accumulation of particulate matter in the chamber. A typical acceptable range in temperature in the empty chamber is $\pm 15^{\circ}$ when the unit is operating at not less than $250^{\circ}$.
-The dry-heat sterilization cycle should be not less than 30
minutes at $250^{\circ}$. ${ }^{\text {2S (USP28) }}$
In addition to the batch process described above, a continuous process
-(i.e., a dry-heat sterilization and depyrogenation tun-
nel), $\quad$ 2S (USP28)
is frequently employed to sterilize and depyrogenate glassware as part of an integrated continuous aseptic filling and sealing system. Heat distribution may be by convection or by direct transfer of heat from
$\square_{\text {a heating element }} \mathrm{or}_{\text {2S (USP28) }}$
an open flame. The continuous system usually requires a much higher temperature than cited above for the batch process because of a much shorter dwell time
-(e.g., $350^{\circ}$ for 5 minutes, although temperatures in the
range of $280^{\circ}$ for 3 minutes are adequate). $\quad$. 2 S (USP28)
However, the total temperature input during the passage of the product should be equivalent to that achieved during the chamber process. The continuous process also usually necessitates a rapid cooling stage prior to the aseptic filling operation. In the qualification and validation program, in view of the short dwell time, parameters for uniformity of the temperature, and particularly the dwell time, should be established.

A mierobial survival probability of $10^{-12}$ is considered achiev able for heat stable articles or compenents. An example of a bio logieal indicator for validating and menitoring dry heat sterilization is a preparation of Bacillus subtilis spores. Since dry heat is frequently employed to render glassware or containers free from pyrogens as well as viable mierobes, a pyrogen challenge, where neeessary, should be an integral part of the validation program, e.g., by ineculating one or more of the articles to be treated with 1000 or more USP Units of bacterial endotoxim. The test with timulus lysate could be used to demonstrate that the endotoxie substanee has been inactivated to not more than $1 / 1000$ of the oris inal amount ( 3 log cyele reduction). For the test to be valid, both the original ameunt and, after aceeptable inactivation, the remaining amount of endotoxin should be measured. For additional infor mation on the endotoxin assay, see Bacterial Endotoxins Test $\langle 85\rangle$ :

- An example of a biological indicator suitable for validating and monitoring dry-heat sterilization is a preparation of $B a$ cillus atrophaeus (formally Bacillus subtilis var. niger)

ATCC 9372 spores. Validation of dry-heat processes using biological indicators is necessary only when depyrogenation is not required. Because dry heat is frequently employed to render glassware or containers free from pyrogens as well as viable microbes, a pyrogen inactivation study is necessary. A common target value for pyrogen inactivation is a $3-\log$ reduction. This study is conducted by inoculating test articles with a concentration of endotoxin suitable to demonstrate a 3-log or greater reduction. The resistance of bacterial endotoxins is quite high; therefore, a process that results in a 3-log endotoxin reduction will also result in material that is sterile. See Bacterial Endotoxins Test $\langle 85\rangle$ for the details of the test method. $\quad$ 2S (USP28)

## Gas

## - Ethylene Oxide ${ }_{\text {n2S }}$ (USP28) Sterilization

The choice of gas sterilization as an alternative to heat is frequently made when the material,

- especially the packaging components, $\quad$ 2S (USP28)
to be sterilized cannot withstand the high temperatures obtained in the steam sterilization or dry-heat sterilization processes.
- Under these circumstances irradiation may be a suitable

## sterilization process. 2 2S (USP28)

The active agent generally employed in gaseous sterilization is ethylene oxide of acceptable sterilizing quality. Among the disadvantages of this sterilizing agent are its highly flammable nature unless mixed with suitable inert gases, its mutagenic properties, and the possibility of toxic residues in treated materials, particularly those containing chloride ions.
-It is also possible that direct contact between the gas and microbial cells does not occur if the organisms are occluded
in crystals or within proteineous material. $\mathbf{W 2 S}^{25}$.(USP28)
The sterilization process is generally carried out in a pressurized chamber designed similarly to a steam autoclave but with the additional features (see below) unique to sterilizers employing this gas. Facilities employing this sterilizing agent should be designed to provide adequate

- presterilization humidification and ${ }_{\mathbf{L S}}$ (USP28)
poststerilization degassing, to enable microbial survivor monitoring, and to minimize exposure of operators to the potentially harmful gas. ${ }^{3}$
-This method should only be used when no other method is
practicable. ${ }^{2 S}$ (USP28)
Qualification of a sterilizing process employing ethylene oxide gas is accomplished along the lines discussed earlier. However, the program is more comprehensive than for the other sterilization procedures, because in addition to temperature, the humidity, vacuum or positive pressure, and ethylene oxide concentration also require rigid control. An important determination is to demonstrate that all critical process parameters in the chamber are adequate during the entire cycle. Because the sterilization parameters applied to the articles to be sterilized are critical variables, it is frequently advisable to precondition the load to achieve the required moisture content in order to minimize the time of holding at the required temperature, prior to placement of the load in the ethylene oxide chamber. The validation process is generally made employing product inoculated with appropriate biological indicators such as spore preparations of Beillhusuthilis.

## - Bacillus atrophaeus (formally Bacillus subtilis var. niger)

ATCC 9372. ${ }^{2 S}$ (USP28)
For validation they may be used in full chamber loads of product, or simulated product. The monitoring of moisture and gas concentration requires the use of sophisticated instrumentation that only knowledgeable and experienced individuals can calibrate, operate, and maintain. The biological indicators may be employed also in monitoring routine runs.
As is indicated elsewhere in this chapter, the biological indicator may be employed in a fraction negative mode to establish the ultimate microbiological survivor probability in designing an ethylene oxide sterilization cycle using inoculated product or inoculated simulated product.
One of the principal limitations of the ethylene oxide sterilization process is the limited ability of the gas to diffuse to the innermost product areas that require sterilization. Package design and chamber loading patterns therefore must be determined so that there is minimal resistance to gas diffusion
-during the sterilization process and degassing. 2S $^{2 S}$ (USP28)

## Sterilization by Ionizing Radiation

The rapid proliferation of medical devices unable to withstand heat sterilization and the concerns about the safety of ethylene oxide have resulted in increasing applications of radiation sterilization. It is, however, applicable also to drug substances and final dosage forms. The advantages of sterilization by irradiation include low chemical reactivity, low measurable residues, and the fact that there are fewer variables to control. In fact, radiation sterilization is unique in that the basis of control is essentially that of the absorbed radiation dose, which can be precisely measured.
-This measurement may be readily used for parametric release of the irradiated articles.■2S (USP28)

[^260]Because of this characteristic, new procedures have been developed to determine the sterilizing dose. These, however, are still under review and appraisal, particularly with regard to the need, or otherwise, for additional controls and safety measures. Irradiation causes only a minimal temperature rise, but can affect certain grades and types of plastics and glass.

The two types of ionizing radiation in use are radioisotope decay (gamma radiation) and electron-beam radiation. In either case the radiation dose to yield the required degree of sterility assurance should be established such that within the range of minimum and maximum doses set, the properties of the article being sterilized are acceptable.

For gamma irradiation, the validation of a procedure includes the establishment of article materials compatibility, establishment of product loading pattern and completion of dose mapping in the sterilization container (including identification of the minimum and maximum dose zones), establishment of a timer setting, and demonstration of the delivery of the required sterilization dose. For electron-beam irradiation, in addition, the on-line control of voltage, current, conveyor speed, and electron beam scan dimension must be validated.

For gamma radiation sterilization, an effective sterilizing dose, which is tolerated without damaging effect, should be selected. Although
-25 kilo Gray unit (kGy) or ${ }^{\text {2S }}$ (USP28)
2.5 megarads (Mrad) of absorbed radiation was historically selected, it is desirable and acceptable in some cases to employ lower doses for devices, drug substances, and finished dosage forms. In other cases, however, higher doses are essential. In order to validate the efficacy particularly of the lower exposure levels, it is necessary to determine the magnitude (number and degree) of the natural radiation resistance of the microbial population of the product. Specific product loading patterns
-and product densities $_{\text {mS }_{\text {(USP28) }}}$
must be established and absorbed minimum and maximum dosage distribution must be determined by use of chemical dosimeters. (These dosimeters are usually dyed plastic cylinders, slides, or squares that show color intensification based directly on the amount of absorbed radiation energy, ; they require carefulealibra tion
$\square_{\text {which }}$ require careful calibration by an outside calibration

## laboratory.) $\mathbf{m 2 S}_{\text {(USP28) }}$

The setting of the preferred absorbed dose has been carried out on the basis of pure cultures of resistant microorganisms and employing inoculated product, e.g., with spores of Bacillus pumilus as biological indicators. A fractional experimental cycle approach provides the data to be utilized to determine the $\mathrm{D}_{10}$ value of the biological indicator. This information is then applied in extrapolating the amount of absorbed radiation to establish an appropriate microbial survivor probability. The most recent procedures for gamma radiation sterilization base the dose upon the radiation resistance of the natural heterogeneous microbial burden contained on the product to be sterilized. Such procedures are currently being refined but may provide a more representative assessment of radiation resistance, especially where significant numbers of radiationresistant organisms are present. ${ }^{4}$ These range from inoculation with standard resistant organisms such as Bacillus pumilus to subprocess (sublethal) dose exposure of finished product samples taken from production lines. Certain hypotheses are common to all of these methods. While the total microbial population present on an article generally consists of a mixture of microorganisms of differing sensitivity to radiation, the step of subjecting the article to a

[^261]less than totally lethal sterilization dose eliminates the less resistant microbial fraction. This results in a residual relatively homogeneous population with respect to radiation resistance, and yields consistent and reproducible results of determinations with the residual population. The amount of laboratory manipulation required is dependent upon the particular procedure used.

One such procedure requires the enumeration of the microbial population on representative samples of independently manufactured lots of the article. The resistance of the microbial population is not determined and dose setting is based on a standard arbitrary radiation resistance assigned to the microbial population, derived from data obtained from manufacturers and from the literature. The assumption is made that the distribution of resistances chosen represents a more severe challenge than the natural microbial population on the product to be sterilized. This assumption, however, is verified by experiment. After verification, the appropriate radiation sterilization dose is read from a table.

Another, more elaborate, method does not require the enumeration of the microbial population but uses a series of incremental dose exposures to allow a dose to be established such that approximately 1 out of 100 samples irradiated at that dose will be nonsterile. This is not the ultimate sterilization dose, but provides the basis to determine the sterilization dose by extrapolation from the dose yielding 1 out of 100 nonsterile samples, using an appropriate resistance factor that characterizes the remaining microorganism-resistant population. A periodic audit is conducted to check that the findings continue to be operative.

More elaborate procedures, requiring more experimentation and including the isolation of microbial cultures, include one where, after determining the substerilization dose (yielding 1 out of 100 nonsterile samples), the resistance of the surviving microorganisms is used to determine the sterilizing dose. Another is based on different determinations, starting with a substerilization incremental dose that results in not more than $50 \%$ of the samples being nonsterile. After irradiation of sufficient samples at this dose, a number of microbial isolates are obtained. The radiation resistance of each of these is determined. The sterilization dose is then calculated using the resistance determinations and the $50 \%$ sterilizing dose initially determined. Audit procedures are required for these methods as for the others described.

Where the required minimum radiation dose has been determined and delivery of that dose has been confirmed (by chemical or physical dosimeters), release of the article being sterilized could be effected within the overall validation of sterility assurance (which may include such confirmation of applied dosage, the use of biological indicators, and other means).

## ■Vapor-Phase Hydrogen Peroxide Sterilization

Hydrogen peroxide may be applied as liquid, vapor, or an aerosol to act as a surface sterilant that breaks down to water and oxygen so that it does not leave toxic residues. It is widely used in aseptic packaging operations in the food, pharmaceutical, and medical device industries. In the pharmaceutical industry it has more recently found application for the decontamination of aseptic processing equipment,
such as isolators and freeze driers. Users should verify the suitability of their process materials for exposure to hydrogen peroxide vapors.

The factors influencing its antimicrobial activity are concentration, dew point, temperature, and contact time. A typical vapor-phase hydrogen peroxide cycle for a freeze-drier would be the evacuation of the air, with its continuous replacement with hydrogen peroxide vapor at concentrations below $10 \mathrm{mg} / \mathrm{L}$ maintained at $50^{\circ}$ for up to 90 min utes. 2SS $^{\text {(USP28) }}$

## Sterilization by Filtration

Filtration through microbial retentive materials is frequently employed for the sterilization of heat-labile solutions by physical removal of the contained microorganisms. A filter assembly generally consists of a porous matrix
$\boldsymbol{m}_{\text {in }}$ the form of a cartridge $\boldsymbol{m}_{2 S}$ (USP28)
sealed or clamped into an impermeable housing. The effectiveness of a filter medium or substrate depends upon the pore size of the porous material and may depend upon adsorption of bacteria on or in the filter matrix or upon a sieving mechanism. There is some evidence to indicate that sieving is the more important component of the mechanism. Fiber-shedding filters, particularly those containing asbestos, are to be avoided unless no alternative filtration procedures are possible. Where a fiber-shedding filter is required, it is obligatory that the process include a nonfiber-shedding filter introduced downstream or subsequent to the initial filtration step.

Filter Rating - Rating the pore size of filter membranes is by a neminal rating that refleets the capability of the filter membrane to retain mierorgenisms of size represented by specified strains, het by determination of an average pore size and statement of distribut tion of sizes.
-The pore size of filter membranes is a nominal rating that reflects the capability of the filter membrane to retain microorganisms of a size represented by specified strains. Poresize rating is not a determination of an average pore size
nor does it address the distribution of sizes. nes $^{2 S}$ (USP28) Sterilizing filter membranes (those which are used for removing a majority of contaminating microorganisms) are membranes capable of retaining $100 \%$ of a culture of $10^{7}$ microorganisms of a strain of Psematander

- Burkholderia diminuta ${ }_{\text {■2S }}$ (USP28)
(ATCC 19146) per square centimeter of membrane surface under a pressure of not less than 30 psi ( 2.0 bar ). Such filter membranes are nominally rated $0.22 \mu \mathrm{~m}$ or $0.2 \mu \mathrm{~m}$, depending on the manufacturer's practice. ${ }^{5}$ This rating of filter membranes is also specified for reagents or media that have to be sterilized by filtration (see treatment of isopropyl myristate under Oils and Oily Solutions or

[^262]Ointments and Creams in the chapter Sterility Tests $\langle 71\rangle$ ). Bacterial filter membranes (also known as analytical filter membranes), which are capable of retaining only larger microorganisms, are labeled with a nominal rating of $0.45 \mu \mathrm{~m}$. No single authoritative method for rating $0.45-\mu \mathrm{m}$ filters has been specified, and this rating depends on conventional practice among manufacturers; $0.45-\mu \mathrm{m}$ filters are capable of retaining particular cultures of Serratia marcescens (ATCC 14756) or Ps. diminter

- Burkholderia diminuta (ATCC 19146)

Test pressures used vary from low ( $5 \mathrm{psi}, \theta .33$
$\mathbf{n 0 . 3 4}_{\text {n2S (USP28) }}$
bar for Serratia, or $0.5 \mathrm{psi}, 0.34$
$\mathrm{m}_{0.034}{ }_{\text {2S (USP28) }}$
bar for Ps. diminimut

- Burkholderia diminuta) $\boldsymbol{m}_{\text {2S (USP28) }}$
to high ( $50 \mathrm{psi}, 3.4 \mathrm{bar}$ ). They are specified for sterility testing (see Membrane Filtration in the section Test for Sterility of the Product to be Examined under Sterility Tests $\langle 71\rangle$ ), where less exhaustive microbial retention is required. There is a small probability of testing specimens contaminated solely with small microorganisms. Filter membranes with a very low nominal rating may be tested with a culture of Acholeplasma laidlawii or other strain of Mycoplasma, at a pressure of $7 \mathrm{psi}(0.7 \mathrm{bar})$
$\mathbf{\bullet}_{(0.48}$ bar) $\mathbf{m}_{2 S}$ (USP28)
and be nominally rated $0.1 \mu \mathrm{~m}$. The nominal ratings, based on microbial retention properties, differ when rating is done by other means (e.g., by retention of latex spheres of various diameters). It is the user's responsibility to select a filter of correct rating for the particular purpose, depending on the nature of the product to be filtered. It is generally not feasible to repeat the tests of filtration capacity in the user's establishment. Microbial challenge tests are preferably performed under a manufacturer's conditions on each lot of manufactured filter membranes.

The user must determine whether filtration parameters employed in manufacturing will significantly influence microbial retention efficiency. Some of the other important concerns in the validation of the filtration process include product compatibility, sorption of drug, preservatives or other additives, and initial effluent endotoxin content.

Because the effectiveness of the filtration process is also influenced by the microbial burden of the solution to be filtered, the determination of the microbiological quality of solutions prior to filtration is an important aspect of the validation of the filtration process in addition to establishment of the other parameters of the filtration procedure, such as pressures, flow rates, and filter unit characteristics. Hence, another method of describing filter-retaining capability is by the log reduction value (LRV). For instance, a $0.2-\mu \mathrm{m}$ filter that can retain $10^{7}$ microorganisms of a specified strain will have an LRV of not less than 7, under the stated conditions.

The process of sterilization of solutions by filtration has recently achieved new levels of proficiency, largely as a result of the development and proliferation of membrane filter technology. This class of filter media lends itself to more effective standardization and quality control and also gives the user greater opportunity to confirm the characteristics or properties of the filter assembly before and after use. The fact that membrane filters are thin polymeric films offers many advantages but also some disadvantages when compared to depth filters such as porcelain or sintered material. Because much of the membrane surface is a void or open space, the properly assembled and sterilized filter offers the advantage of a high flow rate. A disadvantage is that because the membrane is usually fragile, it is essential to determine that the assembly was properly made and that the membrane was not ruptured during assembly, sterilization, or use. The housings and filter assemblies that are chosen should first be validated for compatibility and in-
tegrity by the user. While it may be possible to mix assemblies and filter membranes produced by different manufacturers, the compatibility of these hybrid assemblies should first be validated. Additionally, there are other tests that are made by the manufacturer of the membrane filter that are not usually repeated by the user. These include microbiological challenge tests. Results of these tests on each lot of manufactured filter membranes should be obtained from the manufacturer by the user for his records.

Filtration for sterilization purposes is usually carried out with assemblies having membranes of nominal pore size rating of 0.2 $\mu \mathrm{m}$ or less, based on the validated challenge of not less than $10^{7}$ Psetedomonas dimintute
$\mathbf{- B u r k h o l d e r i a ~ d i m i n u t a ~}_{\mathbf{\square} 2 \mathrm{~S}}$ (USP28)
(ATCC No. 19146) suspension per square centimeter of filter surface area. Membrane filter media that are now available include cellulose acetate, cellulose nitrate, fluorocarbonate, acrylic polymers, polycarbonate, polyester, polyvinyl chloride, vinyl, nylon, polytef, and even metal membranes, and they may be reinforced or supported by an internal fabric. A membrane filter assembly should be tested for initial integrity prior to use, provided that such test does not impair the validity of the system, and should be tested after the filtration process is completed to demonstrate that the filter assembly maintained its integrity throughout the entire filtration procedure. Typical use tests are the bubble point test, the diffusive airflow test, the pressure hold test, and the forward flow test. These tests should be correlated with microorganism retention.
-The test limits may be established for the filters wetted with Water for Injection (prior to use) or product (post use).■2S (USP28)

## Aseptic Processing

While there is general agreement that sterilization of the final filled container as a dosage form or final packaged device is the preferred process for ensuring the minimal risk of microbial contamination in a lot, there is a substantial class of products that are not terminally sterilized but are prepared by a series of aseptic steps. These are designed to prevent the introduction of viable mi eroorganisms into compenents, where-sterile, or once an intermediate proeess has rendered the bulk product or its eompenents free frem viable miereorganisms.
-Advances in aseptic processing have resulted in manufacturing operations that produce a product that is extremely safe and has a very low probability of microbial contamination. Aseptic processes are designed to prevent the introduction of viable microorganisms into components, where sterile, or once an intermediate process has rendered the bulk product or its components free from viable microorga-

## nisms.n2S (USP28)

This section provides a review of the principles involved in producing aseptically processed products with a minimal risk of microbial contamination in the finished lot of final dosage forms.

A product defined as aseptically processed is likely to consist of components that have been sterilized by one of the processes described earlier in this chapter. For example, the bulk product, if a filterable liquid, may have been sterilized by filtration. The final
empty container components would probably be sterilized by heat, dry heat being employed for glass vials and an autoclave being employed for rubber closures. The areas of critical concern are the immediate microbial environment where these presterilized components are exposed during assembly to produce the finished dosage form and the aseptic filling operation.
The requirements for a properly designed, validated and maintained filling or other aseptic processing facility are mainly directed to (i) an air environment free from viable microorganisms, of a proper design to permit effective maintenance of air supply units and (ii) the provision of trained operating personnel who are adequately equipped and gowned.
-Studies done on aseptic processing environments have consistently reported that the human operator is the only significant source of microbial contamination in the manufacturing process. Therefore, operator training and the consistent use of proper gowning and aseptic handling tech-
niques are vital to achieving asepsis. ${ }^{2 S}$ (USP28)
The desired environment may be achieved through the high level of air filtration technology now available, which contributes to the delivery of air of the requisite microbiological quality. ${ }^{6}$ The facilities include both primary (in the vicinity of the exposed article) and secondary (where the aseptic processing is carried out) barrier systems.
For a properly designed aseptic processing facility or aseptic filling area, consideration should be given to such features as nonporous and smooth surfaces, including walls and ceilings that can be sanitized frequently; gowning rooms with adequate space for personnel and storage of sterile garments; adequate separation of preparatory rooms for personnel from final aseptic processing rooms, with the availability where necessary of such devices as airlocks or air showers; proper pressure differentials between rooms, the most positive pressure being in the aseptic processing rooms or areas; the employment of laminar (unidirectional) airflow in the immediate vicinity of exposed product or components, and filtered air exposure thereto, with adequate air change frequency; appropriate humidity and temperature environmental controls; and a documented sanitization program. Proper training of personnelin hygienic and gowning techniques should be undertaken so that, for example, gowns, gloves, and other body eoverings substantially eover expesed skin surfaces.

■2S (USP28)

[^263]Certification and validation of the aseptic process and facility are achieved by establishing the efficiency of the filtration systems, by employing microbiological environmental monitoring procedures, and by processing of sterile culture medium as simulated product.
-The efficiency of the air filters should be checked on a routine basis, typically at least annually.m2S (USP28)

Monitoring of the aseptic facility should include periodic environmental filter examination as well as routine particulate and microbiological environmental monitoring, and may include periodic sterile culture medium processing.
-See Microbiological Evaluation of Clean Rooms and other
Controlled Environments $\langle 1116\rangle \cdot$.n2S (USP28)

## Change to read:

## STERILITY TESTING OF LOTS

It should be recognized that the referee sterility test might not detect microbial contamination if present in only a small percentage of the finished articles in the lot because the specified number of units to be taken imposes a significant statistical limitation on the utility of the test results. This inherent limitation, however, has
-It should also be noted that the sensitivity of the sterility test may not be sufficient in all cases to recover very small numbers of viable organisms. These inherent limitations,

## however, have $\mathbf{m}^{2 S}$ (USP28)

to be accepted because current knowledge offers no nondestructive alternatives for ascertaining the microbiological quality of every finished article in the lot, and it is not a feasible option to increase the number of specimens significantly.

The primary means of supporting the claim that a lot of finished articles purporting to be sterile meets the specifications consist of the documentation of the actual production and sterilization record of the lot and of the additional validation records that the sterilization process possesses the capability of totally inactivating the established product microbial burden or a more resistant challenge. Further, it should be demonstrated that any processing steps involving exposed product following the sterilization procedure are performed in an aseptic manner, to prevent contamination. If data derived from the manufacturing process sterility assurance validation studies and from in-process controls are judged to provide greater assurance that the lot meets the required low probability of containing a contaminated unit (compared to sterility testing results from finished units drawn from that lot), any sterility test procedures adopted may be minimal, or dispensed with on a routine basis. However, assuming that all of the above production criteria have been met, it may still be desirable to perform sterility testing on samples of the lot of finished articles. Such sterility testing is usually carried out directly after the lot is manufactured as a final product quality control test. ${ }^{7}$ Sterility tests employed in this way in manufacturing control should not be confused with those described under Sterility Tests $\langle 71\rangle$. The procedural details may be the same

[^264]with regard to media, inocula, and handling of specimens, but the number of units and incubation time(s) selected for testing may differ. The number should be chosen relative to the purpose to be served (i.e., according to whether greater or lesser reliance is placed on sterility testing in the context of all the measures for sterility assurance in manufacture). Also, longer times of incubation would make the test more sensitive to slow-growing microorganisms. In the growth promotion tests for media, such slow growers, particularly if isolated from the product microbial burden, should be included with the other test stains. Negative or satisfactory sterility test results serve only as further support of the existing evidence concerning the quality of the lot if all of the pertinent production records of the lot are in order and the sterilizing or aseptic process is known to be effective. Unsatisfactory test results, however, in manufacturing quality control indicate a need for further action (see Performance, Observation, and Interpretation).

## Definition of a Lot and Selection of Specimens for Sterility Test Purposes

Articles may be terminally sterilized either in a chamber or by a continuous process. In the chamber process, a number of articles are sterilized simultaneously under controlled conditions, for example, in a steam autoclave, so that for the purpose of sterility testing, the lot is considered to be the contents of a single chamber. In the continuous process, the articles are sterilized individually and consecutively, for example, by exposure to electron-beam radiation, so that the lot is considered to be not larger than the total number of similar items subjected to uniform sterilization for a period of not more than 24 hours.

For aseptic fills, the term "filling operation" describes a group of final containers, identical in all respects, that have been aseptically filled with the same product from the same bulk within a period of time not longer than 24 consecutive hours without an interruption or change that would affect the integrity of the filling assembly. The items tested should be representative of each filling assembly and should be selected at appropriate intervals throughout the entire filling operation. If more than three filling machines, each with either single or multiple filling stations, are used for filling a single lot, a minimum of 20 filled containers (not less than 10 per medium) should be tested for each filling machine, but the total number generally need not exceed 100 containers.

For small lots, in the case of either aseptic filling or terminal sterilization, if the number of final containers in the lot is between 20 and 200 , about $10 \%$ of the containers should usually be tested. If the number of final containers in the lot is 20 or less, not fewer than 2 final containers should be tested.

## Change to read:

## PERFORMANCE, OBSERVATION, AND INTERPRETATION

## -PERFORMANCE AND OBSERVATION ${ }_{\text {■2S }}$ (USP28)

The facility for sterility testing should be such as to offer no greater a microbial challenge to the articles being tested than that of an aseptic processing production facility. The sterility testing procedure should be performed by individuals having a high level of aseptic technique proficiency. The test performance records of these individuals should be documented.

The extensive aseptic manipulations required to perform sterility testing may result in a probability of nonproduct-related contamination of the order of $10^{-3}$, a level similar to the overall efficiency
of an aseptic operation and comparable to the microbial survivor probability of aseptically processed articles. This level of probability is significantly greater than that usually attributed to a terminal sterilization process, namely, one in one million or $10^{-6}$ microbial survivor probability. Appropriate, known-to-be-sterile, finished articles should be employed periodically as negative controls as a check on the reliability of the test procedure. Preferably, the technicians performing the test should be unaware that they are testing negative controls. Of these tests, a false positive frequency not exceeding $2 \%$
$\mathbf{m}_{0} 0.1 \%$ (USP28)
is desirable.
For aseptically processed articles, these facts support the routine use of the test set forth under Sterility Tests $\langle 71\rangle$ or a more elaborate one. The production and validation documentation should be acceptable and complete. For effectively terminally sterilized products, however, the lower microbial survivor probability may direct the use of a less extensive test than the compendial procedure specified under Sterility Tests $\langle 71\rangle$, or even preclude the necessity altogether for performing one

■and using parametric release to evaluate the sterility assurance of the products (see Terminally Sterilized Pharmaceu-
tical Products--Parametric Release <1222〉). [2S (USP28)
This added reliability of sterility assurance of terminal sterilization depends upon a properly validated and documented sterilization process. Sterility testing alone is no substitute.

## Interpretation of Quality Control Tests

The overall responsibility for the operation of the test unit and the interpretation of test results in relation to acceptance or rejection of a lot should be in the hands of those who have appropriate formal training in microbiology and have knowledge of industrial sterilization, aseptic processing, and the statistical concepts involved in sampling. These individuals should be knowledgeable also concerning the environmental control program in the test facility to assure that the microbiological quality of the air and critical work surfaces are consistently acceptable.

Quality control sterility tests (either according to the official referee test or modified tests) may be earied out in separate stag es in order to rule out false positive results. First Stage. Regardless of the sampling plan used, if no evidence of mierobial growth is found, the results of the test may be taken as indicative of absence of intrinsic contamination of the lot.

If mierobial growth is foumd, proeed to the Second Stage (ma less the First Stege test can be invalidated). Evidence for invalidat ing a First Stage test in order to repent it as a First Stage test may be obtained frem a review of the testing envirenment and the relerant records thereto. Finding of mierobial growth in negative con frols need not be considered the sole-grounds for invalidating a First Stage test. When proeeding to the Seend Stage, partieularly where depending on the results of the test for lot release, coneur rently, initiate and document a complete review of all applicable production and control records. In this review, consideration should be paid to the following: (1) a check on monitoring records of the validated sterilization eycle applieable to the product; (2) sterility test history relating to the particular product for both fimished and in process samples, as wellas sterilization records of support ing equipment, containers/elosures, and sterile compenents, if any; and (3) environmental control data, ineluding those obtained from
media fills, expesure plates, filtering records, any sanitization re eords and microbial monitoring records of operators, gowns, gloves, and garbing practices.

Failing any lead from the above review, the eurrent mierebiat profile of the product should be checked against the known histor ieal profile for possible change. Records should be checked con eomitantly for any changes in souree of product eompenents and/or in processing procedures that might be contributory. Depending on the findings, and in extreme cases, consideration may have to be given to revalidation of the total manufacturing process. For the Second Stage, it is not pessible to specify a particular num ber of specimens to be taken for testing. It is usual to select double the number speciffed for the Finst Stege under Sterility Tests $\langle 74\rangle$; of other reasonable number. The minimum volumes tested frem each specimen, the media, and the incubation periods are the same as these indieated for the First Stege.

If no mierobial growth is found in the Second Stage, and the documented roview of appropriate records and the indieated product investigation does not suppert the possibility of intrinsic eontamination, the lot may meet the requirements of a test for sterility. If growth is found, the lot fails to mee the requirements of the test. As was indien for the Finst Stage test, the Second Stage test may similarly be invalidated with appropriate vidence, and, if so done, repeated as a Second Stage test.
-Given the low probability of detecting nonsterile units in a sterility test, repeat sterility testing is not recommended. Repeat testing should only be undertaken when a laboratory investigation supplies evidence that the test was invalid during test sample integrity, media or diluents contamination, or gross loss of environmental controls in the sterility testing area.
If microbial growth is found, a complete review of all applicable production and control records should be initiated and documented. In this review consideration should be paid to the following: (1) a check on monitoring records of the validated sterilization cycle applicable to the product; (2) sterility test history relating to the particular product for both finished and in-process samples, as well as sterilization records of supporting equipment, containers-closures, and sterile components, if any; (3) environmental control data, including those obtained from media fills, exposure plates, filtering records, any sanitization records and microbial monitoring records of operators, gowns, gloves, and garbing practices.п2S (USP28)

## BRIEFING

$\langle\mathbf{1 2 1 6}\rangle$ Tablet Friability, USP 27 page 2621 and page 891 of PF 28(3) [May-June 2002]. The United States Pharmacopeia is the coordinating pharmacopeia for the international harmonization of the specifications provided in this general information chapter. The Stage 5B Consensus harmonization draft for this chapter has been signed off by the Pharmacopeial Discussion Group members. The regional ADOPTION STAGE 6A text presented herein is being published in the In-Process Revision section in this issue of $P F$ for information only, not for public comment. This text is scheduled for publication in the Second Supplement to USP 28-NF 23, with a scheduled implementation date of 1 August 2005.

Major differences between the current text and that of the Stage 4 Official Inquiry harmonization draft, as published in the $P F$ 28(3) reference previously cited, are listed below.
(1) Paragraph 4-The maximum weight loss percentage value is revised to reflect the intended upper limit restriction of $1.04 \%$. The text is also revised to clarify that, when it is necessary to perform the test two additional times, the mean weight loss from the three samples tested is taken as the test result. Deletion of the last sentence is proposed because it is not considered necessary to distinguish "new formulations" from others.
(2) Paragraph 6-Deletion of the text regarding special packaging for effervescent tablets and chewable tablets is proposed because this packaging statement is considered to be irrelevant to the current context. The proposed deletion of the text specifying a relative humidity less than $40 \%$ for testing of hygroscopic tablets is intended to allow for the use of any appropriate relative humidity based on the individual dosage form under test. Effervescent tablets, for example, may require a relative humidity of $20 \%$ rather than simply "less than $40 \%$."
(3) Paragraph 7-The revised text is intended to broaden the types of apparatuses permitted for use in this test.

## 〈1216〉 TABLET FRIABILITY

This chapter provides guidelines for the friability determination of compressed, uncoated tablets. The test procedure presented in this chapter is generally applicable to most compressed tablets. Measurement of tablet friability supplements other physical strength measurements, such as tablet crushing strength.

Use a drum,* with an internal diameter between 283 and 291 mm and a depth between 36 and 40 mm , of transparent synthetic polymer with polished internal surfaces, and not subject to static buildup (see figure for a typical apparatus). One side of the drum is removable. The tablets are tumbled at each turn of the drum by a curved projection with an inside radius between 75.5 and 85.5 mm that extends from the middle of the drum to the outer wall. The drum is attached to the horizontal axis of a device that rotates at $25 \pm 1 \mathrm{rpm}$. Thus, at each turn the tablets roll or slide and fall onto the drum wall or onto each other.

[^265]

## Tablet Friability Apparatus

For tablets with a unit mass equal to or less than 650 mg , take a sample of whole tablets corresponding to 6.5 g . For tablets with a unit mass of more than 650 mg , take a sample of 10 whole tablets. The tablets should be carefully dedusted prior to testing. Accurately weigh the tablet sample, and place the tablets in the drum. Rotate the drum 100 times, and remove the tablets. Remove any loose dust from the tablets as before, and accurately weigh.

Generally, the test is run once. If obviously cracked, cleaved, or broken tablets are present in the tablet sample after tumbling, the sample fails the test. If the results are doubtful or if the weight loss is greater than the targeted value, the test should be repeated twice and the mean of the three tests determined. A maximum

```
■mean_\2S (USP28)
weight loss
```

${ }^{-}$from the three samples $\boldsymbol{m}_{2 S}$ (USP28) of not more than $1 \%$ of the weight of the tablets being tested
${ }^{-1.0 \%}{ }^{\text {m }}$ 2S (USP28)
is considered acceptable for most products. In the ease of new for mulations, an initial weight loss of $0.8 \%$ would be permitted untit suffieient packaging data are-obtained to extend the limit to a tar geted value of $1 \%$.

## ■2S (USP28)

If tablet size or shape causes irregular tumbling, adjust the drum base so that the base forms an angle of about $10^{\circ}$ with the bench top and the tablets no longer bind together when lying next to each other, which prevents them from falling freely.

Effervescent tablets and chewable tablets may have different specifications as far as friability is concerned, and these
nermally require-special packaging.

- ${ }^{\text {2S }}$ (USP28)

In the case of hygroscopic tablets, a
$\square_{\text {an }}$ appropriate $\mathbf{n}_{2 S}$ (USP28)
humidity-controlled environment (relative hunidity less than-40\%)

- ${ }^{-2 S}$ (USP28)
is required for testing.
Adrum with duat seooping supperts for the rumning of two sam ples at one time is also permitted.
-Drums with dual scooping projections, or an apparatus with more than one drum, for the running of multiple samples at one time, are also permitted.■2S (USP28)

BRIEFING
$\langle\mathbf{1 2 2 2}\rangle$ Terminally Sterilized Pharmaceutical ProductsParametric Release, page 3144 of the First Supplement. It is proposed to clarify the use of the sterility asurance level (SAL) with aseptic processing. It is also proposed to revise the discussion of the number of spores required for the evaluation of a sterilization process and to change the exponent referring to SAL in the section Radiation Sterilization from positive to negative. In addition, a number of editorial changes are also proposed.
(AMB: D. Porter) RTS-41618-1

## Change to read:

## INTRODUCTION

Parametric release is defined as the release of terminally sterilized batches or lots of sterile products based upon the compliance with the defined critical parameters of sterilization without having to perform the requirements under Sterility Tests $\langle 71\rangle$. Parametric release is a possibility when the mode of sterilization is very well understood, the physical parameters of processing are well defined, predictable, and measurable, and the lethality of the cycle has been microbiologically validated through the use of appropriate biological indicators or, in the case of ionizing radiation, the appropriate microbiological and dosimetric tests. The use of parametric release for sterilization processes requires prior FDA approval. It should be expected that the regulatory agencies evaluating submissions including the use of parametric product release would insist upon a well supported scientific rationale for the sterilization process and well documented validation data. The agencies would need assurance that any marketed sample of product will be sterile and would pass the requirements for sterility as found in the general chapter Sterility Tests $\langle 71\rangle$.

It is important to consider the limitations of the Sterility Tests $\langle 71\rangle$ in the evaluation of terminally sterilized products. The sterility test described in general chapter $\langle 71\rangle$ is limited in its sensitivity and is statistically ill-suited to the evaluation of terminally sterilized products given the exceedingly low probability of contaminated units. Therefore, once a sterilization process is fully validated and operates consistently, a combination of physical sterilization data such as accumulated lethality or dosimetry in combination with other methods, such as biological indicators or physicochemical integrators, can provide more accurate information than the sterility test regarding the release of terminally sterilized product to the marketplace.

There are four modes of sterilization that theoretically and practically could qualify for parametric release: moist heat, dry heat, ethylene oxide, and ionizing radiation sterilization. This information chapter first will cover the general issues related to parametric
release, regardless of the modes of sterilization, and then discuss some specific modes of sterilization. The chapter will not address the parametric release of terminally sterilized medical devices.

Terminally sterilized products represent the lowest risk category of sterile pharmaceutical products. Unlike products aseptically manufactured in a microbiologically controlled environment, terminally sterilized products are in a mierobially lethal preeess. The processes used to render terminally sterilized products free of microbial contamination are known to provide a greater degree of sterilization assurance than produets produced only by a septic proeessing.
$\square_{\text {subjected to }}$ a sterilization process the microbiological lethality of which can be quantified. Because aseptic processing relies on exclusion of microbiological contamination and is not based upon lethality imparted on the product in its sealed container, it is not possible to establish a quantitative estimate of the sterility assurance level, or SAL. Although the term SAL is often used to describe the process capability of aseptic processes, it is important to note that in the case of aseptic processing, SAL can only be estimated from media fill contamination rates or other forms of risk assessment. In the case of terminal sterilization, it is possible to calculate a minimum SAL or Probability of Nonsterility (PNS) quite accurately. Therefore, the term SAL has different contextual meanings when used to describe aseptic rather than terminal processes and it is important that this difference is fully understood by scientists and engineers working in the field of sterile product manufacturing and control. The terms PNS and SAL are often used interchangeeably.m2S (USP28)

Terminally sterilized products must have a probability of nonsterility (PNS) of not more than one in a million units produced. This is often stated as a PNS
$\square_{\text {Or SAL }}^{\text {(12S (USP28) }}$
of $10^{-6}$, or the probability of product bioburden surviving the sterilization process in any single unit of product is less than one in one million. The proof that a terminally sterilized product complies with the $10^{-6}$ PNS can be accomplished by several different sterilization cycle development approaches. The proper application of these methods requires extensive scientific knowledge regarding the sterilization method selected for use with a specific product.

The general methods used for
$\boldsymbol{m}_{\text {strategies used to }}$ validate $\mathrm{a}_{\mathbf{\square} 2 \text { (USP28) }}$
terminal sterilization process development fall into three categories:

1. Bioburden-based process.
2. Biological indicator/bioburden combined process.
3. Overkill process.

The bioburden-based process is not frequently used, and
2S (USP28)
requires extensive knowledge of product bioburden. It should be noted that several radiation dose-setting procedures involve establishing radiation processes on the basis of bioburden count and radiation resistance. This method requires that at least a $10^{-6} \mathrm{PNS}$ be attained for bioburden by the sterilization process. This means that if the product bioburden action level is 10 microorganisms or one logarithm, at least seven logarithms of bioburden must be inactivated to assure a $10^{-6}$ PNS. The bioburden-based method requires the user to develop suitable critical control points within the process to control the bioburden titer. Products that readily permit bioburden survival require more controlled manufacturing environments and more precise in-process control. This process is better suited for cycle development for clean or ultra-clean products containing fewer than 10 mierobes per unit
-a consistently low level of colony forming units (CFU) per
product unit ${ }_{\text {2S }}$ (USP28)
with a low frequency of spore-forming microorganisms. Also, this process may be necessary to permit terminal sterilization of a product that may potentially lose key qualities or attributes as a result of a more rigorous sterilization process.

Certain bioburden processes may include products that may be inherently antimicrobial or that can withstand more lethal sterilization processes. Products in this category will require correspondingly less rigorous control of the manufacturing process and less restrictive in-process control points. The microbiologist may find that formal hazard analysis procedures, such as Hazard Analysis Critical Control Point (HACCP), are useful in establishing appropriate manufacturing control conditions and in-process control parameters.

The biological indicator/bioburden combined process is generally used when the manufacturer desires a sterilization process that demonstrates the inactivation of high numbers of biological indicator microorganisms known to be resistant to the process. While the manufacturer may have preferred utilizing an overkill process, potential loss of some product attributes may occur in an overkill process thereby necessitating the use of a biological indicator/bioburden combined process. This process requires knowledge of the bioburden load on and in the product, and a database relative to the sterilization resistance of the bioburden. The relative resistance of the selected biological indicator to that of the bioburden must be established on or in the product. Frequently, biological indicator counts of approximately $10^{6}$ spores per indicator are used in the development of such processes. Fractional exposure cycles are generally conducted to determine the relative sterilization resistance (or D value) between product inoculated with the biological indicator microorganism(s) and frequently encountered bioburden. This process is frequently used for sterilization cycle development by manufacturers of terminally sterilized parenteral products and for ethylene oxide sterilization of medical devices.

The overkill process is frequently used when the article being sterilized is completely inert to the sterilizing agent and sterilization cycle conditions without any concern for loss of product attributes or quality. When using this process, some bioburden knowledge should be available especially
-to ensure that the materials are not adulterated before ster-
ilization. These data may include ${ }_{\square 2 S}{ }^{\text {(USP28) }}$
product bioburden count data and knowledge concerning the prevalence of spore formers. The database for this process need not be as extensive as bioburden data required for the bioburden process or the biological indicator/bioburden process. Generally, process resistant biological indicators containing approximately $10^{6}$ spores are used to establish the endpoint of the sterilization process. This process is then doubled to provide a $10^{\text {² }}$ SAL for the biolegient indienter. The premise is that this proeess will exeeed the requirements neessay to inactivate bioburden to a $10^{-6}$ PNS. This pro-
eess is frequently used to sterilize certain fabricated metal emponents, tools, and equipment sterilized prior to use in an aseptic processing area.
-However, a spore population of $N_{0}$ can be chosen to provide an appropriate challenge to evaluate the process. Overkill is generally defined as a process that would produce a minimum of $F_{0}$ of 12 minutes (see Critical Operating Parameters below) and is demonstrated biologically based upon the spore log reduction of calibrated biological indicators. D2S $^{\text {(USP28) }}$

## Change to read:

## GENERAL REVIEW

## Validation of Sterilization Process

Parametric release first requires that the chosen sterilization process be designed and validated to achieve a $10^{-6} \mathrm{PNS}$ relative to the inactivation of bioburden. Validation of most sterilization processes includes the validation of physical parameters of the process and of its microbiological effectiveness through the use of biological indicators. The use of biological indicators for establishing or periodically validating gamma radiation sterilization processes is not required. Widely recognized biological indicator organisms are used in the validation of moist heat process

## ${ }^{\square}$ processes $_{\text {■2S }}$ (USP28)

because they provide a means of comparing physically measured lethality data with biological lethality. There should be a reasonable correlation between physically measured lethality data $\left(F_{0}\right)^{1}$ and biological lethality as determined by the evaluation of the process with biological indicators.
Because the predictability of effectiveness of bioburden based temminal sterilization is associated with the number and resistance of mieroorganisms on or in a product, one of the compenents of parametric release is an active-sterilization mierobiology eontrol program to menitor the count and sterilization resistance of product bioburden.
-The predictable effectiveness of bioburden-based terminal sterilization is based on the number and resistance of microorganisms on or in a product. For this reason, one component of parametric release is an active microbiology control program to monitor the count and sterilization resistance of product bioburden. 2 2S (USP28)
Bioburden control and enumeration is of far less significance when the overkill process design is used. In many cases, overkill processes do not require extensive ongoing assessment of bioburden and require less in-process control of the manufacturing environment.

[^266]
## Sterilization Microbiology Control Program

The purpose of this control program is to ensure that the microbiological status of the product, prior to being terminally sterilized, has not significantly deviated from the established microbiological control level used for validation of the sterilization process. The microbiology control program includes the monitoring of the bioburden on or in the product and the monitoring of the microbiological status of any necessary containers, closures, or packaging materials. Also included is a program to evaluate the microbiological status of the environment where the product is processed. The control program is particularly important in cases where the terminal sterilization is not based on overkill, but rather on the bioburden or combined bioburden/biological indicator cycle development approach. In many cases, bioburden control and manufacturing environmental monitoring will not be required for overkill process designs, where the $F_{0}$ of the process is at least 12 minutes. In other cases, even when overkill processes are employed, some limited monitoring will be needed. Monitoring of overkill processes for bioburden is generally required only in cases where the product is supportive of microbial growth, and, therefore, biological amplification of any bioburden is likely. Of particular concern in this case is the potential for the product to be contaminated with microbial toxins or to be degraded by microorganisms.

The frequency of monitoring will depend on the variations of bioburden from potential sources. The number of microorganisms, their identification, as well as their resistance to the specified sterilization mode should be considered when parametric release of terminally sterilized product is established. Resistance to a specified sterilization mode by different species can influence sterilization effectiveness and the determination of sterilization process conditions when using the bioburden or combined bioburden/biological indicator method of cycle development. In the bioburden approach to process development, indicator organisms more resistant than typical bioburden may be used, although extreme differentials in resistance are not required. Information on the performance of biological indicators may be found in the general chapter Biological Indicators-Resistance Performance Tests $\langle 55\rangle$.

## Change Control System

Changes introduced to the sterilization processing equipment could result in a significant departure of the initially validated parametric release process. It is, therefore, essential that a change control system be instituted. A change control system is a formal system with appropriate standard operating procedures, which would include approval of changes in the sterilization processing equipment. This system would assess all the changes in relation to the critical parameters included in parametric release. The change control system also includes technical and management review and "go-no go" hurdles. If a change would significantly affect any critical parameter, each parameter would have to be revalidated in terms of sterility assurance of the pharmaceutical product to a minimum $10^{-6} \mathrm{PNS}$. Appropriate regulatory notification would also be part of the revalidation process.

## Release Procedures

A quality assurance program should be established that describes in detail the batch or lot release steps for parametric release of sterilized products and the required documentation. Although the assessment of the sterility assurance of products is primarily based on measurement of physical process parameters, a number of areas should be reviewed, documented, and approved for the parametric release of these products. These areas can include the following: a review of bateh records; a review of the ongoing mi
erobiologieal environmental contrel program results; a review of any process physicochemical or bioburden indicators or integra ters; a review of the maintenance status of processing equipment, ehange orders, and deviation control reeords; produet bioburden data and any revalidation data; and the-status-ofequipment calibration.
-These areas may include the following: a review of batch records; a review of the ongoing microbiological environmental control program results and presterilization bioburden; and a review of records of thermographic data and results of indicators that may have been used to demonstrate process control. It is also important to ensure that the sterilizer is current relative to calibration, maintenance, and revalidation.■2S (USP28)
The implementation and practice of parametric release is not an intermittent program. Once such a program is implemented, release of the sterilized product is made in accordance with the requirements of the regulatory approved program. Product release by other means is not acceptable if the predefined critical operational parameters are not achieved.

## Change to read:

## MODES OF STERILIZATION

## Moist Heat Sterilization

Moist heat sterilization of pharmaceutical products includes several types of sterilizing environments and sterilizing media. Saturated steam, hot water spray, and submerged hot water processes are all considered as moist heat sterilizing environments. Different processes may be used to sterilize products by moist heat, and they include batch-type sterilizers and continuous-type sterilizers.

## CRITICAL OPERATING PARAMETERS

A defined list of key process parameters and their respective operating limits are defined and established in the sterilization process specifications. Critical operating parameters are those that are absolutely essential to ensure product sterilization to a $10^{-6} \mathrm{PNS}$. Examples of critical operating parameters may include, but are not limited to, minimum and maximum limits for process peak dwell temperature, average peak dwell temperature, and the results of the batch or lot release test that satisfies the requirements of CFR, Part 211. $F_{0}$ is not listed as a critical parameter because a specific $F_{0}$ range can be achieved by variable temperature and time relationships. The target $F_{0}$ range, however, could be listed as a secondary (noncritical) parameter provided the specific time at temperature range was specified to achieve the target $F_{0}$ range. Other measured parameters may be considered secondary (or noncritical) parameters and may include maximum and minimum time to peak dwell, chamber pressure, and if applicable, chamber water level, sterilizing water time above defined temperature limits, and recirculating water pump pressure differential.

## Ethylene Oxide Sterilization

The application of parametric release of pharmaceutical products sterilized by ethylene oxide is more difficult than parametric release of products sterilized by moist heat processes. Sterilization by ethylene oxide (ETO) has more critical parameters than moist heat sterilization that are interrelated and that determine whether, at a minimum, a $10^{-6} \mathrm{PNS}$ is obtained when these parameters are within the specified limits of a validated cycle.

## CRITICAL OPERATING PARAMETERS

These eritieal parameters include the following: temperature, a meunt of relative humidity present, ethylene-oxide coneentration, everall expesure time, produet and lead density, and gas permeability factors.
-Critical parameters may include the following: temperature, amount of relative humidity present, ethylene oxide concentration, overall exposure time, product and load density, and gas permeability factors. ${ }^{2 S}$ (USP28)

Parametric release of pharmaceutical products can be achieved if an automated measurement system for the critical parameters is employed and sterilization loads are closely defined and validated relative to product types, densities, packaging materials, and overall load configurations. An example of the measurement of critical factors that may be considered for parametric release would be the use of calibrated ETO pressure recordings to provide an estimate of ETO concentration during the process hold time or the use of direct measurement of ETO concentration by IR or gas chromatography. Because of variances that might occur in the key parameters during sterilization, parametric release is not widely used for products sterilized by ETO.
However, to ensure parametric release, in addition to the attainment of critical parameters of the ethylene oxide sterilization process, biological indicators (and their sterility testing after sterilization processing) or the use of physicochemical integrators for the ethylene oxide sterilization can be used in each sterilized load.

## Radiation Sterilization

Two radiation sterilizing processes have been used: gamma and electron beam sterilization (i.e., ionizing radiation). Some pharmaceutical products, either in bulk or in their finished formats, have been sterilized by radiation. In discussing the critical parameters of radiation sterilization necessary for parametric release, it is customary to refer to parametric release as dosimetric release. Dosimetric release is provided by the use of a chemical dosimeter that measures the delivery of a minimum specified radiation dosage, which has been shown to provide sterilization of the product to a minimum $10^{-6} \mathrm{PNS}$.

The use of a dosimeter in ionizing radiation sterilization measures delivery of a minimum absorbed radiation dose to a pre-established low dose zone in the irradiated product carrier. This will require mapping of the profile of absorbed ionizing radiation across the density ranges processed in the product carrier. The lowest specified radiation dosage for the process is correlated to predictable bioburden reduction levels by any one of the three documented methods. ${ }^{2}$ An alternative method may be considered whereby extensive product bioburden count and radiation resistance data are available. Dose verification studies would be conducted to en-
${ }^{2}$ ANSI/AAMI/ISO 11137-1996, Sterilization of Health Care ProductsRequirements for Validation and Routine Control-Radiation Sterilization, July 11, 1994.
sure that the worst case bioburden load, relative to resistance and numbers, can be inactivated at the lowest dose zone in the carrier system to provide at least a $10^{6}$

## ${ }^{-10^{-6}}$ 2S (USP28)

SAL. This method would of course require an ongoing program of bioburden assessment. The target for the radiation cycle is a minimum $10^{-6}$ PNS relative to the product bioburden. Because the radiation cycle is calculated on the basis of the bioburden, dosimetric release should include a batch evaluation of the bioburden number and of its radiation resistance.

Dosimetric release of a radiation-sterilized product depends on the delivery of at least a minimum dosage; thus, the critical operational parameters that govern the delivery of that dosage must be within specified limits. These operational critical parameters may include the following: a stacking configuration within the radiation carrier, bulk density of the product, speed of the conveyor or carrier system, distance to the radiation source, duration of product exposure, and appropriate defined adjustments for a decaying radiation source. Demonstration of consistency in the absorbed radiation dosage at areas of minimum and maximum zones of radiation absorption within the fully loaded carriers on a batch-to-batch basis is a necessary condition for dosimetric release of radiation-sterilized pharmaceutical products.

## Change to read:

## SUMMARY

The conversion to parametric release in lieu of product sterility testing as described in general chapter Sterility Tests $\langle 71\rangle$ requires prior FDA approval. Parametric release is advantageous for terminally sterilized products. The extensiveness of data required to establish parametric release,
-compared to the general chapter $\langle 71\rangle$ procedures, which lack sensitivity to very low levels of microbial contamina-
tion, $\mathbf{m}_{2 S}$ (USP28)
can result in a more accurate and reliable assessment of the probability of nonsterility of product lots. than the procedures as defined in chapter $\langle 74\rangle$ because these lack sensitivity to very low levels of mierebial contamination.

■ $\mathbf{m}^{\text {S }}$ (USP28)

## BRIEFING

〈1231 > Water for Pharmaceutical Purposes, USP 27 page 2628 and page 1641 of PF 29(5) [Sept.-Oct. 2003]. The Pharmaceutical Waters Expert Committee received numerous letters commenting on the proposed revision of this general information chapter, which is indicative of the importance placed on the information in this chapter by users of pharmaceutical waters. The Expert Committee met on March 4, 2004 to address all of these concerns and have revised many parts of the chapter. The Expert Committee believes that this revised document covers most aspects of pharmaceutical waters. With further enhancements, the Expert Committee believes that this chapter could serve as a guidance document for regulatory purposes, but recommended that this concept be re-evaluated during the next Convention cycle (2005-
2010) when a new Expert Committee will be on board. Please direct comments to Frank Barletta, liaison to the Pharmaceutical Waters Expert Committee.

## Change to read:

## 〈1231〉 WATER FOR PHARMACEUTICAL PURPOSES

Water is the mest widely used substanee, raw material, or ingredient in the production, processing, and formutation of compendial artieles. Control of the mierobiologieal quality of these waters is impertant beeause proliferation of mierorgenaisms ubiquitous to water may oceur during the purifieation, storage, and distribution of this substane. If water is used in the final product, these miereerganisms or their metabolic produets may eventtally catuse ad verse consequences.

Water that is used in the early stages of the production of drug substanees and that is the semree or feed water for the preparation of the various typer of purified waters must meet the requirements of the National Primary Drinking Water Regulations. (NPDWR) (40-CFR 141) isstred by the Environmental Protection Ageney (EPA). Comparable regulations for drinking water of the Etropean Union or Japan are acceptable. These requirements ensure the $a b-$ sence of coliferms, which, if determined to be of fecal origin, may pertend or indiente the presence of other microorganisms of feed origin, including viruses that may be pathogenic for humams. On the other hand, meeting these National Drinking Water Regulations would not rule out the presence of other mieroorganisms, whieh, while not considered a major public health concern, could, if present, constitute a hazarder be considered undesirable in a drug substance or formulated product. For this reason, there are many dif ferent grades of pharmaceutieal waters.

## TYPES-OF-WATER

Prinking Water Drinking Water is not eovered by a compendial menegraph but must cemply with the quality attributes of the EPA NPDWN or comparable regulations of the Emropean Union-or Japan. It may be derived from variety of sourees ineluding a publie water utility, a private water supply (e.g., a well), or a combi nation of mere than one of these sotrees. Drimking Water may be used in the early stages of chemieal synthesis and in the early stay es of the cleaning of pharmaceutical manufacturing equipment. It is the preseribed serree feed water for the production of phatmaceut tieal waters. As seasenal variations in the quality attributes of the drinking water supply ean ecur, processing steps in the produetion ef pharmaceutieal waters must be designed for this characteristic.

Purified-Water Purified Water (see USP menegraph) is used as an exeipient in the production of official preparations; in phar maceutieal applientions, such as cleaning of certain equipment; and in the preparation of some bulk pharmaceutical chemieals. Purified Water mast meet the requirements for ionic and organic chemieal purity and must be protecte from mierobial proliferation. It is prepared using Drinking Water as a feed water and is purified using thit operations that melude deionzation, distillation, ion ex ehange, revers osmesis, filtration, or other suitable procedures. Purified Water systems must be validated.

Purified Water systems that produce, store, and cireulate water under ambient conditions are susceptible to the establishment of tenacious biofilms of mieroorgonisms, which can be the source of undesirable levels of viable mieroorganisms or endotoxins in the effluent water. These systems require frequent sanitization and mierobiologieal monitoring to ensure water of appropriate mi erobiologieal quality at the points of use.
Sterile Purified-Water Sterile-Puriffed-Water [USP mene graph to come] is Purified Water that is packaged and rendered sterile. It is used in the preparation of nomparenteral compendial dosage forms where a sterile form of Purified Water is required.

Water for Injection Water for Injection (see USP menograph) is an excipient in the production of injections and for use in phar maceuticalapplications, suchas cleaning of certain equipment, and in the preparation of some bulk pharmaceutieal-chemieals. The source or feed water for this article is Drinking Water, which may have been preliminarily purified but which is finally subjected to distillation or reverse osmesis. It must meet all of the chemical requirements for Purified Water and in addition the requirements
 from mierobial contamination. The system used to produee, store, and distribute Water for Injection must be designed to prevent mi erobial contamination and the formation of mierobial endorins, and it must be validated.

Sterile-Water for Injection_Sterile-Water for Injection (see USP monegraph) is Water for Injection that is packaged and ren dered sterile. Sterile-Water for Injection is intended for extempera neous preseription compounding and is distributed in sterile units. It is used as a diltuent for parenteral products. It is packaged in sim gle dose containers not larger than 1 liter in size.
Bacteriostatic-Water for Injection-Bacteriostatic Water for thjection (see USP monograph) is sterile- Water for Injection to which has been added one or more suitable antimicrobial preserva tives. It is intended to be used as a diluent in the preparation of parenteral products. It may be packaged in single dose or multiple dose containers not larger than 30 mb .
Sterile-Water for Irrigation-Sterile-Water for Irrigntion (see USP monograph) is Water for Injection, packaged in-single dose en andiners of larger than 1 liter in size, that is intended to be deliv ered rapidly and is rendered sterile. It need not meet the requirement under small volume injections in the chapter Particulate Matter $\langle 788$ ) -
Sterile-Water for Inhalation-Sterile Water for Inhalation (see USP menegraph) is Water for Injection that is packaged and ren dered sterile and is intended for use in imhalators and in the preparation of inhalation solutions.

## VALDAFION AND-QUAЦIFICATION-OF WATER PURIFICATION, STORAGE, AND DISTRHBUTION SYSTEMS

Establishing the dependability of pharmaceutienl water purifien tion, storage, and distribution systems requires an appropriate period of menitoring and observation. Ordinarily, few problems are encountered in maintaining the chemieal purity of Purified Water and-Water for Injection. However, it is more diffieult to meet established mierobiologieal quality criteria consistently. A typieat program involves intensive daily sampling and testing of major proeess points for at least one month after operational criteria have been established for each sampling peint.
Validation is the procedure whereby substantiation to a high ler el of assurne that a specific proeess will consistently produce a product eonforming to an established set of quality attributes is at quired and doeumented. The validation defines the critieal process parameters and their operating ranges. A validation program qual iffes the design, installation, operation, and performanee of equip-
ment. It begins when the system is defined and moves through sev eral stages: qualification of the installation (M), operational quat iffation ( $(Q)$ ), and performance qualification (PQ). A graphical
representation of a typieal water system validation life cycle is shown in Figurre 1. A validation plan for a water system ypieally includes the following steps:
(1) Establishing standards for quality attributes andoperating parameters.

(2) Defining systems and subsystems suitable to produce the desired quality attributes frem the available source water. (3) Selecting equipment, controls, and menitoring teehnolegies.
(4) Develeping an IQ stage consisting of instrument calibra tiens, inspections to verify that the drawings aceurately depiet the as built configuration of the water system and, where nee essary, special tests to verify that the installation meets the design requirements.
(5) Developing an OQ stagensisting of tests and inspec tions to verify that the equipment, system alerts, and controls are operating reliably and that appropriate Alert and Action Levels are established. This phase of qualification may over tap with aspects of the next step.
(6) Developing a prospective PQ stage to confirm the appropriateness of critical process parameter operating ranges. $A$ eeneurrent or retrespective PQ - is performed to demenstrate system reproducibility over an appropriate time period. During this phase of validation, Alert and Action Levels for key equality attributes and operating parameters are veriffed. (7) Supplementing a validation maintenance program (alse ealle continuous validation life eyele) that includes a mechanism to control changes to water system and establishes and carries out seheduled preventive maintenance including recalibration of instruments. In addition, validation maintenance includes a monitoring program for critical process pa rameters and a corrective action program.
(8) Instituting a schedule for periodic review of the system performance and requalification.
$(\vartheta)$ Completing protocols and doemmenting Steps 18.

## PHARMACEUTICAL WATER SYSTEMS

The quality attributes of water for a partieular applieation are dietated by the requirements of its usage. Sequential processing steps that are used for treating water for different pharmaeeutieat
purposes are shown in Figutre 2. A typical evaluation process to select an appropriate water quality for a particular pharmaceutieal purpese is shown in the decision tree in Figure 3. These diagrams may be used to assist in defining requirements for specific water uses and in the selection of unit operations.

[^267]

Fig. 3. Selection-of water for pharmareutienl purposes.

## PURIFID-WATER AND-WATER FOR INJECTHN SYSTEMS

The design, installation, and operation of systems to produce Purifed Hater and Hater for Injection inelude similariompenents, eentrol techniques, and procedures. The quality attributes of both waters differ only in the presence of a bacterial endotoxin requirement for Water for Injection and in their methods of preparation, at least at the last stage of preparation. The similarities in the quality attributes provide considerable commen ground in the design of water systems to mee either requirement. The-critical difference is the degree of eontrolof the system and the final purifieation steps needed to enstre bacterial and bacterial endotoxin removal.

Production of pharmaceutical water employs sequential unit operations (processing steps) that address specific water quality attri butes and protee the peration of subsequent treatment steps. The
fanal unit operations used to produce Water for Injection have been limited to distillation and reverse osmesis. Distillation has a long history of reliable performance and can be validated as a unit operation for the production of Water for Injection. Other technologies such as ultrafltration may be suitable in the production of Hater for Injection, but at this time experience with this proeess is not widespread.
The validation plan should be designe to establish the suitabil ity of the system and to provide a therough understanding of the purification mechanism, range of operating conditions, required pretreatment, and the most likely mode of failure. It is also neeessary to demenstrate the effectiveness of the monitering seheme and to establish the requirements for validation maintenance.

Trials conducted in a pilot installation can be valuable in defining the operating parameters and the expected water quality and in identifying failure modes. However, qualification of the specific unit operation can only be performed as part of the validation of the installed operational-system.

The selection of specific unit operations and design-characteris ties for a water system should take into consideration the quality of the feed water, the technology chesen for subsequent processing steps, the extent and complexity of the water distribution system, and the appropriat compendial requirements. For example, in the design of a system for Water for Injection, the final process (distil fation or reverse osmesis) must have effective bacterial endotoxin reduction capability and must be validated.

The following is a brief description of selected unit operations and the operation and validation concerms associated with them. This review is not comprehensive in that not all unit operations are discussed, ner are all potential problems addressed. The pur pose is to highlight issues that foeus on the design, installation, op eration, maintenanee, and monitoring parameters that facilitate water system validation.

Filtration tee hmology plays an impertant role in water systems, and filtration units are available in a wide range of designs and for various applientions. Removalefficiencies differ signifienntly from eoarse filters, such as gramular anthracite, quartz, or sand for larger water systems and depth cartridges for smaller water systems, to membrane filters for very small particle control. Unit and system ennfigurations wary widely in type of filtering media and loeation in the process. (Use of membrane filters is diseussed in a later paragraph.)

Gramlar or eartridge filters are used for prefiltration. They remove solid contaminants frem the water supply and protect downstream system compenents from contamination that can inhibit equipment performance and shorten their effective life. Design and operational issues that may impact performane of depth filters include channeling of the filtering media, blockage from silt, mi erobial growth, and filtering media loss. Control measures inelude pressure and flow monitoring, backwashing, samitizing, andreplac ing filtering media. An impertant design concern is sizing of the filter to prevent channeling or media loss resulting from inapprepriate water flow rates.

Aetivated earbon-beds adsorb low molecular weight organie material and oxidizing additives, such as chlorine compounds, and remove them frem the water. They are used to achieve certain quality attributes and to protect against reaction with downstream stainless steel surfaces, resins, and membranes. The chief operating eoneerns regarding activated earbon beds inelude the propensity to suppert bacteria growth, the petential for hydraulic chammeling, the inability to be regenerated in situ, and the shedding of bacteria, en dotoxins, orgenic chemicals, and fine carbon paritieles. Control meastres include appropriate high water flow rates, samitization with hot water or steam, backwashing, testing for adserption capacity, and frequent replacement of the earben bed. Alternative teeh nologies sueh as chemieal additives and regenerable organie sear enging deviees can be used in place of activated carben beds.

Chemieal additives are used in water systems to control miere orgunisms by use of chlorine compounds and ozone, to enhance the removal of suspended solids by use of floceulating agents, to remove chlorine compernds, to adjust pH , and to remeve carbenate eompounds. Subsequent processing steps are required to remove the added chemienls. Control of additives and subsequent menitor ing to enstre remoral of additive and of any of their reaction prod uets should be designed into the system and ineluded in the menitering pregram.

Organie seavenging deviees use macroreticular anion en ehange resins eapable of removing organie material and endotox ins from the water. They can be regenerated with appropriate biocidal caustic solutions. Operating eoneerns are associated with seavenging eapacity and shedding of resin fragments. Control mea sures include testing of effluent, monitoring performance, and using downstream filters to remove resin fines.

Water softeners remove cations such as calcium and magnesium that interfere with the performance of downstream processing equipment such as reverse osmosis membranes, deionization col umms, and distillation units. Water seftener resin beds are regenerated with sodium chloride solution (brine). Coneerns inelude mierorgenism proliferation, channeling due to inappropriate wa ter flow rates, orgenic fouling of resin, fracture of the resin beads, and contamination frem the brine-solution used for regeneration. Control measures include recireulation of water during periods of low water use, periodic sanitization of the resin and brine-sys tem, use of mierobial control deviees (e.g., UV and ehlorine), appropriate regeneration frequeney, eflluent monitoring (hardness), and downstream filtration to remove resin fines.

Peionization( P ), eleetrodeionization(EDI) and Eleetrodialysis (EPR) are effective methods of improving the chemieal qual ity attributes of water by removing cations and anions.

DI systems have charged resins that require periodic regenera tion with an acid and base. Typically, cationic resins are regenerat ed with either hydrechloric or sulfuric acid, which replace the eaptured positive ions with hydrogen ions. Anionic resins are regenerated with sodium or petassimm hydroxide, which replace tured negative ions with hydroxide ions. Both regenerant ehemicals are biocidal and offer a meastre of mierobial control. The system can be designed so that the cation and anion resins are separated or that they form a mixed bed. Rechargeable resim eanisters can also be used for this purpose.

The EDI system use a combination of mixed resin, selectively permeable membranes, and an electrie eharge to provide contint ous flow (product and waste concentrate) and contintrous regeneration. Water enters beth the resin section and the waste (eencentrate) section. As it passes through the resin, it is deionized to become product water. The resin acts as aconductor enabling the electrical potential to drive the captrred cations and anions through the resin and appropriate membranes for concentration and remor al in the waste water stream. The electrieal potential also separates the water in the resin (product) section into hydrogen and hydrox ide ions. This permits continueus regeneration of the resin witheut the need for regenerant additives.

Electrodialysis (EDR) is similar proess that uses only electric ity and selectively permeable membranes to separate, concentrate, and flush the removedions from the water stream. It, however, is less efficient than EDI beeause it contains no resin to enhanee ion removal and eurrent flow. Also, EDR units require periodic polar ity reversal and flushing to maintain-operating performance.

Goncerns for all forms of deionization units inelude mierobiat and-endotoxin control, chemieal additive impact on resins and membranes, and loss, degradation, and fouling of resin. Issues of eoncern specifie to DI units include regeneration frequeney, chan neling, complete resin separation for mixed bed regeneration, and mixing air contamination (mixed beds). Control measures vary but fypieally inelude recireulation loops, mierobial eontrol by UV light, conductivity monitoring, resin testing, mieropereus filtration of mixing air, mierobial menitoring, frequent regeneration to min imize and control mieroorganism growth, sizing the equipment for suitable water flow, and use of elevated temperatures. Regeneration piping for mixed bed units should be configured to ensure that regeneration chemieals contact all internal-surfaces and resins. Reehargeable canisters can be the-source of contamination and should be carefully monitored. Full knowledge of previous resin use, minimum strage time between regeneration and use, and appropriate sanitizing procedures are critical factors ensuring proper performance.

Reverse osmosis ( $\mathrm{R} 日$ ) units employ a semipermeable membrane and a substantial prescure differential to drive water threugh the membrane to achieve chemied, mierebial, and endotoxin quality improvement. The proeess streams eonsist of supply water, product water (permeate), and waste water (reject). Pretreat ment and system configuration variations may be necessary de pending on souree water to achieve desired performance and reliability. Concerns associated with the design and operation of

RO units include membrane material sensitivity to bacteria and sanitizing agents, membrane fouling, membrane integrity, seal in tegrity, and the volume of waste water. Failure of membrane or seat integrity will result in produet water contamination. Methods of eontrol consist of suitable pretreatment of the water stream, appropriate membrane-material selection, integrity challenges, membran design such as spiral wound to promete flushing action, periodic sanitization, menitoring of differential pressures, conductivity, microbial levels, and total organic carben. The configuration of the RO unit effers controloppertunities by expanding the singlepass seheme to parallel staged, reject staged, two pass, andeombination designs. An example would be the use of a pass design to improve reliability, quality, and efficieney. RO units ean be used alone or in combination with DI and EDI units for operational and quality enhaneements.

Ultrafiltration is another technology that uses a permeable membrane, but unlike $R O$ it works by mechanieal separation rather than-osmesis. Due to the filtration ability of the membrane, mac remolecular and mierobial impurities, such as endotoxins, are redured. This technelogy may be appropriate as an intermediate or final purification step. Similar to PO , suecessfulperformane is dependent upen other system unit operations and system configurn tion.

Isstes of concern include compatibility of membrane material with sanitizing agents, membrane integrity, fouling by particles and mieroorgmisms, eartridge contaninant retention, and senl in tegrity. Control measures include sanitization, designs capable of flushing the membrane curface, integrity challenges, regular ear tridge changes, elevated feed whter temperature, and monitoring talorganie earben and differential pressure. Additional flexibility in operation is possible based on the way units are arranged such as in a parallel or series configuration. Care should be taken to avoid stagnant water conditions that could promote mieroorganism growth in back up or standby units.

Mierobial retentive filters (membrane flters) prevent the passage of mieroorganisms and very small particles. They are used in tank air and inert gas vents and for filtration of compressed air gases used in the regeneration of mixed bed deionization units. Areas of concern are blockage of tank vents by condensed water vapor, which ean eatse mechaniend damage to the tank, andeoncentration of mierergenisms on the surface of the membrane filter, creating the potential for contamination of the tank or deionizer contents. Control measures include the use of hydrophebic filters and heat fracing vent flter housings to prevent vaper condensation. Sterili zation of the unit prior to initial use and periodieally thereafter or regular filter changes are also recommended control methods. Mierobial retentive filters are sometimes incorporated into purifica tion systems or in water distribution piping. This appliention should be carefully controlled beeause as noted above, these units ean become a souree for mierobial contamination. The petentiat exists for the release of mieroorganisms should the membrane filter fupture or as a result of mierobial grow through. Other means of eontrolling mieroorganisms and fine partieles can be employed in place of membrane filters in the purification and distribution see tion of water systems. Filters that are intended to be mieroretentive should be sanitized and integrity tested prior to initial use and at appropriate intervals thereafter.

Positively charged filter media reduce endotoxin levels by electrostatic attraction and adsorption. Applieation may be mit operation or distribution systemrelated depending upen the mierobiat entrol requirements. Filter media that are mierobial retentive require the same coneems and controls as indiented in the provious paragraph. Concerms include flow rate, membrane and seal integ rity, and retention capacity, which can be affected by the develop ment of a finite charge potential on the filter. Control measures inelude menitoring differential pressure and endotoxin levels, proper sizing, testing membrane-integrity, and configuring units in series to centrol break through.

Distillation units provide chemical and microbial purification via thermal vaporization, mist elimination, and condensing. A variety of designs are wailable including single effect, multiple of fect, and vaper compression. The latter two configurations are normally used in larger systems beeause of their generating ea pacity andefficieney. Distilled water systems may require less ris orous control of feed water quality than do membrane systems. Ar eas of concern include carry over of impurities, evaporator flooding, stagnant water, pump and compressor seal design, and eonductivity (quality) variations during start up and operation. Methods of control consist of reliable mist elimination, vistal of automated high water level indieation, use of sanitary pumps and eompressors, proper drainage, blow down control, and use of on line conduetivity sensing with automated diversion of unaceept able quality water to the waste stream.

Storage tanks are included in water distribution systems to optimize processing equipment capacity. Storage also allous for rou tine maintenance while maintaining continuous supply to meet manufacturing needs. Design and operation considerations are needed to prevent the development of biefllm, to minimize corro sion, to aid in the use of chemieal sanitization of the tanks, and to safeguard mechanical integrity. These considerations may inelude using elosed tanks with smooth interiors and the ability to spray the tank head space. This minimizes corrosion and biofilm development and dids in sanitizing thermally or chemically.
Storage tanks require venting to compensate for the dymamies of ehanging water levels. This ean be aceomplished with a hydrephebie mierobial retentive membrane filter fitted ento an atmospherie vent. Alternatively, an attomatic membrane filtered compressed gas pressurization and venting system may be used. Rupture disks equipped with a rapture alarm deviee serve as a farther safeguare for the mechanieal integrity of the tank.

Distribution configuration should allow for the continuous flow of water in the piping by means of recireulation or should provide for the periodic flushing of the system. Experienee has shown that eontintrously recireulated systems are easier to maintain.

Pumps should be designed to deliver fully turbulent flow eonditions to retard the development of biofilms. Compenents and dis tribution lines should be sloped and fitted with drain peints so that the system can be completely drained. In distribution systems, where the water is cireulated at a high temperature, dead legs and low flow conditions should be avoided, and valved tie in peints should have length to diameter ratios of 6 or less. In ambi ent emperature distribution systems, partieular care-should beexereised to avoid poeket areas and provide for complete drainage. Water exiting from a loop should not be returned to the system. Distribution design should include the placement of sampling valves in the storage tank and at other locations such as in the refan line of the reeireulating water system. The primary sampling site for water should be the valves that deliver water to the peint of use. Direct connections to processes or auxiliary equipment should be designed to prevent reverse flow into the controlled water sys tem. The distribution system should permit sanitization for mieroerganism contrel. The system may be contintously operated at sanitizing conditions or sanitized periodienlly.

## INSTAぬLATION AND MATERHALS OF GONSTRUCTHO AND-COMPONENT SELECTHON

Installation techniques are important beeause they can affect the mechanieal, corresive, and sanitary integrity of the system. Valve installation attitude-should promete-gravity drainage. Pipe supports should provide appropriate slopes for drainage and should be designed to support the piping adequately under worst ease thermalconditions. Methods of connecting system compenents in eluding units of operation, tanks, and distribution piping require eareful attention to preclude potential problems.

Stainless steel welds should provide reliable joints that are inter nally smooth and corrosion free. Low carbon stainless-steel, com patible wire filler, where necessary, inert gas, automatic welding machines, and regular inspection and doeumentation help to ensure acceptable weld quality. Follow ap cleaning and passivation are important for removing contamination and corrosion products and to reestablish the passive comrosion resistant surface. Plastic materials can be fused (welded) in seme cases and also require smooth, uniform internal surfaces. Adhesives should be avoided due to the potential for voids and chemieal reactions. Mechanieal methods of joining, such as flange fittings, require care to avoid the ereation of offsets, sepps, penetrations, and voids. Control meastres inelude go alignment, properly sized gaskets, appropriate spae ing, uniform sealing foree, and the avoidanee of threaded fittings.

Materials of eonstruetion-should be selected to be compatible with control measures such as sanitizing, cleaning, and passivating. Femperature rating is a critical factor in choosing appropriate materials because surfaces may be required to handle elevated oper ating and sanitization temperatures. Should chemieals or additives be used to clean, control, or sanitize the system, materials resistant t these chemieals or additives must be utilized.

Materials should be capable of handling turbulent flow andele wated velocities without wear on the corrosive barrier impact, such as the passivation related chromium oxide surface of stainless steel. The finish on metallic materials such as stainless steel, whether it be a refined mill finish, polished to a specific grit, or an electropelished treatment, should complement system design and provide-satis factory corrosion and mierobial activity resis tance. Auxiliary equipment and fittings that require-seals, sackets, diaphragms, filter media, and membranes shouldexelude materials that permit the possibility of extactables, shedding, and mierobiat activity.

Insulating materials exposed to stainless steel surface should be free of ehlerides to avoid the phenemenen of stress corresion eracking that can lead to system contamination and the destruction of tanks and critienl system components.

Specifications are impertant to ensure proper selection of materials and to serve as areference for system qualification and main tenance. Information such as mill reports for stainless steel and reperts of compesition, ratings, and material handling capabilities for nonmetallic substances should be reviewed for suitability and retained for reference.

Component (atuxiliary equipment) selection should be made with assuranee that it doe not creat a souree for contamination intusion. Heat exchangers should be double tube sheet or coneen trie tube desigh. They should inelude differential pressure menitor ing or utilize heat transfer medium of equal or better quality to avoid problems should leaks develop. Pumps should be of sanitary design with seals that prevent contamination of the water. Valves should have smoeth internal surface with the seat andelesing deviee expesed to the flushing action of water, such as oceurs in diaphragm valves. Valves with poeket areas or clesing devices (e.g., ball, plug, gate, globe) that move into and out of a flow area should be avoided.

## SANHTHZATHON

Mierobial control in water systems is achieved primarily through sanitization practices. Systems can be sanitized using either ther mal or chemieal means. In line UV light at a wavelength of 254 nm ean also be used "s "snitize" water in the system contint eusly.

Thermal appreaches to system sanitization include periodic or eentinurusly eireulating het water and the use of steam. These feehniques are limited to systems that are compatible with the high er temperatures needed to achieve sanitization, such as stainless steel and some polymer formulations. Although thermal methods eontrol biofflm development, they are net effective in removing es ablished biofflms.

Chemical methods, where compatible, can be used on a wider variety of construction materials. These methods typieally employ oxidizing agents such as halogenated compounds, hydrogen perox ide, ozone, or peracetic acid. Halogenated eompounds are effective sanitizers but are diffieult to flush from the system and tend to leave biofllms intact. Compounds such as hydrogen peroxide, ozone, and peracetic acid oxidize bacteria and biofilms by forming reactive peroxides and free radieals (notably hydroxyl radieals). The shori half life of these compounds, particularly ozone, may require that it be added eontintrously during the sanitization process. Hydrogen peroxide andozone rapidly degrade to water andoxygen; peracetie acid degrades to acetic acid in the presence of UV light.

UV light impacts on the development of biofilms by reduring the rate of new mierobial colenization in the system; however, it is only partially effective against planktonic mieroorganisms. Alone, UV light is not an effective tool beenuse it does not elimi nate existing biofilm. However, when coupled with conventional thermal or chemieal sanitization technologies, it is most effective and ean prolong the interval be ween system sanitizations. The use of UV light also facilitates the degradation of hydregen peroxide and ozone.
Sanitization steps require validation to demenstrate the capabil ity of reducing and holding mierobial contamination at aceeptable levels. Validation of thermal methods should inelude a heat distri bution study to demenstrate that sanitization temperatures are a ehieved throughout the system. Validation of chemieal methods require a demenstration of adequate chemieal-concentrations throughout the system. In addition, when the sanitization proeess is completed, effective removal of chemieal residues must be dem enstrated.
The frequency of sanitization is generally dictated by the results of system menitering. Conclusions derived from the trend analysis of the mierobiologieal dat should be used as the alert mechanism for maintenance. The frequency of sanitization should be estabtished such that the system operates in a state of mierobiologieal control and doe not exeeed Alert Levels.

## OPERATION, MAINTENANCE, AND CONTROL

A preventive maintenanee program should be established to en stre that the water system remains in a state of control. The program should include (1) procedures for operating the system, (2) monitoring programs for critieal quality attributes and operating eonditions ineluding calibration of eritieal instruments, (3) sehed the for periodic sanitization, (4) preventive maintenance of compo nents, and (5) centrol of ehanges to the meehanienl system and to eperating conditions.

Operating Proeedures. Procedures for operating the water system and performing routine maintenance and corrective action should be written, and they should also-define the point when at tion is required. The procedures should be well documented, detail the function of each job, assign whe is respensible for performing the work, and describe how the job is to be conducted.
Monitoring Program- Gritieal quality attributes andoperating parameters should be documented and monitored. The program may inelude a combination of in line sensors or recorders (e.g., a eondtretivity meter and recorder), manual documentation of oper ational parameters (such as carbon filter pressure drop) and labor atory tests (e.g., total microbial counts). The frequency of sampling, the requirement for evaluating test results, and the neeessity for initiating corrective action should be ineluded.
Sanitization- Depending on system design and the selected units of operation, routine periodic sanitization may be necessary to maintain the system in a state of mierobial control. Technolegies for sanitization are deseribed above.

Preventive Maintenance A preventive maintenance program should be in effeet. The program should establish what preventive maintenance is to be performed, the frequency of maintenance work, and how the work should be documented.

Change-Contrel. The mechanical eonfiguration andoperating eonditions must be controlled. Propesed changes should be valuated for their impact on the whole system. The need to requalify the system after changes are made should be determined. Following a decision to modify a water system, the affeeted drawings, manmals, and procedures should be revised.

## SAMPLING CONSIPERATHONS

Water systems should be monitered at a frequeney that is suffit eient to ensure that the system is in contrel and contintes to produee water of aceptable quality. Samples should be taken from representative locations within the processing and distribution system. Established sampling frequeneies should be based on system validation data and should cover critieal areas. Unit operation sites might be sampled less frequently than peint of use sites. The sampling plan should take into consideration the desired attributes of the water being sampled. For example, systems for Water for Injec tion, beeause of their mere-critieal mierobiologieal requirements, may require a more rigoreus sampling frequeney.

When sampling water systems, special care should be taken to ensure that the sample is representative. Sampling perts should be sanitized and thoreughly flushed before a sample is taken. Samples eontaining chemical sanitizing agents require neutralization prior to mierobiologieal analysis. Samples for mierobiologieal analysis should be tested immediately or suritably protected to preserve the sample until analysis ean begin.

Samples of flowing water are only indieative of the concentrat tion of planktonic (free floating) mieroerganisms present in the system. Benthic (attached) mieroorganisms present as biofilms are generally present in greater numbers and are the source of the planktonic population. Mieroorganisms in biofilms represent a continuous soure of contamination and are diffieult to sample and quantify. Consequently, the planktonic pepulation is used as an indieator of system contamination levels and is the basis for sys tem Alert Levels. The censistent appearance of elevated planktenic levels is usually an indiention of advaneed biofilm development in need of remedial control. System control and sanitization arekey in eontrolling biofilm formation and the consequent planktonic population.

## MICROBHAL CONSIPERATHONS

The major exogenous souree of mierobial contamination is seuree or feed water. Feed water quality must, at a minimum, meet the quality attributes of drinking water for which the level of coli forms are regulated. A wide varie of other mieroorganisms, chief ly Gram negative bacteria, may be present. These mierereganisms may compromise subsequent purification steps.
Examples of other potential exogenous sources of microbial eontamination inelude umprotected vents, faulty air filters, back flow from contaminated outlets, drain air breaks, and replacement activat carben and deionizer resins. Sufficient eare should be given to system design and maintenance in order to min imize mierobial contamination from these sources.

Unit operations can be a major source of endogenous microbiat eontamination. Mieroorganisms present in feed water may udsorb to carben beds, deionizer resins, filter membranes, and other unit eperation surfaces and initiate the formation of a biofilm. Bioflmis an adaptive respense by certain mieroorganisms to survive in a fow nutrient envirenment. Mierorgenisms in a biofilm are protected from the action of many biocides. Downstream colenization ean oceur when mieroorganisms are sloughed off and earried in other areas of the water system. Mieroorganisms may also attach
to suspended particles such as carben bed fines and serve as a source of contamination to subsequent purification equipment and-distribution systems.
Anether souree of endegeneus mierobial contamination is the distribution system. Mieroorganisms can colonize pipe-strafaces, walves, and other areas. There they proliferate, forming a biofllm, which then provides a continterns souree of mierobial contamination.

Endotoxins are lipopolysaceharides from the cell envelope that is external to the cell wall of Gram negative bacteria. Gram negative bacteria readily form biofilms that can beeome a source of en dotoxins. Endotoxins may either be associated with living mieroorganisms or fragments of dead mieroorganisms, or they may be free molecules. The free form of endotexims may be reteased fromeell surface or biofilms that colenize the water system, or they may enter the water system via the feed water. Endotoxim levels may be minimized by controlling the introduction of mieroerganisms and mierobial proliferation in the system. This may be aceomplished through the nommal exelusion or removal action af forded by various unit operations within the treatment system as well as threugh system sanitization. Other control methods inelude the use of ultrafliters or charge modified filters, either in line or at the point of use. The presence of endotoxins may be monitored as described in the chapter Bacterial Endoxins Test (85):

## МЕТНӨВӨЦӨGICAL CONSHERATIONS*

The objective of a water system mierobiolegieal menitoring program is to provide sufffient information to control the mierobio logieal quality of the water produced. Product quality requirements should dictate water quality needs. An appropriate level of control may be maintained by using dat trending techniques and limiting specific antraindieated miereorganisms. Consequently, it may net be necessary to detect all of the mieroorganisms present. The monitoring program and methodology should indicate adverse trends and detect mieroorganisms that are potentially harmful to the fin ished product or consumer.

Final selection of method variables should be based on the individual requirements of the system being menitored. It should be recognized that there is no single methed that is capable of detect ing all of the potential mierobial contaminants of a water system. Methods selected should be capable of isolating the numbers and typer of organisms that have been deemed significent relative to system eontrol and product impact for each individual system.

Several criteria should be considered when selecting a methodte menitor the mierobial content of a pharmaceutienl water system. These include method sensitivity, range of organisms recovered, sample throughput, incubation period, cost, and teehnieal complexity. An additional consideration is the use of the classieal "eut ture" approaches vs. a sophisticated instrument approach.

## THE CLASSICAL CULTURE APPROACH

Classical culture appreaches for mierobial testing of water in elude but are not limited to pour plates, spread plates, membrane filtration, and mest prebable number (MPN) tests. These metheds are-generally easy to perform, are less expensive, and provide ex eellent sample precessing throughput. Method sensitivity ean be increased via the use of larger sample sizes. This strategy is used in the membrane filtration method.

Culture approaches are further defined by the type of medium used in combination with the ineubation temperature and duration. This combination should be selected aceording to the monitoring

[^268]needs presented by a specific water system as well as its ability to recover mieroorganisms that could have a detrimental effect on the product or process.

There are basic forms of media available for traditional mierebielegieal analysis. "high" mutrient and "'low" nutrient. Hight futrient media are intended as seneral media for the-isolation and enumeration of heterotrophic bacteria. Low nutrient media are benefficial for isolating slow growing bacteria and bacteria that have been injured by previous exposure to disinfectants and sanitizers sueh as chlorine. Low nutrient media may be compared to high mutrient media, especially during the validation of a water system, in order to determine-if any additional mambers or ypes of bacteria are present so that their impact on the end use may be assessed. Additionally, the effleaey of system eontrols and sanitization on these slower growing or impaired bacteria can alse be assessed.

Duration and temperature of incubation are also critieal aspeets of a mierebiolegieal test method. Classieal methodelegies usimes high nutrient media have required ineubation at $30^{\circ} \mathrm{C}$ to $35^{\circ} \mathrm{C}$ for 48 to 72 hours. In certain water systems ineubation at lower temperatures (e.s., $20^{\circ} \mathrm{C}$ to $25^{\circ} \mathrm{C}$ ) and lenger periods (e.5., 5-10.7 days) ean produce higher counts when compared to lassieal metheds. Whether or not a partieular system needs to be menitered using lower incubation temperatures or longer incubation times sheuld be determined during system validation.

The decision to use longer ineubation periods should be made after considering the need for timely information and the ype-of eerrective actions required when an Alert or Action Level is ex ceeded. The advantages gained by ineubating for longer times, namely recovery of injured miereorganisms, slow growers, or more fastidious mieroerganisms, should be balanced against the need to have a timely investigation and to take corrective aetion, as well as the ability of these mieroergenisms to detrimentally af feet products or processes.

## "INSTRUMENT" APPROACH

Examples of imstrument approaches include mieroscopic direet eounting teehniques (e.g., epifluoreseenee and immanofluoreseence), radiemetric, impedemetric, and biechemieally based methedelegies. These metheds all persess a variety of advantages and disadvantages.

One advantage is their precision and aceuracy. In general, instru ment appreaches often have a-shorter lead time-for obtainimes results, which facilitates timely system control. This advantage, however, is often counterbalaneed by limited sample proeessing throughput due to laber intensive sample processing or other in strument limitations. In addition, instrumental approaches are de structive in that further iselate manipulation for characterization purpeses are precluded. Generally, some form of mierobial isolate eharacterization may be arequired element of water system menitoring. Consequently, eulturing approaches have traditionally been preferred over imstrumental approaches beeatse they offer a balance-of desirable test attributes and pest test eapabilities.

## RECOMAMNDED-METHЮDӨЦӨGIES

The following general methods obtained from Standard Meth ods for the Examination of Water and Wastewater, 18 th Edition, American Public Health Association, Washingten, DC 20005, are considered appropriate for establishing trends in the number of celony forming units observed in the routine mierebiolegieat menitering of ingredient water. It is recegnized, hewever, that othercombinations of media, time, and temperature of ineubation may eceasienally or even consistently result in higher numbers of coleny forming units being observed. The-extended-ineubation periods that are usually required by some of the alternative methods available offer disadvantages that may outweigh the hight
er counts obtained. The somewhat higher baseline counts would not necessarily have greater utility in detecting an exeursion-or a trend.

Methodelegies that ean be recemmended as-generally satisfacfory for menitoring pharmaceutical water systems are as follows:-

| Prinking Water: | POUR PLATE METHЮР |
| :---: | :---: |
|  | Minimmam sample 1.0 mE |
|  | Plate-count agar |
|  | Plateceumt agar |
|  | 42 to 72 heurs ineubation at $30^{\circ} \mathrm{C}$ ${ }^{5}-35^{\circ} \mathrm{C}$ |
| Purified Water: | POUR PLATE METHЮР |
|  | Minimman-sample 1.0 mL |
|  | Platecount agar |
|  | $48+72$ hems ineubation at $30^{\circ} \mathrm{C}$ ${ }_{-}-35^{\circ} \mathrm{C}$ |
| Weter for Injection: | MEMBRANE FILTRATION METЮЮР Minimum-sample 100 mL |
|  | Plate count agar |
|  | 48 to 72 heurs ineubation at |
|  | $30^{\circ} \mathrm{C}-35^{\circ} \mathrm{C}$ |

## Identifieation of Mieroorganisms

Identifying the isolates recovered from water monitoring meth ods may be impertant in instances where-specific waterborne mi eroorganisms may be detrimental to the product or processes in which the water is used. Mieroorganism information such as this may alse be usefut when identifying the seuree of mierobial cen tamination in a product or process.

Often a limited group of mieroorganisms are continuously reeovered from a water system. After repented characterization, an experienced mierobiologist may beeome proficient at their identifieation basedenenly a few traits sueh as colonial merphology and staining characteristies. This level of characterization is adequate for mest situations.

## Alert and Action Levels

The individual menegraphs for Purfifed Water and Water for In jection do not inelude-specific mierobial limits. These were pur pesefully omitted since most current microbiological techniques available require at least 48 hours to obtain definitive results. By that time, the water from which the sample was ataken has already been employed in the production proeess. Failure to meet a com pendial specification would require rejecting the product lot in volved, and this is not the intent of an alert or action guideline. The establishment of quantitative mierobiologieal gridelines for water for pharmaceutical purposes is in order because such guidelines will establish procedures that are to be implemented in the event that signifieant exeursions beyend these limits oceur:

Water systems should be mierobiologieally monitored to confrm that they continue operate within their design specifientions and produre water of aceeptable quality. Menitering data may be empared to established process parameters or product speciffen tions. A refinement to the use of process parameters and product specifications is the establishment of Alert and Action Levels, which signal a shift in process performance. Alert and Action Lev els are distinet from proeess parameters and product specifieations in that they are used for monitoring and control rather than aceept or reject decisions.

Alert Levels are levels or ranges that, when eveeded, indieate that a process may have drifted frem its normal operating condition. Alert Levels constitute a warning and do not necessarily require a corrective action.

Action Levels are levels or ranges that, when exceeded, indicate that a process has drifted from its normal operating range. Exceed ing an Action Level indicates that corrective action should be aken to bring the preeess back inte its nermal operating range.

Alert and Action Levels are established within process and prod Het specifieation tolerances and are basedonacombination of teeh nieal and product related considerations. Consequently, eweeding an Alert or Action Level doe not imply that product quality has been compromised.

Technieal censiderations used to establish Alert and Action Ler els should inelude a review of equipment design specifieations to ensure that the purification equipment is capable of achieving the required level of purity. In addition, samples should be collected and analyzed over a period of time to develop data reflecting nor mal water quality trends. Historieal or statistically based levels ean be established using the above data. Levels astablished in this way measure process performance and are independent of product eoneerns.

Product related Alert and Action Levels-should represent both product quality coneerns and the ability to effectively manage the purifieation proeess. These levels are ypieally based on a review of proeess data and an assessment of product sensitivity to ehemical and mierobiologieal contamination. The assessment of product susceptibility might include preservative efficacy, water activity, pH , ete. The levels should be set such that, when exeed ed, produret quality is not compromised.

Monitering data should be analyzed on an ongoing basis to en sure that the proeess eontintes to perform within aceeptable limits. An analysis of data trends is often used to a mance. This information ean be used to prediet depatures from established operating parameters, thereby signaling the need for appropriate preventative maintenance.

It should be reeognized that the mierobial Alert and Action Lev els established for any pharmaceutical water system are necessarily linked to the monitoring method chosen. Using the recommended methodologies, generally considered appropriate Aetion Levels are 500 coleny forming units (efu) per mL for Drinking Water, 100 eft per mL for Purified Whter and 10 efuper 100 mL for Heter for Iniection.

It should be emphasized that the above action guidelines are net intended to be totally inelusive for every situation where ingredient waters are employed. For example, Gram negative miereorganisms are not excluded from ingredient waters, nor is the presence of Gram negative mieroorganisms prohibited in Drinking Weter in the Federal Regulations. The reason for this is that these miereor ganisms are ubiquiteus to the aqueus enviromment and theirex elusion would likely require a sterilization process that would not be appropriate or feasible in many manufacturing seenarios. How ever, there are situations where they might not be tolerated: in top ieal products and in some oral dosage forms. It is, therefore, incumbent upen the manufacturer to supplement the general action gridelines to fit each partieular manufacturing sittation.

## -INTRODUCTION

Water is widely used as a raw material, ingredient, and solvent in the processing, formulation, and manufacture of pharmaceutical substances and compendial articles. Its breaduse makes it an impertant substance whese quality requires careftuly established specifieations to render it suit able for the majority of its uses. Because these varied uses
each require failored specifieations, a number ofeompendiat menegraphs havebeencreated products, active pharmaceutical ingredients (APIs) and intermediates, compendial articles, and analytical reagents. This general information chapter provides additional information about water, its quality attributes that are not included within a water monograph, processing techniques that can be used to improve water quality, and a description of minimum water quality standards that should be considered when selecting a water source.

This information chapter is not intended to replace existing regulations or guides that already exist to cover USA and International (ICH or WHO) GMP issues, engineering guides, or other regulatory (FDA, EPA, or WHO) guidances for water. The contents will help users to better understand pharmaceutical water issues and some of the microbiological and chemical concerns unique to water. This chapter is not an all-inclusive writing on pharmaceutical waters. It contains points that are basic information to be considered, when appropriate, for the processing, holding, and use of water. It is the user's responsibility to assure that pharmaceutical water and its production meet applicable governmental regulations, guidances, and the compendial specifications for the types of water used in compendial articles.

Control of the chemical purity of these waters is important and is the main purpose of the monographs in this compendium. Unlike other official articles, the bulk water monographs (Purified Water and Water for Injection) also limit how the article can be produced because of the belief that the nature and robustness of the purification process is directly related to the resulting purity. The chemical attributes listed in these monographs should be considered as a set of minimum specifications. More stringent specifications may be needed for some applications to ensure suitability for par-
ticular uses. Basic guidance on the appropriate applications of these waters is found in the monographs and is further explained in this chapter.

Control of the microbiological quality of water is important for many of its uses. All packaged forms of water are requiredtebe-sterile-either beeatise their uses require this attribute or beeause potential contaminating miereorganisms, if not removed or killed prier to packaging, eould contintue to grow tnehecked to extremely high levets after packaging, rendering the water potentially unsuitable for many of its other nonsterile uses. that have monograph standards are required to be sterile because some of their intended uses require this attribute for health and safety reasons. USP has determined that a microbial specification for the bulk monographed waters is inappropriate seral and has not been included within the monographs for these waters. These waters can be used in a variety of applications, some requiring extreme microbiological control and others requiring none. Unlike for packed waters, the The needed microbial specification for a given bulk water depends upon its use. A single specification for this dif-ficult-to-control attribute would unnecessarily burden some water users with irrelevant specifications and testing. However, ther some applications may require even more careful microbial control to avoid the proliferation of microorganisms ubiquitous to water during the purification, storage, and distribution of this substance. Anether rean steh a A microbial specification would be inapprepriate is also be inappropriate when related to the "utility" or continuous supply nature of this raw material. A microbial specifications are typically assessed by test methods that take at least 48 to 72 hours to generate results. Because pharmaceutical waters are generally produced by continuous processes and used in products and manufacturing processes soon after generation, the water is likely to have been used well before
definitive test results are available. Failure to meet a compendial specification whether relevant to that particular He or not, would require rejecting would require investigating the impact and making a pass/fail decision on all product lots between the previous sampling's acceptable test result and a subsequent sampling's acceptable test result. How ever, the establishment of quantitative microbiological guidelines for specific phamaceutical water uses is not to tally inappropriate for especially critieal uses. In these sitt ations, manufacturing at risk (using the water in a entinuous mode prior to availability of test results) may be contraindieated. Instead, action and alert levels should be used as in process controls to keep the mierobial quality of the water within levels that reflect a state of control of the Water system with mierobial counts well under any speciff eation established for a specific eritieal use. The technical and logistical problems created by a delay in the result of such an analysis does not eliminate the user's need for microbial specifications. Therefore, such water systems need to be operated and maintained in a controlled environment that requires that the system be validated to provide assurance of operational stability and that its microbial attributes be quantitatively monitored against established alert and action levels that would provide an early indication of system control. The issues of water system validation and alert/action levels and specifications are included in this chapter.

## SOURCE OR FEED WATER CONSIDERATIONS

To ensure adherence to certain minimal chemical and microbiological quality standards, water used in the production of drug substances or as source or feed water for the preparation of the various types of purified waters must meet the requirements of the National Primary Drinking Water Regulations (NPDWR) (40 CFR 141) issued by the U.S. Environmental Protection Agency (EPA) or
regulations for drinking water of the European Union or Jathe drinking water regulations of the European Union or Japan, or the WHO drinking water guidelines. Limits on the types and quantities of certain organic and inorganic contaminants ensure that the water will contain only small, safe quantities of potentially objectionable chemical species. Therefore, water pretreatment systems will only be challenged to remove small quantities of these potentially difficult-to-remove chemicals. Also, control of objectionable chemical contaminants at the source-water stage eliminates the need to specifically test for some of them (e.g., trihalomethanes and heavy metals) after the water has been further purified.
Microbiological requirements of drinking water ensure the absence of coliforms, which, if determined to be of fecal origin, may indicate the potential presence of other potentially pathogenic microorganisms and viruses of fecal origin. Meeting these microbiological requirements does not rule out the presence of other microorganisms, which could be considered undesirable if found in a drug substance or formulated product.

On the other hand, meeting these regulations does not rule out the presence of other mieroorganisms, which, while net eonsidered a major public health concern could, if present, eonstitute a hazard or be considered undesirable in a druty substance or formulated product.
To accomplish microbial control, Municipal Water Authorities add drinking water, among other things, disindisinfectants to drinking water. Chlorinecontaining and other oxidizing substances have been used for many decades for this purpose and have generally been
considered to be relatively innocuous to humans. However, these oxidants can interact with naturally occurring organic matter to produce disinfection by-products (DBPs), such as trihalomethanes (THMs, including chloroform, bromodichloromethane, and dibromochloromethane) and haloacetic acids (HAAs, including dichloroacetic acid and trichloroacetic acid). The levels of DBPs produced vary with the level and type of disinfectant used and the levels and types of organic materials found in the water, which can vary seasonally. of herrly.

Because high levels of DBPs are considered a health hazard so control of their levels is mandated by Drinking Water Regulations intended to redure exposure to these substanees to nomhazardous levels. in drinking water, Drinking Water Regulations mandate their control to generally accepted nonhazardous levels. However, depending on the unit operations used for further water purification, a small fraction of the DBPs in the starting water may carry over to the finished water. Therefore, the importance of having minimal levels of DBPs in the starting water, while achieving effective disinfection, is important.

DBP levels in drinking water can be minimized by using disinfectants such as ozone, chloramines, or chlorine dioxide. Like chlorine, their oxidative properties are sufficient to damage some pretreatment unit operations and must be removed early in the pretreatment process. The complete removal of some of these disinfectants can be ehallenging. problematic. For example, chloramines may degrade during the disinfection process or during pretreatment removal, thereby releasing ammonia, which in turn can carry over to the finished water. Pretreatment unit operations must be
designed and operated to adequately remove the disinfectant, drinking water DBPs, and objectionable disinfectant degradants. A serious problem can occur if unit operations designed to remove chlorine were, without warning, challenged with chloramine-containing drinking water from a municipality that had been mandated to cease use of chlorine disinfection to comply with ever tightening EPA Drinking Water THM specifications. The dechlorination process might incompletely remove the chloramine, which could irreparably damage downstream unit operations, but also the release of ammonia during this process might carry through pretreatment and prevent the finished water from passing compendial conductivity specifications. The purification process must be reassessed if the drinking water disinfectant is changed, emphasizing the need for a good working relationship between the pharmaceutical water manufacturer and the drinking water provider.

## TYPES OF WATER

There are many different grades of water used for pharmaceutical purposes. Several of the are described in USP monographs that specify uses, acceptable methods of preparation, and quality attributes. These waters can be divided into two general types: bulk waters, which are typically produced on site where they are used; and
packaged waters, which are produced, packaged, and sterilized to preserve microbial quality throughout their packaged shelf life. There are several specialized types of packaged waters, differing in their designated applications, packaging limitations, and other quality attributes.

There are also other types of water for which there are no monographs. These are all bulk waters, with names given for descriptive purposes only. Most of these waters are used in specific analytical methods. The associated text may not specify or imply certain quality attributes or modes of preparation. These nonmonographed waters may not necessarily adhere strictly to the stated or implied modes of preparation or attributes. Waters produced by other means or controlled by other test attributes may equally satisfy the intended uses for these waters. It is the user's responsibility to ensure that such waters, even if produced and controlled exactly as stated, be suitable for their intended use. Wherever the term "water" is used within this compendia without other descriptive adjectives or clauses, the intent is that water of no less purity than Purified Water be used.
What follows is a brief description of the various types of pharmaceutical waters and their significant uses or attributes. Figure 1 may also be helpful in understanding some of the various types of waters.

Fig. 1. Water for phamacentieal purpeses.

Fig. 1. Water for pharmaceutical purposes.

Bulk Monographed Waters and Steam
The following waters are typically produced in large volume by a multiple-unit operation water system and distributed by a piping system for use at the same site. These particular pharmaceutical waters must meet the quality attributes as specified in the related monographs., but the for lowing disenssion gives further insight as to their uses and requirements.

Purified Water—Purified Water (see USP monograph) is used as an excipient in the production of nonparenteral preparations and in other pharmaceutical applications, such as cleaning of certain equipment and nonparenteral productcontact components. Unless otherwise specified, Purified Water is also to be used for all tests and assays for which water is indicated (see General Notices and Requirements). Purified Water is also referenced throughout the $U S P-N F$. Regardless of the font and letter case used in its spelling, water complying with the Purified Water monograph is intended. Purified Water must meet the requirements for ionic
and organic chemical purity and must be protected from microbial contamination. The minimal quality of source or feed water for the production of Purified Water is Drinking Water. This source water may be purified using unit operations that include deionization, distillation, ion exchange, reverse osmosis, filtration, or other suitable purification procedures. Purified water systems must be validated to reliably and consistently produce and distribute water of acceptable chemical and microbiological quality. Purified water systems that function under ambient conditions are particularly susceptible to the establishment of tenacious biofilms of microorganisms, which can be the source of undesirable levels of viable microorganisms or endotoxins in the effluent water. These systems require frequent sanitization and microbiological monitoring to ensure water of appropriate microbiological quality at the points of use.

The Purified Water monograph also allows bulk packaging for commercial use elsewhere. When this is done, the required specifications are those of the packaged water Sterile Purified Water, except for Sterility and Labeling. There is a potential for microbial contamination and other quality changes of this bulk packaged non-sterile water to occur. Therefore, this form of Purified Water should be prepared and stored in such a fashion that limits microbial growth and/or simply used in a timely fashion before microbial proliferation renders it unsuitable for its intended use. Also depending on the material used for packaging, there will be extractable compounds leaching into the water from the packaging. Though this article may meet its required chemical attributes, such extractables may render the water an inappropriate choice for some applications. It is the user's responsibilitiy to assure fitness for use of this packaged article when used in manufacturing, clinical, or analytical applications where the pure bulk form of the water is indicated.

Water for Injection—Water for Injection (see USP monograph) is used as an excipient in the production of parenteral and other preparations where product endotoxin content must be controlled, and in other pharmaceutical applications, such as cleaning of certain equipment and parenteral product-contact components. The minimum quality of source or feed water for the generation of Water for Injection is Drinking Water as defined by the U.S. EPA, EU, Japan, or the WHO. This source water may be preliminarily purified pre-treated to render it suitable for subsequent distillation (or whatever other validated process is used according to the monograph). The resulting finished water must meet all of the chemical requirements for Purified Water as well as an additional bacterial endotoxin specification. Since endotoxins are produced by the kinds of microorganisms that are prone to inhabit water, the equipment and procedures used by the system to purify, store, and distribute Water for Injection must be designed to minimize or prevent microbial contamination as well as remove incoming endotoxin from the starting water. Water for Injection systems must be validated to reliably and consistently produce and distribute this quality of water.

The Water for Injection monograph also allows it to be packed in bulk for commercial use. Required specifications include the test for Bacterial endotoxins, and those of the packaged water Sterile Purified Water, except for Labeling. Bulk packaged Water for Injection is required to be sterile, thus eliminating microbial contamination quality changes. However, packaging extractables may render this water an inappropriate choice for some applications. It is the user's responsibility to ensure fitness for use of this packaged article when used in manufacturing, clinical, or analytical applications where the purer bulk form of the water is indicated.

Water for Hemodialysis—Water for Hemodialysis (see USP monograph) is used for hemodialysis applications, primarily the dilution of hemodialysis concentrate solutions. It is produced and used on-site and is made from EPA Drinking Water which has been further purified to reduce chemical and microbiological components. It may be packaged and stored in unreactive containers that preclude bacterial entry. The term "unreactive containers" implies that the container, especially its water contact surfaces, are not changed in any way by the water, such as by leaching of container-related compounds into the water or by any chemical reaction or corrosion caused by the water. The water contains no added antimicrobials and is not intended for injection. Its attributes include specifications for Water conductivity, Total organic carbon (or oxidizable substances), Microbial limits, and Bacterial endotoxins. The water conductivity and total organic carbon attributes are identical to those established for Purified Water and Water for Injection; however, instead of total organic carbon, the organic content may alternatively be measured by the test for Oxidizable substances. The Microbial limits attribute for this water is unique among the "bulk" water monographs, but is justified on the basis of this water's specific application that has microbial content requirements related to its safe use. The Bacterial endotoxins attribute is likewise established at a level related to its safe use.

Pure Steam—Pure Steam (USP monograph to come) is intended for use in steam sterilizing porous loads and equipment and in other processes such as cleaning where condensate would directly contact official articles, containers for these articles, process surfaces that would in turn contact these articles, or materials which are used in analyzing such articles. Pure Steam is also intended to be used for air humidification in controlled manufacturing areas where official articles or article-contact surfaces are exposed to the
resulting conditioned air. The primary intent of using this quality of steam is to ensure that official articles or articlecontact surfaces exposed to it are not contaminated by residues within the steam. Pure Steam is prepared from suitably pretreated source water, analogous to the pretreatment used for Purified Water or Water for Injection, vaporized with a suitable mist elimination, and distributed under pressure. The sources of undesirable contaminants within Pure Steam could be derived from entrained source water droplets, anticorrosion steam additives, or particulate matter from the steam production and distribution system itself; therefore, the attributes in the monograph should preclude most of the contaminants that could arise from these sources.

These purity attributes are measured on the condensate of the article, rather than the article itself. This, of course, imparts great importance to the cleanliness of the Pure Steam condensate generation and collection process because it must not adversely impact the quality of the resulting condensed fluid.

Other steam attributes not detailed in the monograph, in particular, the presence of even small quantities of noncondenseable gases or the existence of a superheated or dry state, may also be important for applications such as sterilization. The large release of energy (latent heat of condensation) as water changes from the gaseous to the liquid state is the key to steam's sterilization efficacy and its efficiency, in general, as a heat transfer agent. If this phase change (condensation) is not allowed to happen because the steam is extremely hot and in a persistent super heated, dry state, then its usefulness could be seriously compromised. Noncondensable gases in steam tend to stratify or collect in certain areas of a steam sterilization chamber or its load. These surfaces would thereby be at least partially insulated from the steam condensation phenomenon, preventing them from experiencing the full energy of the sterilizing conditions.

Therefore, control of these kinds of steam attributes, in addition to its chemical purity, may also be important for certain Pure Steam applications. However, because these additional attributes are use-specific, they are not mentioned in the Pure Steam monograph.

Note that less pure plant steam may be used for steam sterilization of nonporous loads, general cleaning and sterilization of nonproduct contact equipment and analytical materials, humidification of air in nonmanufacturing areas, where used as a nonproduct contact heat exchange medium, and in all compatible applications involved in bulk pharmaceutical chemical and API manufacture.

## Packaged Monographed Waters

The following monographed waters are packaged forms of either bulk Purified Water or bulk Water for Injection that have been sterilized to preserve their microbiological properties. These waters may have specific intended uses as indicated by their names and may also have restrictions on packaging configurations related to those uses. In general, these packaged waters may be used in lieu of the bulk form of water from which they were derived. However, the user should take into consideration that the packaging and sterilization processes used for the articles may leach materials from the packaging material into the water over its shelf life, rendering it less pure than the original water placed into the package. The chemical attributes of these waters are still defined primarily by the wet chemistry methods and specifications similar to those formerly used for the bulk pharmaceutical waters prior to their replacement with water conductivity and total organic carbon (TOC). It is the user's responsibility to ensure fitness for use of this article when used in manufacturing, clinical, or analytical applications where the purer bulk form of the water is indicated.

Sterile Purified Water-Sterile Purified Water (see USP monograph) is Purified Water, packaged and rendered sterile. It is used in the preparation of nonparenteral compendial dosage forms or in analytical applications requiring Purified Water where access to a validated Purified Water system is not practical, where only a relatively small quantity is needed, where sterile Purified Water is required, or where bulk packaged Purified Water is not suitably microbiologically controlled. of sterile Purifit Water is required.

Sterile Water for Injection—Sterile Water for Injection (see USP monograph) is Water for Injection packaged and rendered sterile. It is used for extemporaneous prescription compounding and as a sterile diluent for parenteral products. It may also be used for other applications where bulk Water for Injection or Purified Water is indicated but where assess to a validated water system is either not practical or where only a relatively small quantity is needed. Sterile Water for Injection is packaged in single-dose containers not larger than 1 L in size.

Bacteriostatic Water for Injection-Bacteriostatic Water for Injection (see USP monograph) is sterile Water for Injection to which has been added one or more suitable antimicrobial preservatives. It is intended to be used as a diluent in the preparation of parenteral products, most typically for multi-dose products that require repeated content withdrawals. It may be packaged in single-dose or multiple-dose containers not larger than 30 mL .

Sterile Water for Irrigation-Sterile Water for Irrigation (see USP monograph) is Water for Injection packaged and sterilized in single-dose containers of larger than 1 L in size that allows rapid delivery of its contents. It need not meet the requirement under small-volume injections in the general test chapter Particulate Matter in Injections $\langle 788\rangle$. It may also be used in other applications, which do not have particulate matter specifications, where bulk Water for In-
jection or Purified Water is indicated but where access to a validated water system is not practical or where somewhat larger quantities than are provided as Sterile Water for Injection are needed.

Sterile Water for Inhalation—Sterile Water for Inhalation (see USP monograph) is Water for Injection that is packaged and rendered sterile and is intended for use in inhalators and in the preparation of inhalation solutions. It carries a less stringent specification for bacterial endotoxins than Sterile Water for Injection, and therefore, is not suitable for parenteral applications.

## Sterile-Water for Hemodialysis Sterile Water for He

 modialysis [USP monograph tocome] is Water for Injection which has additional attributes for certain ehemieals whieh have been shown to be problematic during hemodialysis. It is used for the dilution of hemodialysis concentrate and oth er hemodialysis applieations.
## Nonmonographed Waters and Steam Manufacturing Waters <br> PharmaeentiealWater Cited in this chapter, this is a

 broad term referring to any water used in the preparation of active pharmaceutical ingredients, exeipients, and fint ished produets as well as any related proeess such as pharmaceutical equipment cleaning or product testing. The term eovers a bread range of water purities, starting with the least pure allowed in any process for USP substances, Drinking Water, and extending to the highest purity reasonably aehievable. The water's purity must be suitable for its intend ed use, but no less pure than the USP andeGMP requirements.Prinking Water Citedin General Notiees and Requirements, the general test chapters, and the dietary supple ment chapters, this water must comply with the quality attributes of the U.S. Environmental Protection Ageney's

National Primaty Drinking Water Regulations (NPDWR) Or comparable regulations of the European Union or Japan. It may be derived from a varie of sourees including a public water utility, a private water supply (e.g., a well), or a eombination of more than one of these sources. Drinking Water may be used in the early stages of eleaning pharmaceutical manufacturing equipment and product-contact eomponents. Drinking Water is also the minimum quality of water which should be used for the preparation of official substances and other bulk pharmaceutical ingredients. Where required by the processing of the materiats to achieve their required fanal purity, higher qualities of water may be needed, perhaps even as pure as-Water for Injection-or Pur rified Water Such higher purity waters might, however, reeeive only selected attributes to be of higher purity than Prinking Water (see-Water for Special Phatmacutical Purpores and Endetoxin and Mierorrganism-Controlled Water below). Drinking Water is the preseribed source feed water for the production of pharmaceutical waters. As seasenal variations in the quality attributes of the Drinking Water supply ean oceur, due consideration to its synthetic and eleaning uses must be given. In addition, the processing steps in the production of pharmaceutieal waters must be designed to aceommodate this variability.

Potable-Water Cited-in the-General Notices and Requirements, the general test chapters, and the dietary supplement chapters, this is an older synonym for Drinking Water (derived from the French adjective potable, meaning drink able).

NPDWR Water Cited in this chapter, this water must eomply with the U.S. Envirenmental Pretection Ageney's National Primary Drinking Water Regulations, the drinking water mandated for use in the United States. The-specifiea-
tions for this water, found in-40 CFP Part 141, inelude max imum contaminant levels for a large number of inorganic, erganic, mierebiolegieal, and radioactive contaminants.

## Water for Special-Pharmaceutical-Purposes-Gited in

 this chapter, this bread term is used to deseribe any type-of water that does not have a menegraph but has special purity requirements stited for its intended purposes.Endotoxin-and-Mieroorganism-Controlled-WaterGited in this chapter, this ype of water has been-subjected foconditions that contrel its mierobial and endotoxin coneentrations at a level suitable for its intended use. It may alse have undergone some level of chemical purification.

LAL Reagent Water Cited in the USP menographs as well as the general chapters, this is a water, usually Water for Injection which may have been sterilized and is free frem a level of endotoxin that would yield any detectable reaction or interference with the Limulus Ameboeyte Lysate reagent used in the Bacterial Endetoxins Test $\langle 85\rangle=$

Endotoxin-Free Water Cited in one USP monograph, this water is a symonymous with LAL Reagent Water.

Carbon-Dioxide-Free-Water Cited in nmmerous-USP monegraphs, general test chapters, and NF menographs, this is Putrified Water or Water for Injection that has been prepared to remove dissolved carben dioxide and biearbenate during its purification and then either protected from earben dioxide reabsorption during its preparation and storage er treated to drive off the dissolved earben dioxide just prior to use, such as by sparging with an inert gas or by boiling. The Reagents section of USP deseribes its preparation as Purified Water that has been boiled for 5 minutes, cooled, and protected from atmospheric carben-dioxide adsorption. Practically speaking, it is extremely diffieult to remove all earben dioxide frem the water by beiling or sparging, and if exposed to air at all, sueh as during cooling or when transferring aquantity of water to a working eontainer for use in a
test, readsorption is inevitable. Deionization by a mixed bed deionizer is an effective initial carben dioxide removal approach. Distillation and reverse osmosis are less effective. Reintrusion of carbon dioxide is pessible if the water is not properly protected after production. The usual uses-of this ype of water are for analyses requiring highly puriffed water or where the test is related to pH , acidity, or alkalinity and the concern is that the carbon dioxide in the water could affeet the test result. The effieacy of the carben dioxide lim itation proeess should be valuated for its impact on the tests in which the water is used. Nermally, the small amount absorbed during reasonably rapid, open to the air handling of truly earben-dioxide-free-water will not affect the testing where Carben Dioxide-Free Water is indicated.

Ammonia-Free-Water Cited in only one USP meno graph, this is Purified-Water or Water for Injection that has been produced in such a way as to prevent the carryover Of ammenia from the source water. Ammenia-is typieally enly a problem in regiens where chloramines are used as the Drinking Water disinfectant. Deionization by a mixed bed deionizer is very effective at removing ammenia, but distillation and reverse osmosis are less effective. In order for distillation and reverse osmosis to produce Ammonia Free-Water in chloramine-using regions, the ammenia must beremoved by earlier unit operations prior to entering the distillation or reverse osmesis units. The use of this water is for a test related to pH and the concern, like with carbon diexide, is that the pH of the water may affect the test result. In most laboratery settings, there is insuffieient atmospheric ammenia to create a need for ammonia reintrusion protec tion, unlike the malogous protection that would be needed for Carbon Dioxide-Free Water:

High Purity Water Cited in one USP monograph and ene-general chapter, this water is well characterized in the general test chapter Containerss $\langle 664\rangle$. In essence, it is water
that is prepared by several sequential steps, an- interim one of which is distillation, that renders it extremely pure rela tive to on line conductivity, particulates, and copper content. This water is used for many of the reagents and tests fer containers int $\langle 664$ ) where less pure-waters would net perform aceeptably, as well as for the reagents employed where cited for the USP monograph tests.

Pistilled-Water Cited in several USP monegraphs and general test chapters, this water is, as the name-suggests, produced by waporizing liquid water and condensing it in a purer state. This water is used primarily for reagent preparation in the USP menegraphs where pure water is needed and in the general test chapter primarily for cleaning purpeses where the leaving of no water impurity residuals is impertant. It is also-cited as the starting water used for making

## High Parity Water.

Freshly Distilled Water Citedin only one USP monegraph, this water is prepared in a similar fashion to Distilled Water, though as the name suggests, immediately before use. It is used for preparing standards and control selations for injection into test animats. Because of this use and the term "freshly", the implied attributes are its chemieal purity as well as its low endetoxin and bioburden (though no ref erence to these mierobial attributes-or specific protection from recontamination is mentioned). Due to the nattre of the testing, Water for Injection could be a reasenable substifate, though as for any test, the suitability of the water must be verifted for this use.

Deionized Water Cited in ntmerous USP menegraphs, general test chapters, and dietary supplement monographs, this water is produeed by an ion exchange process in which the contaminating ions are replaced with either $\mathrm{H}^{+}$-or $\mathrm{OH}^{-}$ iens. In the USP monographs and general test chapters, this water is indieated for cleaning and reagent preparation purpeses. In one general test chapter, it is listed as a suitable
substitute for Purified Water In the dietary supplement men egraphs, it is listed as the water to be used wherever "water" is mentioned, which ineludes reagent and artiele preparations as well as for cleaning. Due to the nature of the testing, Purified Water could be a reasomable-substitute, though as for any test, the suitability of the water must be verified for these uses.

Freshly Deionized-Water Cited in-only two related USP menegraphs, this water is prepared in similar fashien to Deimized Water, theugh as the name-suggests, immediately before it is to be used. This implies the need to avoid any adventitious contamination from the air or container leachables, which in turn implies a reasenably high degree of purity. This water is indieated for use wherever "water" is mentioned, which includes reagent and article preparations as well as for cleaning. Due to the nature of the testing, Putrified Weter could be a reasenable-substitute for mest of the applieations mentioned, though as for any test, the suit ability of the water must be verified for these uses, particu larly for its indicated use in preparing mobile phase solutions where highly deionized water is needed.

Deionized-Distilled-Water Citedin only two USP menegraphs, this water is produced by deionizing (see De imized Water above) Pistilled Water (also-see above). This water is used as a reagent in a chrematography test that requires a high purity. Because of the impertance of this high purity, water that barely meets the requirements for Purified Water would not be acceptable.

Beacrated-Water Cited in USP menographs and wo general infermation chapters, this water is Purifed Water that has been treated to reduce the content of dissolved air by any suitable means stuch as by reducing the headspace air pressure-in a closed container, beiling for at least five minttes, or senication. The Reagents section of USP alse describes its preparation. Deatated Water is primarily indi-
eated for use-in dissolution testing where the presence-of high levels of dissolved gases could outgas during the test and interfere with the test results or aceurate voltametric withdrawals.

Clean Steam Clean Steam (also commonly known as Pure-Steam or Additive-Free Steam) is not specifieally cited in USP, but is commenly used threughout the pharmaceutieal industry. Its quality is sometimes confusingly identified in various references by either the quality of the water from which it is produced or by the quality of the condensate formed from it, both of which make reference to a-USP monegraphed bulk water. Theugh these various preparation and end quality definitions may serve their respective purpeses in isolation, their inconsistently assigned descriptive names create confusion when taken out of context. Therefore, the purpose of this diseussion is to clarify the term "Clean Steam," its production, uses, and quality. Clean Steam may be prepared analogeusly to either Purfified Water or Water for Injection but vaperized and distributed in such a fashion as to render its condensate equivalent in quality to that of Water for Injection It is used where-its condensate directly contacts product or product contact surfaces sueh as during cleaning or sterilization of products, product compenents, and other product contact surfaces and where there is ne subsequent precessing-step to remove any codeposited impurity residtues. The primary intent of using this quatity of steam is to ensure that articles-or product contact surfaces expesed to it are net contaminated by residues that may be deposited by the steam. The souree of this contamination could originate from-entrained source-water, steam additives, or the stemm production and distribution system itself. Depending on its use in sterilization, such as for perous att toclave loads and SIP systems, the presence of even-small quantities of nencondensable gases or an unsaturated or
dry state, such as would exist in a-superheated condition, eould compromise the-steam's sterilizing properties. Therefore, control of these attributes may also be necessary.
In addition to the bulk monographed waters described above, nonmonographed waters can also be used in pharmaceutical processing steps such as cleaning, synthetic steps or as a starting material for further purification. The following is a description of several of these nonmonographed waters as cited in various locations within this compendia.

Drinking Water-This type of water can be referred to as Potable Water (meaning drinkable or fit to drink), National Primary Drinking Water, Primary Drinking Water, or National Drinking Water. Except where a singular drinking water specification is stated (such as the NPDWR [U.S. Environmental Protection Agency's National Primary Drinking Water Regulations as cited in 40 CFR Part 141]), this water must comply with the quality attributes of either the NPDWR, or the drinking water regulations of the European Union or Japan, or the WHO Drinking Water Guidelines. It may be derived from a variety of sources including a public water utility, a private water supply (e.g., a well), or a combination of these sources. Drinking Water may be used in the early stages of cleaning pharmaceutical manufacturing equipment and product-contact components. Drinking Wa$t e r$ is also the minimum quality of water that should be used for the preparation of official substances and other bulk pharmaceutical ingredients. Where compatible with the processes, the allowed contaminant levels in Drinking Water are generally considered safe for use, at least in early synthetic stages, for official substances and other drug substances. Where required by the processing of the materials to achieve their required final purity, higher qualities of water may be needed for these manufacturing steps, perhaps even as pure as Water for Injection or Purified Water. Such higher purity waters, however, might require only selected
attributes to be of higher purity than Drinking Water (see Figure 2 below). Drinking Water is the prescribed source or feed water for the production of bulk monographed pharmaceutical waters. The use of Drinking Water specifications establishes a reasonable set of maximum allowable levels of chemical and microbiological contaminants with which a
water purification system will be challenged. As seasonal variations in the quality attributes of the Drinking Water supply can occur, due consideration to its synthetic and cleaning uses must be given. The processing steps in the production of pharmaceutical waters must be designed to accommodate this variability.

＊Drinking Uiate ris water complying with US $⿴ 囗 十 A N C O U R$ or drinking wate r regulations of EU or dapan or WiHO drinking water guidelines．
＊x Water for sterile API＇s or dosage forms must first be rendered sterile ifthere is not a subsequent sterilization step in the process where used．
＊xx See guidance in this chapter where waters other than Purified Uoater are required by some USP tests and assays．
Note：All water systems should be validated with whatever microbial control is needed to suit the intended purposes of the water．

Fig．2．Selection of water for pharmaceutical purposes．

Hot Purified Water－This water is used in the prepara－ tion instructions for $U S P-N F$ articles and is clearly intended to be Purified Water that has been heated to an unspecified temperature in order to enhance solubilization of other in－
gredients．There is no upper temperature limit for the water （other than being less than $100^{\circ}$ ），but for each monograph there is an implied lower limit below which the desired solubilization effect would not occur．

## Nonmonographed Analytical Waters

Both General Notices and Requirements and the introductory section to Reagents, Indicators, and Solutions clearly state that where the term "water," without qualification or other specification, is indicated for use in analyses, the quality of water shall be Purified Water. However, numerous such qualifications do exist. Some of these qualifications involve methods of preparation, ranging from specifying the primary purification step to specifying additional purification. Other qualifications call for specific attributes to be met that might otherwise interfere with analytical processes. In most of these latter cases, the required attribute is not specifically tested. Rather, a further "purification process" is specified that ostensibly allows the water to adequately meet this required attribute.

However, preparation instructions for many reagents were carried forward from the innovator's laboratories to the originally introduced monograph for a particular $U S P-N F$ article or general test chapter. The quality of the reagent water described in these tests may reflect the water quality designation of the innovator's laboratory. These specific water designations may have originated without the innovator's awareness of the requirement for Purified Water in USP$N F$ tests. Regardless of the original reason for the creation of these numerous special analytical waters, it is possible that the attributes of these special waters could now be met by the basic preparation steps and current specifications of Purified Water. In some cases, however, some of the cited post-processing steps are still necessary to reliably achieve the required attributes.

Users are not obligated to employ specific and perhaps archaically generated forms of analytical water where alternatives with equal or better quality, availability, or analytical performance may exist. The consistency and reliability for producing these alternative analytical waters should be ver-
ified as producing the desired attributes. In addition, any alternative analytical water must be evaluated on an application-by-application basis by the user to ensure its suitability. Following is a summary of the various types of nonmonographed analytical waters that are cited varions tonendian within this $U S P-N F$.

Distilled Water-This water is produced by vaporizing liquid water and condensing it in a purer state. It is used primarily as a solvent for reagent preparation, but it is also specified in the execution of other aspects of tests, such as for rinsing an analyte, transferring a test material as a slurry, as a calibration standard or analytical blank, and for test apparatus cleaning. It is also cited as the starting water to be used for making High Purity Water. Because none of the cited uses of this water imply a need for a particular purity attribute that can only be derived by distillation, water meeting the requirements for Purified Water derived by other means of purification could be equally suitable where Distilled Water is specified.

Freshly Distilled Water—Also called "recently distilled water", it is produced in a similar fashion to Distilled Water and should be used shortly after its generation. This implies the need to avoid endotoxin contamination as well as any other adventitious forms of contamination from the air or containers that could arise with prolonged storage. It is used for preparing solutions for subcutaneous test animal injections as well as for a reagent solvent in tests for which there appears to be no particularly high water purity needed that could be ascribable to being "freshly distilled". In the "testanimal" use, the term "freshly distilled" and its testing use imply a chemical, endotoxin, and microbiological purity that could be equally satisfied by Water for Injection (though no reference is made to these chemical, endotoxin, or microbial attributes or specific protection from recontamination). For nonanimal uses, water meeting the require-
ments for Purified Water derived by other means of purification and/or storage periods could be equally suitable where "recently distilled water" or Freshly Distilled Water is specified.

Deionized Water-This water is produced by an ion-exchange process in which the contaminating ions are replaced with either $\mathrm{H}^{+}$or $\mathrm{OH}^{-}$ions. Similarly to Distilled Water, Deionized Water is used primarily as a solvent for reagent preparation, but it is also specified in the execution of other aspects of tests, such as for transferring an analyte within a test procedure, as a calibration standard or analytical blank, and for test apparatus cleaning. Also, none of the cited uses of this water imply any needed purity attribute that can only be achieved by deionization. Therefore, water meeting the requirements for Purified Water that is derived by other means of purification could be equally suitable where Deionized Water is specified.

Freshly Deionized Water-This water is prepared in a similar fashion to Deionized Water, though as the name suggests, it is to be used shortly after its production. This implies the need to avoid any adventitious contamination that could occur upon storage. This water is indicated for use as a reagent solvent as well as for cleaning. Due to the nature of the testing, Purified Water could be a reasonable alternative for these applications.

Deionized Distilled Water-This water is produced by deionizing (see Deionized Water ) Distilled Water. This water is used as a reagent in a liquid chromatography test that requires a high purity. Because of the importance of this high purity, water that barely meets the requirements for Pu rified Water may not be acceptable. High Purity Water (see below) could be a reasonable alternative for this water.

Filtered Distilled or Deionized Water-This water is essentially Purified Water produced by distillation or deionization that has been filtered through a $1.2-\mu \mathrm{m}$ rated
membrane. This water is used in particulate matter testing where the presence of particles in the water could bias the test results (see Particulate Matter in Injections $\langle 788\rangle$ ). Because the chemical water purity needed for this test could also be afforded by water purification processes other than distillation or deionization, filtered water meeting the requirements for Purified Water, but produced by means other than distillation or deionization could be equally suitable.

Filtered Water-This water is Purified Water that has been filtered to remove particles that could interfere with the analysis where the water is used. Where used for preparing samples for particulate matter testing (see Particulate Matter in Injections $\langle 788\rangle$ ), though unspecified in monographs, water filtration should be through a $1.2-\mu \mathrm{m}$ filter to be consistent with the general test chapter. Where used as a chromatography reagent, monograph-specified filter ratings range from $0.5 \mu \mathrm{~m}$ to unspecified.

High Purity Water-The preparation of this water is defined in Containers $\langle 661\rangle$. It is water that is prepared by deionizing previously distilled water, and then filtering it through a $0.45-\mu \mathrm{m}$ rated membrane. This water must have an in-line conductivity of not greater than $0.15 \mu \mathrm{~S} / \mathrm{cm}$ (6.67 Megohm-cm) at $25^{\circ}$. For the sake of purity comparison, the analogous Stage 1 and 2 conductivity requirements for Purified Water at the same temperature are $1.3 \mu \mathrm{~S} / \mathrm{cm}$ and $2.1 \mu \mathrm{~S} / \mathrm{cm}$, respectively. The preparation specified in Containers $\langle 661\rangle$ uses materials that are highly efficient deionizers and that do not contribute copper ions or organics to the water, assuring a very high quality water. If the water of this purity contacts the atmosphere even briefly as it is being used or drawn from its purification system, its conductivity will immediately degrade, by as much as about $1.0 \mu \mathrm{~S} / \mathrm{cm}$, as atmospheric carbon dioxide dissolves in the water and equilibrates to bicarbonate ions. Therefore, if the analytical use requires that water purity remains as high
as possible, its use should be protected from atmospheric exposure. This water is used as a reagent, as a solvent for reagent preparation, and for test apparatus cleaning where less pure waters would not perform acceptably. However, if a user's routinely available purified water is filtered and meets or exceeds the conductivity specifications of High Purity Water, it could be used in lieu of High Purity Water.

Ammonia-Free Water-Functionally, this water must have a negligible ammonia concentration to avoid interference in tests sensitive to ammonia. It has been equated with High Purity Water that has a significantly tighter Stage 1 conductivity specification than Purified Water because of the latter's allowance for a minimal level of ammonium among other ions. However, if the user's Purified Water were filtered and met or exceeded the conductivity specifications of High Purity Water, it would contain negligible ammonia or other ions and could be used in lieu of High Purity Water.

Carbon Dioxide-Free Water-The introductory portion of the Reagents, Indicators, and Solutions section defines this water as Purified Water that has been vigorously boiled for at least 5 minutes, then cooled and protected from absorption of atmospheric carbon dioxide. Because the absorption of carbon dioxide tends to drive down the water pH , most of the uses of Carbon Dioxide-Free Water are either associated as a solvent in pH -related or pH -sensitive determinations or as a solvent in carbonate-sensitive reagents or determinations. Another use of this water is for certain optical rotation and color and clarity of solution tests. Though it is possible that this water is indicated for these tests simply because of its purity, it is also possible that the pH effects of carbon dioxide containing water could interfere with the results of these tests. A third plausible reason that this water is indicated is that outgassing air bubbles might interfere with these photometric-type tests. The
boiled water preparation approach will also greatly reduced the concentrations of many other dissolved gases along with carbon dioxide. Therefore, in some of the applications for Carbon Dioxide-Free Water, it could be the inadvertent deaeration effect that actually renders this water suitable. In addition to boiling, deionization is perhaps an even more efficient process for removing dissolved carbon dioxide (by drawing the dissolved gas equilibrium toward the ionized state with subsequent removal by the ion-exchange resins). If the starting Purified Water is prepared by an efficient deionization process and protected after deionization from exposure to atmospheric air, water that is carbon dioxidefree can be effectively made without the application of heat. However this deionization process does not deaerate the water, so if Purified Water prepared by deionization is considered as a substitute water in a test requiring Carbon DioxideFree Water, the user must verify that it is not actually water akin to Deaerated Water (discussed below) that is needed for the test. As indicated in the High Purity Water, even brief contact with the atmosphere can allow small amounts of carbon dioxide to dissolve, ionize, and significantly degrade the conductivity and lower the pH . If the analytical use requires the water to remain as pH -neutral and as carbon dioxide-free as possible, even the analysis should be protected from atmospheric exposure. However, in most applications, atmospheric exposure during testing does not significantly affect its suitability in the test.

Ammonia- and Carbon Dioxide-Free Water-As implied by the name, this water should be prepared by approaches compatible with those mentioned for both Ammonia-Free Water and Carbon Dioxide-Free Water. Because the carbon dioxide-free attribute requires post-production protection from the atmosphere, it is appropriate to first render the water ammonia-free using the High Purity Water process followed by the boiling and carbon dioxide-pro-
tected cooling process. The High Purity Water deionization process for creating Ammonia-Free Water will also remove the ions generated from dissolved carbon dioxide and ultimately, by forced equilibration to the ionized state, all the dissolved carbon dioxide. Therefore, depending on its use, an acceptable procedure for making Ammonia- and Carbon Dioxide-Free Water could be to transfer and collect High Purity Water in a carbon dioxide intrusion-protected container.

Deaerated Water-This water is Purified Water that has been treated to reduce the content of dissolved air by "suitable means". In the Reagents section, approaches for boiling, cooling (similar to Carbon Dioxide-Free Water but without the atmospheric carbon dioxide protection), and sonication are given as applicable for test uses other than dissolution and drug release testing. Though Deaerated Water is not mentioned by name in Dissolution $\langle 711\rangle$, suggested methods for deaerating dissolution media (which may be water) include warming to $41^{\circ}$, vacuum filtering through a $0.45-\mu \mathrm{m}$ rated membrane, and vigorously stirring the filtrate while maintaining the vacuum. This chapter specifically mentions indicates that other validated approaches may be used. In other monographs that also do not mention Deaerated Water by name, degassing of water and other reagents is accomplished by sparging with helium. Deaerated Water is used in both dissolution testing as well as liquid chromatography applications where outgassing could either interfere with the analysis itself or cause erroneous results due to inaccurate volumetric withdrawals. Applications where ambient temperature water is used for reagent preparation, but the tests are performed at elevated temperatures, are candidates for outgassing effects. If outgassing could interfere with test performance, including, chromatographic flow, colorimetric, or photometric measurements, or volumetric accuracy, then Deaerated Water should probably be used,
whether called for in the analysis or not. The above deaeration approaches might not render the water "gas-free". At best, they reduce the dissolved gas concentrations so that outgassing caused by temperature changes is not likely.

Recently Boiled Water-This water may include recently or freshly boiled water (with no mention of cooling in the title), but cooling prior to use is clearly intended. Occasionally it is necessary to use when hot. Recently Boiled Water is specified because it is used in a pH -related test or carbonatesensitive reagent, in an oxygen-sensitive test or reagent, or in a test where outgassing could interfere with the analysis, such as specific gravity or an appearance test.

Oxygen-Free Water-The preparation of this water is not specifically described in the compendia. Neither is there an oxygen specification or analysis mentioned. However, all uses involve analyses of materials that could be sensitive to oxidation by atmospheric oxygen. Procedures for the removal of dissolved oxygen from solvents, though not necessarily water, are mentioned in Polarography $\langle 801\rangle$ and Spectrophotometry and Light-Scattering $\langle 851\rangle$. These procedures involve simple sparging of the liquid with an inert gas such as nitrogen or helium followed by inert gas blanketing to prevent oxygen reabsorption. The sparging times cited range from 5 to 15 minutes to an unspecified period. Some Purified Water and Water for Injection systems produce water that is maintained in a hot state and that is inert gas blanketed during its preparation and storage and distribution. Though oxygen is poorly soluble in hot water, such water may not be oxygen-free. Whatever procedure used for removing oxygen should be verified as reliably producing water that is fit for use.

LAL Reagent Water-This water is also referred to as endotoxin-free water. This is usually Water for Injection, which may have been sterilized. It is free from a level of
endotoxin that would yield any detectable reaction or interference with the Limulus amebocyte lysate reagent used in the Bacterial Endotoxins Test $\langle 85\rangle$.

Organic-Free Water-This water is defined by Organic Volatile Impurities $\langle 467\rangle$ as producing no significantly interfering gas chromatography peaks. Referenced monographs specify using this water as the solvent for standard and test solution preparation for the Organic volatile impurities test.

Lead-Free Water-This water is used as a transferring diluent for an analyte in a Lead $\langle 251\rangle$ test. Though no specific instructions are given for its preparation, it must not contain any detectable lead. Purified Water should be a suitable substitute for this water.

Chloride-Free Water-This water is specified as the solvent for use in an assay that contains a reactant that precipitates in the presence of chloride. Though no specific preparation instructions are given for this water, its rather obvious attribute is having a very low chloride level in order to be unreactive with this chloride sensitive reactant. Purified Water could be used for this water but should be tested to assure it is unreactive.

Hot Water-The uses of this water include solvents for achieving or enhancing reagent solubilization, restoring the original volume of boiled or hot solutions, rinsing insoluble analytes free of hot water soluble impurities, solvents for reagent recrystallization, apparatus cleaning, and as a solubility attribute for various $U S P-N F$ articles. In only one monograph is the temperature of "hot" water specified; so in all the other cases, the water temperature is less important, but should be high enough to achieve the desirable effect. In all cases, the chemical quality of the water is implied to be that of Purified Water.

## VALIDATION AND QUALIFICATION OF WATER PURIFICATION, STORAGE, AND DISTRIBUTION SYSTEMS

Establishing the dependability of pharmaceutical water purification, storage, and distribution systems requires an appropriate period of monitoring and observation. Ordinarily, few problems are encountered in maintaining the chemical purity of Purified Water and Water for Injection Nevertheless, the advent of using conductivity and TOC to define chemical purity has allowed the user to more quantitatively assess the water's chemical purity and its variability as a function of routine pretreatment system maintenance, regeneration, etc. Even the presence of such unit operations as heat exchangers and use point hoses can compromise the chemical quality im of water within and delivered from an otherwise well-controlled water system. Therefore, an assessment of the consistency of the water's chemical purity over time must be part of the validation program. However, even with the most well controlled chemical quality, it is often more difficult to consistently meet established microbiological quality criteria owing to phenomena occurring during and after chemical purification. A typical program involves intensive daily sampling and testing of major process points for at least one month after operational criteria have been established for each unit operation, point of use, and sampling point.

An overlooked aspect of water system validation is the delivery of the water to its actual location of use. If this transfer process from the distribution system outlets to the water use locations (usually with hoses) is defined as outside the water system, then this transfer process still needs to be validated to not adversely affect the quality of the water to the extent it becomes unfit for use. Because routine microbial monitoring is performed for the same transfer process
and components (e.g., hoses and heat exchangers) as that of routine water use (see Sampling Considerations), there is some logic to include this water transfer process within the distribution system validation.

Validation is the process whereby substantiation to a high level of assurance that a specific process will consistently produce a product conforming to an established set of quality attributes is acquired and documented. Prior to and during the very early stages of validation, the critical process
parameters and their operating ranges are established. A validation program qualifies and documents the design, installation, operation, and performance of equipment. It begins when the system is defined and moves through several stages: installation qualification (IQ), operational qualification ( OQ ), and performance qualification (PQ). A graphical representation of a typical water system validation life cycle is shown in Figure 3.

Fig. 3. Water system validation life cycle.

A validation plan for a water system typically includes the following steps: (1) establishing standards for quality attributes andererating parameters; of the finished water and the source water; (2) defining systems and stitable subsystems to produce the desired suitable unit operations and their operating parameters for achieving the desired finished water quality attributes from the available source water; (3) selecting piping, equipment, controls, and monitoring technologies; (4) developing an IQ stage consisting of instrument calibrations, inspections to verify that the drawings accurately depict the frillt final configuration of the water system and, where necessary, special tests to verify that the installation meets the design requirements; (5) developing an OQ stage consisting of tests and inspections to verify that the equipment, system alerts, and controls are operating reliably and that appropriate alert and action levels are established (This phase of qualification may overlap with aspects of the next step.); and (6) developing a prospective PQ stage to confirm the appropriateness of critical process parameter operating ranges (During this phase of validation, alert and action levels for key quality attributes and operating parameters are verified.); (7) supplementing a validation maintenance program (also called continuous validation life eycle) that imeludes a mechanism to-contrel-changes to the water system and establishes and carries out seheduled preventive maintenance-ineluding reealibration of instruments (In addition, validation maintenamee includes a menitoring program for eritical process parameters and acorrective action program.); (8) instituting aschedule for periodie review Of the-system perfermance and requaliffeation; and(9)eempleting protecols and deeumenting Steps 1 through 8. (7) assuring the adequacy of ongoing control procedures, e.g., sanitization frequency; (8) supplementing a validation maintenance program (also called continuous validation life cycle) that includes a mechanism to control changes to the
water system and establishes and carries out scheduled preventive maintenance including recalibration of instruments (In addition, validation maintenance includes a monitoring program for critical process parameters and a corrective action program.); (9) instituting a schedule for periodic review of the system performance and requalification, and (10) completing protocols and documenting Steps 1 through 9.

## PURIFIED WATER AND WATER FOR INJECTION SYSTEMS

The design, installation, and operation of systems to produce Purified Water and Water for Injection include similar components, control techniques, and procedures. The quality attributes of both waters differ only in the presence of a bacterial endotoxin requirement for Water for Injection and in their methods of preparation, at least at the last stage of preparation. The similarities in the quality attributes provide considerable common ground in the design of water systems to meet either requirement. The critical difference is the degree of control of the system and the final purification steps needed to ensure bacterial and bacterial endotoxin removal.

Production of pharmaceutical water employs sequential unit operations (processing steps) that address specific water quality attributes and protect the operation of subsequent treatment steps. in Figure 3. A typical evaluation process to select an appropriate water quality for a particular pharmaceutical purpose is shown in the decision tree in Figure 2. These diagrams This diagram may be used to assist in defining requirements for specific water uses and in the selection of unit operations. The final unit operations used to produce Water for Injection are limited to distillation and superior to distillation in the removal of chemical impurities as well as microorganisms and their components. Distillation has a long history of reliable performance and can be
validated as a unit operation for the production of Water for Injection, but other technologies or combinations of technologies can be validated as being equivalently effective. Other technologies, such as ultrafiltration following other chemical purification process, may be suitable in the production of Water for Injection but this time experience with this process is not widespread. if they can be shown through validation to be as effective and reliable as distillation. The advent of new materials for older technologies, such as reverse osmosis and ultrafiltration, that allow intermittent or continuous operation at elevated, microbial temperatures, show promise for a valid use in producing Water for Injection.

The validation plan should be designed to establish the suitability of the system and to provide a thorough understanding of the purification mechanism, range of operating conditions, required pretreatment, and the most likely modes of failure. It is also necessary to demonstrate the effectiveness of the monitoring scheme and to establish the documentation and qualification requirements for the system's validation maintenance. Trials conducted in a pilot installation can be valuable in defining the operating parameters and the expected water quality and in identifying failure modes. However, qualification of the specific unit operation can only be performed as part of the validation of the installed operational system. The selection of specific unit operations and design characteristics for a water system should take into account the quality of the feed water, the technology chosen for subsequent processing steps, the extent and complexity of the water distribution system, and the appropriate compendial requirements. For example, in the design of a system for Water for Injection, the final process (distillation or reverse osmesis) (distillation or whatever
other validated process is used according to the monograph) must have effective bacterial endotoxin reduction capability and must be validated.

## UNIT OPERATIONS CONCERNS

The following is a brief description of selected unit operations and the operation and validation concerns associated with them. Not all unit operations are discussed, nor are all potential problems addressed. The purpose is to highlight issues that focus on the design, installation, operation, maintenance, and monitoring parameters that facilitate water system validation.

## Prefiltration

Filtration eechnolegy plays an impertant role in water systems, and filtration units are available-in awiderange-of designs and for varieus applications. Removal efficiencies differ signiffeantly from cearse fiters, such as mattimedia Or sand for larger water systems and depth cartridges for smaller water systems, to membrane flters for very smalt particlecontrol. Unit and system configurations vary widely in type-of flttering media and lecation in the process. (The tse-of membrane-flters is diseussed in a later paragraph.) Gramular or cartridge filters are used for prefltration and are-often situated at or near the head of the water pretreatment system prior to thit operations designedtoremove the setree water disimfectants. This lecation, however, dees net prectude the need for periedic mierobial contrel since bieflm eanstill proliferate-in the presence-of setree-water disinfectants, albeit slewer than in their absence. These preflters remove-solid contaminants-dewn to a-size-of 7 te 10 رum from the water supply and protect downstream-sys tem compenents from partieulates that can inhibit equipment perfermance and sherten their effective-life. Designt
and operational isstes that may impact performance-of depth filters include channeling of the filtering media, blockage frem-silt, mierebial growth, and filtering media loss during improper backwashing. Control measures in elude pressure and flow monitoring during use and backwashing, sanitizing, and replacing fltering media. An important design concern is sizing of the filter to prevent ehanneling or media loss resulting from inappropriate water flow rates as well as proper sizing to minimize exeessive frequent or infrequent backwashing or cartridge filter replace-

## ment.

The purpose of prefiltration-also referred to as initial, coarse, or depth filtration-is to remove solid contaminants down to a size of 7 to $10 \mu \mathrm{~m}$ from the incoming source water supply and protect downstream system components from particulates that can inhibit equipment performance and shorten their effective life. This coarse filtration technology utilizes primarily sieving effects for particle capture and a depth of filtration medium that has a high "dirt load" capacity. Such filtration units are available in a wide range of designs and for various applications. Removal efficiencies and capacities differ significantly, from granular bed filters such as multimedia or sand for larger water systems, to depth cartridges for smaller water systems. Unit and system configurations vary widely in type of filtering media and location in the process. Granular or cartridge prefilters are often situated at or near the head of the water pretreatment system bfore prior to unit operations designed to remove the source water disinfectants. This location, however, does not preclude the need for periodic microbial control because biofilm can still proliferate, although at a slower rate in the presence of source water disinfectants. Design and operational issues that may impact performance of depth filters include channeling of the filtering media, blockage from silt, microbial growth, and filtering-media loss during improper
backwashing. Control measures involve pressure and flow monitoring during use and backwashing, sanitizing, and replacing filtering media. An important design concern is sizing of the filter to prevent channeling or media loss resulting from inappropriate water flow rates as well as proper sizing to minimize excessively frequent or infrequent backwashing or cartridge filter replacement.

## Activated Carbon

Activated carben beds adserb-low molecular weight organic material and oxidizing additives, such as chlorine and chloramine eompounds, removing them from the water. They are used to achieve certain quality attributes and to pretect against reaction with downstream stainless steelsurfaces, resins, and membranes. The chief operating concerns regarding activated carbon beds include the propensity to stppert bacteria growth, the petential for hydratlic channeling, the inability to be regenerated in sitt, and the-shed ding of bacteria, endotoxins, organic chemicals, and fine earbon particles. Control measures inelude appropriate high water flow rates, sanitization with hot water or steam, back washing, testing for adsorption eapacity, and frequent replacement of the carbon bed. It is impertant to note that the use of steam for carben bed sanitization is often incompletely effective due to channeling rather than even permeation through the bed. This phenemenen can ustally be avoided by using het water sanitization. Alternative technolegiesto aetivated carben beds can be used in order to avoid their mierobial problems, sueh as disinfectant neutralizing chemieat additives and regenerable organic seavenging devices. However, these alternatives do not function by the same mechanisms as activated carben, may not be as-effective at removing some-organies, and have a different set of operating concerns and control measures that may be nearly as troubleseme as activated carben beds. Granular activated
carbon beds adsorb low molecular weight organic material and oxidizing additives, such as chlorine and chloramine compounds, removing them from the water. They are used to achieve certain quality attributes and to protect against reaction with downstream stainless steel surfaces, resins, and membranes. The chief operating concerns regarding activated carbon beds include the propensity to support bacteria growth, the potential for hydraulic channeling, the organic adsorption capacity, appropriate water flow rates and contact time, the inability to be regenerated in situ, and the shedding of bacteria, endotoxins, organic chemicals, and fine carbon particles. Control measures may involve monitoring water flow rates and differential pressures, sanitizing with hot water or steam, backwashing, testing for adsorption capacity, and frequent replacement of the carbon bed. If the activated carbon bed is intended for organic reduction, it may also be appropriate to monitor influent and effluent TOC. It is important to note that the use of steam for carbon bed sanitization is often incompletely effective due to steam channeling rather than even permeation through the bed. This phenomenon can usually be avoided by using hot water sanitization. It is also important to note that microbial biofilm development on the surface of the granular carbon particles (as well as on other particles such as found in deionizer beds and even multimedia beds) can cause adjacent bed granules to "stick" together. When large masses of granules are agglomerated in this fashion, normal backwashing and bed fluidization flow parameters may not be sufficient to disperse them, leading to ineffective removal of trapped debris, loose biofilm, and penetration of microbial controlling conditions (as well as regenerant chemicals as in the case of agglomerated deionizer resins). Alternative technologies to activated carbon beds can be used in order to avoid their microbial problems, such as disinfectant-neutralizing chemical additives and regenerable organic scav-
enging devices. However, these alternatives do not function by the same mechanisms as activated carbon, may not be as effective at removing disinfectants and some organics, and have a different set of operating concerns and control measures that may be nearly as troublesome as activated carbon beds.

## Additives

Chemical additives are used in water systems (a) to control microorganisms by use of sanitants such as chlorine compounds and ozone, (b) to enhance the removal of suspended solids by use of flocculating agents, (c) to remove chlorine compounds, (d) to avoid scaling on reverse osmosis membranes, and (e) to adjust pH for more effective removal of carbonate and ammonia compounds by reverse osmosis. These additives do not constitute "added substances" as long as they are either removed by subsequent processing steps or they nattrally and completely attodegrade or equilibrate to ions and molecules native to the water such as hy drogen and hydroxide ions, oxygen, or water itself. are otherwise absent from the finished water. Control of additives to ensure a continuously effective concentration and subsequent monitoring to ensure their removal as well as their nen native reation/degradation products should be designed into the system and included in the monitoring program.

## Organic Scavengers

Organic scavenging devices use macroreticular weakly basic anion-exchange resins capable of removing organic material and endotoxins from the water. They can be regenerated with appropriate biocidal caustic brine solutions. Operating concerns are associated with organic scavenging capacity, particulate, chemical and microbiological fouling
of the reactive resin surface, flow rate, regeneration frequency , and shedding of resin fragments. Control measures include TOC testing of influent and effluent, backwashing, monitoring hydraulic performance, and using downstream filters to remove resin fines.

## Softeners

Water softeners may be located either upstream or downstream of disinfectant removal units. They utilize sodiumbased cation-exchange resins to remove water-hardness ions, such as calcium and magnesium, that could foul or interfere with the performance of downstream processing equipment such as reverse osmosis membranes, deionization devices, and distillation units. Water softeners can also be used to remove other lower affinity cations, such as the ammonium ion, that may be released from chloramine disinfectants commonly used in drinking water and which might otherwise carryover through other downstream unit operations. If ammonium removal is one of its purposes, the softener must be located downstream of the disinfectant removal operation, which itself may liberate ammonium from neutralized chloramine disinfectants. Water softener resin beds are regenerated with concentrated sodium chloride solution (brine). Concerns include microorganism proliferation, channeling caused by biofilm agglomeration of resin particles, appropriate water flow rates and contact time, ion-exchange capacity, organic and particulate resin fouling, organic leaching from new resins, fracture of the resin beads, resin degradation by excessively chlorinated water, and contamination from the brine solution used for regeneration. Control measures involve recirculation of water during periods of low water use, periodic sanitization of the resin and brine system, use of microbial control devices (e.g., UV light and chlorine), locating the unit upstream of the disinfectant removal step (if used only
for softening), appropriate regeneration frequency, effluent chemical monitoring (e.g., hardness ions and possibly ammonium), and downstream filtration to remove resin fines. If a softener is used for ammonium removal from chloraminecontaining source water, then capacity, contact time, resin surface fouling, pH , and regeneration frequency are very important.

## Deionization

Deionization (DI), electronizan(EDI), and continuous deionizan (CDI) electrodeionization (CEDI) are effective methods of improving the chemical quality attributes of water by removing cations and anions. DI systems have charged resins that require periodic regeneration with an acid and base. Typically, cationic resins are regenerated with either hydrochloric or sulfuric acid, which replace the captured positive ions with hydrogen ions. Anionic resins are regenerated with sodium or potassium hydroxide, which replace captured negative ions with hydroxide ions. Because free endotoxin is negatively charged, there is some removal of endotoxin achieved by the anionic resin. Both regenerant chemicals are biocidal and offer a measure of microbial control. The system can be designed so that the cation and anion resins are in separate or "twin" beds or they can be mixed together to form a mixed bed. Twin beds are easily regenerated but deionize water less efficiently than mixed beds, which have a considerably more complex regeneration process. Rechargeable resin canisters can also be used for this purpose.
The EDI CDI CDI CEDI system uses a combination of mixed resin, selectively permeable membranes, and an electric charge, providing continuous flow (product and waste concentrate) and continuous regeneration. Water enters both the resin section and the waste (concentrate) section. As it passes through the resin, it is deionized to become
product water. The resin acts as a conductor enabling the electrical potential to drive the captured cations and anions through the resin and appropriate membranes for concentration and removal in the waste water stream. The electrical potential also separates the water in the resin (product) section into hydrogen and hydroxide ions. This permits continuous regeneration of the resin without the need for regenerant additives. However, unlike conventional deionization, EDI and-CDI units mest staft with water that is already pretreat to be fairly pure beeatre they cannot handle the heavier ion load of mpurified source water. CEDI units must start with water that is already partially purified because they generally cannot produce Purified Water quality when starting with the heavier ion load of unpurified source water.

Concerns for all forms of deionization units include microbial and endotoxin control, chemical additive impact on resins and membranes, and loss, degradation, and fouling of resin. Issues of concern specific to DI units include regeneration frequency and completeness, channeling, caused by biofilm agglomeration of resin particles, organic leaching from new resins, complete resin separation for mixed bed regeneration, and mixing air contamination (mixed beds). Control measures vary but typically include recirculation loops, effluent microbial control by UV light, conductivity monitoring, resin testing, microporous filtration of mixing air, microbial monitoring, frequent regeneration to minimize and control microorganism growth, sizing the equipment for suitable water flow and contact time, and use of elevated temperatures. Internal distributor and regeneration piping for mixed bed units should be configured to ensure that regeneration chemicals contact all internal bed and piping surfaces and resins. Rechargeable canisters can be the source of contamination and should be carefully monitored. Full
knowledge of previous resin use, minimum storage time between regeneration and use, and appropriate sanitizing procedures are critical factors ensuring proper performance.

## Reverse Osmosis

Reverse osmosic ( RO ) units employ a semipermeable membrane and a-substantial pressure-differential to-drive water threugh the membrane to achieve chemical, mierobial, andendetoxin quality improvement. The process streams eomsist of stpply water, product water (permeate), and wastewater (rejeet). Pretreatment and system eonfiguration variations and chemieat additives may be necessary depending on-source-water to achieve-desired performance and retiability. Concerns asseciated with the design and operation of RO units include membrane materials that are extremely semsitive to-sanitizing agents; to partieulate, chemical, and mierobiatmembrane-fouling; to membrane and sealintegrity; te the passage of dissolved gases, such as earben dioxide and ammenia; and to the volume of wastewater. Failure-of membrane or sealimtegrity will result in prodtet water con tamination. Methods of eentrel consist of suitable pretreat ment of the water stream, appropriate-membrane-materiat selection, integrity challenges, membrane design and heat telerance, periodic sanitization, and menitering of differential pressures, conductivity, mierobial levels, and total organic carbon. The eonfiguration of the $R \Theta$ unit offers eontrol-eppertunities by expanding the single pass scheme to parallelstaged, reject staged, two pass, and combination designs. An example would be the use-of atwo pass designt to improve reliability, quality, andeffeieney. The-development of RO units that can tolerate sanitizing water temper attres as well as-operate-effeiently at elevated temperatures has added greatly to their mierebialcentreland te the aveid
ance of biofouling. RO units can be used alone or in com bination with DI and EDI units for operational and quality

## enhancements.

Reverse osmosis (RO) units employ semipermeable membranes. The "pores" of RO membranes are actually intersegmental spaces among the polymer molecules. They are big enough for permeation of water molecules, but too small to permit passage of hydrated chemical ions. However, many factors including pH , temperature, and differential pressure across the membrane affect the selectivity of this permeation. With the proper controls, RO membranes can achieve chemical, microbial, and endotoxin quality improvement. The process streams consist of supply water, product water (permeate), and wastewater (reject). Depending on source water, pretreatment and system configuration variations and chemical additives may be necessary to achieve desired performance and reliability.

A major factor affecting RO performance is the permeate recovery rate, that is, the amount of the water passing through the membrane compared to the amount rejected. This is influenced by the several factors, but most significantly by the pump pressure. Recoveries of $75 \%$ are typical, and can accomplish a 1 to $2 \log$ purification of most impurities. For most feed waters, this is usually not enough to meet Purified Water conductivity specifications. A second pass of this permeate water through another RO stage usually achieves the necessary permeate purity if other factors such as pH and temperature have been appropriately adjusted and the ammonia from chloraminated source water has been previously removed. Increasing recoveries with higher pressures in order to reduce the volume of reject water will lead to reduced permeate purity. If increased pressures are needed over time to achieve the same permeate flow, this
is an indication of partial membrane blockage that needs to be corrected before it becomes irreversibly fouled, and expensive membrane replacement is the only option.

Other concerns associated with the design and operation of RO units include membrane materials that are extremely sensitive to sanitizing agents and to particulate, chemical, and microbial membrane fouling; membrane and seal integrity; the passage of dissolved gases, such as carbon dioxide and ammonia; and the volume of wastewater, particularly where water discharge is tightly regulated by local authorities. Failure of membrane or seal integrity will result in product water contamination. Methods of control involve suitable pretreatment of the influent water stream, appropriate membrane material selection, integrity challenges, membrane design and heat tolerance, periodic sanitization, and monitoring of differential pressures, conductivity, microbial levels, and TOC.
The development of RO units that can tolerate sanitizing water temperatures as well as operate efficiently and continuously at elevated temperatures has added greatly to their microbial control and to the avoidance of biofouling. RO units can be used alone or in combination with DI and CEDI units as well as ultrafiltration for operational and quality enhancements.

## Ultrafiltration

Ulraflitration is another teehnology that uses a permeable membrane, but unlike RO , it works by mechanieal separafien rather than osmesis. Due to the ability of the membrane to sieve out macromolecules (typically greater tham about 20 K daltons) depending on pere size and other factors, macromolecular and mierobial impurities, steh as endetoxins, ean be retained by these membranes, effectively removing them frem the effluent. This technology may be apprepriate as an intermediate or final purifieation step. Similar to RO , sue
eessful performance is dependent upen pretreatment of the water by upstream unit operations. Issues of concern inelude eompatibility of membrane material with heat and sanitizing
agents, membrane integrity, fouling by partieles and mieroorganisms, and seal integrity. Control measures inelude fit tration medium selection, sanitization, tangential flow designs capable of flushing the membrane surface, integrity ehallenges, regular eartridge changes, elevated feed water temperature, and monitoring totalorganic carbon and differential pressure. Additional flexibility in operation is pessible based on the way units are arranged such as in a parallel or series configuration. Care should be taken to avoid stagnant water conditions that could promete miereorgenism growth in back up or standby units.

Ultrafiltration is a technology most often employed in pharmaceutical water systems for removing endotoxins from a water stream. It can also use semi-permeable membranes, but unlike RO, these typically use polysulfone membranes whose intersegmental "pores" have been purposefully exaggerated during their manufacture by preventing the polymer molecules from reaching their smaller equilibrium proximities to each other. Depending on the level of equilibrium control during their fabrication, membranes with differing molecular weight "cutoffs" can be created such that molecules with molecular weights above these cutoffs ratings are rejected and cannot penetrate the filtration matrix.

Ceramic ultrafilters are another molecular sieving technology. They are cakes of ultra-fine silicate particles, the size of which ultimately determines the molecular porosity, that have been partially sintered together at high temperatures. Ceramic ultrafilters are self supporting and extremely durable, backwashable, chemically cleanable, and steam sterilizable. However, they generally require higher operating pressures than membrane type ultrafilters.

All ultrafiltration devices work primarily by a molecular sieving principle. Ultrafilters with molecular weight cutoff ratings in the range of 10,000 to $20,000 \mathrm{Da}$ are typically used in water systems for removing endotoxins. This technology may be appropriate as an intermediate or final purification step. Similar to RO, successful performance is dependent upon pretreatment of the water by upstream unit operations.
Issues of concern for ultrafilters include compatibility of membrane material with heat and sanitizing agents, membrane integrity, fouling by particles and microorganisms, and seal integrity. Control measures involve filtration medium selection, sanitization, flow design (dead end vs. tangential), integrity challenges, regular cartridge changes, elevated feed water temperature, and monitoring TOC and differential pressure. Additional flexibility in operation is possible based on the way ultrafiltration units are arranged such as in a parallel or series configurations. Care should be taken to avoid stagnant water conditions that could promote microorganism growth in back-up or standby units.

## Charge-Modified Filtration

Charge-modified filters are usually microbially retentive filters that are treated during their manufacture to have a positive charge on their surfaces. Microbial retentive filtration will be disescribed in a subsequent section, but the significant feature of these membranes is their electrostatic surface charge. Such charged filters can reduce endotoxin levels in the fluids passing through them by their adsorption (owing to endotoxin's negative charge) onto the membrane surfaces. Though ultrafilters are more often employed as a unit operation for endotoxin removal in water systems, charge-modified filters may also have a place in endotoxin removal particularly where available upstream pressures are not sufficient for ultrafiltration and for a single,
relatively short term use. Charge-modified filters may be difficult to validate for long-term or large-volume endotoxin retention. Even though their purified standard endotoxin retention can be well characterized, their retention capacity for "natural" endotoxins is difficult to gauge. Nevertheless, utility could be demonstrated and validated as short-term, single-use filters at points of use in water systems that are not designed for endotoxin control or where only an endotoxin "polishing" (removal of only slight or occasional endotoxin levels) is needed. Control and validation concerns include volume and duration of use, flow rate, water conductivity and purity, and constancy and concentration of endotoxin levels being removed. All of these factors may have to be evaluated and challenged prior to using this approach, making this a difficult-to-validate application. Even so, there may still be a possible need for additional backup endotoxin testing both upstream and downstream of the filter.

#### Abstract

Mieroporoust Microbial-Retentive Filtration

Microbial-retentive membrame filters have a larger effec tive pere-size than ultrafiters and are-used to prevent the passage of miereorganisms and similarly sized particles. Fil ters are rated by their manufacturer for the theoretiealsmallest size of bacterial cell they are eapable of retaining. The generally aceepted rating considered to retain all bacteria from a gas stream is 0.2 or 0.22 Hm (absolute, net nominal rating). When used on air or gas vents for tanks and other thit operations, as well as for compressed air gases used in the regeneration of mixed bed deionization units, the membrane surface is typieally hydrophobic (nenwettable by water). Areas of concern are-bleckage-of tank vents by eendensed water vaper or trapped partieutate matter, whieh eancause mechaniealdamage to the tank, andeoncentration of miereorganisms on the surface of the membrane filter,

ereating the petential for contamination of the tank or deionizer contents. Control meastres include heat tracing and proper orientation of vent filter housings to prevent aceumtt lation of vaper condensate. Sterilization of the unit prier to initial use, and periedically thereafter, as well as regular flt ter changes are recemmended control methods.

Mierobial retentive filters are also sometimes used for water filtration in the purification systems or in distribution piping. Though mierobial retentive filters, treated to be hydrophilic and having an absolute filter rating of 0.2 or $0.22 \mu \mathrm{~m}$, are considered to be sterilizing filters for process streams and product formulations, their use in water systems should either be avoided or very careftlly controlled beeause these units can become a source for microbial contamination. The potential exists for the release of microrganisms should the membrane filter rupture or as a result of mierobial grow threugh. There is also evidence that the kinds of micreorganisms that proliferate in ambient wa ter systems are of a size and possess cell strface properties that could allow their passage through these filters. Filters of smaller retention ratings (e.g., $0.1 \mu \mathrm{~m}$ ) may be necessary to more definitively retain these aquatic mierourganisms.

Filters that are intended to be microretentive should be sanitized and integrity tested prior to initialuse and at appropriate intervals thereafter. It may also be neeessary to frequently replace these filters to avoid grow through as well as release of endetoxin from the aecummated bioburdenen the upstream side of the filters. As an added meastre of protection, in line ultraviolet lamps, apprepriately sized for the flow rate, may be used just upstream of mieroretentive filters to inactivate mieroorganisms prior to their capture by the fit ter to woid or greatly delay filter grow hrough.
Mieroretentive filters may be use downstream of unitoperations that tend to release mieroerganisms or upstream of thit operations that are sensitive to microorganisms. Miero-
retentive filters may also be used to filter water feeding the distribution system. Concerns include flow rate, membrane and seal integrity, retention capacity, and service-duration. Gentrol measures include monitoring differential pressure and endetoxin levels, proper sizing, membrane integrity testing, placing ultraviolet lamps immediately upstream, and configuring units in series to control break through.

These hydrophilic filters can also be treated to have a positive charge on the surface of the filter media. Such eharged filters can additionally be used to reduce endotoxin levels in the fluids passing through them by electrostatic attraction and adsorption. However, such applications are diffieult to validate for endotoxin retention beeatse their endotoxin retention capacity for "natural" endotoxim is difficult to gatege from purified endotoxin retention and because the amount of endotoxin in the water, or pyreburden, can be quite variable. These factors make usage duration diffieut to validate.

Microbial-retentive membrane filters have experienced an evolution of understanding in the past decade that has caused previously held theoretical retention mechanisms to be reconsidered. These filters have a larger effective "pore size" than ultrafilters and are intended to prevent the passage of microorganisms and similarly sized particles without unduly restricting flow. This type of filtration is widely employed within water systems for filtering the bacteria out of both water and compressed gases as well as for vent filters on tanks and stills and other unit operations. However, the properties of the water system microorganisms seem to challenge a filter's microbial retention from water with phenomena absent from other aseptic filtration applications, such as filter sterilizing of pharmaceutical formulations prior to packaging. In the latter application, sterilizing grade filters are generally considered to have an assigned rating of 0.2 or $0.22 \mu \mathrm{~m}$. This rather arbitrary rat-
ing is associated with filters that have the ability to retain a high level challenge of a specially prepared inoculum of Brevundimonas (formerly Pseudomonas) diminuta. This is a small microorganism originally isolated decades ago from a product that had been "filter sterilized" using a $0.45-\mu \mathrm{m}$ rated filter. Further study revealed that a percentage of cells of this microorganism could reproducibly penetrate the $0.45-\mu \mathrm{m}$ sterilizing filters. Through the suessful use in product solution filter sterilization, retention filters assigned the historic correlation of B. diminuta retaining tighter filters, thought to be twice as good as $0.45-\mu \mathrm{m}$ filter, assigned ratings of 0.2 or $0.22 \mu \mathrm{~m}$ with their successful use in product solution filter sterilization, both this filter rating and the associated high level B. diminuta challenge have become the current benchmarks for sterilizing filtration. New evidence now suggests that for microbial-retentive filters used for pharmaceutical water, B. diminuta may not be the best model microorganism.

An archaic understanding of microbial retentive filtration would lead one to equate a filter's rating with the false impression of a simple sieve or screen that absolutely retains particles sized at or above the filter's rating. A current understanding of the mechanisms involved in microbial retention and the variables that can affect those mechanisms has yielded a far more complex interaction of phenomena than previously understood. A combination of simple sieve retention and surface adsorption are now known to contribute to microbial retention.

The following all interact to create some unusual and surprising retention phenomena for water system microorganisms: the variability in the range and average pore sizes created by the various membrane fabrication processes, the variability of the surface chemistry and three-dimensional structure related to the different polymers used in these filter matrices, and the size and surface properties of the mi-
croorganism intended to be retained by the filters. B. diminuta may not the best challenge microorganisms for demonstrating bacterial retention for $0.2-$ to $0.22-\mu \mathrm{m}$ rated filters for use in water systems because it appears to be more easily retained by these filters than some water system flora. The well-documented appearance of water system microorganisms on the downstream sides of some 0.2 - to $0.22-\mu \mathrm{m}$ rated filters after a relatively short period of use seems to support that some penetration phenomena are at work. Unknown for certain is if this downstream appearance is caused by a "blow-through" or some other pass-through phenomenon as a result of tiny cells or less cell "stickiness", or by a "growth through" phenomenon as a result of cells hypothetically replicating their way through the pores to the downstream side. Whatever is the penetration mechanism, 0.2 - to $0.22-\mu \mathrm{m}$ rated membranes may not be the best choice for some water system uses.

Microbial retention success in water systems has been reported with the use of some manufacturers' filters arbitrarily rated as $0.1 \mu \mathrm{~m}$. There is general agreement that for a given manufacturer, their $0.1-\mu \mathrm{m}$ rated filters are tighter than their 0.2 - to $0.22-\mu \mathrm{m}$ rated filters. However, comparably rated filters from different manufacturers in water filtration applications may not perform equivalently owing to the different filter fabrication processes and the nonstandardized microbial retention challenge processes currently used for defining the $0.1-\mu \mathrm{m}$ filter rating. It should be noted that use of $0.1-\mu \mathrm{m}$ rated membranes generally results in a sacrifice in flow rate compared to 0.2 - to $0.22-\mu \mathrm{m}$ membranes, so whatever membranes are chosen for a water system application, the user must verify that the membranes are suitable for their intended application, use period, and use process, including flow rate.

For microbial retentive gas filtrations, the same sieving and adsorptive retention phenomena are at work as in liquid filtration, but the adsorptive phenomenon is enhanced by additional electrostatic interactions between particles and filter matrix. These electrostatic interactions are so strong that particle retention for a given filter rating is significantly more efficient in gas filtration than in water or product solution filtrations. These additional adsorptive interactions render filters rated at 0.2 to $0.22 \mu \mathrm{~m}$ unquestionably suitable for microbial retentive gas filtrations. When microbially retentive filters are used in these applications, the membrane surface is typically hydrophobic (non-wettable by water). A significant area of concern for gas filtration is blockage of tank vents by condensed water vapor, which can cause mechanical damage to the tank. Control measures include electrical or steam tracing and a self-draining orientation of vent filter housings to prevent accumulation of vapor condensate. However, a continuously high filter temperature will take an oxidative toll on polypropylene components of the filter, so sterilization of the unit prior to initial use, and periodically thereafter, as well as regular visual inspections, integrity tests, and changes are recommended control methods.

In water applications, microbial retentive filters may be used downstream of unit operations that tend to release microorganisms or upstream of unit operations that are sensitive to microorganisms. Microbial retentive filters may also be used to filter water feeding the distribution system. It should be noted that regulatory authorities allow the use of microbial retentive filters within distribution systems or even at use points if they have been properly validated and are appropriately maintained. A point-of-use filter should only be intended to "polish" the microbial quality of an otherwise well-maintained system and not to serve as the primary microbial control device. The efficacy of system microbial control measures can only be assessed by
sampling the water upstream of the filters. As an added measure of protection, in-line UV lamps, appropriately sized for the flow rate (see Sanitization), may be used just upstream of microbial retentive filters to inactivate microorganisms prior to their capture by the filter. This tandem approach tends to greatly delay potential microbial penetration phenomena and can substantially extend filter service life.

## Ultraviolet Light

The use of UV light for mierobial contrel is diseussed under the Sanitization, but its applications to chemical purift eation are also emerging. At wavelengths of 185 nm, UV light has demenstrated utility in the destruction of the chlerine containing disinfectants used in sotree water as well as for interim stages of water pretreatment. This wavelength of UV light has also been used to reduee TOC levels in recir eulating distribution systems. Areas of concem inelude ad equate UV intensity and residence time, unforeseen hyperchlorination of the source water overwhelming the pho degradation capability, release of ammonia from the photodegradation of chloramines, and mapparent UV bulb failure. The use of low-pressure UV lights that emit a 254nm wavelength for microbial control is discussed under Sanitization, but the application of UV light in chemical purification is also emerging. This $254-\mathrm{nm}$ wavelength is also useful in the destruction of ozone. With intense emissions at wavelengths around 185 nm (as well as at 254 nm ), medium pressure UV lights have demonstrated utility in the destruction of the chlorine containing disinfectants used in source water as well as for interim stages of water pretreatment. High intensities of this wavelength alone or in combination with other oxidizing sanitants, such as hydrogen peroxide, have been used to lower TOC levels in recirculating distribution systems. The organics are typically converted to carbon dioxide, which equilibrates to bicarbonate, and
incompletely oxidized carboxylic acids, both of which can easily be removed by polishing ion-exchange resins. Areas of concern include adequate UV intensity and residence time, gradual loss of UV emissivity with bulb age, gradual formation of UV-absorbing film at the water contact surface, incomplete photodegradation during unforeseen source water hyperchlorination, release of ammonia from chloramine photodegradation, unapparent UV bulb failure, and conductivity degradation in distribution systems using $185-\mathrm{nm}$ UV lights. Control measures include regular inspection or emissivity alarms to detect bulb failures or film occlusions, regular UV bulb sleeve cleaning and wiping, downstream chlorine detectors, downstream polishing deionizers, and regular (approximately yearly) bulb replacement.

## Distillation

Distillation units provide chemical and microbial purification via thermal vaporization, mist elimination, and water vapor condensation. A variety of designs is available including single effect, multiple effect, and vapor compression. The latter two configurations are normally used in larger systems because of their generating capacity and efficiency. Distilled water systems may require less rigorous control of feed water quality than do membrane systems. Areas ofeoneern include carry over of gaseous impurities such as ammonia and carbon dioxide, faulty mist elimination, evaporator flooding, inadequate blowdown, stagnant water in condensers and raporators, pump and compressor seat design, pinhole evaporater and condenser leaks, andeonductivity (quality) variations during stant up and operation. require different feed water controls than required by membrane systems. For distillation, due consideration must be given to prior removal of hardness and silica impurities that may foul or corrode the heat transfer surfaces as well as prior removal of those impurities that could volatize and
condense along with the water vapor. In spite of general perceptions, even the best distillation process cannot afford absolute removal of contaminating ions and endotoxin. Most stills are recognized as being able to accomplish at least a 3 to $4 \log$ reduction in these impurity concentrations. Areas of concern include carry-over of volatile organic impurities such as trihalomethanes (see Source and Feed Water Considerations) and gaseous impurities such as ammonia and carbon dioxide, faulty mist elimination, evaporator flooding, inadequate blowdown, stagnant water in condensers and evaporators, pump and compressor seal design, pinhole evaporator and condenser leaks, and conductivity (quality) variations during start-up and operation.

Methods of control consist of preliminary decarbenation steps, reliable mist elimination, visual or autemated hight water level indication, use of sanitary pumps and eompressers, proper drainage during inactive periods, blow down eontrel, on line conductivity sensing with autemated diver sion of unacceptable quality water to the waste stream, and periodic integrity testing for pinhole leaks. Methods of control may involve preliminary decarbonation steps to remove both dissolved carbon dioxide and other volatile or noncondensable impurities; reliable mist elimination to minimize feedwater droplet entrainment; visual or automated high water level indication to detect boiler flooding and boil over; use of sanitary pumps and compressors to minimize microbial and lubricant contamination of feedwater and condensate; proper drainage during inactive periods to minimize microbial growth and accumulation of associated endotoxin in boiler water; blow down control to limit the impurity concentration effect in the boiler to manageable levels; on-line conductivity sensing with automated diversion to waste to prevent unacceptable water upon still startup or still malfunction from getting into the finished water distribute sys-
tem; and periodic integrity testing for pinhole leaks to routinely assure condensate is not compromised by nonvolatized source water contaminants.

## Storage Tanks

Storage tanks are included in water distribution systems to optimize processing equipment capacity. Storage also allows for routine maintenance within the pretreatment train while maintaining continuous supply to meet manufacturing needs. Design and operation considerations are needed to prevent or minimize the development of biofilm, to minimize corrosion, to aid in the use of chemical sanitization of the tanks, and to safeguard mechanical integrity. These considerations may include using closed tanks with smooth interiors, the ability to spray the tank headspace using sprayballs on recirculating loop returns, and the use of heated, jacketed/insulated tanks. This minimizes corrosion and biofilm development and aids in thermal and chemical sanitization. Storage tanks require venting to compensate for the dynamics of changing water levels. This can be accomplished with a hydrophobic mierobial retentive membrane filter fitt with a properly oriented and heat-traced filter housing fitted with a hydrophobic microbial retentive membrane filter affixed to an atmospheric vent. Alternatively, an automatic membrane-filtered compressed gas pressurization and venting blanketing system may be used. In both cases, rupture disks equipped with a rupture alarm device should be used as a further safeguard for the mechanical integrity of the tank. Areas of concern include microbial growth or corrosion due to irregular or incomplete sanitization and microbial contamination from unalarmed rupture disk failures that are caused by condensate eclusion of hydrephebie occluded vent filters.

## Distribution Systems

Distribution system configuration should allow for either the continuous flow of water in the piping by means of recirculation. or should provide for the periodic flushing of momrecireulating, deadend, or one way systems. Use of nonrecirculating, dead-end, or one-way systems or system segments should be avoided whenever possible. If not possible, these systems should be periodically flushed and more closely monitored. Experience has shown that continuously recirculated systems are easier to maintain. Pumps should be designed to deliver fully turbulent flow conditions to facilitate thorough heat distribution (for hot water sanitized systems) as well as thorough chemical sanitant distribution. Pumps Turbulent flow also appear to either retard the development of biofilms or foree its development be less eeptible to shearing int the or reduce the tendency of those biofilms to shed bacteria into the water. If redundant pumps are used, they should be configured and used to avoid microbial contamination of the system.

Components and distribution lines should be sloped and fitted with drain points so that the system can be completely drained. In stainless steel distribution systems where the water is circulated at a high temperature, dead legs and lowflow conditions should be avoided, and valved tie-in points should have length-to-diameter ratios of six or less. If constructed of heat tolerant plastic, this ratio should be even less to avoid cool points where biofilm development could occur. In ambient temperature distribution systems, particular care should be exercised to avoid or minimize dead leg of any length ratios of any size and provide for complete drainage. If the system is intended to be steam sanitized, careful sloping and low-point drainage is crucial to eess. If system drainage is intended as a mierobial controt strategy, it should also be configured to be dried by passage of dry compressed air or nitrogen throughout the system be-
eatse drained meist piping will also-suppert mierebial preliferation. Water exiting from the distribution system should net be rettrned to the system. condensate removal and sanitization success. If drainage of components or distribution lines is intended as a microbial control strategy, they should also be configured to be completely dried using dry compressed air (or nitrogen if appropriate employee safety measures are used). Drained but still moist surfaces will still support microbial proliferation. Water exiting from the distribution system should not be returned to the system without first passing through all or a portion of the purification train.

The distribution design should include the placement of sampling valves in the storage tank and at other locations, such as in the return line of the recirculating water system. Where feasible, the primary sampling sites for water should be the valves that deliver water to the points of use. Direct connections to processes or auxiliary equipment should be designed to prevent reverse flow into the controlled water system. Hoses and heat exchangers that are attached to points of use in order to deliver water for a particular use must not chemically or microbiologically degrade the water quality. The distribution system should permit sanitization for microorganism control. The system may be continuously operated at sanitizing conditions or sanitized periodically.

## INSTALLATION, MATERIALS OF

## CONSTRUCTION, AND COMPONENT SELECTION

Installation techniques are important because they can affect the mechanical, corrosive, and sanitary integrity of the system. Valve installation attitude should promote gravity drainage. Pipe supports should provide appropriate slopes for drainage and should be designed to support the piping adequately under worst-case thermal and flow conditions. The methods of connecting system components including
units of operation, tanks, and distribution piping require careful attention to preclude potential problems. Stainless steel welds should provide reliable joints that are internally smooth and corrosion-free. Low-carbon stainless steel, compatible wire filler, where necessary, inert gas, automatic welding machines, and regular inspection and documentation help to ensure acceptable weld quality. Follow-up cleaning and passivation are important for removing contamination and corrosion products and to re-establish the passive corrosion resistant surface. Plastic materials can be fused (welded) in some cases and also require smooth, uniform internal surfaces. Adhesive glues and solvents should be avoided due to the potential for voids and ehemieal reactions. extractables. Mechanical methods of joining, such as flange fittings, require care to avoid the creation of offsets, gaps, penetrations, and voids. Control measures include good alignment, properly sized gaskets, appropriate spacing, uniform sealing force, and the avoidance of threaded fittings.

Materials of construction should be selected to be compatible with control measures such as sanitizing, cleaning, and passivating. Temperature rating is a critical factor in choosing appropriate materials because surfaces may be required to handle elevated operating and sanitization temperatures. Should chemicals or additives be used to clean, control, or sanitize the system, materials resistant to these chemicals or additives must be utilized. Materials should be capable of handling turbulent flow and elevated velocities without wear of the corrosion-resistant film such as the passive chromium oxide surface of stainless steel. The finish on metallic materials such as stainless steel, whether it is a refined mill finish, polished to a specific grit, or an electropolished treatment, should complement system design and provide satisfactory corrosion and microbial activity resistance as well as chemical sanitizability. Auxiliary equipment and fittings
that require seals, gaskets, diaphragms, filter media, and membranes should exclude materials that permit the possibility of extractables, shedding, and microbial activity. Insulating materials exposed to stainless steel surfaces should be free of chlorides to avoid the phenomenon of stress corrosion cracking that can lead to system contamination and the destruction of tanks and critical system components.

Specifications are important to ensure proper selection of materials and to serve as a reference for system qualification and maintenance. Information such as mill reports for stainless steel and reports of composition, ratings, and material handling capabilities for nonmetallic substances should be reviewed for suitability and retained for reference. Component (auxiliary equipment) selection should be made with assurance that it does not create a source of contamination intrusion. Heat exchangers should be double shee or eoneentric tube design. They should inelude differential pressure monitoring or utilize heat transfer medium of equal or better quality to aveid problems should leaks develop. constructed to prevent leakage of heat transfer medium to the pharmaceutical water and, for heat exchanger designs where prevention may fail, there should be a means to detect leakage. Pumps should be of sanitary design with seals that prevent contamination of the water. Valves should have smooth internal surfaces with the seat and closing device exposed to the flushing action of water, such as occurs in diaphragm valves. Valves with pocket areas or closing devices (e.g., ball, plug, gate, globe) that move into and out of the flow area should be avoided.

## SANITIZATION

Microbial control in water systems is achieved primarily through sanitization practices. Systems can be sanitized using either thermal or chemical means. Thermal approaches to system sanitization include periodic or continuously cir-
culating hot water and the use of steam. Temperatures of at least $80^{\circ}$ are most commonly used for this purpose, but continuously recirculating water of at least $65^{\circ}$ has also been used effectively in insulated stainless steel distribution systems when attention is paid to uniformity and distribution of such self-sanitizing temperatures. These techniques are limited to systems that are compatible with the higher temperatures needed to achieve sanitization., such as stainless steel and some polymer formulations. Although thermal methods control biofilm development by either continuously inhibiting their growth or, in intermittent applications, by killing the microorganisms within biofilms, they are not effective in removing established biofilms. that beeme antri ent source for rapid biofilm regrowth after the sanitizing enditions are removedor halted. Chemical metheds, where empatible, can be used on a wider variety of construction materials. These metheds typieally employ oxidizing agents steh as halogenated compounds, hydrogen peroxide, ozone, peracetic acid, or combinations thereof. Halogenated com peunds are effeetive sanitizers but are diffieult to flush from the system and may leave biofilms intact. Compounds such as hydrogen peroxide, ozone, and peracetic acid oxidize bacteria and biofilms by forming reactive peroxides and free radieals (netably hydroxyl radieals). The shert half life of these compounds, partieularly ozone, may require that it be added continuously during the sanitization process. Hy drogen peroxide andozone rapidly degrade to water andox ygen; peracetic acid degrades to acetic acid in the presence of ultraviolet light. It is important to note that mieroorga nisms in a biefilm can be extremely difficult to kill, even by aggressive oxidizing biocides. The less developed the biofllm, the more effective the biocidalaction. Therefore, eptimal biocide entrol is achieved by frequent biocide use that does not allow significant biofilm development be Killed but intact biofilms can become a
nutrient source for rapid biofilm regrowth after the sanitizing conditions are removed or halted. In such cases, a combination of routine thermal and periodic supplementation with chemical sanitization might be more effective. The more frequent the thermal sanitization, the more likely biofilm development and regrowth can be eliminated. Chemical methods, where compatible, can be used on a wider variety of construction materials. These methods typically employ oxidizing agents such as halogenated compounds, hydrogen peroxide, ozone, peracetic acid, or combinations thereof. Halogenated compounds are effective sanitizers but are difficult to flush from the system and may leave biofilms intact. Compounds such as hydrogen peroxide, ozone, and peracetic acid oxidize bacteria and biofilms by forming reactive peroxides and free radicals (notably hydroxyl radicals). The short half-life of ozone in particular, and its limitation on achievable concentrations require that it be added continuously during the sanitization process. Hydrogen peroxide and ozone rapidly degrade to water and oxygen; peracetic acid degrades to acetic acid in the presence of UV light. In fact, ozone's ease of degradation to oxygen using 254nm UV lights at use points allow it to be most effectively used on a continuous basis to provide continuously sanitizing conditions.

In-line UV light at a wavelength of 254 nm can also be used to continuously "sanitize" water ciculating in the system, but these devices must be properly sized for the water flow. Such devices inactivate a high percentage (but not $100 \%$ ) of microorganisms that flow through the device but cannot be used to directly control existing biofilm upstream or downstream of the device. However, when coupled with conventional thermal or chemical sanitization technologies or located immediately upstream of a microbially retentive filter, it is most effective and can prolong the interval between system sanitizations. The ultraviole light of
the proper wavelength also facilitates the degradation of hy drogen peroxide and ozone, peracetic acid, and ehlorinated

## water disinfectants.

It is important to note that microorganisms in a well-developed biofilm can be extremely difficult to kill, even by aggressive oxidizing biocides. The less developed and therefore thinner the biofilm, the more effective the biocidal action. Therefore, optimal biocide control is achieved by frequent biocide use that does not allow significant biofilm development between treatments.

Sanitization steps require validation to demonstrate the capability of reducing and holding microbial contamination at acceptable levels. Validation of thermal metheds sheuld inelude a heat distribution study to demenstrate that sanitization temperatures are achieved throughout the system. Va lidation of chemical methods require demonstrating adequate chemical concentrations throughout the system. In addition, when the sanitization process is completed, of feetive removal of chemieal residues must be demonstrated. The frequeney of sanitization is generally dietated by the results of systernern should include a heat distribution study to demonstrate that sanitization temperatures are achieved throughout the system, including the body of use point valves. Validation of chemical methods require demonstrating adequate chemical concentrations throughout the system, exposure to all wetted surfaces, including the body of use point valves, and complete removal of the sanitant from the system at the completion of treatment. Methods validation for the detection and quantification of residues of the sanitant or its objectionable degradants is an essential part of the validation program. The frequency of sanitization should be supported by, if not triggered by, the results of system microbial monitoring. Conclusions derived from trend analysis of the microbiological data should be used as the alert mechanism for
maintenance. The frequency of sanitization should be established in such a way that the system operates in a state of microbiological control and does not routinely exceed alert levels (see Alert and Action Levels and Specifications).

## OPERATION, MAINTENANCE, AND CONTROL

A preventive maintenance program should be established to ensure that the water system remains in a state of control. The program should include (1) procedures for operating the system, (2) monitoring programs for critical quality attributes and operating conditions including calibration of critical instruments, (3) schedule for periodic sanitization, (4) preventive maintenance of components, and (5) control of changes to the mechanical system and to operating conditions.

Operating Procedures-Procedures for operating the water system and performing routine maintenance and corrective action should be written, and they should also define the point when action is required. The procedures should be well documented, detail the function of each job, assign who is responsible for performing the work, and describe how the job is to be conducted. The effectiveness of these procedures should be assessed during water system validation.

Monitoring Program—Critical quality attributes and operating parameters should be documented and monitored. The program may include a combination of in-line sensors or automated instruments (e.g., for TOC, conductivity, hardness, chlorine, etc.), automated or manual documentation of operational parameters (such as flow rates or pressure drop across a carbon bed, filter, or RO unit), and laboratory tests (e.g., total microbial counts). The frequency of sampling, the requirement for evaluating test results, and the necessity for initiating corrective action should be included.

Sanitization-Depending on system design and the selected units of operation, routine periodic sanitization may be necessary to maintain the system in a state of microbial control. Technologies for sanitization are described above.

Preventive Maintenance-A preventive maintenance program should be in effect. The program should establish what preventive maintenance is to be performed, the frequency of maintenance work, and how the work should be documented.

Change Control-The mechanical configuration and operating conditions must be controlled. Proposed changes should be evaluated for their impact on the whole system. The need to requalify the system after changes are made should be determined. Following a decision to modify a water system, the affected drawings, manuals, and procedures should be revised.

## SAMPLING CONSIDERATIONS

Water systems should be monitored at a frequency that is sufficient to ensure that the system is in control and continues to produce water of acceptable quality. Samples should be taken from representative locations within the processing and distribution system. Established sampling frequencies should be based on system validation data and should cover critical areas including unit operation sites. The sampling plan should take into consideration the desired attributes of the water being sampled. For example, systems for Water for Injection because of their more critical microbiological requirements, may require a more rigorous sampling frequency.

Where possible, samples should be collected from use peints using the same delivery deviees, stuch as hoses, and procedures, sueh as prelimimary hose or outlet flushing, as are employed for normal water use from those use points. Where use points samples are not practical, specialsam-
pling ports may be used, but in both cases, consideration must be given to sample collection so that it aceurately represents the quality attributes of the water delivered by the system. This may include sampling pert or use point sanitization and thereugh flushing before a sample is taken if such practiees are employed during routine water use or delivery frem the system. Analyses of water samples often serve two purposes: in-process control assessments and final quality control assessments. In-process control analyses are usually focused on the attributes of the water within the system. Quality control is primarily concerned with the attributes of the water delivered by the system to its various uses. The latter usually employs some sort of transfer device, often a flexible hose, to bridge the gap between the distribution system use-point valve and the actual location of water use. The issue of sample collection location and sampling procedure is often hotly debated because of the typically mixed use of the data generated from the samples, for both in-process control and quality control. In these single sample and mixed data use situations, the worst-case scenario should be utilized. In other words, samples should be collected from use points using the same delivery devices, such as hoses, and procedures, such as preliminary hose or outlet flushing, as are employed by production from those use points. Where use points per se cannot be sampled, such as hard-piped connections to equipment, special sampling ports may be used. In all cases, the sample must represent as closely as possible the quality of the water used in production. If a point of use filter is employed, sampling of the water prior to and after the filter is needed because the filter will mask the microbial control achieved by the normal operating procedures of the system.
Samples containing chemical sanitizing agents require neutralization prior to microbiological analysis. Samples for microbiological analysis should be tested immediately,
or suitably refrigerated to preserve the original microbial attributes until analysis can begin. Samples of flowing water are only indicative of the concentration of planktonic (free floating) microorganisms present in the system. Biofilm microorganisms (those attached to water system surfaces) are usually present in greater numbers and are the source of the planktonic population recovered from grab samples. Microorganisms in biofilms represent a continuous source of contamination and are difficult to directly sample and quantify. Consequently, the planktonic population is usually used as an indicator of system contamination levels and is the basis for system Alert and Action Levels. The consistent appearance of elevated planktonic levels is usually an indication of advanced biofilm development in need of remedial control. System control and sanitization are key in controlling biofilm formation and the consequent planktonic population.

Sampling for chemical analyses is also done for in-process control and for quality control purposes. However, unlike microbial analyses, chemical analyses can be and often are performed using on-line instrumentation. Such on-line testing has unequivocal in-process control purposes because it is not performed on the water delivered from the system. However, unlike microbial attributes, chemical attributes are usually not significantly degraded by hoses. Therefore, through verification testing, it may be possible to show that the chemical attributes detected by the on-line instrumentation (in-process testing) are equivalent to those detected at the ends of the use point hoses (quality control testing). This again creates a single sample and mixed data use scenario. It is far better to operate the instrumentation in a continuous mode, generating large volumes of in-process data, but only using a defined small sampling of that data for QC purposes. Examples of acceptable approaches include using highest values for a given period, highest time-weighted average
for a given period (from fixed or rolling sub-periods), or values at a fixed daily time. Each approach has advantages and disadvantages relative to calculation complexity and reflection of continuous quality, so the user must decide which approach is most suitable or justifiable.

## CHEMICAL CONSIDERATIONS

The chemical attributes of USP Waters prior 1997-Purified Water and Water for Injection were specified by a series of chemistry tests for various specific and nonspecific attributes with the intent of detecting chemical species indicative of incomplete or inadequate purification. Many tests dated back to the 19th century, were nonquantitative, and represented long since outmeded analytieal teehnologies. While these methods could have been considered barely adequate to control the quality of these waters, they nevertheless stood the test of time. This was partly because the operation of water systems was, and still is, based on online conductivity measurements and specifications generally thought to these archaic chemistry attribute tests.
USP moved away from these chemical attribute tests to contemporary analytical technologies for the bulk waters Purified Water and Water for Injection. The intent was to upgrade the analytical technologies without tightening the quality requirements. The two contemporary analytical technologies employed were TOC and conductivity. The TOC test replaced the test for Oxidizable substances that primarily targeted organic contaminants. A multistaged Conductivity test which detects ionic (mostly inorganic) contaminants replaced, with the exception of the test for Heavy metals, all of the inorganic chemical tests (i.e., Ammonia, Calcium, Carbon dioxide, Chloride, Sulfate).

Replacing the heavy metals attribute was considered unnecessary because (a) the source water specifications (found in the NPDWR) for individual Heavy metals were tighter than the empirically determined limit found in the approximate limit of detection of the Heavy metals test for USP XXII Water for Injection and Purified Water menegraph (approximately 0.1 ppm ), (b) contemporary water system construction materials do not leach heavy metal contaminants, and (c) test results for this attribute have uniformly been negative-there has not been a confirmed occurrence of a singular test failure (failure of only the Heavy metals test with all other attributes passing) since the current heavy metal drinking water standards have been in place. Nevertheless, since the presence of heavy metals in Purified Water or Water for Injection could have dire consequences, its absence should at least be documented during new water system commissioning and validation or through prior test results records.

## The only remainimg original "inorganie" tests net eer ered by the eonduetivity specifteations were Total Solids

 and $p H$. Total solids and $p H$ are the only tests not covered by conductivity testing. The test for Total solids was considered redundant because the nonselective tests of conductivity and TOC could detect most chemical species other than silica, which could remain undetected in its colloidal form. Colloidal silica in Purified Water and Water for Injection is easily removed by most water pretreatment steps and even if present in the water, constitutes no medical or functional hazard except under extreme and rare situations. In such extreme situations, other attribute extremes are also likely to be detected. It is, however, the user's responsibility to ensure fitness for use. If silica is a significant component inthe source water, and the purification unit operations could be operated or fail and selectively allow silica to be released into the finished water (in the absence of co-contaminants detectable by conductivity), then either silica-specific or a total solids type testing should be utilized the af fecers to monitor and control this rather rare problem.

The pH attribute was eventually recognized to be redundant to the conductivity test (which included pH as an aspect of the test and specification); therefore, $p H$ was dropped as a separate attribute test.

The rationale used by USP to establish its conductivity specification took into consideration the conductivity contributed by the two least conductive former attributes of Chloride and Ammonia, thereby precluding their failure had those wet chemistry tests been performed. In essence, the Stage 3 conductivity specifications (see Water Conductivity $\langle 645\rangle$ ) were established from the sum of the conductivities of eontributing ions as a function of pH of chloride (from pH 5.0 to 6.2) or ammenia (from pH 6.3 to 7.0), plus the unavoidable contribution the limit concentrations of chloride ions (from pH 5.0 to 6.2 ) and ammonia ions (from pH 6.3 to 7.0 ), plus the unavoidable contribution of other conductivity-contributing ions from water $\left(\mathrm{H}^{+}\right.$and $\mathrm{OH}^{-}$), dissolved atmospheric $\mathrm{CO}_{2}$ (as $\mathrm{HCO}_{3}{ }^{-}$), and an elec-tro-balancing quantity of either $\mathrm{Na}^{+}$of $\mathrm{Cl}^{-}$, depending on the pH -induced ionic imbalance (see Table 1). The Stage 2 conductivity specification is the lowest value on this table, 2.1 $\mu \mathrm{S} / \mathrm{cm}$. The Stage 1 specifications, designed primarily for on-line measurements, were derived essentially by summing the lowest values in each column for a-series the contributing ion columns for each of a series of tables similar to Table 1, created for each $5^{\circ}$ increment between $0^{\circ}$ and $100^{\circ}$. For example purposes, the italicized values in Table 1, the conductivity data table for $25^{\circ}$, were summed to yield a con-
servative value of $1.3 \mu \mathrm{~S} / \mathrm{cm}$, the Stage 1 specification for a nontemperature compensated, nonatmosphere equilibrated water sample that actual had a measured temperature of
$25^{\circ}$ to $29^{\circ}$. Each $5^{\circ}$ increment table was similarly treated to yield the individual values listed in the table of Stage 1 specifications (see Water Conductivity $\langle 645\rangle$ ).

Table 1. Contributing Ion Conductivities of the Chloride-Ammonia Model as a Function of pH
(in atmosphere-equilibrated water at $25^{\circ}$ )

|  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |  |

As stated above, this rather radical change to a conductivity attribute as well as the inclusion of a TOC attribute allowed for on-line measurements. This was a major philosophical change and allowed major savings to be real-
ized by industry. The TOC and conductivity tests can also be performed "off-line" in the laboratories using collected samples, though sample collection tends to introduce oppor-
tunities for adventitious contamination that can cause false high readings. The collection of on-line data is not, however, without challenges. The continuous readings tend to create voluminous amounts of data where before only a single data point was available. Contimuous dataisexcellent for thelerstanding how a water system performs during allofits various usage and maintenance events in real time, but it tends to overwhelm quality control data systems that are de signed for far less data. In such situations, the user must deeide how to limit the data be used for routine quality control purposes. Examples of aceeptable approaches int elude using highest values for a given period, highest time-weighted average for agiven period (from fixedor roll ing subperiods), or values at a fixed daily time. Each approach has advantages and disadvantages relative to ealeulation complexity and reflection of contintrous quality, so the user must decide which approach is most sutable or justifiable. As stated under Sampling Considerations, continuous in-process data is excellent for understanding how a water system performs during all of its various usage and maintenance events in real time, but is too much data for QC purposes. Therefore, a justifiable fraction or averaging of the data can be used that is still representative of the overall water quality being used.

Packaged waters present a particular dilemma relative to the attributes of conductivity and TOC. The package itself is the source of chemicals (inorganics and organics) that leach over time into the water and can easily be detected. The irony of organic leaching from plastic packaging is that when the Oxidizable substances test was the only "organic contaminant" test for both bulk and packaged waters, that test's insensitivity to those organic leachables rendered their presence in packaged water at high concentrations (many times the TOC specification for bulk water) virtually undetectable. Similarly, glass containers can also leach inorganics, such as
sodium, which are easily detected by conductivity, but are undetected by the wet chemistry tests for water (other than pH or Total solids). Most of these leachables are considered harmless by current perceptions and standards at the rather significant concentrations present. Nevertheless, they effectively degrade the quality of the high-purity waters placed into these packaging system. Some packaging materials contain more leachables than others and may not be as suitable for holding water and maintaining its purity.

The attributes of conductivity and TOC tend to reveal more about the packaging leachables than they do about the water's original purity. These "allowed" leachables could render the packaged versions of originally equivalent bulk water essentially unsuitable for many uses where the bulk waters are perfectly adequate.

## MICROBIAL CONSIDERATIONS

The major exogenous source of microbial contamination of bulk pharmaceutical water is source or feed water. Feed water quality must, at a minimum, meet the quality attributes of Drinking Water for which the level of coliforms are regulated. A wide variety of other microorganisms, chiefly Gram-negative bacteria, may be present in the incoming water. These microorganisms may compromise subsequent purification steps. Examples of other potential exogenous sources of microbial contamination include unprotected vents, faulty air filters, backflow from contaminated outlets, drain air breaks, and replacement activated earbon, deionizer resins, and regenerant chemicals. ruptured rupture disks, backflow from contaminated outlets, unsanitized distribution system "openings" including routine component replacements, inspections, repairs, and expansions, inadequate drain and air-breaks, and replacement activated carbon, deionizer resins, and regenerant chemicals. In these situations, the exogenous contaminants may not
be normal aquatic bacteria but rather microorganisms of soil or even human origin. The detection of nonaquatic microorganisms may be an indication of a system component failure, which should trigger investigations that will remediate their source. Sufficient care should be given to system design and maintenance in order to minimize microbial contamination from these exogenous sources.

Unit operations can be a major source of endogenous microbial contamination. Microorganisms present in feed water may adsorb to carbon bed, deionizer resins, filter membranes, and other unit operation surfaces and initiate the formation of a biofilm. In a high-purity water system, biofilm is an adaptive response by certain microorganisms to survive in this low nutrient environment. Downstream colonization can occur when microorganisms are sloughed eff shed from existing biofilm-colonized surfaces and carried to other areas of the water system. Microorganisms may also attach to suspended particles such as carbon bed fines or fractured resin particles. When the microorganisms become planktonic, they serve as a source of contamination to subsequent purification equipment (compromising its functionality) and to distribution systems.

Another source of endogenous microbial contamination is the distribution system itself. Microorganisms can colonize pipe surfaces, rough welds, badly aligned flanges, valves, unidentified dead legs, etc. where they proliferate, forming a biofilm. and beoming a contintous soure of mierobial contamination. The smoothness and composition of the surface may affect the rate of initial microbial adsorption, but once adsorbed, biofilm development, unless otherwise inhibited by sanitizing conditions, will occur regardless of the surface. Once formed, the biofilm becomes a continuous source of microbial contamination.

## ENDOTOXIN CONSIDERATIONS

Endotoxins are lipopolysaccharides found in and shed from the cell envelope that is external to the cell wall of Gram-negative bacteria. Gram-negative bacteria that form biofilms can become a source of endotoxins in pharmaceutical waters. Endotoxins may occur as clusters of lipopolysaccharide molecules associated with living microorganisms, fragments of dead microorganisms or the polysaccharide slime surrounding biofilm bacteria, or as free molecules. The free form of endotoxins may be released from cell surfaces of the bacteria that colonize the water system, or from the feed water that may enter the water system. Because of the multiplicity of endotoxin sources in a water system, endotoxin quantitation in a water system is not a good indicator of the level of biofilm abundance within a water system.

Endotoxin levels may be minimized by controlling the introduction of free endotoxins and microorganisms in the feed water and minimizing microbial proliferation in the system. This may be accomplished through the normal exclusion or removal action afforded by various unit operations within the treatment system as well as through system sanitization. Other control methods include the use of ultrafilters or charge-modified filters, either in-line or at the point of use. The presence of endotoxins may be monitored as described in the general test chapter Bacterial Endotoxins Test $\langle 85\rangle$.

## MICROBIAL ENUMERATION CONSIDERATIONS

The objective of a water system microbiological monitoring program is to provide sufficient information to control and assess the microbiological quality of the water produced. Product quality requirements should dictate water quality specifications. An appropriate level of control may be maintained by using data trending techniques and, if
necessary, limiting specific contraindicated microorganisms. Consequently, it may not be necessary to detect all of the microorganisms species present in a given sample. The monitoring program and methodology should indicate adverse trends and detect microorganisms that are potentially harmful to the finished product, process, or consumer. Final selection of method variables should be based on the individual requirements of the system being monitored.

It should be recognized that there is no single method that is capable of detecting all of the potential microbial contaminants of a water system. The methods used for microbial monitoring should be capable of isolating the numbers and types of organisms that have been deemed significant relative to in-process system control and product impact for each individual system. Several criteria should be considered when selecting a method to monitor the microbial content of a pharmaceutical water system. These include method sensitivity, range of organisms types or species recovered, sample processing throughput, incubation period, cost, and methodological complexity. An alternative consideration to the use of the classical "culture" approaches is a sophisticated instrumental or hybrid apreach rapid test method that may yield more timely results. However, care must be exercised in selecting such an alternative approach to ensure that it has both sensitivity and correlation to classical culture approaches, which are generally considered the be "gold stadard" of accepted standards for microbial enumeration.

Consideration should also be given to the timeliness of microbial enumeration testing after sample collection. The number of detectable planktonic bacteria in a sample col-
lected in a scrupulously clean sample container will usually drop as time passes. The planktonic bacteria within the sample will tend to either die or to irretrievably adsorb to the container walls reducing the number of viable planktonic bacteria that can be withdrawn from the sample for testing. The opposite effect can also occur if the sample container is not scrupulously clean and contains a low concentration of some microbial nutrient that could promote microbial growth within the sample container. Because the number of recoverable bacteria in a sample can change positively or negatively over time after sample collection, it is best to test the samples as soon as possible after being collected. If it is not possible to test the sample within about 2 hours of collection, the sample should be held at refrigerated temperatures $\left(2^{\circ}\right.$ to $\left.8^{\circ}\right)$ for a maximum of about 12 hours to maintain the microbial attributes until analysis. In situations where even this is not possible (such as when using off-site contract laboratories), testing of these refrigerated samples should be performed within 48 hours after sample collection. In the delayed testing scenario, the recovered microbial levels may not be the same as would have been recovered had the testing been performed shortly after sample collection. Therefore, studies should be performed to determine the existence and acceptability of potential microbial enumeration aberrations caused by protracted testing delays.

## The Classical Culture Approach

Classical culture approaches for microbial testing of water include but are not limited to pour plates, spread plates, membrane filtration, and most probable number (MPN)
tests. These methods are generally easy to perform, are less expensive, and provide excellent sample processing throughput. Method sensitivity can be increased via the use of larger sample sizes. This strategy is used in the membrane filtration method. Culture approaches are further defined by the type of medium used in combination with the incubation temperature and duration. This combination should be selected according to the monitoring needs presented by a specific water system as well as its ability to recover the microorganisms of interest: those that could have a detrimental effect on the product or process uses as well as those that reflect the microbial control status of the system.

There are two basic forms of media available for traditional microbiological analysis: "high nutrient" and "low nutrient". High-nutrient media such as plate count agar (TGYA) and m-HPC agar (formerly m-SPC agar), are intended as general media for the isolation and enumeration of heterotrophic or "copiotrophic" bacteria. Low-nutrient media such as R2A agar and NWRI agar (HPCA), may be beneficial for isolating slow growing "oligotrophic" bacteria and bacteria that require lower levels of nutrients to grow optimally. Often some facultative oligotrophic bacteria are able to grow on high nutrient media and some facultative copiotrophic bacteria are able to grow on low-nutrient media, but this overlap is not complete. Low-nutrient and high-nutrient cultural approaches may be concurrently used, especially during the validation of a water system, as well as periodically thereafter. in order to determine if any additional mmmbers or types of bacteria are present so that their impact on the
determine if any additional numbers or types of bacteria can be preferentially recovered by one of the approaches. If so, the impact of these additional isolates on system control and the end uses of the water could be assessed. Also, the efficacy of system controls and sanitization on these stower growing baldial addional isolates could be assessed.

Duration and temperature of incubation are also critical aspects of a microbiological test method. Classical methodologies using high nutrient media are typically incubated at $30^{\circ}$ to $35^{\circ}$ for 48 to 72 hours. Because of the flora in certain water systems, incubation at lower temperatures (e.g., $20^{\circ}$ to $25^{\circ}$ ) for longer periods (e.g., 5 to 7 days) can recover higher microbial counts when compared to classical methods. Low-nutrient media are designed for these lower temperature and longer incubation conditions (sometimes as long as 14 days to maximize recovery of very slow growing oligotrophs or sanitant injured microorganisms), but even high-nutrient media can sometimes increase their recovery with these longer and cooler incubation conditions. Whether or not a particular system needs to be monitored using highor low-nutrient media with higher or lower incubation temperatures or shorter or longer incubation times should be determined during or prior to system validation and periodically reassessed as the microbial flora of a new water system gradually establish a steady state relative to its routine maintenance and sanitization procedures. The establishment of a "steady state" can take months or even years and can be perturbed by a change in use patterns, a change in routine and preventative maintenance or sanitization procedures, and frequencies, or any type of system intrusion, such as for component replacement, removal, or addition. The decision to use longer incubation periods should be made after
and the type of corrective actions required when an alert or action level is exceeded with the ability to recover the microorganisms of interest.

The advantages gained by incubating for longer times, namely recovery of injured microorganisms, slow growers, or more fastidious microorganisms, should be balanced against the need to have a timely investigation and to take corrective action, as well as the ability of these microorganisms to detrimentally affect products or processes. In no case, however, should incubation at $30^{\circ}$ to $35^{\circ}$ be less than 48 hours or less than 96 hours at $20^{\circ}$ to $25^{\circ}$.
Normally, the microorganisms that can thrive in extreme environments are best cultivated in the laboratory using conditions simulating the extreme environments from which they were taken. Therefore, thermophilic bacteria might be able to exist in the extreme environment of hot pharmaceutical water systems, and if so, could only be recovered and cultivated in the laboratory if similar thermal conditions were provided. Thermophilic aquatic microorganisms do exist in nature, but they typically derive their energy for growth from harnessing the energy from sunlight, from oxidation/reduction reactions of elements such as sulfur or iron, or indirectly from other microorganisms that do derive their energy from these processes. Such chemical/nutritional conditions do not exist in high purity water systems, whether ambient or hot. Therefore, it is generally considered pointless to search for thermophiles from hot pharmaceutical water systems owing to their inability to grow there.

The microorganisms that inhabit hot systems tend to be found in much cooler locations within these systems, for example, within use-point heat exchangers or transfer hoses. If this occurs, the kinds of microorganisms recovered are usually of the same types that might be expected from ambient
water systems. Therefore, the mesophilic microbial cultivation conditions described later in this chapter are usually adequate for their recovery.

## "Instrumental" Approaches

Examples of instrumental approaches include microscopic visual counting techniques (e.g., epifluorescence and immunofluorescence) and similar automated laser scanning approaches and radiometric, impedometric, and biochemically based methodologies. These methods all possess a variety of advantages and disadvantages. One adwage is their precision and acemracy. Advantages could be their precision and accuracy or their speed of test result availability as compared to the classical cultural approach. In general, instrument approaches often have a shorter lead time for obtaining results, which could facilitate timely system control. This advantage, however, is often counterbalanced by limited sample processing throughput due to extended sample collection time, costly and/or labor-intensive sample processing, or other instrument and sensitivity limitations.

## Instrumental appreaches are typieally destrutive becatuse

further isolate manipulation for characterization purposes is preeluded. Generally, some form of mierobial isolate characterization may be raquired element of water system menitering. Consequently, eulturing approaches have traditionally been preferred over instrumental approaches be eatse they offer a batance of desirable test attributes and inilies. Furthermore, instrumental approaches are typically destructive, precluding subsequent isolate manipulation for characterization purposes. Generally, some
form of microbial isolate characterization, if not full identification, may be a required element of water system monitoring. Consequently, culturing approaches have traditionally been preferred over instrumental approaches because they offer a balance of desirable test attributes and post-test capabilities.

## Suggested Methodologies

The following general methods were originally derived from Standard Methods for the Examination of Water and Wastewater, $17^{\text {th }}$ Edition, American Public Health Association, Washington, DC 20005. Even though this publication has undergone several revisions since its first citation in this chapter, the methods are still considered appropriate for establishing trends in the number of colony-forming units observed in the routine microbiological monitoring of pharmaceutical waters. It is recognized, however, that other combinations of media and incubation time and temperature may occasionally or even consistently result in higher numbers of colony-forming units being observed and/or different species being recovered.

The extended incubation periods that are usually required by some of the alternative methods available offer disadvantages that may outweigh the advantages of the higher counts
that may be obtained. The somewhat higher baseline counts that might be observed using alternate cultural conditions would not necessarily have greater utility in detecting an excursion or a trend. In addition, some alternate cultural conditions using low-nutrient media tend to lead to the development of microbial colonies that are much less differentiated in colonial appearance, an attribute that microbiologists rely on when selecting representative microbial types for further characterization. It is also ironical that the nature of some of the slow growers and the extended incubation times needed for their development into visible colonies may also lead to those colonies being largely nonviable, which limits their further characterization and precludes their subculture and identification.

Methodologies that can be suggested as generally satisfactory for monitoring pharmaceutical water systems are as follows. However, it must be noted that these are not referee methods nor are they necessarily optimal for recovering microorganisms from all water systems. The users mest decide should determine through experimentation with various approaches which methodologies are best for monitoring their water systems and recovering for in-process control and quality control purposes as well as for recovering any contraindicated species they may have specified.

## IDENTIFICATION OF MICROORGANISMS

Identifying the isolates recovered from water monitoring methods may be important in instances where specific waterborne microorganisms may be detrimental to the products or processes in which the water is used. Microorganism information such as this may also be useful when identify-
ing the source of microbial contamination in a product or process. Often a limited group of microorganisms is routinely recovered from a water system. After repeated recovery and characterization, an experienced microbiologist may become proficient at their identification based on only a few recognizable traits such as colonial morphology and staining characteristics. This level of characterization may be ad-
equate for most situations. This may allow for a reduction in the number of identifications to representative colony types, or, with proper analyst qualification, may even allow testing short cuts to be taken for these microbial identifications.

## ALERT AND ACTION LEVELS AND SPECIFICATIONS

Water systems should be mierobiologieally monitored to eon frm that they continte to operate within their design specifieations and produce water of aceeptable quality. Menitoring data may be eempared to established proeess parameters or product specifiea tions.

A refinement to the use of process parameters and product speeiffeations is the establishment of Alert and Aetion Levels, which signal a shift in proeess performance. Alert and Aetion Levels are distinet frem proess parameters and product specifieations in that they are used for menitoring and control rather than aceept or reject decisions. Alert Levels are levels, events, or ranges that, when ex ceeded, indicate that a process may have drifted from its normat eperating eondition. Alewt Levels constitute a warning and do not necessarily require a corrective action. Action Levels are levels, events, or ranges that, when exceeded, indicate that a process has drifted from its nermal operating range. Exeeeding an Aetion tevel indientes that corrective action should be taken to bring the proeess back inte its normal operating range. Alert and Aetion Lev els are established within process and product specification toler ances and are based on a combination of technieal and product related considerations. Consequently, exeeding an Alert or Aetion tevel does not imply that product quality has been eompromised.

Technieal considerations used to establish Alert and Aetion Lev els should inelude a review of equipment design speciffeations to ensure that the prrification equipment is capable of achieving the required level of purity. In addition, samples should be collected and analyzed over a period of time to develep data reflecting nor mat water quality trends. Historieal or statistieally based levels ean be established using the above data. Levels established in this way measure process performanee and are independent of product con eems.

Product related Alert and Aetion Levels should represent both product quality concerns and the ability to effectively manage the purification process. These levels are typieally based on a review of process dat and an assessment of product sensitivity to ehemical and mierobiologieal contamination. The assessment of product suseeptibility might inelude preservative-efficacy, water activity, pH , ete. The levels should be set sueh that, when exeeed ed, product quality is not compromised. Menitoring data should be analyzed on an ongoing basis to enstre that the process contintes to perform within aceeptable limits. An analysis of data trends is often used to valuate precess performance. This information can be used to predict departures from established operating parameters, thereby signaling the need for appropriate preventative main tenamee.

It should be recosnized that the mierobial Alert and Aetion Lev elf established for any phamacentien water system are neeessarily linked to the monitoring method chosen. Using the suggested methodolegies above, generally considered maximmm Action Lev els are 500 colony forming units (efu) per mL for Drinking Water, 100 efuper mL for Purified Water and 10 efuper 100 mL for Water for Injection. However, if a given water system controls mieroor ganisms much more tightly than these levels, appropriate Alert and Aetion Levels should be lower to truly indieate when water systems may be starting to trend out of control. It is appropriate that, where
possible, these in process control parameters should be established well below mierobial levels that could be problematic for products and processes where used.

It should be emphasized that these in process eontrol guidelines are not intended to be totally inclusive for every sittation where ingredient waters are employed. For example, Gram negative mieroorganisms are not exeluded from ingredient waters, nor is the presence of Gram negative mierorgenisms prohibited in Drinking Water in the Federal Regulations. The reason for this is that these mierorgsanisms are ubiquitous to the aqueus envirenment and their exclusion would likely require a sterilization process that would not be appropriate or feasible in many manufacturing see narios. However, there are sittations where they might not be tol erated in certain products, sueh as some topieal products intended for use on broken skin or in some oral dosage forms. It is, therefore, ineumbent upen the manufacturer to supplement the general in process control guidelines to fit each partieular manufacturing and product use situation.

Though the use of alert and action levels is most often associated with microbial data, they can be associated with any attribute. In pharmaceutical water systems, almost every quality attribute, other than microbial quality, can be very rapidly determined with near-real time results. These short-delay data can give immediate system performance feedback, serving as ongoing process control indicators. However, because some attributes may not continuously be monitored or have a long delay in data availability (like microbial monitoring data), properly established Alert and Action Levels can serve as an early warning or indication of a potentially approaching quality shift occurring between or at the next periodic monitoring. In a validated water system, process controls should yield relatively constant and more than adequate values for these monitored attributes such that their Alert and Action Levels are infrequently broached.

As process control indicators, alert and action levels are designed to allow remedial action to occur that will prevent a system from deviating completely out of control and producing water unfit for its intended use. This "intended use" minimum quality is sometimes referred to as a "specification" or "limit". In the opening paragraphs of this chapter, rationale was presented for no microbial specifications being included within the body of the bulk water (Purified Water and Water for Injection) monographs. This does not
mean that the user should not have microbial specifications for these waters. To the contrary, in most situations such specifications should be established by the user. The microbial specification should reflect the maximum microbial level at which the water is still fit for use without compromising the quality needs of the process or product where the water is used. Because water from a given system may have many uses, the most stringent of these uses should be used to establish this specification.

Where appropriate, a microbial specification could be qualitative as well as quantitative. In other words, the number of total microorganisms may be as important as the number of a specific microorganism or even the absence of a specific microorganism. Microorganisms that are known to be problematic could include opportunistic or overt pathogens, nonpathogenic indicators of potentially undetected pathogens, or microorganisms known to compromise a process or product, such as by being resistant to a preservative or able to proliferate in or degrade a product. These microorganisms comprise an often ill-defined group referred to as "objectionable microorganisms". Because objectionable is a term relative to the water's use, the list of microorganisms in such a group should be tailored to those species with the potential to be present and problematic. Their negative impact is most often demonstrated when they are present in high numbers, but depending on the species, an allowable level may exist, below which they may not be considered objectionable.

As stated above, alert and action levels for a given process control attribute are used to help maintain system control and avoid exceeding the pass/fail specification for that attribute. Alert and action levels may be both quantitative and qualitative. They may involve levels of total microbial counts or recoveries of specific microorganisms. Alert levels are events or levels that, when they occur or are exceeded,
indicate that a process may have drifted from its normal operating condition. Alert level excursions constitute a warning and do not necessarily require a corrective action. However, alert level excursions usually lead to the alerting of personnel involved in water system operation as well as QA. Alert level excursions may also lead to additional monitoring with more intense scrutiny of resulting and neighboring data as well as other process indicators. Action levels are events or higher levels that, when they occur or are exceeded, indicate that a process is probably drifting from its normal operating range. Examples of kinds of action level "events" include exceeding alert levels repeatedly; or in multiple simultaneous locations, a single occurrence of exceeding a higher microbial level; or the individual or repeated recovery of specific objectionable microorganisms. Exceeding an action level should lead to immediate notification of both QA and personnel involved in water system operations so that corrective actions can immediately be taken to bring the process back into its normal operating range. Such remedial actions should also include efforts to understand and eliminate or at least reduce the incidence of a future occurrence. A root cause investigation may be necessary to devise an effective preventative action strategy. Depending on the nature of the action level excursion, it may also be necessary to evaluate its impact on the water uses during that time. Impact evaluations may include delineation of affected batches and additional or more extensive product testing. It may also involve experimental product challenges.
Alert and action levels should be derived from an evaluation of historic monitoring data called a trend analysis. Other guidelines on approaches that may be used, ranging from "inspectional" to statistical evaluation of the historical data have been published. The ultimate goal is to understand the normal variability of the data during what is considered a
typical operational period. Then, trigger points or levels can be established that will signal when future data may be approaching (alert level) or exceeding (action level) the boundaries of that "normal variability". Such alert and action levels are based on the control capability of the system as it was being maintained and controlled during that historic period of typical control.

In new water systems where there is very limited or no historic data from which to derive data trends, it is common to simply establish initial alert and action levels based on a combination of equipment design capabilities but below the process and product specifications where water is used. It is also common, especially for ambient water systems, to microbiologically "mature" over the first year of use. By the end of this period, a relatively steady state microbial population (microorganism types and levels) will have been allowed or promoted to develop as a result of the collective effects of routine system maintenance and operation, including the frequency of unit operation rebeddings, backwashings, regenerations, sanitizations, etc. This microbial population will typically be higher than was seen when the water system was new, so it should be expected that the data trends (and the resulting alert and action levels) will increase over this "maturation" period and eventually level off.

A water system should be designed so that performancebased alert and action levels are well below water specifications. With poorly designed or maintained water systems, the system owner may find that initial new system microbial levels were acceptable for the water uses and specifications, but the mature levels are not. This is a serious situation, which if not correctable with more frequent system maintenance and sanitization, may require expensive water system renovation or even replacement. Therefore, it cannot be
overemphasized that water systems should be designed for ease of microbial control, so that when monitored against alert and action levels, and maintained accordingly, the water continuously meets all applicable specifications.

An action level should not be established at a level equivalent to the specification. This leaves no room for remedial system maintenance that could avoid a specification excursion. Exceeding a specification is a far more serious event than an action level excursion. A specification excursion may trigger an extensive finished product impact investigation, substantial remedial actions within the water system that may include a complete shutdown, and possibly even product rejection.

Another scenario to be avoided is the establishment of an arbitrarily high and usually nonperformance based action level. Such unrealistic action levels deprive users of meaningful indicator values that could trigger remedial system maintenance. Unrealistically high action levels allow systems to grow well out of control before action is taken, when their intent should be to catch a system imbalance before it goes wildly out of control.

Because alert and action levels should be based on actual system performance, and the system performance data are generated by a given test method, it follows that those alert and action levels should be valid only for test results generated by the same test method. It is invalid to apply alert and action level criteria to test results generated by a different test method. The two test methods may not equivalently recover microorganisms from the same water samples. Similarly invalid is the use of trend data to derive alert and action levels for one water system, but applying those alert and action levels to a different water system. Alert and action levels are water system and test method specific.

Nevertheless, there are certain maximum microbial levels above which action levels should never be established. Water systems with these levels should unarguably be considered out of control. Using the microbial enumeration methodologies suggested above, generally considered maximum action levels are 100 cfu per mL for Purified Water and 10 cfu per 100 mL for Water for Injection. However, if a given water system controls microorganisms much more tightly than these levels, appropriate alert and action levels should be established from these tighter control levels so that they can truly indicate when water systems may be starting to trend out of control. These in-process microbial control parameters should be established well below the us-er-defined microbial specifications that delineate the water's fitness for use.

Special consideration is needed for establishing maximum microbial action levels for Drinking Water because the water is often delivered to the facility in a condition over which the user has little control. High microbial levels in Drinking Water may be indicative of a municipal water system upset, broken water main, or inadequate disinfection, and therefore, potential contamination with objectionable microorganisms. Using the suggested microbial enumeration methodology, a reasonable maximum action level for Drinking Water is 500 cfu per mL . Considering the potential concern for objectionable microorganisms raised by such high microbial levels in the feedwater, informing the municipality of the problem so they may begin corrective actions should be an immediate first step. In-house remedial actions may or may not also be needed, but could include performing additional coliform testing on the incoming water and pretreating the water with either additional chlorination or UV light irradiation or filtration or a combination of approaches. $\quad$ 2S (USP28)

## BRIEFING

$\langle 1232\rangle$ Instrumentation for Analysis of High Purity Pharmaceutical Waters, page 303 of PF 30(1) [Jan.-Feb. 2004]. It is proposed to (1) delete a sentence from the Technology Summary in the section on Total Organic Carbon (TOC) because it was reported to be inaccurate and (2) correct the formulas in the section on Conductivity. In addition, minor editorial style changes have been made.

## ■ $<1232\rangle$ INSTRUMENTATION FOR ANALYSIS OF HIGH PURITY PHARMACEUTICAL WATERS

## INTRODUCTION

In the production of Purified Water and Water for Injection (WFI) the term "quality of water" is not rigorously defined, but it is generally accepted to mean "the concentration and type of impurities" found in the water. Advances in the science of water treatment have resulted in technologies that produce more water at lower cost and of higher quality. Consequently, the amount of impurities found in Purified Water and Water for Injection has decreased. The analytical methods have also improved to keep up with the improving water quality.

It would be impractical to describe all of the possible impurities because of the number of organic, inorganic, and ionic species that could enter a water system from the outside environment. The number of known chemicals is in the hundreds of thousands, and, theoretically, many could be found at a very low concentration in a water system. The nature of water treatment systems is such that very few unit operations are designed to selectively remove specific contaminants. There are notable exceptions such as water soft-
eners that are effective at displacing calcium and magnesium with sodium to protect systems from scale. It becomes expensive and very impractical to identify all impurity species in a pharmaceutical water system. The analytical instrumentation required to measure alkaline metal and heavy metal impurities (by atomic absorption or ion chromatography) is expensive, and the technology is not commercially available for measurement of specific organics in the $\mu \mathrm{g} / \mathrm{L}$ (ppb) range.

The more practical approach is to categorize impurities according to various attributes such as chemical properties, physical properties, organic/inorganic, oxidizability, toxicity, etc. One practical method of categorizing the impurity species is a determination of the degree of ionic behavior of the chemical moiety. For example, $\mathrm{H}^{+}, \mathrm{OH}^{-}, \mathrm{Na}^{+}, \mathrm{Ca}^{2+}$, $\mathrm{Mg}^{2+}, \mathrm{HCO}_{3}^{-}, \mathrm{Cl}^{-}, \mathrm{HSO}_{4}^{-}$, and other ionic species are commonly found in pharmaceutical water systems. All of these ions have a physical property in common: namely, that they are charged species and, therefore, detectable by conductivity. The majority of species that would be nonionic are organic. These consist of low molecular weight alcohols, ketones, and organic acids that, because of their size or polarity, are not completely removed by water systems. A valuable method for detecting these organic species is the use of a test for total organic carbon (TOC).

Both conductivity and TOC have the advantage of quantifying these types of impurities in the aggregate with great sensitivity. The advantage is also a disadvantage as neither measurement can distinguish or measure individual impurities, only the aggregate.

Not all types of impurities fall into the ionic/nonionic (conductive or TOC) category. Another class of impurities can be described as inorganic and nonionic (and therefore nonconductive). They include some dissolved metals, metal oxides, other metal forms, and semimetals such as those that
are silica-based. These species may be very weakly ionized and, therefore, would not be detectable by any conventional conductivity or TOC method. Particles also represent another class of impurity. These could be carbonaceous or silicabased, but they are not normally detectable by conductivity or TOC because they are typically nonionic and exist at concentrations undetectable by TOC analysis. However, the presence of substantive concentrations of these types of impurities is unlikely if the water treatment system is effective.
The final significant category of impurities consists of microorganisms. Although microorganisms are carbonaceous material, the detectability by conductivity or TOC is not practical because their molecular concentrations are too low to be detected by these methods. Microorganisms deserve special note because they can grow and interfere with drug chemistry and cause harm to the patient if they are not controlled (see Water for Pharmaceutical Purposes <1231〉).
Until USP 23, Supplement 5, the primary methods for ensuring the quality of bulk Purified Water and Water for Injection were a series of wet chemistry tests sitive to detect the presence of ammonia, calcium, chloride, carbon dioxide, sulfate, and oxidizable substances. The tests for these six species were subjective, unreliable, and not predictive of the true quality of water. The quality of water is better described by its conductivity and TOC and the primary methods for verifying water quality have shifted to these measurements.

Neither conductivity nor TOC are specific to any of the ions or species listed above. TOC is considered a one-forone replacement for the Oxidizable Substances (potassium permanganate) test, while conductivity is a sensitive test for all ionic (i.e., conductive) species. Both methods have
the advantages of being quantitative, numerical, robust, available for use on-line or off-line, and useful for quality control.

## TOTAL ORGANIC CARBON (TOC)

Organic chemistry is the study of carbon-containing compounds. The fully oxidized form of carbon, carbon dioxide $\left(\mathrm{CO}_{2}\right)$, is inorganic. $\mathrm{CO}_{2}$ is mildly reactive with water, and it is usually detected by its concomitant compounds and ions: carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$, bicarbonate $\left(\mathrm{HCO}_{3}{ }^{-}\right)$, and carbonate $\left(\mathrm{CO}_{3}{ }^{2-}\right)$. These three species are the result of the dissolution of $\mathrm{CO}_{2}$ in water and subsequent acid dissociation; they are not included in the TOC definition. Our concern is the remaining carbonaceous species that are not completely oxidized. These are the organic compounds that provide a fuel source for microorganisms, sustain biofilm, and may adversely impact drug chemistry.

Organic carbon enters the water system from several locations. The usual source of TOC is from the municipal water supply or from private wells. In January, 2002, the Environmental Protection Agency began regulating TOC levels in municipalities serving a population of 10,000 or more. Source water TOC can vary anywhere from 1 to 10 mg of carbon per L. The primary source of this TOC is the decomposition of plants and animals and subsequent runoff or leaching into the municipal feed water sources. The composition of these TOC products range from low molecular weight species such as urea to high molecular weight humic acids that give water an "iced tea" coloring. Other organic compounds found in water can be the direct result of industrial pollutants, pesticides, herbicides, and other man-made contaminants.

Other sources of TOC are the accidental introduction of TOC into the pharmaceutical water system and the degradation of water system components. The former is the result of
error, such as opening a wrong valve. The latter could be the breakdown of a plastic component in the water system or the presence of holes in the reverse osmosis (RO) membrane system. Regardless of the source, any of these TOC contaminants can be detrimental to the control of the water system.
Treatment methods to reduce TOC are discussed in Water for Pharmaceutical Purposes $\langle 1231\rangle$. In brief, various methods such as RO and filtration can reduce TOC concentration. Also, oxidizing agents such as chlorine and ozone can break up organic molecules. They are not, however, very selective and will attack nearly all organic molecules. The cleavage of large molecules creates smaller organic molecules that are easily digested and assimilated by microorganisms. Dead bacteria can also produce decomposition products called endotoxins that may produce a fever when injected into the body. The quantity of total organic carbon in pharmaceutical waters is of primary concern because it can enhance microorganism growth.

Volatile organic compounds are not a major contaminant in pharmaceutical water systems. Most contaminants are nonvolatile and are naturally occurring or anthropogenic organics. TOC measurements provide a single nonspecific measurement, detecting a broad spectrum of compounds without performing tests for individual contaminants.

## Laboratory TOC Technologies

TOC analysis was developed initially for the measurement of relatively high levels of TOC in water and waste water. Technological advances, however, have produced instruments that measure low levels of TOC in water down to sub-ppb levels, thus allowing for its application in the pharmaceutical industry. The principal TOC technologies are based on the oxidation of organic carbon to $\mathrm{CO}_{2}$ and subsequent detection of the $\mathrm{CO}_{2}$ by either conductometric or photometric means.

Some water samples contain dissolved $\mathrm{CO}_{2}$ (and $\mathrm{HCO}_{3}{ }^{-}$ and $\mathrm{CO}_{3}{ }^{2-}$ ) at the outset of the analysis, so the inorganic carbon (IC) must be removed or measured as part of the analysis. For any oxidation technology, depending on the TOC and IC levels, removal of the dissolved $\mathrm{CO}_{2}$ is always an option. In order to achieve accurate measurement of TOC in some samples, it is necessary to minimize the contribution of IC to the total signal. If it is determined that IC background is detrimental to the sample measurement, then the IC can be purged from the water sample by vacuum, nitrogen sparging, or acid addition, depending on the technology. This should not be necessary unless the TOC is very low and the IC very high. In pharmaceutical bulk water supplies, IC concentrations are typically low, and removal is not required for accurate TOC results. The basic oxidation and detection techniques used in TOC equipment are described below; however, other combinations of technologies that are not described may also be in use.

Combustion Oxidation/Nondispersive Infrared Detection (NDIR)—This technology combination is most often configured for laboratory use. Combustion oxidation uses oxygen and high temperatures ( $>600^{\circ}$ ) and a catalyst such as platinum ( Pt ) to facilitate the oxidation and convert the organic compounds to $\mathrm{CO}_{2}$. This technique has demonstrated high oxidation efficiency for both dissolved and particulate organics. The catalyst, however, can become poisoned and cause low recovery. NDIR is selective for $\mathrm{CO}_{3}$ in the preser. After oxidation of the sample, the $\mathrm{CO}_{2}$ is delivered to the detection chamber by a carrier gas. The concentration of $\mathrm{CO}_{2}$ is directly proportional to the absorption response according to Beer's Law. As with any absorption spectrophotometric method, NDIR is most sensitive at higher concentrations. Compared to oth-
er detectors, NDIR detectors can exhibit extended warm-up times at start-up. NDIR detectors typically require a comparatively higher calibration frequency.
Heated Persulfate Oxidation/NDIR Detection-Heated persulfate oxidation instruments generate hydroxyl radicals $(\cdot \mathrm{OH})$ by heating the persulfate to $>95^{\circ}$. The hydroxyl radicals act as powerful oxidizing agents. The cation form of the persulfate and its concentration vary, with concentrations ranging from $2 \%$ to $15 \%$. Heated persulfate is typically combined with the previously described NDIR detection method to measure $\mathrm{CO}_{2}$. This technology combination is typically applied in laboratory instrument configurations. Heated persulfate is a very efficient oxidation method. Its main disadvantages are the volume of reagent required.

UV Oxidation/NDIR Detection—UV oxidation uses UV light to generate hydroxyl radicals from the photolysis of water. In some instruments persulfate, which is activated by UV to increase the oxidative capacity, is added. This technology combination is most commonly found in laboratory configurations. The natural spectral output of a low pressure Hg lamp generates light of wavelength 253.7 and 184.9 nm . The shorter wavelength generates the oxidizing radicals, while both wavelengths are efficient at cleaving bonds in large and small organic molecules. This combination provides an efficient oxidation and measurement system. UV oxidation methods are particularly well suited for lower TOC concentrations found in pharmaceutical waters. The main advantage is the oxidation efficiency at lower TOC concentrations. The disadvantages are that the UV Hg lamps must be periodically replaced and that, as previously described, the NDIR detector systems are complex.

## UV/Persulfate Oxidation/Membrane Conductometric

Detection-In this technology, $\mathrm{CO}_{2}$ is generated by UV radiation (as described above), and the dissolved $\mathrm{CO}_{2}$ passes through a gas-permeable membrane to an on-board source
of low conductivity water. The resulting increase in conductivity in this water is directly proportional to the $\mathrm{CO}_{2}$ produced from the UV oxidation. Persulfate is typically added to enhance oxidation at TOC concentrations greater than 1 ppm. This technology combination makes use of the high sensitivity that conductivity measurements have at low concentrations of $\mathrm{CO}_{2}$, and the membrane separation helps to eliminate the typical chemical interferences that can disrupt conductivity measurements.

## Sampling Techniques for Laboratory Analysis-Be-

 cause compendial pharmaceutical waters have very low TOC (the USP limit is about $500 \mu \mathrm{~g}$ of carbon/L, but $<50 \mu \mathrm{~g}$ of carbon/L, and lower, is more likely), pharmaceutical waters require the following special handling to have valid TOC measurements.1. The water should be delivered from a hose or delivery receptacle in the same manner in which it is used in production.
2. The storage container may be any type that does not shed or leach TOC, and it must be scrupulously clean. Many plastic or polymeric containers are either unacceptable because of extractable TOC or they are too difficult to clean. Limited types of materials such as PTFE, PFA, and PVDF have found acceptance because of their low leach rates. Glass is an excellent material due to its negligible TOC leach rate and its cleanability. Cleaning of the glass according to Cleaning Glass Apparatus $\langle 1051\rangle$ is advised.
3. The container should be completely filled with the sample to keep the trapped air to a minimum. The container should be closed immediately to prevent atmospheric contamination.
4. The time between sampling and analysis should be kept to a minimum. If the samples are analyzed by an offsite laboratory, they should be refrigerated to minimize microbial growth.
5. The setting of the flow control valve should not be changed, and the sample bottle should not touch the port while taking the sample.
6. For compendial purposes, the water should be tested at a point that is equivalent to the quality of water used in production. This may require testing at several points, or at a location after the last-use point before the return to the tank in a recirculating system.

## On-Line TOC Technologies

The most common on-line TOC methods used in pharmaceutical applications employ UV oxidation and conductivity detection. These technologies are designed for exclusive use with low conductivity water supplies and with the device connected directly to the sample to eliminate exposure to the atmosphere. The low sample conductivity ensures an IC concentration so low that its removal is not necessary. No reagents are required because at TOC concentrations of 500 ppb or less, UV oxidation alone is usually sufficient for complete recovery.

UV oxidation can be applied on a fixed volume of sample or by irradiating a continuous stream to the UV source. Conductivity measurements are made during or immediately following the oxidation step. In one configuration, a gaspermeable membrane is used after the UV oxidation to separate $\mathrm{CO}_{2}$ from other potentially conductive oxidation by-products.

The main advantages of on-line technologies are the benefit of continuous unattended measurement of TOC, the availability of continuous trending of the water system, the
ability to respond to a disturbance immediately, and the elimination of sample collection, handling, and transportation errors.

## Sampling Techniques for On-Line TOC Analysis-

On-line TOC analysis has the advantage of being able to provide data continuously and without the difficulties in sample handling that accompany off-line TOC measurements. Typically, clean tubing is attached to the water system and water flow is directed to the inlet of the TOC instrument. Appropriate care should be taken to eliminate dead-legs and subsequent backflow of the sample line when the instrument is not in use.

## Technology Summary

Some of the oxidation and detection techniques work in tandem and are ideally suited for Purified Water and Water for Injection. These methods have the necessary resolution and sensitivity to perform the basic TOC measurement functions. The main differences between the technologies are the capital costs, consumables (UV lamps, gases, reagents), and maintenance and labor (preparing reagents, replacing catalysts, installing gas generators), and suitability for laboratory or on-line analysis.

Detection limits will vary by technology, and the analysis method must be able to meet the System Suitability requirements and detect the levels of TOC prescribed in Total Organic Carbon $\langle 643\rangle$. IR-based detection methods involve a well-established technique that requires a large sample size, a purge gas, long warm-up times, and frequent calibration. These detection methods are well suited to high TOC concentrations and are not susceptible to interferences that may be found in water. UV/eonductivity metheds are best suited
for on line process use in pharmaceutieal waters, where the sensitivity of conductivity measurements is ideally suited to meastring the conduetivity of $\mathrm{CO}_{2}$-containing solutions; the enductivity based techniques are capable of a much lower timitan The analysis time for each technology can vary from 0.5 to 30 minutes. Calibration requirements will also differ, varying from daily or weekly to annually. Calibration may be done by the user in-place or may require special attention by factory or trained personnel. Gases, chemicals, lamps, and other supplies will impact operating costs.

## CONDUCTIVITY

A conductivity measurement system is similar in concept to a TOC measurement system. A TOC analyzer cannot quantify individual organic species, only the aggregate carbon in the form of $\mathrm{CO}_{2}$. Likewise, a conductivity measurement does not distinguish between ions. It measures the total conductivity of charged ionic species.

A conductivity measurement is performed by measuring the AC resistance (conductance $=1 /$ resistance) between two electrodes of a known geometrical construction. The resistance of the fluid between the two electrodes will increase with electrode distance, $d$, and decrease with electrode area, $A$. To correct for this geometrical factor, the cell constant, $\phi$, of the sensor is equivalent to the distance between the electrodes divided by the area of the electrodes.

$$
\begin{equation*}
\varphi\left(\mathrm{cm}^{-1}\right)=\frac{d}{A} \tag{1}
\end{equation*}
$$

The cell constant normalizes the resistance, in $\Omega$, (or conductance, in $S$, to eliminate the impact of the sensor geometry, thereby resulting in the familiar water quality measurement of resistivity, $\rho$ (or conductivity, $\kappa$ ). The equations that relate these measurements are the following:

$$
\begin{align*}
& \frac{\text { resistance( } \Omega \text { ( } \Omega-\mathrm{cm})}{\varphi\left(\mathrm{cm}^{+1}\right)} \\
& \rho(\Omega-\mathrm{cm})=\frac{\operatorname{resistance}(\Omega)}{\varphi\left(\mathrm{cm}^{-1}\right)}  \tag{2}\\
& \kappa(\mathrm{S} / \mathrm{cm})=\text { conductance }(\mathrm{S}) \times \varphi\left(\mathrm{cm}^{-1}\right) \\
& \xrightarrow[\varphi(\mathrm{S} / \mathrm{cm})=-\frac{1}{\varphi(\Omega-\mathrm{cm})} \quad(4)]{ } \\
& \kappa(S / \mathrm{cm})=\frac{1}{\rho(\Omega-\mathrm{cm})} \tag{4}
\end{align*}
$$

A temperature device, such as a resistance temperature device (RTD) or thermistor, will be embedded in most conductivity sensors. The meter will measure the resistance of that device and convert it to a temperature according to its known temperature-resistance relationship.

The fundamental operation of conductivity measurement systems consists of measurement of the resistance between the electrodes, correction for the cell constant to get a conductivity or resistivity measurement, and then compensation for the raw measurement for temperature using an algorithm
in the meter. In order to meet the requirements of Water Conductivity $\langle 645\rangle$, the temperature compensation feature is disabled, and the uncompensated measurement is used to determine water quality acceptance.

## Impact of Water Chemistry on Conductivity

Electrical conductivity of water is a measure of the ionfacilitated flow of current between two electrodes through the water. The fundamental equation to describe the conductivity is the following:

$$
\begin{equation*}
\kappa=10^{-3} \sum_{i}^{\substack{\text { all } \\ \text { ions }}} \Lambda_{i}^{\circ} C_{i} \tag{5}
\end{equation*}
$$

in which $\kappa$ is the conductivity (Siemens $/ \mathrm{cm}$ ), $\Lambda_{i}$ is the limiting molar conductivity of ion $i$ (Siemens $-\mathrm{cm}^{2} / \mathrm{mol}$ ), and $C_{i}$ is the concentration of ion $i(\mathrm{~mol} / \mathrm{L})$. The equation is summed over all ions present in the water. If the concentrations are expressed in molality ( $\mathrm{mol} / \mathrm{kg}$ of water), then the equation is adjusted for the water density.

Water molecules dissociate into $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$according to the following equation:

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{O} \rightleftharpoons\left[\mathrm{H}^{+}\right]+\left[\mathrm{OH}^{-}\right] \tag{6}
\end{equation*}
$$

and the extent of the reaction is determined by the dissociation constant, $K_{w}$.

$$
\begin{gather*}
K_{w}=\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.00 \times 10^{-14} \text { at } 25^{\circ} \\
p K_{w}=-\log \left(K_{w}\right)=14 \text { at } 25^{\circ} \tag{8}
\end{gather*}
$$

In the absence of any other chemical species, electroneutrality and Equation 7 require that

$$
\begin{equation*}
\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]=1 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \tag{9}
\end{equation*}
$$

The limiting molar conductivities at $25^{\circ}$ of $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ are 349.8 and $198.6 \mathrm{~S}_{\mathrm{S}} \mathrm{cm}^{2} / \mathrm{mol}$, respectively. The resulting conductivity of pure water is $5.48 \times 10^{-8} \mathrm{~S} / \mathrm{cm}(0.0548 \mu \mathrm{~S} /$ cm ). The resistivity is the multiplicative inverse (Equation 4) of the conductivity, or 18.2 Megohm- $\mathrm{cm}(\mathrm{M} \Omega-\mathrm{cm})$.

At temperatures other than $25^{\circ}$ (the commonly used reference temperature), two phenomena directly impact the conductivity of pure water. First, the dissociation constant of water varies significantly over the range of $0^{\circ}$ to $100^{\circ}$. The value of $K_{w}$ changes by a factor of 400 , as the $p K_{w}$ is 14.9 at $0^{\circ}$ and 12.2 at $100^{\circ}$. The resulting change in $K_{w}$ causes a true increase in the ion concentrations as the temperature increases. The second effect is the temperature dependence of the ion mobility. [NOTE-The ion mobility, a measure of the ability of ions to conduct, is directly related to each ion's limiting molar conductivity.] The mobility of both ions increases by a factor of $\sim 3$ over the range of $0^{\circ}$ to $100^{\circ}$. The combination of these two effects causes the conductivity of pure water to increase from $0.0116 \mu \mathrm{~S} / \mathrm{cm}$ at $0^{\circ}$ to $0.777 \mu \mathrm{~S} / \mathrm{cm}$ at $100^{\circ}(86.1 \mathrm{M} \Omega-\mathrm{cm}$ to $1.29 \mathrm{M} \Omega-\mathrm{cm})$.

Although it is not unusual for some compendial water systems to produce pure water, most water treatment systems that produce Purified Water and Water for Injection have small amounts of impurities that pass through the water system. The impurities are usually simple alkali metal ions, possibly some lighter transition metal ions, and common counter ions such as $\mathrm{Cl}^{-}, \mathrm{SO}_{4}{ }^{2-}$, and $\mathrm{HCO}_{3}^{--}$. In addition, some gases, most notably $\mathrm{CO}_{2}$, readily dissolve in water and react to form $\mathrm{H}^{+}$and $\mathrm{HCO}_{3}^{-}$, predictably affecting conductivity and pH . Regardless of the ionic impurity, each has its
own characteristic limiting molar conductivity. Thus the measured conductivity of the water in a pharmaceutical system is determined from Equation 5, after consideration of all ions present at their respective concentrations.

## Temperature Compensation

Temperature compensation is the adjustment of a chemical or physical measurement at any temperature to its value at a reference temperature, $25^{\circ}$ in this case. The purpose of the compensation is to provide a universal reference point so that measurements taken at different temperatures can be properly compared. For example, if the conductivity of the water system is $0.11 \mu \mathrm{~S} / \mathrm{cm}$ at $37^{\circ}$, but later in the day it is $0.13 \mu \mathrm{~S} / \mathrm{cm}$ at $40^{\circ}$, the increase can be the result of the natural increase in ion mobility due to temperature, or it could be the result of more impurities in the water. The benefit of temperature compensation is that it can distinguish natural changes from water quality changes.

Prior to the application of microprocessors, temperature compensation was performed either by "correcting the signal" with the addition of analog circuitry or by numerically adjusting postmeasurement. Temperature compensation is currently performed automatically by the chemically-based numerical algorithms in the instrumentation.
Temperature compensation for conductivity measurements of pure water is difficult to perform accurately. For almost all types of fluids except pure water, the dependence of the conductivity on temperature is, on the average, about $1.9 \%$ to $2.2 \%$ per degree over the entire $0^{\circ}$ to $100^{\circ}$ range. This linear compensation factor applies for most process fluids and drinking waters, because the conductivity is dominated by the ions that are not related to water dissociation. However, because of the low impurity levels found in Purified Water or Water for Injection systems, the chemical composition of the ions in water is primarily due to $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$,
with smaller (or similar) amounts of other ions. The temperature dependence of the conductivity, therefore, becomes less predictable because of the temperature dependence of the water chemistry. For example, at $0^{\circ}$ the conductivity of pure water changes at a rate of $>7 \%$ per degree, while at $100^{\circ}$ the temperature dependence is $<2.5 \%$ per degree. As the impurity levels increase, the temperature dependence moderates until it reaches $\sim 2 \%$ per degree. The appropriate correction for temperature compensation varies and must be accounted for correctly, depending on the temperature and the impurity level. On-line process instrumentation performs this correction automatically, but the algorithms remain trade secrets.

As the chapter Water Conductivity $\langle 645\rangle$ was being developed in the early 1990s, it was established that the measurements would be made in a nontemperature-compensated mode to eliminate the variability that is found from one instrument manufacturer to another. This resulted in the table, Stage 1-Temperature and Conductivity Requirements in the chapter Water Conductivity $\langle 645\rangle$ that set conductivity limits that are temperature dependent. The table takes into account the natural increase in conductivity as a function of temperature, while ensuring that certain impurity levels are not exceeded.

## Conductivity Technologies

Conductivity Sensors-A conductivity sensor used in pharmaceutical water measurements typically consists of two concentric electrodes, separated by an inert electrical insulator, with a cell constant that is usually anywhere from 0.01 to $0.1 \mathrm{~cm}^{-1}$. For on-line measurements, the sensor should be inserted into the tee of a piping system. Sidestream measurements are possible, but direct immersion into the piping are less costly (i.e., no water loss with no risk
to the water system). The electrode material should be compatible with the water system to prevent galvanic action between the water piping and the sensor. The insulator should be resistant to the water and to the processing conditions that may be present. The sensor design and geometry should be invariant to the high temperatures (up to steam sterilizable conditions at $131^{\circ}$ and 40 psia or higher), sanitization chemicals, UV, pressure, and flow rates that the sensor might be exposed to. Any Handling of the conductivity sensor is critical as any change in the geometric construction of the sensor will cause a change in the apparent measurement of the conductivity.

Stainless steel electrodes should be passivated, at a minimum, to reduce the possibility of corrosion or rouging. Passivation materials such as nitric acid, phosphoric acid, and citric acid are commonly used. Surface finishes having exposed surfaces with Roughness Average $\left(R_{a}\right)<10 \mu$ in (better than standard machine finishes) are readily attainable. The process connection to the water system can be any suit able connection type; however, a sanitary tri-clamp flange and gasket to provide a clean, tight seal between the sensor flange and water system are recommended. Welding of the electrodes to the flange should be clean and of pharmaceutical grade. Threaded process connections should be avoided to eliminate deadlegs; however, this parameter has no impact on the conductivity measurement.
The electrode material and insulator for off-line measurements are not critical, provided they give accurate measurements. Environmental factors are not present. To make accurate measurements, platinum electrodes should be avoided because a process called platinization is required periodically to recondition the surface of the electrode. However, this process is not robust, and it is difficult to determine when platinization is necessary, except by alternative verification measurements. An adverse impact to
measurement accuracy is also greatest at low conductivity. Common electrode materials include stainless steel, titanium, hastelloy, and graphite to a lesser extent. Titanium is widely used in the microelectronics industry because of its naturally passive surface and resistance to pure water. All of these electrode materials require low maintenance, if properly sanitized and cleaned. Repassivation of stainless steel electrodes may be needed if the material rouges or becomes scratched.

The concentric electrode design is not required, but it does result in mechanically rugged sensor construction that can withstand the pressures and flow changes in a water system. Also, the grounded shield design protects the sensor from any nearby surfaces that will impact the electric field and cause altered measurement in unshielded electrodes. Other subtle factors impacting sensor design and system accuracy are the electrode's macroscopic and microscopic properties. Large cell areas are preferable because this reduces the metal-water impedance that is formed at the electrode surface. Smaller cell areas can cause an undesirable increase in the measured cell resistance.

The two principal types of temperature devices are negative temperature coefficient (NTC) thermistors and 100 or 1000 platinum resistance temperature devices (RTDs). Both device types operate on the principle that their resistance changes in known and precise ways as a function of temperature. Both types are low in cost and have desirable electrical response characteristics. NTC thermistors have a very high, nonlinear sensitivity over a narrow temperature range, and their sensitivity drops markedly as the temperature increases. Platinum RTDs have a more linear response over a very wide dynamic range, and they are mechanically more robust than NTC thermistors. Repeatability of the resis-tance-temperature response for RTDs tends to be better than NTC thermistors.

Conductivity Instrumentation-The primary function of the conductivity meter is to make the AC resistance and the temperature measurements and to display the conductivity. The frequency of the AC measurement is critical to the accuracy of the measurement. At lower conductivity, lower measurement frequencies ( $<200 \mathrm{~Hz}$ ) are utilized to provide enough time to charge up the sensor to make an accurate measurement. At higher conductivity (nonpharmaceutical water), the AC measurement is made at a much higher frequency (up to $10,000 \mathrm{~Hz}$ ). High frequencies are required to reduce polarization (collection of ions) at the electrodes. If the AC frequency is too low and the ion concentration is too high, ions will collect at each electrode and disrupt the flow of current and subsequently disrupt the measurement. Cable capacitance and fluid capacitance also greatly impact the measurement accuracy, especially at the lowest conductivity; therefore, unique analog measurement systems are applied to make accurate measurements.
Most conductivity meters have multiple circuits to operate at multiple frequencies over a wide dynamic range. This operating frequency and range of the meter are executed internally and automatically by the meter. Older instruments and some hand-held meters may require manual adjustment of the operating range.
A meter may be placed as far as 100 meters away from the sensor, so the capability of transferring analog or digital signals over these distances necessitates the use of appropriate cable shielding. Also, the use of 3 - and 4 -wire measurements is commonly applied to reduce the negative impact of leadwire resistance, especially for long cables.
Although temperature compensation is not intended in Water Conductivity $\langle 645\rangle$, temperature compensation is used by a pharmaceutical facility to monitor and control the water system, in which case accurate temperature measurement is critical. At $20^{\circ}$, a $1^{\circ}$ measurement error will re-
sult in a $5 \%$ error in the calculated compensated conductivity. At $80^{\circ}$, the same error will result in a $10 \%$ error in the calculated compensated conductivity. Accurate temperature calibration is necessary to ensure accurate measurements.

Other features found in on-line conductivity analyzers are multiple channel inputs, setpoint alarms, relay control, 0/420 mA output, digital output, and multiple types of measurements (conductivity, resistivity), multiple compensation options, and several units of expression. The common set of units is $\mathrm{S} / \mathrm{cm}$ or $\mu \mathrm{S} / \mathrm{cm}$, but there is a small growing trend toward displaying measurements in $\mathrm{S} / \mathrm{m}$, which is an SI unit. Another requirement in Water Conductivity $\langle 645\rangle$ is a display resolution of $0.1 \mu \mathrm{~S} / \mathrm{cm}$, though more resolution is typical.

## Conductivity System Calibration

When a complete conductivity system calibration is required, it should be performed in the following sequence. Calibrate the meter first, then the sensor afterwards. The sensor may be calibrated on the same meter or on a different, calibrated meter.

Conductivity Meter Calibration-The purpose of this calibration is to verify and adjust, if necessary, the temperature measurement circuit and AC conductivity measurement circuit of the meter. There is no requirement for accuracy of the temperature circuit in general chapter Water Conductivity $\langle 645\rangle$, but an accuracy of $\pm 0.25^{\circ}$ is typical. Calibration is performed by removing the sensor from the meter and replacing the sensor with a precision resistor of known value. The resistor is a simulator of a specific tem-
perature. Comparison of the simulated and measured temperature will result in an adjustment of the temperature measurement circuit. There should be a provision within the meter to adjust the circuit calibration for temperature.

The same procedure is done for the AC conductivity measurement circuit. Replace the sensor with another precision resistor. Compare the simulated and measured conductivity and adjust, if necessary. Because of the multiple AC measurement circuits in these meters, calibrate either all of the circuits or the circuit that is in use during normal operation. Specific details for selecting the resistor values and calibrating the meter are supplied by instrument manufacturers. The accuracy required in Water Conductivity $\langle 645\rangle$ is $\pm 0.1 \mu \mathrm{~S} /$ cm . There should be a provision within the meter to adjust the circuit calibration for conductivity.

Conductivity Sensor Calibration-Calibration of the sensor is performed by accurately measuring the cell constant. Standard manufacturing practices can generate sensors with repeatable nominal cell constants, but typical tolerances can lead to variations up to $\pm 10 \%$. Calibration of the sensor in solutions of known, traceable conductivity is the only acceptable method.

The sources of primary standard solutions for cell constant calibration include the following:

- The preparation of ASTM solutions according to D1125 or D5391
- NIST standard solutions
- Pure water with no impurities

Most commercial sensors are not calibrated in primary standard solutions, but they are calibrated in a solution whose conductivity is known by a secondary transfer con-
ductivity standard. The secondary standard is determined by calibration in the primary standard solutions, usually in an ASTM standard solution(s), and this secondary sensor is used to calibrate commercial sensors.

This presents a dilemma for the pharmaceutical user because the primary standard solutions are all $>100 \mu \mathrm{~S} / \mathrm{cm}$, while the user is operating at $<5 \mu \mathrm{~S} / \mathrm{cm}$, and commonly at $<0.2 \mu \mathrm{~S} / \mathrm{cm}$. This problem is solved in one of two ways. First, if the conductivity measurement system (sensor and meter) has sufficient dynamic range and it is demonstrably accurate over the applicable range-from the calibration solution to the normal operating condition-then the sensor can be calibrated in the higher conductivity solution and then used in the low conductivity pharmaceutical water. Another method is calibration of the sensor in a recirculating pure water system generated by a mixed-bed de-ionization loop. The conductivity of pure water as a function of temperature is well documented. With an accurate temperature measurement, the conductivity is accurately known and can be used as a primary reference in the normal operating range of the sensor and meter. This technique results in a sensor that is calibrated very accurately, but it is impractical for most end-users, themselves, to execute.

Calibration of sensors in standard solutions that are $<10$ $\mu \mathrm{S} / \mathrm{cm}$ is possible but has several nuances. Solutions in this conductivity range may be unstable, because of the intrusion of $\mathrm{CO}_{2}$ (from the air) into the solutions. Once the containers are opened, the $\mathrm{CO}_{2}$ reacts immediately with water to form carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$ that weakly dissociates into $\mathrm{H}^{+}$and $\mathrm{HCO}_{3}{ }^{-}$, and these can impact the conductivity by up to $1 \mu \mathrm{~S} /$ cm unless preventive measures are taken. Another difficulty
is the increased level of cleanliness that is needed to perform the calibration. If there is any residue on the sensor before immersion into the standard solution, the cleanliness and accuracy of the solution is compromised. The advantage of the high conductivity primary standard is that it can better tolerate trace impurities. The advantage of the pure water standard is that it never has impurities. In Water Conductivity $\langle 645\rangle$, calibration accuracy of the cell constant is required to be $\pm 2 \%$, and this is readily achieved.

Frequency of Calibration-Water Conductivity $\langle 645\rangle$ makes no recommendation on the frequency of calibrating conductivity meters or sensors. The frequency should be based on historical data, system performance, and the manufacturer's recommendations. For conductivity meters, a 6month calibration cycle, or longer, is typical. For sensors, the materials, type of construction, and operating conditions can influence the calibration cycle. A sensor calibration certificate with a 6 -month to 1 -year expiration is typical. Ultimately, it is the amount of risk the user is willing to take that is the deciding factor. Documentation of all calibrations is vital for regulatory purposes.
During normal operation, calibration of robust conductivity sensors should not be required more than every 6 months to 1 year. Only mechanical or chemical disturbances of the sensor should impact the cell constant. For example, 0.1 $\mathrm{cm}^{-1}$ sensors tend to be more robust than $0.01 \mathrm{~cm}^{-1}$ sensors because the higher cell constant sensors have greater spacing (d) between the electrodes than the lower cell constant sensors. As a result, minor mechanical disturbances have a greater impact on the lower cell constant sensors.

## Off-Line Conductivity Measurements

Care should be taken when conductivity measurements of Purified Water or Water for Injection are taken off-line, e.g., in a laboratory. If the water conductivity (measured on-line) is $<1 \mu \mathrm{~S} / \mathrm{cm}$, then virtually any measurement of that same water made in the laboratory will result in a higher conductivity. The immediate reaction of $\mathrm{CO}_{2}$ with the water will cause the formation of $\mathrm{H}_{2} \mathrm{CO}_{3}$ as described above, and cause the conductivity to rapidly and immediately increase. As a result, it is very difficult to correlate on-line measurements to laboratory measurements.

For example, a water system with filtration, reverse osmosis, and mixed-bed de-ionization may be consistently producing Purified Water with a nominal quality of $0.055 \mu \mathrm{~S} /$ $\mathrm{cm}(18 \mathrm{M} \Omega-\mathrm{cm})$ water. When the water conductivity is measured in-line, the measurement may vary from 0.054 to $0.057 \mu \mathrm{~S} / \mathrm{cm}$. However, when the same water is transported into the laboratory, the conductivity may vary from 0.8 to $1.5 \mu \mathrm{~S} / \mathrm{cm}$. The conductivity increase will be due solely to the $\mathrm{CO}_{2}$. The increase in the variability in this off-line measurement will also be significant (almost $100 \%$ ), while the on-line measurement varies about $5 \%$. The increased fluctuation is due to the variations in concentration of $\mathrm{CO}_{2}$ in the ambient area at the time. Pristine air will have a concentration of about $375 \mathrm{ppm} \mathrm{CO}_{2}$, but normal industrial conditions would have the $\mathrm{CO}_{2}$ concentration vary from 500 to 1200 ppm . The variability in the $\mathrm{CO}_{2}$ concentration is completely beyond the control of the analyst, but it grossly impacts the measurement and completely obscures any possible correlation of off-line with on-line measurements. $\boldsymbol{m}^{2 S}$ (USP28)

## DIETARY SUPPLEMENTS

## General Chapters-General Information

## Briefing

<2023〉Microbiological Attributes of Nonsterile Nutritional and Dietary Supplements, page 3155 of the First Supplement. It is proposed to clarify the discussion of the Test for Aflatoxins in the section Absence of Objectionable Microorganisms. It is also proposed to change the entry for Teas in Tables 1 and 2 to Botanicals to be treated with boiling water before use.
(AMB: D. Porter) RTS-41615-1

## Change to read:

## SUPPLEMENT COMPONENTS

Raw materials, excipients, and active substances as components of nutritional and dietary supplements can be a primary source of microbiological contamination. Specifications should be developed and sampling plans and test procedures should be employed to guarantee the desired microbiological attributes of these materials. The nature and extent of microbiological testing should be based upon a knowledge of the material's origin, its manufacturing process, its use, and historical data and experience. For instance, materials of animal or botanical origin that are not highly refined might require special, more frequent testing than synthetic products.

Since members of the family Enterobacteriaceae are a major component of the normal epiphytic and endophytic microflora (e.g., members of genera Klebsiella, Enterobacter, and Erwinia) and have been associated with the seeds, pods, roots, leaves, and stems of plants of economic importance, Coliform or Enterobacteriaceae counts will not be an appropriate general microbiological criterion for botanicals. However, when it is considered advantageous, Coliform or Enterobacteriaceae counts may be included in the individual monographs. Typically on new leaves, bacteria predominate in the microflora, while yeast and filamentous fungi succeed bacteria and become dominant late in the growing season. With dried botanicals, the bacterial population will tend to change from Gram-negative bacteria to Gram-positive spore formers and fungi. Refinement of botanicals from chopped or powdered plant material to powdered extracts using alcoholic, alkaline, or acid hy-dro-alcoholic, or aqueous extracting materials will reduce the likelihood of vegetative microorganisms within the botanical material. The classification of botanical materials is contained in Table 1.

Table 1. Definitions of a Range of Botanical Materials

| Botanical Preparation | Definition |
| :--- | :--- |
| $\begin{array}{l}\text { Chopped or Powdered } \\ \text { Botanicals }\end{array}$ | $\begin{array}{r}\text { Hand-picked portions of the botanical (i.e., leaves, flowers, roots, } \\ \text { tubers, etc.) that are air dried, and chopped, flaked, sectioned, } \\ \text { ground, or pulverized to the consistency of a powder. } \\ \text { Extracts are solids or semisolid preparations of a botanical that are pre- } \\ \text { pared by percolation, filtration, and concentration by evaporation } \\ \text { of the percolate. The extracting material may by alcoholic, alkaline, } \\ \text { or acid hydro-alcoholic or aqueous in nature. Typically an extract } \\ \text { is } 4 \text { to } 10 \text { times as strong as the original botanical. The extracts } \\ \text { may be semisolids or dry powders termed powdered extracts. }\end{array}$ |
| Tinctures are solutions of botanical substances in alcohol obtained by |  |
| extraction of the powdered, flaked or sectioned botanical. |  |$\}$| Infusions are solutions of botanical principles obtained by soaking the |
| :--- |
| powdered botanical in hot or cold water for a specified time and |
| straining. Typically infusions are $5 \%$ in strength. |

## Change to read:

## MICROBIOLOGICAL TESTING

## Frequency of Sampling and Testing

Microbiological attribute sampling and testing plans vary widely. In some cases no sampling or testing is necessary; in other cases periodic monitoring is warranted; and yet for some articles each batch requires sampling and testing. The design of the sampling and testing plans and the kind of attributes examined depend on the application and the type of the product, the potential for contamination from components and processing, the growth promotion or inhibition properties of the formulation, and the target population for the supplement. For example, a powdered botanical may have highly variable microbiological attributes so that an incoming batch would be sampled and composite testing would not be advised, while a highly refined botanical extract may not require
routine microbial testing. Similarly, products with a low water activity will not be susceptible to microbial growth during their shelf life provided they are protected from elevated humidity by their containers.

## Microbial Enumeration Tests

See the Introduction under Microbial Enumeration Tests-Nutritional and Dietary Supplements $\langle 2021\rangle$. These tests provide meaningful information regarding the microbiological acceptability of excipients, active substances, and nonsterile supplement formulations. If the individual monograph does not specify microbial enumeration limits, the guidance provided in this chapter is used. Acceptable general limits of microbial levels for raw materials, excipients, and botanical products are shown in Table 2; and those for raw materials, excipients, active ingredients, and other nonsterile finished articles that are nutritional supplements but do not contain botanicals are shown in Table 3.

Table 2. Recommended Microbial Limits for Botanical Ingredients and Products

| Material | Recommended Microbial Limit Requirements (cfu/g or mL ) |
| :---: | :---: |
| Dried or Powdered Botanicals | Total Aerobic Microbial Count NMT 105 |
|  | Total Combined Yeast \& Mold Count NMT $10^{3}$ |
|  | Bile-tolerant Gram-negative Bacteria NMT 103 |
|  | Absence of Salmonella spp. \& E. coli in 10 g |
| Powdered Botanical Extracts | Total Aerobic Microbial Count NMT $10^{4}$ |

Table 3. Recommended Microbial Limits for Dietary Supplement Ingredients and Products
$\left.\begin{array}{ll}\hline \text { Material } & \begin{array}{c}\text { Recommended Microbial Limit Requirements } \\ (\mathrm{cfu} / \mathrm{g} \text { or mL) }\end{array} \\ \hline \begin{array}{l}\text { Other raw materials and dietary } \\ \text { supplement ingredients }\end{array} & \begin{array}{l}\text { Total Aerobic Microbial Count NMT 103 } \\ \text { Total Combined Yeast \& Mold Count NMT } 10^{2}\end{array} \\ \begin{array}{l}\text { Nutritional supplements with synthetic or } \\ \text { highly refined ingredients }\end{array} & \begin{array}{l}\text { Absence of } E \text {. coli in } 10 \mathrm{~g}\end{array} \\ \hline\end{array} \begin{array}{l}\text { Total Aerobic Microbial Count NMT 103 } \\ \text { Total Combined Yeast \& Mold Count NMT 102 } \\ \text { Absence of E. coli in } 10 \mathrm{~g}\end{array}\right]$

## Absence of Objectionable Microorganisms

See Introduction under Microbiological Procedures for Absence of Specified Microorganisms-Nutritional and Dietary Supplements $\langle 2022\rangle$. Absence of one or more species of objectionable microorganisms is required in some individual monographs.

Test for Aflatoxins-Dietary and nutritional articles containing botanical products with a history of mycotoxin contamination are also typically tested for aflatoxins, especially if the material is obtained from roots or rhizomes. Where nessary, this test is inelud ed in the individual menegraph. Details of the Test for Aftatexins may be found in Artieles of Botanical Origin- 564 ):

- See Articles of Botanical Origin $\langle 561\rangle$ for the details of a test for aflatoxins. Where necessary, this test is included in the individual monograph.■2S (USP28)

Solid Oral Dosage Forms-Among all dosage forms, solid oral dosage forms present the lowest microbiological risk because of their method of manufacture, low water activity, and route of administration. When justified, reduced microbiological testing may be appropriate.

Other Concerns-The presence of some microorganisms in articles can be an indicator of processes that are not under microbiological control. For example, Purified Water used at some stage of the manufacture of these products might contain a typical flora of Gram-negative microorganisms. As with pharmaceutical products, inadequate processing of water and poor maintenance of water systems may result in the contamination of processed formulations by Gram-negative microorganisms.

## REAGENTS, INDICATORS, AND SOLUTIONS Reagent Specifications

## BRIEFING

Piperazine. It is proposed to add this new reagent.
(HDQ: M. Marques) RTS-41497-1

## Add the following:

■Piperazine (Diethylenediamine), $\mathrm{C}_{4} \mathrm{H}_{10} \mathrm{~N}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}-$ 194.23-Use a suitable grade.■2S (USP28)

## REFERENCE TABLES

## Briefing

Container Specifications for Capsules and Tablets, USP 27 page 2741, page 3352 of the Second Supplement, and page 1404 of PF 30(4) [May-June 2004].
(HDQ) RTS-39507-2; 39869-2; 40078-1; 40078-2; 40078-3; 41479-1; 41480-1

The following table is provided as a reminder for the pharmacist engaged in the typical dispensing situation who already is acquainted with the Packaging and storage requirements set forth in the individual monographs. It lists the capsules and tablets that are, or will be, official in the United States Pharmacopeia and indicates the relevant tight (T), well-closed (W), and light-resistant (LR) specifications applicable to containers in which the drug that is repackaged should be dispensed.

This table is not intended to replace, nor should it be interpreted as replacing, the definitive requirements stated in the individual monographs.

Container Specifications for Capsules and Tablets
Container

Small Intestinal Submucosa Wound Matrix－See PF Vol． 30 No．2， page 538.
Xylazine－See PF Vol． 29 No．6，page 2004.
Xylazine Hydrochloride－See PF Vol． 29 No．6，page 2005.
Yohimbine Hydrochloride－See PF Vol． 29 No．6，page 2005.
Zidovudine－See PF Vol． 29 No．6，page 2006.
Zileuton－See PF Vol． 30 No．3，page 948.
Zinc Gluconate－See PF Vol． 29 No．3，page 683.
Zinc Sulfide Topical Suspension－See PF Vol． 30 No．2，page 546.

## DIETARY SUPPLEMENTS

## MONOGRAPHS

Chaste Tree－See PF Vol． 30 No．2，page 546.
Powdered Chaste Tree Extract－See PF Vol． 29 No．4，page 1269.
Horse Chestnut－See PF Vol． 30 No．2，page 550.
Powdered Horse Chestnut Extract－See PF Vol． 30 No．2，page 550.

Choline Bitartrate－See PF Vol． 30 No．3，page 950.
Choline Chloride－See PF Vol． 30 No．3，page 951.
Chondroitin Sulfate Sodium－See PF Vol． 30 No．1，page 197.
Chondroitin Sulfate Sodium Tablets－See PF Vol． 30 No．1，page 200.

Red Clover－See PF Vol． 30 No．2，page 550.
Powdered Red Clover Extract－See PF Vol． 30 No．2，page 552.
Black Cohosh－See PF Vol． 28 No．5，page 1455.
Powdered Black Cohosh－See PF Vol． 28 No．5，page 1460.
Powdered Black Cohosh Extract－See PF Vol． 28 No．5，page 1461.

Black Cohosh Tablets－See PF Vol． 28 No．5，page 1462.
Cranberry Liquid Preparation－See PF Vol． 30 No．3，page 951.
Docosahexaenoic Acid－See PF Vol． 26 No．6，page 1648.
Docosahexaenoic Acid Capsules－See PF Vol． 26 No．6，page 1651.

Docosahexaenoic Acid Oil—See PF Vol． 26 No．6，page 1652.
Echinacea angustifolia－See PF Vol． 30 No．2，page 552.
Powdered Echinacea angustifolia Extract－See PF Vol． 30 No．2， page 554.
Echinacea pallida－See PF Vol． 30 No．2，page 555.
Powdered Echinacea pallida Extract－See PF Vol． 30 No．2，page 556.

Echinacea purpurea Aerial Parts－See PF Vol． 30 No．2，page 557.
Echinacea purpurea Root－See PF Vol． 30 No．2，page 561.
Powdered Echinacea purpurea Extract－See PF Vol． 30 No．2， page 561.
Eleuthero－See PF Vol． 26 No．6，page 1596.
Fish Oil Rich in Omega－3 Acids－See PF Vol． 29 No．4，page 1272.

Fish Oil Rich in Omega－3 Acids Capsules－See PF Vol． 29 No．4， page 1278.
Ginger Capsules－See PF Vol． 28 No．3，page 814.
Powdered Ginkgo Extract－See PF Vol． 27 No．2，page 2233.
Ginkgo Capsules－See PF Vol． 27 No．2，page 2238.
Ginkgo Tablets－See PF Vol． 27 No．2，page 2240.
American Ginseng－See PF Vol． 30 No．2，page 563.
American Ginseng Capsules－See PF Vol． 30 No．2，page 565.
American Ginseng Tablets－See PF Vol． 30 No．2，page 567.
Powdered American Ginseng－See PF Vol． 30 No．2，page 564.
Powdered American Ginseng Extract－See PF Vol． 30 No．2，page 564.

Asian Ginseng－See PF Vol． 30 No．2，page 569.
Asian Ginseng Capsules－See PF Vol． 30 No．2，page 571.
Asian Ginseng Tablets－See PF Vol． 30 No．2，page 573.
Powdered Asian Ginseng－See PF Vol． 30 No．2，page 570.
Powdered Asian Ginseng Extract－See PF Vol． 30 No．2，page 570.

Glucosamine and Chondroitin Sulfate Sodium Tablets－See PF Vol． 30 No．1，page 201.
Goldenseal－See PF Vol． 30 No．3，page 952.
Powdered Goldenseal－See PF Vol． 30 No．3，page 953.
Powdered Goldenseal Extract－See PF Vol． 30 No．3，page 954.
Licorice－See PF Vol． 26 No．5，page 1363.
Powdered Licorice Extract－See PF Vol． 30 No．2，page 574.
Lutein－See PF Vol． 29 No．2，page 470.
Lutein Preparation－See PF Vol． 29 No．2，page 472.
Lycopene－See PF Vol． 30 No．2，page 574.
Lycopene Preparation－See PF Vol． 30 No．2，page 576.
Lycopene Tomato Extract－See PF Vol． 30 No．2，page 578.
Milk Thistle Capsules－See PF Vol． 29 No．2，page 479.
Minerals Capsules－See PF Vol． 28 No．5，page 1543.
Minerals Tablets－See PF Vol． 28 No．5，page 1543.
Pygeum－See PF Vol． 30 No．3，page 954.
Pygeum Capsules－See PF Vol． 30 No．3，page 959.
Pygeum Extract－See PF Vol． 30 No．3，page 956.
Pyridoxine Hydrochloride Injection－See PF Vol． 30 No．2，page 583.

Powdered St．John＇s Wort Extract－See PF Vol． 30 No．2，page 584.

Ubidecarenone Capsules－See PF Vol． 30 No．1，page 202.
Valerian Capsules－See PF Vol． 27 No．1，page 1825.
Oil－and Water－Soluble Vitamins Tablets－See PF Vol． 30 No．2， page 585.
Oil－and Water－Soluble Vitamins with Minerals Capsules－See PF Vol． 28 No．5，page 1544.

Air－Nitrous Oxide Certified Standard－See PF Vol． 28 No．4，page 1234.

Ammonium Hydroxide， 6 N－See PF Vol． 30 No．4，page 1389.
Ammonium Pyrrolidinedithiocarbamate－See PF Vol． 30 No．3， page 1043 ．
Anion－exchange Resin，Styrene－Divinylbenzene－See PF Vol． 30 No．3，page 1043.
Anti－A Blood Grouping Reagent，Anti－B Blood Grouping Re－ agent，and Anti－A，B Blood Grouping Reagent－See PF Vol． 29 No．2，page 505.
Anti－D（Rho）Reagent－See PF Vol． 29 No．2，page 505.
Anti－D Reagent－See PF Vol． 29 No．2，page 506.
Antihuman Globulin Reagent－See PF Vol． 29 No．2，page 506.
Antithrombin III for Amidolytic Test－See PF Vol． 29 No．1，page 264.

Bacterial Alkaline Protease Preparation－See PF Vol． 30 No．2， page 644.
Barbituric Acid－See PF Vol． 29 No．1，page 265.
Benzamidine Hydrochloride Hydrate－See PF Vol． 30 No．2，page 644.

Benzil－See PF Vol． 28 No．4，page 1305.
Blood Group $\mathrm{A}_{1}$ and Blood Group B Red Blood Cells－See PF Vol． 29 No．2，page 506.
Bovine Collagen－See PF Vol． 30 No．2，page 644.
Rat Tail Collagen－See PF Vol． 30 No．2，page 644.
Branched Polymeric Sucrose－See PF Vol． 27 No．6，page 3363.
Bromelain－See PF Vol． 28 No．2，page 552.
Bromofluoromethane－See PF Vol． 30 No．4，page 1389.
1，4－Butanediol－See PF Vol 25 No．5，page 8747.
Calf Thymus DNA－See PF Vol． 30 No．4，page 1389.
dl－Camphene－See PF Vol． 28 No．6，page 1951.

Cation-exchange Resin, Styrene-Divinylbenzene-See PF Vol. 30 No. 3, page 1043.
p-Chlorophenol-See PF Vol. 30 No. 3, page 1044.
4-Chlorophenol-See PF Vol. 30 No. 3, page 1045.
Chromotrope 2R-See PF Vol. 30 No. 4, page 1390.
Citric Acid, Anhydrous-See PF Vol. 30 No. 3, page 1044.
Collagen-See PF Vol. 30 No. 4, page 1390.
Collagenase-See PF Vol. 30 No. 4, page 1390.
Cyclohexylmethanol-See PF Vol. 30 No. 2, page 644.
DEAE-Agarose-See PF Vol. 29 No. 1, page 265.
Deoxyadenosine Triphosphate-See PF Vol. 27 No. 6, page 3364.
Deoxycytidine Triphosphate-See PF Vol. 27 No. 6, page 3364.
Deoxyguanosine Triphosphate-See PF Vol. 27 No. 6, page 3364.
Deoxyribonucleic Acid Polymerase-See PF Vol. 27 No. 6, page 3365.

Deoxythymidine Triphosphate-See PF Vol. 27 No. 6, page 3365.
Deuterated Methanol-See PF Vol. 29 No. 6, page 2054.
Dicyclohexyl-See PF Vol. 30 No. 2, page 645.
Dicyclohexyl Phthalate-See PF Vol. 26 No. 2, page 504.
Diethylpyrocarbonate-See PF Vol. 27 No. 6, page 3365.
Diisobutylene-See PF Vol. 28 No. 4, page 1305.
1,5-Dimethyl-1,5-diazundecamethylene Polymethobromide-See PF Vol. 30 No. 1, page 315.
$N, N$-Dimethylformamide Diethyl Acetal—See PF Vol. 29 No. 5, page 1681.
$N, N$-Dimethyldodecylamine- $N$-oxide-See PF Vol. 27 No. 4, page 2837.

1,9-Dimethyl-Methylene Blue-See PF Vol. 30 No. 2, page 645.
Dimethyl Sulfoxide-See PF Vol. 30 No. 3, page 1045.
3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyl Tetrazolium Bro-mide-See PF Vol. 27 No. 6, page 3365.
Dioleoylglycerol-See PF Vol. 26 No. 6, page 1622.
1,2-Dioleoyl-3-linoleoyl-rac-glycerol-See PF Vol. 28 No. 3, page 849.

Direct Red 80-See PF Vol. 30 No. 4, page 1390.
Disodium Arsenate-See PF Vol. 28 No. 4, page 1305.
3-(Dodecyldimethylammonio)propanesulfonate-See PF Vol. 30 No. 2, page 645.
Drabkin's Reagent-See PF Vol. 29 No. 2, page 507.
Escin-See PF Vol. 27 No. 4, page 2837.
Ether, Peroxide-Free-See PF Vol. 30 No. 4, page 1390.
Ethidium Bromide-See PF Vol. 27 No. 6, page 3366.
Ethylbenzene-See PF Vol. 30 No. 2, page 645.
Fast Green FCF-See PF Vol. 30 No. 4, page 1391.
Fibroblast Growth Factor-2-See PF Vol. 30 No. 2, page 645.
9-Fluorenylmethyl Chloroformate-See PF Vol. 25 No. 5, page 8916.

Formamide, Anhydrous-See PF Vol. 27 No. 5, page 3115.
Glucose-See PF Vol. 28 No. 3, page 850.
L-Glutamic Acid-See PF Vol. 27 No. 6, page 3366.
L-Glutamine-See PF Vol. 27 No. 6, page 3366.
Guanidine Isothiocyanate-See PF Vol. 27 No. 6, page 3366.
Hexadecane-See PF Vol. 28 No. 4, page 1305.
Hexadimethrine Bromide-See PF Vol. 29 No. 1, page 265.
Hexane, Solvent-See PF Vol. 30 No. 3, page 1045.
Hexane, Solvent, Chromatographic-See PF Vol. 30 No. 3, page 1046.

Hexanes-See PF Vol. 30 No. 3, page 1046.
L-Histidine Hydrochloride Monohydrate-See PF Vol. 27 No. 6, page 3366.
Homatropine Hydrobromide-See PF Vol. 28 No. 4, page 1305.
Hydrocodone Diol-See PF Vol. 28 No. 4, page 1306.
2'-(4-Hydroxyphenyl)-5-(4-methyl-1-piperazinyl)-2,5'-bi-1 $H$-benzimidazole Trihydrochloride Pentahydrate-See PF Vol. 30 No. 4, page 1391.
IgG-Coated Red Cells-See PF Vol. 29 No. 2, page 507.
Iodine-See PF Vol. 30 No. 4, page 1391.
Iodoethane-See PF Vol. 24 No. 6, page 7327.
Isoferulic Acid-See PF Vol. 27 No. 4, page 2837.
Isovaleric Acid-See PF Vol. 30 No. 3, page 1046.
Lanthanum Chloride-See PF Vol. 29 No. 2, page 507.

Lanthanum Oxide-See PF Vol. 28 No. 3, page 851.
Lauryl Dimethyl Amine Oxide-See PF Vol. 30 No. 2, page 645.
Linoleic Acid-See PF Vol. 27 No. 6, page 3367.
$\alpha$-Lipoic Acid-See PF Vol. 27 No. 6, page 3367.
Melamine-See PF Vol. 29 No. 6, page 2055.
Methanol, Aldehyde-Free-See PF Vol. 30 No. 2, page 646.
Methoxyphenylacetic Acid-See PF Vol. 30 No. 3, page 1046.
Methylbenzothiazolone Hydrazone Hydrochloride-See PF Vol. 30 No. 2, page 646.
3-Methyl-2-benzothiazolinone Hydrazone Hydrochloride-See PF Vol. 25 No. 3, page 8280.
Methyl Iodide-See PF Vol. 30 No. 3, page 1046.
4-Methylpentan-2-ol-See PF Vol. 30 No. 2, page 646.
Methyl Sulfoxide-See PF Vol. 30 No. 3, page 1047.
Methylene Blue-See PF Vol. 30 No. 4, page 1391.
Monooleoylglycerol-See PF Vol. 26 No. 6, page 1622.
Nonionic Wetting Agent-See PF Vol. 30 No. 3, page 1047.
Nonylphenol Polyoxyethylene Ether-See PF Vol. 27 No. 6, page 3368.

Octoxynol-See PF Vol. 30 No. 4, page 1392.
Oligo-deoxythymidine-See PF Vol. 27 No. 6, page 3368.
Oxygen-Helium Certified Standard-See PF Vol. 30 No. 2, page 646.

Pentadecanoic Acid Methyl Ester-See PF Vol. 26 No. 6, page 1622.

Phenol Red, Sodium-See PF Vol. 27 No. 6, page 3368.
Phenylmethylsulfonyl Fluoride-See PF Vol. 30 No. 2, page 647.
Polyoxyethylene (23) Lauryl Ether-See PF Vol. 29 No. 2, page 507.

Polyoxyethylene (20) Sorbitan Monolaurate-See PF Vol. 27 No. 6, page 3368.
Propionaldehyde-See PF Vol. 30 No. 2, page 647.
Putrescine Dihydrochloride-See PF Vol. 27 No. 6, page 3369.
Red-Cell Lysing Agent-See PF Vol. 29 No. 2, page 507.
Reverse Transcriptase-See PF Vol. 27 No. 6, page 3369.
Rhodamine 6G-See PF Vol. 30 No. 4, page 1392.
Ribonuclease Inhibitor-See PF Vol. 27 No. 6, page 3369.
Sodium Arsenite, Twentieth-Molar ( 0.05 M )-See PF Vol. 29 No. 4, page 1250.
Sodium 1-Heptanesulfonate-See PF Vol. 30 No. 3, page 1047.
Sodium 1-Heptanesulfonate Monohydrate-See PF Vol. 30 No. 2, page 647.
Sodium 1-Hexanesulfonate-See PF Vol. 30 No. 3, page 1048.
Sodium Hydrogen Sulfate-See PF Vol. 29 No. 5, page 1682.
Sodium Iodate-See PF Vol. 27 No. 6, page 3369.
Sodium Phosphate, Monobasic-See PF Vol. 30 No. 4, page 1392.
1,1,4,4-Tetraphenyl-1,3-butadiene-See PF Vol. 26 No. 6, page 1623.

Thrombin Human-See PF Vol. 29 No. 6, page 2055.
Thymidine-See PF Vol. 27 No. 6, page 3369.
Thyroglobulin-See PF Vol. 30 No. 1, page 316.
1,3,7-Trichlorodibenzo- $p$-dioxin-See PF Vol. 30 No. 4, page 1392.

Trioleoylglycerol-See PF Vol. 26 No. 6, page 1623.
Tritirachium Album Proteinase K-See PF Vol. 30 No. 2, page 647.

Tropic Acid—See PF Vol. 30 No. 3, page 1048.
Tropine-See PF Vol. 30 No. 2, page 647.
L-Tyrosine Disodium-See PF Vol. 27 No. 6, page 3370.
Tuberculin, Purified Protein Derivative (Tuberculin PPD)-See PF Vol. 29 No. 5, page 1682.
2-Vinylpyridine-See PF Vol. 26 No. 2, page 504.
Wright's Stain-See PF Vol. 30 No. 1, page 316.
Zinc Sulfate Heptahydrate-See PF Vol. 26 No. 2, page 504.

## Indicator Test Papers

Methyl Green-See PF Vol. 28 No. 4, page 1306.
Methyl Green-Iodomercurate Paper-See PF Vol. 28 No. 4, page 1306.

Nickel Standard Solution TS—See PF Vol. 27 No. 5, page 3117.

Ninhydrin TS——See PF Vol. 28 No. 3, page 852.
Perchloric Acid TS—See PF Vol. 27 No. 1, page 1905.

## Test Solutions

Ammonia TS—See PF Vol. 30 No. 4, page 1392.
Folin-Ciocalteu Phenol TS-See PF Vol. 30 No. 1, page 316.
Hydroxylamine Hydrochloride TS-See PF Vol. 30 No. 4, page 1393.

Iodine and Potassium Iodide TS $1 —$ See PF Vol. 30 No. 4, page 1393.

Iodine and Potassium Iodide TS 2—See PF Vol. 30 No. 4, page 1393.

Methyl Yellow TS—See PF Vol. 30 No. 4, page 1393.
Potassium Pyroantimonate TS—See PF Vol. 30 No. 4, page 1393.

## Volumetric Solutions

Ammonium Thiocyanate, Tenth-Normal (0.1 N)—See PF Vol. 30 No. 4, page 1393.
Bromine, Tenth-Normal ( 0.1 N )—See PF Vol. 30 No. 4, page 1393.

Ceric Ammonium Nitrate, Twentieth-Normal ( 0.05 N )—See PF Vol. 30 No. 4, page 1394.
Ceric Sulfate, Tenth-Normal ( 0.1 N )—See PF Vol. 30 No. 4, page 1394.

Cupric Nitrate, Tenth Normal ( 0.1 N )—See PF Vol. 30 No. 4, page 1394.

Standard Dichlorophenol-Indophenol Solution-See PF Vol. 30 No. 4, page 1394.
Edetate Disodium, Twentieth-Molar (0.05 M)—See PF Vol. 30 No. 4, page 1395.
Ferric Ammonium Sulfate, Tenth-Normal ( 0.1 N )—See PF Vol. 30 No. 4, page 1395.
Ferrous Ammonium Sulfate, Tenth-Normal (0.1 N)—See PF Vol. 30 No. 4, page 1395.
Hydrochloric Acid, Normal ( 1 N )—See PF Vol. 30 No. 4, page 1395.

Hydrochloric Acid, Half-Normal ( 0.5 N )—See PF Vol. 30 No. 4, page 1395 .
Hydrochloric Acid, Half-Normal ( 0.5 N ) in Methanol-See PF Vol. 30 No. 4, page 1396.
Hydrochloric Acid, Alcoholic, Tenth-Molar (0.1 M)—See PF Vol. 30 No. 4, page 1396.
Iodine, Tenth-Normal ( 0.1 N )-See PF Vol. 30 No. 4, page 1396.
Iodine, Hundredth-Normal ( 0.01 N )-See PF Vol. 30 No. 4, page 1396.

Lead Perchlorate, Tenth-Molar (0.1 M)—See PF Vol. 30 No. 4, page 1396.
Lead Perchlorate, Hundredth-Molar (0.1 M)—See PF Vol. 30 No. 4, page 1397 .
Lithium Methoxide, Fiftieth-Normal ( 0.02 N ) in Methanol-See PF Vol. 30 No. 4, page 1397.
Lithium Methoxide, Tenth-Normal ( 0.1 N ) in Toluene-See PF Vol. 30 No. 4, page 1397.
Lithium Methoxide, Tenth-Normal ( 0.1 N ) in ChlorobenzeneSee PF Vol. 30 No. 4, page 1397.
Mercuric Nitrate, Tenth-Molar ( 0.1 M )—See PF Vol. 30 No. 4, page 1398.
Morpholine, Half-Normal $(0.5 \mathrm{~N})$ in Methanol-See PF Vol. 30 No. 4, page 1398.
Oxalic Acid, Tenth-Normal ( 0.1 N )—See PF Vol. 30 No. 4, page 1398.

Perchloric Acid, Tenth-Normal ( 0.1 N ) (in Glacial Acetic Acid)See PF Vol. 30 No. 4, page 1398.
Perchloric Acid, Tenth-Normal ( 0.1 N ) in Dioxane-See PF Vol. 30 No. 4, page 1398.
Potassium Bromate, Tenth-Normal ( 0.1 N )—See PF Vol. 30 No. 4, page 1399.
Potassium Bromide-Bromate, Tenth-Normal ( 0.1 N )—See PF Vol. 30 No. 4, page 1399.

Potassium Dichromate, Tenth-Normal (0.1 N)—See PF Vol. 30 No. 4, page 1399.
Potassium Ferricyanide, Twentieth-Molar ( 0.05 M )-See PF Vol. 30 No. 4, page 1399.
Potassium Hydroxide, Normal (1 N)—See PF Vol. 30 No. 4, page 1399.

Potassium Hydroxide, Alcoholic, Half-Normal ( 0.05 N )—See PF Vol. 30 No. 4, page 1399.
Potassium Hydroxide, Alcoholic, Tenth Molar (0.1 M)—See PF Vol. 30 No. 4, page 1400.
Potassium Hydroxide, Methanolic, Tenth-Normal ( 0.1 N )—See PF Vol. 30 No. 4, page 1400.
Potassium Permanganate, Tenth-Normal (0.1 N)-See PF Vol. 30 No. 4, page 1400.
Silver Nitrate, Tenth-Normal ( 0.1 N )—See PF Vol. 30 No. 4, page 1400.

Sodium Hydroxide, Normal ( 1 N )—See PF Vol. 30 No. 4, page 1400.

Sodium Hydroxide, Alcoholic, Tenth-Normal ( 0.1 N )—See PF Vol. 30 No. 4, page 1401.
Sodium Methoxide, Tenth-Normal ( 0.1 N ) (in Toluene)-See PF Vol. 30 No. 4, page 1401.
Sodium Methoxide, Half-Normal ( 0.5 N ) in Methanol-See PF Vol. 30 No. 4, page 1401.
Sodium Nitrite, Tenth-Molar (0.1 M)—See PF Vol. 30 No. 4, page 1401.

Sodium Tetraphenylboron, Fiftieth-Molar ( 0.02 M )-See PF Vol. 30 No. 4, page 1402.
Sodium Thiosulfate, Tenth-Normal (0.1 N)—See PF Vol. 30 No. 4, page 1402.
Sulfuric Acid, Half-Normal ( 0.5 N ) in Alcohol-See PF Vol. 30 No. 4, page 1402.
Tetrabutylammonium Hydroxide, Tenth-Normal (0.1 N)—See PF Vol. 30 No. 4, page 1402.
Tetrabutylammonium Hydroxide in Methanol/Isopropyl Alcohol, 0.1 N -See PF Vol. 30 No. 4, page 1403.

Tetramethylammonium Bromide, Tenth-Molar ( 0.1 M )—See PF Vol. 30 No. 4, page 1403.
Tetramethylammonium Chloride, Tenth-Molar (0.1 M)—See PF Vol. 30 No. 4, page 1403.
Titanium Trichloride, Tenth-Normal ( 0.1 N )-See PF Vol. 30 No. 4, page 1403.
Zinc Sulfate, Twentieth-Molar ( 0.05 M )—See PF Vol. 30 No. 4, page 1403.

## Reagent Footnotes

Reagent Footnotes-See PF Vol. 30 No. 2, pages 647-648.

## HARMONIZATION

This section contains monographs or chapters undergoing harmonization by the Pharmacopeial Discussion Group (PDG). The PDG consists of the United States Pharmacopeia (USP), the European Pharmacopoeia (EP), and the Japanese Pharmacopoeia (JP). The process of harmonization is composed of several steps (Stages).

Stage 1: Identification The PDG identifies items to be harmonized and designates a coordinating pharmacopeia for each item. The PDG distributes the work by consensus among the three participating pharmacopeias. Harmonization may be carried out retrospectively for existing monographs or chapters, or prospectively for new monographs or chapters.

Stage 2: Investigation The investigation process conducted by the coordinating pharmacopeia results in the preparation of a Stage 3 draft monograph or chapter accompanied by a report giving the rationale for the proposal and including validation data where appropriate. This report is based on input that comes from users, authorities, producers, associations, literature, experts, and staff.

Stage 3: Proposal The Stage 3 draft is reviewed and commented on by the other two pharmacopeias. The coordinating pharmacopeia reviews those comments, prepares a harmonized Stage 4 draft, and sends it to the other two participating pharmacopeias.

Stage 4: Official Inquiry The Stage 4 draft is published in the Forum of each pharmacopeia. In $P F$, this stage appears as OFFICIAL INQUIRY STAGE 4 in the Harmonization section. Each pharmacopeia analyzes the comments it receives and submits the consolidated comments to the coordinating pharmacopeia, which then reviews those comments, prepares a harmonized Stage 5A draft, and sends it to the other two participating pharmacopeias.

## Stage 5: Consensus

## A. Provisional

The Stage 5A draft is reviewed and commented on by the other two pharmacopeias. When consensus is reached, a CONSENSUS STAGE 5B document is prepared by the coordinating pharmacopeia.

## B. Final

The Stage 5B draft (consensus document) is sent by the coordinating pharmacopeia to the other two participating pharmacopeias for final approval.

Stage 6: Adoption Each pharmacopeia incorporates the harmonized Stage 5B draft according to its own procedure. Adopted items are published by the three pharmacopeias in their Supplements or, where applicable, in a new edition of their Pharmacopeias.

Stage 7: Date of Implementation The pharmacopeias inform each other of the date of implementation in the particular region.

## MONOGRAPHS (USP)

## BRIEFING

Alcohol, USP 27 page 59 and page 669 of $P F 30(2)$ [Mar.-Apr. 2004]. The European Pharmacopoeia is the coordinating pharmacopoeia for the international harmonization of compendial standards for the Alcohol monograph, as part of the process of international harmonization of monographs and general analytical methods of the European, Japanese, and United States pharmacopeias. The following monograph, which represents the ADOPTION STAGE 6 document, is based in part on comments from the Japanese Pharmacopoeia and the United States Pharmacopeia in response to the Provisional Harmonized Text Stage 5A and 5B drafts prepared by the European Pharmacopoeia.

Pharmacopeial Discussion Group Sign-Off Document

| Attributes | EP | JP | USP |
| :--- | :---: | :---: | :---: |
| Identification A | + | + | + |
| Identification B | + | + | + |
| Appearance | + | + | + |
| Acidity or alkalinity | + | + | + |
| Relative density | + | + | + |
| Absorbance | + | + | + |
| Volatile impurities | + | + | + |
| Residue on <br> evaporation | + | + | + |
| Storage | + | + | + |

Legend: + will adopt and implement; - will not stipulate.
Nonharmonized attributes: Characters.
Definition and Relative density: Each pharmacopeia specifies a different range for the content; the values for relative density vary accordingly and, in addition, are expressed at different temperatures.

Reagents and reference materials: Each pharmacopeia will adapt the text to take account of local reference substances and spectra and reagent specifications.

Differences between the ADOPTION STAGE 6 document and the current $U S P$ monograph include the following:
(1) Definition-No change.
(2) Packaging and storage-Storage conditions to protect from light are added.
(3) USP Reference standards-A reference standard for Alcohol is added for use in the Identification test.
(4) Identification-Tests $A$ and $B$ are replaced with a more definitive IR absorption test, and the test for specific gravity is moved under Identification.
(5) Clarity of solution-This test is added to comply with EP standards.
(6) Color of solution-This test is added to comply with EP standards.
(7) Specific gravity-No change.
(8) Acidity-This test is replaced by a test for Acidity or alkalinity to comply with EP standards.
(9) Limit of nonvolatile residue-The sample size is increased from 40 to 100 mL .
(10) Ultraviolet absorbance-The standards have been modified to comply with EP standards. Corrections are made to the cell dimensions to comply with the signed off draft.
(11) Water-insoluble substances-This test is deleted. Because the monograph contains tests for Nonvolatile residue and Volatile impurities, this test is no longer needed.
(12) Aldehydes and other foreign organic substances-This test is replaced with a Volatile impurities test.
(13) Amyl alcohol and nonvolatile, carbonizable substancesThis test is replaced with a Volatile impurities test.
(14) Ultraviolet absorbance-This test is added to comply with EP standards. Corrections are made to the cell dimensions to comply with the signed off draft.
(15) Limit of acetone and isopropyl alcohol-This test is replaced with a Volatile impurities test.
(16) Methanol-This test is replaced with a Volatile impurities test.
(17) Volatile impurities-This chromatographic test is added to limit a wide array of volatile impurities within a single test method. Clarification is made under Procedure to analyze all of the standard solutions.
(EMC: J. Lane) RTS-41486-3

## Change to read:

## Aleohel

$\mathrm{E}_{2} \mathrm{H}_{6} \Theta \quad 46.07$
Ethanol.
Ethylaleohel [64-17.5].
H-Aleohel contains net less than-92.3 percent and not more than 93.8 percent, by weight, correspending to not less than 94.9 pereent and not more than 96.0 pereent, by volume, at $15.56^{\circ}$, of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$.

Packaging and-storage Preserve-in tight containers, remote frem fire.

## Identifieation-

A: Mix 5 dreps in a small beaker with 1 mL of petassium per mangenate solution ( 1 in 100) and 5 dreps of 2 N sulfuric acid, and eover the beaker immediately with a filter paper meistened with a solution recently prepared by dissolving 0.1 g of soditm nitrofer ricymide and 0.25 gof piperazine in 5 mL of water: an intense blue eolor is produced on the filter paper, the color becoming paler after a few mintutes.

B: To 5 mL of a solution ( 1 in 10 ) add 1 mL of 1.0 N sodium hydroxide, then slowly (over a period of 3 minutes) add 2 mL of $\theta .1 \mathrm{~N}$ iodine: the odor of iodoform develops, and a yellow precipi tate is formed within 30 mintres.
Speeifie gravity $\langle 844\rangle$ :- between 0.812 and- 0.816 at $15.56^{\circ}$, in dicating between $92.3 \%$ and $93.8 \%$, by weight, or between $94.9 \%$ and $96.0 \%$, by volume, of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$.

Acidity To 50 mL , in a glass stoppered flack, add 50 mL of re cently boiled water. Add phenolphthalein TS, and titrate with 0.020 N sodim hydroxide to a pink color that persists for 30 sec ends: net mere than 0.90 mL of 0.020 N soditm hydrexide is required for neutralization.
Limit of nonvolatile residue-Evaporate 40 mL in a tared dishon a water bath, and dry at $105^{\circ}$ for 1 hour: the weight of the residue does not exeed 1 me.
Water-insoluble substances Dilute it with an equal volume of water: the mixture is clear and remains clear for 30 minutes after eooling to $10^{\circ}$.
Aldehydes and-0ther foreign-0rganic substances Place 20 mL in a glass-stoppered eylinder that has been thoroughly cleaned with hydrochlerie acid, then rinsed with water and fanally with the At eohol to be tested. Cool the contents to approximately $15^{\circ}$, and add, by means of a carefully cleaned pipet, 0.10 mL of 0.10 N pe tassium permanganate, neting aceurately the time of addition. Mix at once by inverting the stoppered cylinder, and allow it to stand at $15^{\circ}$ for 5 minutes: the pink color does not entirely disappear.
Amylaleoholandmonvolatile, carbonizable substanees-Allow 25 mL to evaperate spentaneously from a pereelain dish, careftlly protect frem dust, until the surface of the dish is barely moist: no redor brown color is produced immediately upen the addition of a few dreps of sulfuric acid.
Limit of aeetone and isopropylaleohol To 1.0 mL add 1.0 mL of water, 1.0 mL of a saturated solution of dibasic sodium phosphate, and 3.0 mL of a saturated solution of potassium permanga nate. Warm the mixture to $45^{\circ}$ to $50^{\circ}$, and allow to stand until the permanganatecolor is discharged. Add 3.0 mL of 2.5 N sodium hydroxide, and filter, without washing, through a sintered glass fit ter. Prepare a control by mixing 1.0 mL of the saturated solution of dibasic sodium phosphate, 3.0 mL of 2.5 N sodium hydroxide, 80 He of acetone, and 5.0 mL of water. To each solution add 1 mL of furfural solution ( 1 in 100), allow to stand for 10 minutes, then to 1.0 mL of each solution add 3 mL of hydrochloric acid: any pink eoler produced in the test solution is not more intense than that in the controt.
Methanol To 1 drop add 1-drop-of water, 1 drop-of dilute phesphoric acid ( 1 in 20), and 1 drep of potassimm permangenate solution ( 1 in 20). Mix, allour to stand for 1 minute, and add sodium metabisulfite solution ( 1 in 20), dropwise, until the permanga nate color is diseharged. If a brown color remains, add 1 drop of the dilute phosphoric acid. To the colorless solution add 5 mL of freshly prepared chromotropic acid TS, and heat on a water bath at $60^{\circ}$ for 10 minntes: any viole color should not exeed that produred by 0.04 mg of methanol in 1 mL of water, treated in the same way as the sample.

## Alcohol

$$
\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O} \quad 46.07
$$

Ethanol.

Ethyl alcohol [64-17-5].
» Alcohol contains not less than 92.3 percent and not more than 93.8 percent, by weight, corresponding to not less than 94.9 percent and not more than 96.0 percent, by volume, at $15.56^{\circ}$, of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$.

Packaging and storage-Preserve in tight containers, protected from light. and remotem from, sparks, or open flames.

USP Reference standards $\langle 11\rangle-U S P$ Alcohol $R S$.
Clarity of solution-[NOTE-The Test solution is to be compared to Reference suspension $A$ and to water in diffused daylight 5 minutes after preparation of Reference suspension $A$.]

Hydrazine solution-Transfer 1.0 g of hydrazine sulfate to a $100-\mathrm{mL}$ volumetric flask, dissolve in and dilute with water to volume, and mix. Allow to stand for 4 to 6 hours.

Methenamine solution-Transfer 2.5 g of methenamine to a $100-\mathrm{mL}$ glass-stoppered flask, add 25.0 mL of water, insert the glass stopper, and mix to dissolve.
Primary opalescent suspension-[NOTE-This suspension is stable for 2 months, provided it is stored in a glass container free from surface defects. The suspension must not adhere to the glass and must be well mixed before use.] Transfer 25.0 mL of Hydrazine solution to the Methenamine solution in the $100-\mathrm{mL}$ glass-stoppered flask. Mix, and allow to stand for 24 hours.

Opalescence standard-[NOTE-This suspension should not be used beyond 24 hours after preparation.] Transfer 15.0 mL of the Primary opalescent suspension to a 1000mL volumetric flask, dilute with water to volume, and mix.

Reference suspensions-Transfer 5.0 mL of the Opalescence standard to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix to obtain Reference suspension
A. Transfer 10.0 mL of the Opalescence standard to a second $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix to obtain Reference suspension B.

Test solution $A$-The substance to be examined.
Test solution B-Dilute 1.0 mL of Test solution $A$ to 20 mL with water, and allow to stand for 5 minutes before testing.

Procedure-Transfer a sufficient portion of Test solution $A$ and Test solution $B$ to separate test tubes of colorless, transparent, neutral glass with a flat base and an internal diameter of 15 to 25 mm to obtain a depth of 40 mm . Similarly transfer portions of Reference suspension A, Reference suspension $B$, and water to separate matching test tubes. Compare Test solution A, Test solution B, Reference suspension $A$, Reference suspension $B$, and water in diffused daylight, viewing vertically against a black background (see Visual Comparison under Spectrophotometry and LightScattering $\langle 851\rangle$ ). [NOTE-The diffusion of light must be such that Reference suspension $A$ can readily be distinguished from water, and that Reference suspension $B$ can readily be distinguished from Reference suspension A.] Test solution $A$ and Test solution $B$ show the same clarity as that of water or their opalescence is not more pronounced than that of Reference suspension $A$.

## Color of solution-

Standard stock solution-Combine 3.0 mL of ferric chloride $\mathrm{CS}, 3.0 \mathrm{~mL}$ of cobaltous chloride $\mathrm{CS}, 2.4 \mathrm{~mL}$ of cupric sulfate CS , and 1.6 mL of dilute hydrochloric acid ( 10 g per L).

Standard solution-[NOTE-Prepare the Standard solution immediately before use.] Transfer 1.0 mL of Standard stock solution to a $100-\mathrm{mL}$ volumetric flask, dilute with dilute hydrochloric acid ( 10 g per L ) to volume, and mix.

Test solution-The substance to be examined.

Procedure-Transfer a sufficient portion of the Test solution to a test tube of colorless, transparent, neutral glass with a flat base and an internal diameter of 15 to 25 mm to obtain a depth of 40 mm . Similarly transfer portions of Standard solution and water to separate, matching test tubes. Compare the Test solution, Standard solution, and water in diffused daylight, viewing vertically against a white background (see Visual Comparison under Spectrophotometry and Light-Scattering $\langle 851\rangle$ ). The Test solution has the appearance of water or is not more intensely colored than the Standard solution.

## Identification-

A: It complies with the test for Specific gravity.
B: Infrared Absorption $\langle 197 \mathrm{~F}\rangle$ or $\langle 197 \mathrm{~S}\rangle$ neat.
Specific gravity $\langle 841\rangle$ : between 0.812 and 0.816 at $15.56^{\circ}$, indicating between $92.3 \%$ and $93.8 \%$, by weight, or between $94.9 \%$ and $96.0 \%$, by volume, of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$.

## Acidity or alkalinity-

Phenolphthalein solution-Dissolve 0.1 g of phenolphthalein in 80 mL of alcohol, and dilute with water to 100 mL .

Procedure-To 20 mL of alcohol, add 20 mL of freshly boiled and cooled water and 0.1 mL of Phenolphthalein solution. The solution is colorless. Add 1.0 mL of 0.01 N sodium hydroxide. The solution is pink ( 30 ppm , expressed as acetic acid).

Ultraviolet absorption-Record the UV absorption spectrum of the test material from 200 to 400 nm in a $1-\mathrm{em} 5-$ cm cell: maximum absorbance 0.40 at $240 \mathrm{~nm}, 0.30$ between 250 and 260 nm , and 0.10 between 270 and 340 nm . Examine between 235 and 340 nm , in a $5-\mathrm{cm}$ cell, using water as the compensation liquid. The absorption curve is smooth.

## Volatile impurities-

Test solution $A$-The substance to be examined.
Test solution B—Add $150 \mu \mathrm{~L}$ of 4-methylpentan-2-o1 to 500.0 mL of the substance to be examined.

Standard solution A-Dilute $100 \mu \mathrm{~L}$ of methanol to 50.0 mL with the substance to be examined. Dilute 5.0 mL of the solution to 50.0 mL with the substance to be examined.

Standard solution B—Dilute $50 \mu \mathrm{~L}$ of methanol and 50 $\mu \mathrm{L}$ of acetaldehyde to 50.0 mL with the substance to be examined. Dilute $100 \mu \mathrm{~L}$ of the solution to 10.0 mL with the substance to be examined.

Standard solution C-Dilute $150 \mu \mathrm{~L}$ of acetal to 50.0 mL with the substance to be examined. Dilute $100 \mu \mathrm{~L}$ of the solution to 10.0 mL with the substance to be examined.

Standard solution D—Dilute $100 \mu \mathrm{~L}$ of benzene to 100.0 mL with the substance to be examined. Dilute $100 \mu \mathrm{~L}$ of the solution to 50.0 mL with the substance to be examined.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The gas chromatograph is equipped with a flame-ionization detector, maintained at about $280^{\circ}$, and a $0.32-\mathrm{mm} \times 30-\mathrm{m}$ fused silica capillary column bonded with a $1.8-\mu \mathrm{m}$ layer of phase G43. The carrier gas is helium with a linear velocity of about 35 cm per second and a split ratio of $1: 20$. The column temperature is maintained at $40^{\circ}$ for the first 12 minutes after an injection is made and is increased from $40^{\circ}$ to $240^{\circ}$ from 12 to 32 minutes after injection. During the period of 32 to 42 minutes after an injection is made the column temperature is maintained at $240^{\circ}$. The injection port temperature is maintained at $200^{\circ}$. Chromatograph Standard solution $B$, and record the peak responses as directed for Procedure: the resolution, $R$, between the first major peak (acetaldehyde) and the second major peak (methanol) is not less than 1.5 .

Procedure-Separately inject equal volumes ( $1.0 \mu \mathrm{~L}$ ) of Test solution $A$ and Test Bration Test solution B, Standard solution A, Standard solution C, and Standard solution D into the chromatograph, record the chromatograms, and measure the major peaks. Calculate the concentration of methanol in Test solution A: not more than half the area of the corresponding peak in the chromatogram obtained with Standard solution $A$ ( 200 ppm ).
Calculate the sum of the contents of acetaldehyde and acetal, expressed as acetaldehyde, using the following formula:

$$
\left[\left(10 \times A_{E}\right) /\left(A_{T}-A_{E}\right)\right]+\left[\left(30 \times C_{E}\right) /\left(C_{T}-C_{E}\right)\right],
$$

in which $A_{E}$ is the area of the acetaldehyde peak in the chromatogram obtained with the Test solution $A ; A_{T}$ is the area of the acetaldehyde peak in the chromatogram obtained with Standard solution $B ; C_{E}$ is the area of the acetal peak in the chromatogram obtained with Test solution $A$; and $C_{T}$ is the area of the acetal peak in the chromatogram obtained with Standard solution C: not more than 10 ppm , expressed as acetaldehyde is found.

Calculate the content of benzene using the following formula:

$$
\left(2 B_{E}\right) /\left(B_{T}-B_{E}\right),
$$

in which $B_{E}$ is the area of the benzene peak in the chromatogram obtained with Test solution $A$; and $B_{T}$ is the area of the benzene peak in the chromatogram obtained with Standard solution D: not more than 2 ppm is found. If necessary, the identity of benzene can be confirmed using another suitable chromatographic system (stationary phase with a different polarity).

The total of all other impurities in the chromatogram obtained with Test solution B: not more than the area of the peak due to 4-methylpentan-2-ol in the chromatogram obtained with Test solution B (300 ppm).

Disregard any peaks that are 0.03 times the area of the peak corresponding to 4-methylpentan-2-ol in the chromatogram obtained with Test solution $B(9 \mathrm{ppm})$.

Limit of nonvolatile residue-Evaporate 100 mL in a tared dish on a water bath, and dry at $100^{\circ}$ to $105^{\circ}$ for 1 hour: the weight of the residue does not exceed 2.5 mg -2S (USP28)

## BRIEFING

Dehydrated Alcohol, USP 27 page 60 and page 673 of $P F$ 30(2) [Mar.-Apr. 2004]. The European Pharmacopoeia is the coordinating pharmacopeia for the international harmonization of compendial standards for the Dehydrated Alcohol monograph, as part of the process of international harmonization of monographs and general analytical methods of the European, Japanese, and United States pharmacopeias. The following monograph, which represents the ADOPTION STAGE 6 document, is based in part on comments from the Japanese Pharmacopoeia and the United States Pharmacopeia in response to the Provisional Harmonized Text Stage 5A and 5B drafts prepared by the European Pharmacopoeia.

## Pharmacopeial Discussion Group Sign-Off Document

| Attributes | EP | JP | USP |
| :--- | :---: | :---: | :---: |
| Definition | + | + | + |
| Identification A | + | + | + |
| Identification B | + | + | + |
| Appearance | + | + | + |
| Acidity or alkalinity | + | + | + |
| Relative density | + | + | + |
| Absorbance | + | + | + |
| Volatile impurities | + | + | + |
| Residue on <br> evaporation | + | + | + |
| Storage | + | + | + |

Legend: + will adopt and implement; - will not stipulate.
Nonharmonized attributes: Characters.
Relative density: The values for relative density are expressed at different temperatures in the three pharmacopeias.

Reagents and reference materials: Each pharmacopeia will adapt the text to take account of local reference substances and spectra and reagent specifications

Differences between the ADOPTION STAGE 6 document and the current USP monograph include the following:
(1) Definition-No change.
(2) Packaging and storage-Storage conditions to protect from light are added.
(3) USP Reference standards-A reference standard for alcohol is added for the Identification test.
(4) Identification-Tests $A$ and $B$ are replaced with a more definitive Infrared absorption test, and the test for Specific gravity is moved under Identification.
(5) Clarity of solution-This test is added to comply with EP standards.
(6) Color of solution-This test is added to comply with EP standards.
(7) Specific gravity-No change.
(8) Acidity-This test is replaced by a test for Acidity or alkalinity to comply with EP standards.
(9) Limit of nonvolatile residue-The sample size is increased from 40 to 100 mL .
(10) Water-insoluble substances-This test is deleted. Because the monograph contains tests for Nonvolatile residue and Volatile impurities, this test is no longer needed.
(11) Aldehydes and other foreign organic substances-This test is replaced with a Volatile impurities test.
(12) Amyl alcohol and nonvolatile, carbonizable substancesThis test is replaced with a Volatile impurities test.
(13) Ultraviolet absorbance-The standards have been modified to comply with EP standards. Corrections are made to the cell dimensions to comply with the signed off draft.
(14) Limit of acetone and isopropyl alcohol-This test is replaced with a Volatile impurities test.
(15) Methanol-This test is replaced with a Volatile impurities test.
(16) Volatile impurities-This chromatographic test is added to limit a wide array of volatile impurities within a single test method. Clarification is made under Procedure to analyze all of the standard solutions.
(EMC: J. Lane) RTS-41486-4

## Change to read:

## Dehydrated Aleohol

$\mathrm{G}_{2} \mathrm{H}_{6} \Theta \quad 46.07$
Ethanel.
Ethylaleohel [64-175].
\# Dehydrated Aleohol contains not less than-99.2 pereent, by weight, correspending to not less than 99.5 pereent, by volume, at $15.56^{\circ}$, of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$.

Packaging and-storage Preserve in tight containers, remete frem fire.

## Identification-

A: Mix 5 drops in a small beaker with 1 mL of potassium per mangenate solution ( 1 in 100) and 5 dreps of 2 N sulfuric acid, and eover the beaker immediately with a filter paper moistened with a solution reeently prepared by dissolving 0.1 g of sodium nitrofer rieyanide and 0.25 g of piperazine in 5 mL of water: an intense blue eelor is produced on the filter paper, the color beeoming paler after a few minntes.

B: To 5 mL of a solution ( 1 i in 10) add 1 mL of 1.0 N sodium hydroxide, then slowly (over a period of 3 minutes) add 2 mL of 0.1 N iodine: the oder of iodoform develops, and a yellow precipi tate is formed within 30 mintutes.
Speeifie gravity $\langle 844\rangle$ : net more than 0.7962 at $15.56^{\circ}$, indieat ing not less than $99.2 \% \mathrm{Of}_{2} \mathrm{H}_{5} \mathrm{OH}$ by weight.
Aeidity $\mathrm{To}-50 \mathrm{~mL}$, in a glass stoppered flask, add 50 mL of reeently boiled water. Add phenolphthalein-TS, and titrate-with 0.020 N sodium hydroxide to a pink coler that persists for 30 sec ends: not more than 0.90 mL of 0.020 N sodium hydroxide is required for neutralization.
Limil of nonvolatile residte-Evaporate -40 mL in a arad dish on a water bath, and dry at $105^{\circ}$ for 1 heur: the weight of the residue does not exeed 1 mg .
Water insoluble substanees-Dilute it with an equal volume of water: the mixture is clear and remains clear for 30 minutes after eoting to $10^{\circ}$
Aldehydes and other foreign-organic substanees. Place 20 mL in a glass stoppered eylinder that has been thoroughly cleaned with hydrochloric acid, then rinsed with water and fanally with the De hydrated Alcohol to be tested. Cool the contents to approximately $15^{\circ}$, and add, by means of a carefully cleaned pipet, 0.10 mL of $\theta .10 \mathrm{~N}$ potassium permanganate, noting necurately the time of at dition. Mix at onee by inverting the stoppered eylinder, and allow it to stand at $15^{\circ}$ for 5 minntes: the pink color does not entirely dis аррепи.
Amylaleoholand nonvolatile, carbonizable substanees Allow 25 mL to evaporate spontaneously from a porcelain dish, carefully protected from dust, until the sufface of the dish is barely moist: ne red or brown color is produced immediately upen the addition of a few drops of sulfuric acid.
Utraviolet absorbanee-Record the UV absorption spectrumbetween 340 nm and 235 mm in a 1 cm cell, with water in a matehed eell in the reference beam: the absorbanee is not more than 0.08 at 240 nm , and 0.02 between 270 nm and 340 nm , and the curve drawn through these peints is smooth.
Limit of acetone and isopropylaleohol, To 1.0 mL add 1 mL of water, 1 mL of a saturated solution of dibasic sodimm phosphate, and $3-\mathrm{mL}$ of a saturated solation of petassium permanganate. Warm the mixture to $-45^{\circ}$ to $50^{\circ}$, and allow to stand until the per mangenate color is diseharged. 1 ddd 3 mL of 2.5 N sodimm hydrox ide, and fllter, without washing, through a sintered glass filter. Prepare a control containing 1 mL of the sattrated solution of dibasic sodium phosphate, 3 mL of 2.5 N sodium hydroxide, and 80 He of acetome in 9 mL . To each solution add 1 mL of furfural sotution ( 1 in 100 ), and allow to stand for 10 minntes, then $10-1.0 \mathrm{~mL}$ of each solution add $3-\mathrm{mL}$ of hydrochloric acid: any pink color produced in the test solution is not more intense than that in the eentrel.
Methanol To 1-drop add 1-drop-of water, 1 drep-of dilute phespheric acid ( 1 in 20 ), and 1 drep of potassium permanganate solution ( 1 in 20). Mix, allow to stand for 1 minnte, and add sodium metabisulfite solution ( 1 in 20), dropwise, until the permangn natecolor is diseharged. If abrown color remains, add 1 drop of the dilute phesphoric acid. To the colorless solution add 5 mL of fresh ly prepared chremetrepic acid TS, and heat on a water bath at $60^{\circ}$ for 10 mintutes: no violet coler appears.

## Dehydrated Alcohol

$$
\mathrm{H}_{3} \mathrm{C} \widehat{\mathrm{OH}}
$$

$\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O} \quad 46.07$

Ethanol.

Ethyl alcohol [64-17-5].

## " Dehydrated Alcohol contains not less than 99.2

 percent, by weight, corresponding to not less than
## 99.5 percent, by volume, at $15.56^{\circ}$, of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$.

Packaging and storage-Preserve in tight containers, protected from light. fremere freser

USP Reference standards $\langle 11\rangle$ —USP Dehydrated Alcohol RS.

Clarity of solution-[NOTE-The Test solution is to be compared to Reference suspension $A$ and to water in diffused daylight 5 minutes after preparation of Reference suspension A.]

Hydrazine solution-Transfer 1.0 g of hydrazine sulfate to a $100-\mathrm{mL}$ volumetric flask, dissolve in and dilute with water to volume, and mix. Allow to stand for 4 to 6 hours. Methenamine solution-Transfer 2.5 g of methenamine to a $100-\mathrm{mL}$ glass-stoppered flask, add 25.0 mL of water, insert the glass stopper, and mix to dissolve.

Primary opalescent suspension-[NOTE-This suspension is stable for 2 months, provided it is stored in a glass container free from surface defects. The suspension must not adhere to the glass and must be well mixed before use.] Transfer 25.0 mL of Hydrazine solution to the Methenamine solution in the $100-\mathrm{mL}$ glass-stoppered flask. Mix, and allow to stand for 24 hours.

Opalescence standard-[NOTE-This suspension should not be used beyond 24 hours after preparation.] Transfer 15.0 mL of the Primary opalescent suspension to a 1000mL volumetric flask, dilute with water to volume, and mix.

Reference suspensions-Transfer 5.0 mL of the Opalescence standard to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix to obtain Reference suspension A. Transfer 10.0 mL of the Opalescence standard to a second $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix to obtain Reference suspension B.

Test solution $A$-The substance to be examined.
Test solution B-Dilute 1.0 mL of Test solution $A$ to 20 mL with water, and allow to stand for 5 minutes before testing.

Procedure-Transfer a sufficient portion of Test solution $A$ and Test solution $B$ to separate test tubes of colorless, transparent, neutral glass with a flat base and an internal diameter of 15 to 25 mm to obtain a depth of 40 mm . Similarly transfer portions of Reference suspension A, Reference suspension $B$, and water to separate, matching test tubes. Compare Test solution A, Test solution B, Reference suspension $A$, Reference suspension $B$, and water in diffused daylight, viewing vertically against a black background (see Visual Comparison under Spectrophotometry and LightScattering $\langle 851\rangle$ ). [NOTE-The diffusion of light must be such that Reference suspension $A$ can readily be distinguished from water, and Reference suspension $B$ can readily be distinguished from Reference suspension A.] Test solution $A$ and Test solution $B$ show the same clarity as that of water, or their opalescence is not more pronounced than that of Reference suspension A.

## Color of solution-

Standard stock solution-Combine 3.0 mL ferric chloride CS, 3.0 mL cobaltous chloride CS, 2.4 mL cupric sulfate CS , and 1.6 mL dilute hydrochloric acid ( 10 g per L ).

Standard solution-[NOTE-Prepare the Standard solution immediately before use.] Transfer 1.0 mL of Standard stock solution to a $100-\mathrm{mL}$ volumetric flask, dilute with dilute hydrochloric acid ( 10 g per L ) to volume, and mix.

Test solution-The substance to be examined.
Procedure-Transfer a sufficient portion of the Test solution to a test tube of colorless, transparent, neutral glass with a flat base and an internal diameter of 15 to 25 mm to obtain a depth of 40 mm . Similarly transfer portions of Standard solution and water to separate matching test tubes. Compare the Test solution, Standard solution, and water in diffused daylight, viewing vertically against a white background (see Visual Comparison under Spectrophotometry and Light-Scattering $\langle 851\rangle$ ). The Test solution has the appearance of water or is not more intensely colored than the Standard solution.

## Identification-

A: It complies with the test for Specific gravity.
B: Infrared Absorption $\langle 197 \mathrm{~F}\rangle$ or $\langle 197 \mathrm{~S}\rangle$ neat.
Specific gravity $\langle 841\rangle$ : not more than 0.7962 at $15.56^{\circ}$, indicating not less than $99.2 \%$ of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$, by weight.

## Acidity or alkalinity-

Phenolphthalein solution-Dissolve 0.1 g of phenolphthalein in 80 mL of alcohol, and dilute with water to 100 mL .

Procedure-To 20 mL of alcohol, add 20 mL of freshly boiled and cooled water and 0.1 mL of Phenolphthalein solution. The solution is colorless. Add 1.0 mL of 0.01 N sodium hydroxide. The solution is pink ( 30 ppm , expressed as acetic acid).

Ultraviolet absorption-Record the UV absorption spectrum of the test material from 200 to 400 nm in a $1-\mathrm{em} 5$ cm cell: maximum absorbance 0.40 at $240 \mathrm{~nm}, 0.30$ between 250 and 260 nm , and 0.10 between 270 and 340
nm . Examine between 235 and 340 nm , in a $5-\mathrm{cm}$ cell, using water as the compensation liquid. The absorption curve is smooth.

## Volatile impurities-

Test solution $A$-The substance to be examined.
Test solution B—Add $150 \mu \mathrm{~L}$ of 4-methylpentan-2-ol to 500.0 mL of the substance to be examined.

Standard solution A-Dilute $100 \mu \mathrm{~L}$ of methanol to 50.0 mL with the substance to be examined. Dilute 5.0 mL of the solution to 50.0 mL with the substance to be examined.

Standard solution B-Dilute $50 \mu \mathrm{~L}$ of methanol and 50 $\mu \mathrm{L}$ of acetaldehyde to 50.0 mL with the substance to be examined. Dilute $100 \mu \mathrm{~L}$ of the solution to 10.0 mL with the substance to be examined.

Standard solution C-Dilute $150 \mu \mathrm{~L}$ of acetal to 50.0 mL with the substance to be examined. Dilute $100 \mu \mathrm{~L}$ of the solution to 10.0 mL with the substance to be examined.

Standard solution D-Dilute $100 \mu \mathrm{~L}$ of benzene to 100.0 mL with the substance to be examined. Dilute $100 \mu \mathrm{~L}$ of the solution to 50.0 mL with the substance to be examined.

Chromatographic system (see Chromatography $\langle 621\rangle$ )The gas chromatograph is equipped with a flame-ionization detector, maintained at about $280^{\circ}$, and a $0.32-\mathrm{mm} \times 30-\mathrm{m}$ fused silica capillary column bonded with a $1.8-\mu \mathrm{m}$ layer of phase G43. The carrier gas is helium with a linear velocity of about 35 cm per second and a split ratio of $1: 20$. The column temperature is maintained at $40^{\circ}$ for the first 12 minutes after an injection is made and is increased from $40^{\circ}$ to $240^{\circ}$ from 12 to 32 minutes after injection. During the period of 32 to 42 minutes after an injection is made the column temperature is maintained at $240^{\circ}$. The injection port temperature is maintained at $200^{\circ}$. Chromatograph Standard solution $B$, and record the peak responses as directed for

Procedure: the resolution, $R$, between the first major peak (acetaldehyde) and the second major peak (methanol) is not less than 1.5 .

Procedure-Separately inject equal volumes $(1.0 \mu \mathrm{~L})$ of Test solution A, Testion B Test solution B, Standard solution A, Standard solution C, and Standard solution $D$ into the chromatograph, record the chromatograms, and measure the major peaks. Calculate the concentration of methanol in Test solution A: not more than half the area of the corresponding peak in the chromatogram obtained with Standard solution $A$ ( 200 ppm ).
Calculate the sum of the contents of acetaldehyde and acetal, expressed as acetaldehyde, using the following formula:

$$
\left[\left(10 \times A_{E}\right) /\left(A_{T}-A_{E}\right)\right]+\left[\left(30 \times C_{E}\right) /\left(C_{T}-C_{E}\right)\right],
$$

in which $A_{E}$ is the area of the acetaldehyde peak in the chromatogram obtained with the Test solution $A ; A_{T}$ is the area of the acetaldehyde peak in the chromatogram obtained with Standard solution $B ; C_{E}$ is the area of the acetal peak in the chromatogram obtained with Test solution $A$; and $C_{T}$ is the area of the acetal peak in the chromatogram obtained with Standard solution $C$ : not more than 10 ppm , expressed as acetaldehyde is found.

Calculate the content of benzene using the following formula:

$$
\left(2 B_{E}\right) /\left(B_{T}-B_{E}\right),
$$

in which $B_{E}$ is the area of the benzene peak in the chromatogram obtained with Test solution $A$, and $B_{T}$ is the area of the benzene peak in the chromatogram obtained with Standard solution $D$ : not more than 2 ppm is found. If necessary, the
identity of benzene can be confirmed using another suitable chromatographic system (stationary phase with a different polarity).

The total of all other impurities in the chromatogram obtained with Test solution $B$ is not more than the area of the peak due to 4-methylpentan-2-ol in the chromatogram obtained with Test solution $B$ ( 300 ppm ). Disregard any peaks that are 0.03 times the area of the peak corresponding to $4-$ methylpentan-2-ol in the chromatogram obtained with Test solution $B(9 \mathrm{ppm})$.

Limit of nonvolatile residue-Evaporate 100 mL in a tared dish on a water bath, and dry at $100^{\circ}$ to $105^{\circ}$ for 1 hour: the weight of the residue does not exceed 2.5 mg . $\mathbf{n}^{2 S}$ (USP28)

## Briefing

Citric Acid, Anhydrous, page 677 of PF 30(2) [Mar.-Apr. 2004]. It is proposed to add Packaging and storage requirements.
(EMC: J. Lane; PSD: C. Okeke) RTS-41486-1

## Add the following:

## ©Citric Acid, Anhydrous Anhydrous Citric Acid

$\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7} \quad 192.13$

1,2,3-Propanetricarboxylic acid, 2-hydroxy-.
Citric acid [77-92-9].
» Anhydrous Citric Acid contains not less than 99.5 percent and not more than 100.5 percent of $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7}$, calculated on the anhydrous basis.

## Add the following:

-Packaging and storage-Preserve in tight containers. No storage requirements specified. ${ }^{2 S}$ (USP28)

Labeling-Where it is intended for use in dialysis solutions, it is so labeled. Where Anhydrous Citric Acid must be subjected to further processing during the preparation of injectable dosage forms to ensure acceptable levels of bacterial endotoxins, it is so labeled. Where Anhydrous Citric Acid is sterile, it is so labeled.

USP Reference standards $\langle 11\rangle$ —USP Citric Acid RS.
Clarity of solution-[NOTE-The Test solution is to be compared to Reference suspension $A$ in diffused daylight 5 minutes after preparation of Reference suspension A.]

Hydrazine sulfate solution-Transfer 1.0 g of hydrazine sulfate to a $100-\mathrm{mL}$ volumetric flask, dissolve in and dilute with water to volume, and mix. Allow to stand for 4 to 6 hours before use.

Hexamethylenetetramine solution Methenamine solu-tion-Transfer 2.5 g of Hexamethylenetetramine Methenamine to a $100-\mathrm{mL}$ glass-stoppered flask, add 25.0 mL of water, insert the glass stopper, and mix to dissolve.
Primary opalescent suspension-[NOTE-This suspension is stable for 2 months, provided it is stored in a glass container free from surface defects. The suspension must not adhere to the glass and must be well mixed before use.] Transfer 25.0 mL of Hydrazine sulfate solution to the Hex Methenamine solution in the $100-\mathrm{mL}$ glass-stoppered flask. Mix, and allow to stand for 24 hours.

Opalescence standard-[NOTE-This suspension should not be used beyond 24 hours after preparation.] Transfer 15.0 mL of the Primary opalescent suspension to a 1000 mL volumetric flask, dilute with water to volume, and mix.

Reference suspensions-Transfer 5.0 mL of the Opalescence standard to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix to obtain Reference suspension A. Transfer 10.0 mL of the Opalescence standard to a second $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix to obtain Reference suspension $B$.

Test solution-Dissolve 2.0 g of Anhydrous Citric Acid in about 5 mL of water, dilute with water to 10 mL , and mix.

Procedure-Transfer a sufficient portion of the Test solution to a test tube of colorless, transparent, neutral glass with a flat base and an internal diameter of 15 to 25 mm to obtain a depth of 40 mm . Similarly transfer portions of Reference suspension $A$, Reference suspension $B$, and water to separate matching test tubes. Compare the Test solution, Reference suspension $A$, Reference suspension $B$, and water in diffused daylight, viewing vertically against a black background (see Visual Comparison under Spectrophotometry and LightScattering $\langle 851\rangle$ ). [NOTE-The diffusion of light must be such that Reference suspension $A$ can readily be distinguished from water, and that Reference suspension $B$ can readily be distinguished from Reference suspension $A$.] The Test solution shows the same clarity as that of water.

## Color of solution-

Standard stock solutions-Prepare three solutions, $A, B$, and $C$, containing, respectively, the following parts of ferric chloride CS, cobaltous chloride CS, cupric sulfate CS, and dilute hydrochloric acid ( 10 g per L ):

$$
\begin{aligned}
& A-2.4: 0.6: 0: 7.0 \\
& B-2.4: 1.0: 0.4: 6.2 \\
& C-9.6: 0.2: 0.2: 0
\end{aligned}
$$

Standard solutions-[NOTE-Prepare the Standard solutions immediately before use.] Transfer 2.5 mL of Standard stock solution $A$ to a $100-\mathrm{mL}$ volumetric flask, dilute with dilute hydrochloric acid ( 10 g per L ) to volume, and mix to obtain Standard solution A. Transfer 2.5 mL of Standard stock solution $B$ to a $100-\mathrm{mL}$ volumetric flask, dilute with dilute hydrochloric acid ( 10 g per L ) to volume, and mix to obtain Standard solution B. Transfer 0.75 mL of Standard stock solution $C$ to a $100-\mathrm{mL}$ volumetric flask, dilute with dilute hydrochloric acid ( 10 g per L ) to volume, and mix to obtain Standard solution C.

Test solution-Use the Test solution prepared as directed in the test for Clarity of solution.

Procedure-Transfer a sufficient portion of the Test solution to a test tube of colorless, transparent, neutral glass with a flat base and an internal diameter of 15 to 25 mm to obtain a depth of 40 mm . Similarly transfer portions of Standard solution A, Standard solution B, and Standard solution C, and water to separate matching test tubes. Compare the Test solution, Standard solution A, Standard solution B, and Standard solution $C$, and water in diffused daylight, viewing vertically against a white background (see Visual Comparison under Spectrophotometry and Light-Scattering $\langle 851\rangle$ ). The Test solution is not more intensely colored than Standard solutions $A, B$, $C$, or water.

Identification, Infrared Absorption $\langle 197 \mathrm{~K}\rangle$-Dry the substance to be examined at $105^{\circ}$ for 2 hours.

Bacterial endotoxins $\langle 85\rangle$-If intended for use in the manufacturing of parenteral dosage forms, without a further appropriate procedtre for the removal of bacterial endetoxins, net mere that 0.5 I . U. of endetoxin per milligram. The level of bacterial endotoxins are such that the requirement under the relevant dosage form monograph(s) in which Anhydrous Citric Acid is used can be met. Where the label states that Anhydrous Citric Acid must be subjected to further process-
ing during the preparation of injectable dosage forms, the level of bacterial endotoxins are such that the requirement under the relevant dosage form monograph(s) in which Anhydrous Citric Acid is used can be met.

Sterility $\langle 71\rangle$ —Where the label states that Anhydrous Citric Acid is sterile, it meets the requirements for Sterility $\langle 71\rangle$ under the relevant dosage form monograph(s) in which Anhydrous Citric Acid is used.

Water, Method I $\langle 921\rangle$ : not more than $1.0 \%$.
Residue on ignition $\langle 281\rangle$ : not more than $0.1 \%$, determined on 1.0 g .

Readily carbonizable substances-Transfer 1.0 g of powdered Anhydrous Citric Acid to a $22-\times 175-\mathrm{mm}$ test tube previously rinsed with 10 mL of sulfuric acid TS and allowed to drain for 10 minutes. Add 10 mL of sulfuric acid TS, agitate until solution is complete, and immerse in a water bath at $90 \pm 1^{\circ}$ for $60 \pm 0.5$ minutes, keeping the level of the acid below the level of the water during the entire period. Cool the tube in running water, and transfer the acid to a color-comparison tube: the color of the acid is not darker than that of a similar volume of Matching Fluid K (see Color and Achromicity $\langle 631\rangle$ ) in a matching tube, the tubes being observed vertically against a white background.

## Sulfate-

Standard sulfate solution A-To 181 mg of dibasic potassium sulfate in a $100-\mathrm{mL}$ volumetric flask, add a few mL of 30 percent alcohol, swirl to dissolve, dilute with 30 percent alcohol to volume, and mix. Immediately before use, transfer 10.0 mL of this solution to a $1000-\mathrm{mL}$ volumetric flask, dilute with 30 percent alcohol to volume, and mix. This solution contains $10 \mu \mathrm{~g}$ of sulfate per mL .

Standard sulfate solution B-To 181 mg of dibasic potassium sulfate in a $100-\mathrm{mL}$ volumetric flask, add a few mL of water, swirl to dissolve, dilute with water to volume, and mix. Immediately before use, transfer 10.0 mL of this solu-
tion to a $1000-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. This solution contains $10 \mu \mathrm{~g}$ of sulfate per mL.

Citric acid solution-Dissolve 2.0 g of Anhydrous Citric Acid in about 10 mL of water, dilute with water to 30 mL , and mix.

Procedure-To 4.5 mL of Standard sulfate solution $A$ add 3 mL of a barium chloride solution (1 in 4), shake, and allow to stand for 1 minute. To 2.5 mL of the resulting suspension, add 15 mL of the Citric acid solution and 0.5 mL of 5 N acetic acid, and mix (test solution). Prepare the Standard solution in the same manner, except use 15 mL of Standard sulfate solution B instead of the Citric acid solution: any turbidity produced in the test solution after 5 minutes standing is not greater than that produced in the Standard solution (0.015\%).

Heavy metals $\langle 231\rangle$ : $0.001 \%$.
Limit of oxalic acid-Prepare a citric acid solution by dissolving 800 mg of Anhydrous Citric Acid in 4 mL of water. Add 3 mL of hydrochloric acid and 1 g of granular zinc, boil for 1 minute, and allow to stand for 2 minutes. Transfer the supernatant to a test tube containing 0.25 mL of a phenylhydrazine hydrochloride solution (1 in 100), and heat to boiling. Cool rapidly, transfer to a graduated cylinder, and add an equal volume of hydrochloric acid and 0.25 mL of a potassium ferricyanide solution (1 in 20). Shake, and allow to stand for 30 minutes (test solution). Concomitantly prepare a control solution in the same manner, except use 4 mL of an oxalic acid solution containing 0.10 mg per mL , equivalent to 0.0714 mg of anhydrous oxalic acid per mL , instead of the citric acid solution: any pink color produced in the test solution is not more intense than that produced in the control solution ( $0.036 \%$ ).

Limit of aluminum (where it is labeled as intended for use in dialysis)-

Standard aluminum solution-To 352 mg of aluminum potassium sulfate in a $100-\mathrm{mL}$ volumetric flask, add a few mL of water, swirl to dissolve, add 10 mL of diluted sulfuric acid, dilute with water to volume, and mix. Immediately before use, transfer 1.0 mL of this solution to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix.
pH 6.0 Acetate buffer-Dissolve 50 g of ammonium acetate in 150 mL of water, adjust with glacial acetic acid to a pH of 6.0 , dilute with water to 250 mL , and mix.

Test solution-Dissolve 20.0 g of Anhydrous Citric Acid in 100 mL of water, and add 10 mL of pH 6.0 Acetate buffer. Extract this solution with successive portions of 20, 20, and 10 mL of a $0.5 \%$ solution of 8 -hydroxyquinoline in chloroform, combining the chloroform extracts in a $50-\mathrm{mL}$ volumetric flask. Dilute the combined extracts with chloroform to volume, and mix.

Standard solution-Prepare a mixture of 2.0 mL of Standard aluminum solution, 10 mL of pH 6.0 Acetate buffer, and 98 mL of water. Extract this mixture as described for the Test solution, dilute the combined extracts with chloroform to volume, and mix.

Blank solution-Prepare a mixture of 10 mL of pH 6.0 Acetate buffer and 100 mL of water. Extract this mixture as described for the Test solution, dilute the combined extracts with chloroform to volume, and mix.

Procedure-Determine the fluorescence intensities of the Test solution and the Standard solution in a fluorometer set at an excitation wavelength of 392 nm and an emission wavelength of 518 nm , using the Blank solution to set the instrument to zero. The fluorescence of the Test solution does not exceed that of the Standard solution $(0.2 \mu \mathrm{~g} \mathrm{per} \mathrm{g})$. Organic volatile impurities, Method IV $\langle 467\rangle$ : meets the requirements.

Assay—Place about 0.550 g of Anhydrous Citric Acid in a tared flask, and weigh accurately. Dissolve in 50 mL of water, add 0.5 mL of phenolphthalein TS, and titrate with 1 N sodium hydroxide VS. Each mL of 1 N sodium hydroxide is equivalent to 64.03 mg of $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7 \cdot \mathbf{\Delta U S P 2 8}}$

## BRIEFING

Citric Acid Monohydrate, page 681 of PF 30(2) [Mar.-Apr. 2004]. It is proposed to add Packaging and storage requirements.
(EMC: J. Lane; PSD: C. Okeke) RTS-41486-2

## Add the following:

## ©Citric Acid Monohydrate

$\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7} \cdot \mathrm{H}_{2} \mathrm{O} \quad 210.14$

1,2,3-Propanetricarboxylic acid, 2-hydroxy-, monohydrate [5949-29-1].
» Citric Acid Monohydrate contains one molecule of water of hydration. It contains not less than 99.5 percent and not more than 100.5 percent of $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7}$, calculated on the anhydrous basis.

## Add the following:

■Packaging and storage-Preserve in tight containers. No storage requirements specified.■2S (USP28)

Labeling-Where it is intended for use in dialysis solutions, it is so labeled. Where Citric Acid Monohydrate must be subjected to further processing during the preparation of injectable dosage forms to ensure acceptable levels of bacterial endotoxins, it is so labeled. Where Citric Acid Monohydrate is sterile, it is so labeled.

USP Reference standards $\langle 11\rangle-U S P$ Citric Acid $R S$.
Clarity of solution-[NOTE-The Test solution is to be compared to Reference suspension $A$ in diffused daylight 5 minutes after preparation of Reference suspension $A$.]

Hydrazine sulfate solution-Transfer 1.0 g of hydrazine sulfate to a $100-\mathrm{mL}$ volumetric flask, dissolve in and dilute with water to volume, and mix. Allow to stand for 4 to 6 hours before use.

Methenamine solution-Transfer 2.5 g of methenamine to a $100-\mathrm{mL}$ glass-stoppered flask, add 25.0 mL of water, insert the glass stopper, and mix to dissolve.

Primary opalescent suspension-[NOTE-This suspension is stable for 2 months, provided it is stored in a glass container free from surface defects. The suspension must not adhere to the glass and must be well mixed before use.] Transfer 25.0 mL of Hydrazine sulfate solution to the Me thenamine solution in the $100-\mathrm{mL}$ glass-stoppered flask. Mix, and allow to stand for 24 hours.

Opalescence standard-[NOTE—This suspension should not be used beyond 24 hours after preparation.] Transfer 15.0 mL of the Primary opalescent suspension to a 1000 mL volumetric flask, dilute with water to volume, and mix.

Reference suspensions-Transfer 5.0 mL of the Opalescence standard to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix to obtain Reference suspension
A. Transfer 10.0 mL of the Opalescence standard to a second $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix to obtain Reference suspension $B$.

Test solution-Dissolve 2.0 g of Citric Acid Monohydrate in about 5 mL of water, dilute with water to 10 mL , and mix.

Procedure-Transfer a sufficient portion of the Test solution to a test tube of colorless, transparent, neutral glass with a flat base and an internal diameter of 15 to 25 mm to obtain a depth of 40 mm . Similarly transfer portions of Reference suspension $A$, Reference suspension $B$, and water to separate matching test tubes. Compare the Test solution, Reference suspension $A$, Reference suspension $B$, and water in diffused daylight, viewing vertically against a black background (see Visual Comparison under Spectrophotometry and LightScattering $\langle 851\rangle$ ). [NOTE-The diffusion of light must be such that Reference suspension $A$ can readily be distinguished from water, and that Reference suspension $B$ can readily be distinguished from Reference suspension $A$.] The Test solution shows the same clarity as that of water.

## Color of solution-

Standard stock solutions-Prepare three solutions, $A, B$, and $C$, containing, respectively, the following parts of ferric chloride CS, cobaltous chloride CS, cupric sulfate CS , and dilute hydrochloric acid ( 10 g per L ):

$$
\begin{aligned}
& A-2.4: 0.6: 0: 7.0 \\
& B-2.4: 1.0: 0.4: 6.2 \\
& C-9.6: 0.2: 0.2: 0
\end{aligned}
$$

Test solution-Use the Test solution prepared in the Clarity of solution test.

Procedure-Transfer a sufficient portion of the Test solution to a test tube of colorless, transparent, neutral glass with a flat base and an internal diameter of 15 to 25 mm to obtain a depth of 40 mm . Similarly transfer portions of Standard solution A, Standard solution B, and Standard solution C, and water to separate matching test tubes. Compare the Test
solution, Standard solution A, Standard solution B, Standard solution $C$, and water in diffused daylight, viewing vertically against a white background (see Visual Comparison under Spectrophotometry and Light-Scattering $\langle 851\rangle$ ). The Test solution is not more intensely colored than Standard solutions $A, B$, $C$ or water.

Identification, Infrared Absorption $\langle 197 \mathrm{~K}\rangle$ — Dry the substance to be examined at $105^{\circ}$ for 2 hours.

Bacterial endotoxins $\langle 85\rangle$-If intended for use in the manufacturing of parenteral dosage forms, witheut a futher appropriate procedure for the removal of bacterial endotoxins, not more that 0.5 IU . of endotoxin per milligram. The level of bacterial endotoxins is such that the requirement under the relevant dosage form monograph(s) in which Citric Acid Monohydrate is used can be met. Where the label states that Citric Acid Monohydrate must be subjected to further processing during the preparation of injectable dosage forms, the level of bacterial endotoxins is such that the requirement under the relevant dosage form monograph(s) in which Citric Acid Monohydrate is used can be met.

Sterility $\langle 71\rangle$-Where the label states that Citric Acid Monohydrate is sterile, it meets the requirements for Sterility $\langle 71\rangle$, under the relevant dosage form monograph(s) in which Citric Acid Monohydrate is used.

Water, Method I $\langle 921\rangle$ : between $7.5 \%$ and $9.0 \%$.
Residue on ignition $\langle 281\rangle$ : not more than $0.1 \%$, determined on 1.0 g .

Readily carbonizable substances-Transfer 1.0 g of powdered Citric Acid Monohydrate, to a $22-\times 175-\mathrm{mm}$ test tube previously rinsed with 10 mL of sulfuric acid TS , and allow to drain for 10 minutes. Add 10 mL of sulfuric acid TS, agitate until solution is complete, and immerse in a water bath at $90 \pm 1^{\circ}$ for $60 \pm 0.5$ minutes, keeping the level of the acid below the level of the water during the entire period. Cool the tube in running water, and transfer the
acid to a color-comparison tube: the color of the acid is not darker than that of a similar volume of Matching Fluid K (see Color and Achromicity $\langle 631\rangle$ ) in a matching tube, the tubes being observed vertically against a white background.

## Sulfate-

Standard sulfate solution A-To 181 mg of dibasic potassium sulfate in a $100-\mathrm{mL}$ volumetric flask, add a few mL of 30 percent alcohol, swirl to dissolve, dilute with 30 percent alcohol to volume, and mix. Immediately before use, transfer 10.0 mL of this solution to a $1000-\mathrm{mL}$ volumetric flask, dilute with 30 percent alcohol to volume, and mix. This solution contains $10 \mu \mathrm{~g}$ of sulfate per mL .

Standard sulfate solution B-To 181 mg of dibasic potassium sulfate in a $100-\mathrm{mL}$ volumetric flask, add a few mL of water, swirl to dissolve, dilute with water to volume, and mix. Immediately before use, transfer 10.0 mL of this solution to a $1000-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. This solution contains $10 \mu \mathrm{~g}$ of sulfate per mL .

Citric acid solution-Dissolve 2.0 g of Citric Acid Monohydrate in about 10 mL of water, dilute with water to 30 mL , and mix.

Procedure-To 4.5 mL of Standard sulfate solution $A$ add 3 mL of a barium chloride solution (1 in 4), shake, and allow to stand for 1 minute. To 2.5 mL of the resulting suspension, add 15 mL of the Citric acid solution and 0.5 mL of 5 N acetic acid, and mix (test solution). Prepare the Standard solution in the same manner, except use 15 mL of Standard sulfate solution B instead of the Citric acid solution: any turbidity produced in the test solution after 5 minutes standing is not greater than that produced in the Standard solution (0.015\%).

Heavy metals $\langle 231\rangle$ : $0.001 \%$.

Limit of oxalic acid—Prepare a citric acid solution by dissolving 800 mg of Citric Acid Monohydrate in 4 mL of water. Add 3 mL of hydrochloric acid and 1 g of granular zinc, boil for 1 minute, and allow to stand for 2 minutes. Transfer the supernatant to a test tube containing 0.25 mL of a phenylhydrazine hydrochloride solution (1 in 100), and heat to boiling. Cool rapidly, transfer to a graduated cylinder, and add an equal volume of hydrochloric acid and 0.25 mL of a potassium ferricyanide solution (1 in 20). Shake, and allow to stand for 30 minutes (test solution). Concomitantly prepare a control solution in the same manner, except use 4 mL of an oxalic acid solution containing 0.10 mg per mL , equivalent to 0.0714 mg of anhydrous oxalic acid per mL , instead of the citric acid solution: any pink color produced in the test solution is not more intense than that produced in the control solution ( $0.036 \%$ ).

Limit of aluminum (where it is labeled as intended for use in dialysis)-

Standard aluminum solution-To 352 mg of aluminum potassium sulfate in a $100-\mathrm{mL}$ volumetric flask, add a few mL of water, swirl to dissolve, add 10 mL of diluted sulfuric acid, dilute with water to volume, and mix. Immediately before use, transfer 1.0 mL of this solution to a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix.
pH 6.0 Acetate buffer-Dissolve 50 g of ammonium acetate in 150 mL of water, adjust with glacial acetic acid to a pH of 6.0 , dilute with water to 250 mL , and mix.

Test solution-Dissolve 20.0 g of Citric Acid Monohydrate in 100 mL of water, and add 10 mL of pH 6.0 Acetate buffer. Extract this solution with successive portions of 20, 20 , and 10 mL of a $0.5 \%$ solution of 8 -hydroxyquinoline in chloroform, combining the chloroform extracts in a $50-\mathrm{mL}$ volumetric flask. Dilute the combined extracts with chloroform to volume, and mix.

Standard solution-Prepare a mixture of 2.0 mL of Standard aluminum solution, 10 mL of pH 6.0 Acetate buffer, and 98 mL of water. Extract this mixture as described for the Test solution, dilute the combined extracts with chloroform to volume, and mix.
Blank solution-Prepare a mixture of 10 mL of pH 6.0 Acetate buffer and 100 mL of water. Extract this mixture as described for the Test solution, dilute the combined extracts with chloroform to volume, and mix.

Procedure-Determine the fluorescence intensities of the Test solution and the Standard solution in a fluorometer set at an excitation wavelength of 392 nm and an emission wavelength of 518 nm , using the Blank solution to set the instrument to zero. The fluorescence of the Test solution does not exceed that of the Standard solution ( $0.2 \mu \mathrm{~g}$ per g ). Assay—Place about 0.550 g of Citric Acid Monohydrate in a tared flask, and weigh accurately. Dissolve in 50 mL of water, add 0.5 mL of phenolphthalein TS, and titrate with 1 N sodium hydroxide VS. Each mL of 1 N sodium hydroxide is equivalent to 64.03 mg of $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7 \cdot \Delta}$ USP28

## Briefing

Talc, USP 27 page 1764. The European Pharmacopoeia is the coordinating pharmacopeia for the international harmonization of the compendial standards for the Talc monograph, as part of the process of international harmonization of monographs and general analytical methods of the European, Japanese, and United States pharmacopeias. The following monograph, which represents the ADOPTION STAGE 6 document, is based on the corresponding monograph for Talc that was prepared by the European Pharmacopoeia. The European Pharmacopoeia draft was based in part on comments from the Japanese Pharmacopoeia and the United States Pharmacopeia in response to the Provisional Harmonized Text Stage 5A and 5B drafts prepared by the European Pharmacopoeia.

* In USP, this section will be included under "Absence of asbestos."

Legend: + will adopt and implement; - will not stipulate.
Nonharmonized attributes: Characters, Water-soluble substances, Labeling, Microbial contamination, Packaging and storage.

Specific local attributes:
Acid-soluble substances, Arsenic (JP).
Identification B and C (USP).
Reagents and reference materials: Each pharmacopeia will adapt the text to take account of local reference substances and spectra and reagent specifications.

Proposed changes from the current $U S P$ monograph include the following:

1. Definition-A more detailed definition that includes the predominant minerals in Talc is used.
2. Packaging and storage-No change.
3. Labeling-A requirement that the labeling indicate its suitability for oral or topical administration is added. A requirement that the labeling indicate the absence of asbestos is also added.
4. Identification-Tests for Infrared absorption and silicates are added.
5. Microbial limits-Requirements are added for topical and oral administration.
6. Acidity and alkalinity-This test is added to better characterize the article.
7. Loss on ignition-The ignition temperature and limit are increased to comply with EP standards.
8. Acid-soluble substances-This test is omitted. Tests for calcium, aluminum, and magnesium are added to strengthen the monograph.
9. Reaction and soluble substances-This test is renamed as Wa-ter-soluble substances.
10. Water-soluble substances-Previously named Reaction and soluble substances.
11. Water-soluble iron-This test is replaced with a quantitative procedure.
12. Limit of iron-This test replaces the previous Water-soluble iron test.
13. Arsenic, Heavy metals, and Lead-This test is replaced with tests for Limit of lead and Limit of aluminum.
14. Absence of asbestos-This section is added to ensure that the article does not contain asbestos. Talc derived from deposits that are known to contain associated asbestos is not suitable for pharmaceutical use.
15. Content of magnesium-This test is added to quantify the major components of Talc.
(EMC: J. Lane; AMB: D. Porter) RTS-41405-1

## Change to read:

## Fate

H-Tale is a native, hydreus magnesitm- silicate, sometimes containing a small propertion of aluminum silieate.

Packaging and-storage-Preserve in well closed containers.
Identification Mix abut 200 mg of anhydrous sodium carbenate with 2 g of anhydrous potassium carbonate, and melt in a plat inum crueible. To the melt add 100 me of the substance under test, and continte heating until fusion is complete. Cool, and transfer the fused mixture to a dish or beaker with the aid-of about 50 mL of hot water. Add hydrechloric acid to the liquid until efferveseence ceases, then add 10 mL more of the acid, and evaporate the mixture on a stem bath to dryness. Cool, add 20 mL of water, boil, and filter the mixture: an insoluble residue of siliea remains. Dissolve in the filtrate about 2 g of ammenimm chloride, and add 5 mL of 6 N ammonimm hydroxide. Filter, if neessary, and add dibasie sodium phesphate TS to the filtrate: a white, crystalline precipitate of magnesitm ammenitm phesphate separates.
Mierobial limits- $\langle 64\rangle$-The total-bacterial count does not exceed 500 per है.
Loss-on ignition- $\langle 733$ ) Weigh neeurately about 1 g and ignite at $1000^{\circ}$ to constant weight: it loses net more than $6.5 \%$ of its weight.
Acid-soluble-substanees-Digest 1.00 s with 20 mL of 3 N hy drochloric acid at $50^{\circ}$ for 15 mintutes, add water to restore the orig inal volume, mix, and filter. To 10 mL of the filtrate add 1 mL of 2 N sulfuric acid, evaporate to dryness, and ignite to constant weight: the weight of the residue does not exeed 10 mg ( $2.0 \%$ ).
Reaction and soluble substanees-Beil 10 g with 50 mL of water for 30 minutes, adding water from time to time omaintain apprex imately the original volume, and filter: the filtrate is neutral to lit mus paper. Evaperate one half of the filtrate to drymess, and dry at $105^{\circ}$ for 1 hour: the weight of the residue does not exceed 5 mg ( $0.1 \%$ ).
Water-soluble iren Slightly acidify with hydrechloric acid the remaining half of the filtrate obtained in the test for Reaction and soluble substanes, and add 1 mL of potassitm ferrecyanide TS: the liquid does not aequire a blue color.

## Arsenie, Heary metals, andHead-

Test solution Transfer 10.0 s a 250 mL flack, and add 50 mL of 0.5 N hydrechloric acid. Attach a reflux eondenser to the flask, heat on a steam bath for 30 minutes, cool, transfer the mixture to a beaker, and allow the undissolved material to settle. Deeant the st pernatant liquid through thick, strong, medium-speed flter paper into 100 mL volumetric flask, retrining as mueh as possible of the insoluble material in the beaker. Wash the slury and beaker with three 10 mL pertions of het water, deennting each washing threugh the filter into the flask. Finally, wash the fllter paper with 15 mL of het water, cool the filtrate to room temperature, dilute with water to volume, and mix. Use this Test solution for the fot fowing tests.

Arsenic, Method $I\langle z 14\rangle$-Use 10 mL of the Test soldtion in preparing the Test Preparation. The limit is 3 ppm.

Heary metals- $\langle 234\rangle$-Use 5 mL of the Test solution in preparing the Test Prepatation. The limit is $0.004 \%$.

Leat $\langle 254\rangle$ - 45 mL pertion of the Test solution contains net
mere than 5 4ig of lead $(0.001 \%)$.

## ■Talc

» Talc is a powdered, selected, natural, hydrated magnesium silicate. Pure talc has the formula $\mathrm{Mg}_{3} \mathrm{Si}_{4} \mathrm{O}_{10}(\mathrm{OH})_{2}$. It may contain variable amounts of associated minerals among which chlorites (hydrated aluminum and magnesium silicates), magnesite (magnesium carbonate), calcite (calcium carbonate), and dolomite (calcium and magnesium carbonate) are predominant.

Packaging and storage-Preserve in well-closed containers.

Labeling-The label states, where applicable, that the substance is suitable for oral or topical administration. The certificate of analysis states the absence of asbestos. It also indicates which method specified under the test for Absence of asbestos was used for analysis.

## Identification-

A: The IR spectrum of a potassium bromide dispersion of it exhibits maxima at $3677 \pm 2 \mathrm{~cm}^{-1}$, at $1018 \pm 2 \mathrm{~cm}^{-1}$, and at $669 \pm 2 \mathrm{~cm}^{-1}$.

B: Mix about 200 mg of anhydrous sodium carbonate with 2 g of anhydrous potassium carbonate, and melt in a platinum crucible. To the melt add 100 mg of the substance under test, and continue heating until fusion is complete. Cool, and transfer the fused mixture to a dish or beaker with the aid of about 50 mL of hot water. Add hydrochloric acid to the liquid until effervescence ceases, then add 10 mL
more of the acid, and evaporate the mixture on a steam bath to dryness. Cool, add 20 mL of water, boil, and filter the mixture: [NOTE-Save the insoluble residue for use in Identification test C.] To 5 mL of the filtrate add 1 mL of 6 N ammonium hydroxide and 1 mL of ammonium chloride TS. Filter, if necessary, and add 1 mL of dibasic sodium phosphate TS to the filtrate: a white crystalline precipitate of magnesium ammonium phosphate is formed.

C: In a lead or platinum crucible and using a copper wire, mix about 100 mg of the insoluble residue as obtained in Identification test $B$ with about 10 mg of sodium fluoride and a few drops of sulfuric acid to give a thin slurry. Cover the crucible with a thin transparent plate of plastic under which a drop of water is suspended, and warm gently. Within a short time, a white ring is rapidly formed around the drop of water.

Microbial limits $\langle 61\rangle$-If intended for topical administration, the total aerobic microbial count does not exceed 100 cfu per g , and the total combined molds and yeasts count does not exceed 50 cfu per g . If intended for oral administration, the total aerobic microbial count does not exceed 1000 cfu per $g$, and the total combined molds and yeasts count does not exceed 100 cfu per $g$.

Acidity and alkalinity-Boil 2.5 g of talc with 50 mL of carbon dioxide-free water under reflux. Filter under vaccum. To 10 mL of the filtrate, add 0.1 mL of bromothymol blue TS. Not more than 0.4 mL of 0.01 N hydrochloric acid is required to change the color of the indicator. To 10 mL of the filtrate, add 0.1 mL of phenolphthalein TS: not more than 0.3 mL of 0.01 N sodium hydroxide is required to change the color of the indicator to pink.

Loss on ignition $\langle 733\rangle$-Weigh accurately about 1 g and ignite at $1075 \pm 25^{\circ}$ to constant weight: it loses not more than $7.0 \%$ of its weight.

Water-soluble substances-To 10.0 g add 50 mL of carbon dioxide-free water, heat to boiling, and boil under a reflux condenser for 30 minutes. Allow to cool, filter, and dilute to 50.0 mL with carbon dioxide-free water: the filtrate is neutral to litmus paper. Evaporate 25.0 mL of the filtrate to dryness, and dry at $105^{\circ}$ for 1 hour: the weight of the residue does not exceed $5 \mathrm{mg}(0.1 \%)$.

## Limit of iron-

Test stock solution-Weigh 10.0 g of Talc into a conical flask fitted with a reflux condenser, gradually add 50 mL of 0.5 N hydrochloric acid while stirring, and heat on a water bath for 30 minutes. Allow to cool. Transfer the mixture to a beaker, and allow the undissolved material to settle. Filter the supernatant into a $100-\mathrm{mL}$ volumetric flask, retaining as much as possible of the insoluble material in the beaker. Wash the residue and the beaker with three $10-\mathrm{mL}$ portions of hot water. Wash the filter with 15 mL of hot water, allow the filtrate to cool, and dilute with water to 100.0 mL .

Test solution- Transfer 2.5 mL of the Test stock solution to a $100-\mathrm{mL}$ volumetric flask, add 50.0 mL of 0.5 N hydrochloric acid, and dilute with water to volume.
Standard iron stock solution- Transfer 863.4 mg of ferric ammonium sulfate to a $100-\mathrm{mL}$ volumetric flask, dissolve in water, add 10 mL of 2 N sulfuric acid, and dilute with water to volume. Pipet 25 mL of this solution into a $100-\mathrm{mL}$ volumetric flask, add 10 mL of 2 N sulfuric acid, dilute with water to volume, and mix. This solution contains the equivalent of $250 \mu \mathrm{~g}$ of iron per mL .

Standard iron solutions-Into four $100-\mathrm{mL}$ volumetric flasks, each containing 50.0 mL of 0.5 N hydrochloric acid, transfer respectively $2.0,2.5,3.0$, and 4.0 mL of the Standard iron stock solution, and dilute each flask with water to volume.

Procedure-Concomitantly determine the absorbance of the Test solution and the Standard iron solutions at the iron emission line of 248.3 nm with an atomic absorption spectrophotometer (see Spectrophotometry and Light-Scattering $\langle 851\rangle$ ) equipped with an iron hollow-cathode lamp and an air-acetylene flame. Make any correction using a deuterium lamp: not more than $0.25 \%$ of iron is found.

## Limit of lead-

Test solution-Use the Test stock solution, prepared as directed in the test for Limit of iron.

Lead standard stock solution-Dissolve 160 mg of lead nitrate in 100 mL water that contains 1 mL of nitric acid, and dilute with water to 1000 mL . Pipet 10 mL of this solution into a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. This solution contains the equivalent of $10 \mu \mathrm{~g}$ of lead per mL .

Lead standard solutions-Into four identical $100-\mathrm{mL}$ volumetric flasks, each containing 50.0 mL of 0.5 N hydrochloric acid transfer respectively $5.0,7.5,10.0$, and 12.5 mL of Lead standard stock solution, and dilute with water to volume.

Procedure-Concomitantly determine the absorbance of the Test solution and the Standard lead solutions at the lead emission line of 217.0 nm with an atomic absorption spectrophotometer (see Spectrophotometry and Light-Scattering $\langle 851\rangle$ ) equipped with a lead hollow-cathode lamp and an air-acetylene flame: not more than $0.001 \%$ of lead is found.

## Limit of calcium-

Cesium chloride solution-Dissolve 2.53 g of cesium chloride in 100 mL of water, and mix.
Lanthanum chloride solution-To 5.9 g of lanthanum oxide slowly add 10 mL of hydrochloric acid, and heat to boiling. Allow to cool, and dilute with water to 100 mL .

Test stock solution-[Caution-Perchlorates mixed with heavy metals are known to be explosive. Take proper precautions while performing this procedure.] Weigh 500 mg of Talc in a $100-\mathrm{mL}$ polytetrafluoroethylene dish, add 5 mL of hydrochloric acid, 5 mL of lead-free nitric acid, and 5 mL of perchloric acid. Stir gently, then add 35 mL of hydrofluoric acid, and evaporate slowly on a hot plate to moist dryness (until about 0.5 mL remains). To the residue, add 5 mL of hydrochloric acid, cover with a watch glass, heat to boiling, and allow to cool. Rinse the watch glass and the dish with water, and transfer into a $50-\mathrm{mL}$ volumetric flask containing 5 mL of the Cesium chloride solution. Rinse the dish again with water, and dilute with water to volume.

Test solution-Transfer 5.0 mL of the Test stock solution to a $100-\mathrm{mL}$ volumetric flask, add 10.0 mL of hydrochloric acid and 10 mL of Lanthanum chloride solution, and dilute with water to volume.

Calcium standard stock solution-Dissolve 3.67 g of calcium chloride dihydrate in diluted hydrochloric acid, and dilute with the same solvent to 1000 mL . Immediately before use, pipet 10 mL of this solution into a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. This solution contains the equivalent of $100 \mu \mathrm{~g}$ of calcium per mL .

Calcium standard solutions-Into four identical 100-mL volumetric flasks, each containing 10.0 mL of hydrochloric acid and 10 mL of Lanthanum chloride solution, transfer respectively $1.0,2.0,3.0$, and 4.0 mL of Calcium standard stock solution, and dilute each flask with water to volume.

Procedure-Concomitantly determine the absorbance of the Test solution and the Standard calcium solutions at the calcium emission line of 422.7 nm with an atomic absorption spectrophotometer (see Spectrophotometry and LightScattering $\langle 851\rangle$ ) equipped with a calcium hollow-cathode lamp and a nitrous oxide-acetylene flame: not more than $0.9 \%$ of calcium is found.

## Limit of aluminum-

Cesium chloride solution and Test stock solution-Proceed as directed in the test for Limit of calcium.

Test solution-Transfer 5.0 mL of the Test stock solution to a $100-\mathrm{mL}$ volumetric flask, add 10 mL of the Cesium chloride solution and 10.0 mL of hydrochloric acid, and dilute with water to volume.

Aluminum standard stock solution- Dissolve 8.947 g of aluminum chloride in water, and dilute with water to 1000 mL . Immediately before use, pipet 10 mL of this solution into a $100-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. This solution contains the equivalent of $100 \mu \mathrm{~g}$ of aluminum per mL.

Standard aluminum solutions-Into four identical 100mL volumetric flasks, each containing 10.0 mL of hydrochloric acid and 10 mL of Cesium chloride solution, transfer respectively $5.0,10.0,15.0$, and 20.0 mL of Aluminum standard stock solution, and dilute with water to volume.

Procedure-Concomitantly determine the absorbance of the Test solution and the Standard aluminum solutions at the aluminum emission line of 309.3 nm with an atomic absorption spectrophotometer (see Spectrophotometry and Light-Scattering $\langle 851\rangle$ ) equipped with an aluminum hol-low-cathode lamp and a nitrous oxide-acetylene flame: not more than $2.0 \%$ of aluminum is found.

Absence of asbestos- [NOTE-Suppliers of Talc may use one of the following methods to determine the absence of asbestos.] Proceed as directed for test $A$ or test $B$. If either test is positive, perform test $C$.

A: The IR absorption spectrum of a potassium bromide dispersion of it at the absorption band at $758 \pm 1 \mathrm{~cm}^{-1}$, using scale expansion, may indicate the presence of tremolite or of chlorite. If the absorption band remains after ignition of the substance at $850^{\circ}$ for at least 30 minutes, it indicates
the presence of the tremolite. In the range $600 \mathrm{~cm}^{-1}$ to 650 $\mathrm{cm}^{-1}$ using scale expansion, any absorption band or shoulder may indicate the presence of serpentines.

B: X-ray diffraction $\langle 941\rangle$ employing the following conditions: $\mathrm{Cu} \mathrm{K} \alpha$ monochromatic 40 kV radiation, 24 mA to 30 mA ; the incident slit is set at $1^{\circ}$; the detection slit is set at $0.2^{\circ}$; the goniometer speed is $1 / 10^{\circ} 2 \Theta$ per minute; the scanning range is $10^{\circ}$ to $13^{\circ} 2 \Theta$ and $24^{\circ}$ to $26^{\circ} 2 \Theta$; the sample is not oriented. Prepare a random sample, and place on the sample holder. Pack and smooth its surface with a polished glass microscope slide. Record the diffractograms: the presence of amphiboles is detected by a diffraction peak at $10.5 \pm 0.1^{\circ} 2 \Theta$, and the presence of serpentines is detected by diffraction peaks at $24.3 \pm 0.1^{\circ} 2 \Theta$ to $12.1 \pm 0.1^{\circ}$ $2 \Theta$.

C: The presence of asbestos (see Optical Microscopy $\langle 776\rangle$ ) is shown if there is a range of length to width ratios of $20: 1$ to $100: 1$, or higher for fibers longer than $5 \mu \mathrm{~m}$; if there is a capability of splitting into very thin fibrils; and if there are two or more of the following four criteria: (1) parallel fibers occurring in bundles, (2) fiber bundles displaying frayed ends, (3) fibers in the form of thin needles, or (4) matted masses of individual fibers and/or fibers showing curvature.

## Content of magnesium-

Lanthanum chloride solution and Test stock solution-
Prepare as directed in the test for Limit of calcium.
Test solution-Dilute 0.5 mL of Test stock solution with water to 100.0 mL . Transfer 4.0 mL of this solution to a $100-\mathrm{mL}$ volumetric flask, add 10.0 mL of hydrochloric acid and 10 mL of Lanthanum chloride solution, and dilute with water to volume.

Magnesium standard stock solution-Dissolve 8.365 g of magnesium chloride in diluted hydrochloric acid, and dilute with the same solvent to 1000 mL . Pipet 5 mL of this solution into a $500-\mathrm{mL}$ volumetric flask, dilute with water to volume, and mix. This solution contains the equivalent of $10 \mu \mathrm{~g}$ of magnesium per mL .

Standard magnesium solutions-Into four identical 100mL volumetric flasks, each containing 10.0 mL of hydrochloric acid and 10 mL of Lanthanum chloride solution, transfer respectively $2.5,3.0,4.0$, and 5.0 mL of Magnesium standard stock solution, and dilute with water to volume.
Procedure-Concomitantly determine the absorbance of the Test solution and the Standard magnesium solutions at the magnesium emission line of 285.2 nm with an atomic absorption spectrophotometer (see Spectrophotometry and Light-Scattering $\langle 851\rangle$ ) equipped with a magnesium hol-low-cathode lamp and an air-acetylene flame: between $17.0 \%$ to $19.5 \%$ of magnesium is found. $\quad$ 2S (USP28)

## MONOGRAPHS (NF)

## Briefing

Corn Starch, page 1457 of $P F$ 30(4) [July-Aug. 2004]; Potato Starch, page 1460 of $P F$ 30(4) [July-Aug. 2004]; Wheat Starch, page 1462 of $P F$ 30(4) [July-Aug. 2004]. In the Packaging and storage section it is proposed to add that no storage requirements are specified. The revision proposed in $P F 30(2)$, to change the name of the section from Packaging and storage to Packaging, was canceled.

## Add the following:

## ©Corn Starch

» Corn Starch consists of the starch granules separated from the mature grain of corn [Zea mays Linné (Fam. Gramineae)].

## Change to read:

Packaging and storage-Preserve in well-closed containers. -No storage requirements specified. $\mathbf{L S S}_{\text {(NF23) }}$

Labeling-Where Corn Starch is intended for use in preparing Absorbable Dusting Powder, it is so labeled and the label states that it must be subjected to further processing during the preparation of Absorbable Dusting Powder.

## Change to read:

## Identification-

A: Under a microscope, using not less than $20 \times$ magnification and using a mixture of glycerin and water $(1: 1)$ as a mounting agent, it appears as either angular polyhedral granules of irregular sizes with diameters ranging from about $2 \mu \mathrm{~m}$ to about $23 \mu \mathrm{~m}$ or as rounded or spheroidal granules of irregular sizes with diameters ranging from about $25 \mu \mathrm{~m}$ to about $35 \mu \mathrm{~m}$. The central hilum consists of a distinct cavity or a two- to five-rayed cleft, and there are no concentric striations. Between crossed nicol prisms, the starch granules show a distinct black cross intersecting at the hilum.

B: Suspend 1 g of it in 50 mL of water, boil for 1 min ute, and cool: a thin, cloudy mucilage is formed.

C: To 10 mL of the mereilage obtained in Identification test $B$, add 0.04 mL of iodine and potassium iodide TS: an erange red to datk blue color is prodtueed, which disappears en heating.

C: To 1 mL of the mucilage obtained in Identification test $B$, add 0.05 mL of tine - iodine and potassium iodide TS 2: $\quad$ 1S (NF23) an orange-red to dark blue color is produced, which disappears on heating.

Iodinesolution Dissolve 12.7gofiodine and 20gofpe-tassitmmiodide-in water, and diltte-with water to 1000.0 mL . Fe 10.0 mL of this seltation, ade 0.6 of of petassitm iodide, and dilute with water to 100.0 mL . Prepare immediately be fereuser ■ils (NF23)

Microbial limits $\langle 61\rangle$ —The total aerobic microbial count does not exceed 1000 cfu per g , the total combined molds and yeasts count does not exceed 100 cfu per g , and it meets the requirements of the test for the absence of Escherichia coli. Where it is intended for use in preparing Absorbable Dusting Powder, it also meets the requirements of the tests for absence of Staphylococcus aureus and Pseudomonas aeruginosa.
$\mathbf{p H}\langle\mathbf{7 9 1}\rangle$ —Prepare a slurry by weighing 5.0 g of Corn Starch, transferring to a suitable nonmetallic container, and adding 25.0 mL of freshly boiled and cooled water. Agitate continuously at a moderate rate for 1 minute. Stop the agitation, and allow to stand for 15 minutes. Determine the pH to the nearest 0.1 unit: the pH , determined potentiometrically, is between 4.0 and 7.0.

Loss on drying $\langle 731\rangle$ —Dry about 1 g , accurately weighed, at $130^{\circ}$ for 90 minutes: it loses not more than $15.0 \%$ of its weight.

## Change to read:

Residue on ignition $\langle 281\rangle$ : not more than $0.6 \%$, determined on a $1.0-\mathrm{g}$ test specimen. Ignition temperature $600 \pm 50^{\circ}-\square_{\text {■1S (NF23) }}$

Limit of iron-Shake 1.5 g of Corn Starch with 15 mL of 2 N hydrochloric acid, and filter. Transfer 10 mL of the filtrate to a test tube, add 2 mL of citric acid solution (2 in 10), 0.1 mL of thioglycolic acid, and mix. Add 10 N ammonium hydroxide until the solution is distinctly alkaline to litmus, dilute with water to 20 mL , and mix (Test Solution). Prepare a Standard Iron Solution containing the equivalent of $10 \mu \mathrm{~g}$ of iron per mL as directed under Iron $\langle 241\rangle$. Immediately before use, quantitatively dilute an accurately measured volume of this solution with water to obtain a Diluted Standard Iron Solution containing the equivalent of $1 \mu \mathrm{~g}$ of iron per mL . Prepare the Standard Solution by transferring 10 mL of the Diluted Standard Iron Solution to a test tube and proceeding in the same manner as directed for the preparation of the Test Solution, beginning with "add 2 mL of citric acid solution (2 in 10)." After 5 minutes, any pink color in the Test Solution is not more intense than that in the Standard Solution, corresponding to a limit of $10 \mu \mathrm{~g}$ of iron per g .

Limit of oxidizing substances-Transfer 4.0 g to a glassstoppered, $125-\mathrm{mL}$ conical flask, and add 50.0 mL of water. Insert the stopper, and swirl for 5 minutes. Transfer to a glass-stoppered, $50-\mathrm{mL}$ centrifuge tube, and centrifuge to clarify. Transfer 30.0 mL of the clear supernatant to a glass-stoppered, $125-\mathrm{mL}$ conical flask. Add 1 mL of glacial acetic acid and 0.5 g to 1.0 g of potassium iodide. Insert the stopper, swirl, and allow to stand for 25 to 30 minutes in the dark. Add 1 mL of starch TS, and titrate with 0.002 N sodium thiosulfate VS to the disappearance of the starch-iodine color. Perform a blank determination, and make any necessary correction. Each mL of 0.002 N sodium thiosulfate is
equivalent to $34 \mu \mathrm{~g}$ of oxidant, calculated as hydrogen peroxide. Not more than 1.4 mL of 0.002 N sodium thiosulfate is required ( $20 \mu \mathrm{~g}$ per g , calculated as $\mathrm{H}_{2} \mathrm{O}_{2}$ ).

Limit of sulfur dioxide-Not more than $50 \mu \mathrm{~g}$ per g . REAGENTS-

Carbon dioxide-Use carbon dioxide, with a flow regulator that will maintain a flow of $100 \pm 10 \mathrm{~mL}$ per minute.
Bromophenol blue indicator solution-Dissolve 100 mg of bromophenol blue in 100 mL of dilute alcohol (1 in 5), and filter if necessary.

Hydrogen peroxide solution-Dilute $30 \%$ hydrogen peroxide with water to obtain a $3 \%$ solution. Just before use, add 3 drops of Bromophenol blue indicator solution, and neutralize to a violet-blue endpoint with 0.01 N sodium hydroxide. Do not exceed the endpoint.
APPARATUS-In this test, the sulfur dioxide is released from the test specimen in a boiling acid medium and is removed by a stream of carbon dioxide. The separated gas is collected in a dilute hydrogen peroxide solution where the sulfur dioxide is oxidized to sulfuric acid and titrated with standard alkali. The apparatus consists essentially of a 500mL three-neck, round-bottom boiling flask, a separatory funnel having a capacity of 100 mL or greater, a gas inlet tube of sufficient length to permit introduction of the carbon dioxide within 2.5 cm of the bottom of the boiling flask, a reflux condenser having a jacket length of 200 mm , and a delivery tube connecting the upper end of the reflux condenser to the bottom of a receiving test tube. Apply a thin film of stopcock grease to the sealing surfaces of all of the joints except the joint between the separatory funnel and the boiling flask, and clamp the joints to ensure tightness.

PROCEDURE-Add 150 mL of water to the boiling flask. Close the stopcock of the separatory funnel, and begin the flow of carbon dioxide at a rate of $100 \pm 5 \mathrm{~mL}$ per minute through the Apparatus. Start the condenser coolant flow.

Add 10 mL of Hydrogen peroxide solution to a receiving test tube. After 15 minutes, without interrupting the flow of carbon dioxide, remove the separatory funnel from the boiling flask, and transfer 25.0 g of test specimen into the boiling flask with the aid of 100 mL of water. Apply stopcock grease to the outer joint of the separatory funnel, and replace the separatory funnel in the boiling flask. Close the stopcock of the separatory funnel, and add 80 mL of 2 N hydrochloric acid to the separatory funnel. Open the stopcock of the separatory funnel to permit the hydrochloric acid solution to flow into the boiling flask, guarding against the escape of sulfur dioxide into the separatory funnel by closing the stopcock before the last few mL of hydrochloric acid drain out. Position the Apparratus in a water bath, and Boil the mixture for 1 hour. Remove the receiving test tube, and transfer its contents to a $200-\mathrm{mL}$ wide-necked, conical flask. Rinse the receiving test tube with a small portion of water, add the rinsing to the $200-\mathrm{mL}$ conical flask, and mix. Heat on a water bath for 15 minutes, and allow to cool. Add 0.1 mL of Bromophenol blue indicator solution, and titrate the contents with 0.1 N sodium hydroxide VS until the color changes from yellow to violet-blue, with the color change lasting for at least 20 seconds. Perform a blank determination, and make any necessary correction (see Titrimetry $\langle 541\rangle$ ). Calculate the content, in $\mu \mathrm{g}$ per g , of sulfur dioxide in the test specimen taken by the formula:

$$
1000(32.03) V N / W,
$$

in which 32.03 is the milliequivalent weight of sulfur dioxide; $V$ is the volume, in mL , of titrant consumed; $N$ is the normality of the titrant; and $W$ is the weight, in g , of test specimen taken.

Organie volatile imptrities, Method $H\langle 467$ ): meets the requirements. $\Delta$ NF23

## BRIEFING

Potato Starch, page 1460 of PF 30(4) [July-Aug. 2004]-See briefing under Corn Starch.

Packaging and storage-Preserve in well-closed containers. ${ }^{-N o}$ storage requirements specified. ${ }^{2 S}$ (NF23)

## Change to read:

## Identification-

A: Under a microscope, using a mixture of glycerin and water ( $1: 1$ ) as a mounting agent, it presents granules, either irregularly shaped, ovoid, or pear-shaped, usually $30 \mu \mathrm{~m}$ to $100 \mu \mathrm{~m}$ in size, but occasionally exceeding $100 \mu \mathrm{~m}$, or rounded, $10 \mu \mathrm{~m}$ to $35 \mu \mathrm{~m}$ in size. There are occasional compound granules having two or four components. The ovoid and pear-shaped granules have an eccentric hilum and the rounded granules acentric or slightly eccentric hilum. All granules show clearly visible concentric striations. Between crossed nicol prisms, the granules show a distinct black cross intersecting at the hilum.

B: Suspend 1 g of it in 50 mL of water, boil for $1 \mathrm{mi}-$ nute, and cool: a thin, cloudy mucilage is formed.

C: To 1 mL of the mucilage obtained in Identification test $B$, add 0.05 mL of iodine and potassium iodide TS
 duced, which disappears on heating.

Microbial limits $\langle 61\rangle$-The total aerobic microbial count does not exceed 1000 cfu per g , the total combined molds and yeasts count does not exceed 100 cfu per g , and it meets the requirements of the test for the absence of Escherichia coli.
$\mathbf{p H}\langle 791\rangle$ —Prepare a slurry by weighing 5.0 g of Potato Starch, transferring to a suitable nonmetallic container, and adding 25.0 mL of freshly boiled and cooled water. Agitate continuously at a moderate rate for 1 minute. Stop the agitation, and allow to stand for 15 minutes. Determine the pH to the nearest 0.1 unit: the pH , determined potentiometrically, is between 5.0 and 8.0.

Loss on drying $\langle 731\rangle$-Dry about 1 g , accurately weighed, at $130^{\circ}$ for 90 minutes: it loses not more than $20.0 \%$ of its weight.

## Change to read:

Residue on ignition $\langle 281\rangle$ : not more than $0.6 \%$, determined on a $1.0-\mathrm{g}$ test specimen. Ignition-temperature $600 \pm 50^{\circ}$. "■ $^{1 S}$ (NF23)

Limit of iron—Shake 1.5 g of Potato Starch with 15 mL of 2 N hydrochloric acid, and filter. Transfer 10 mL of the filtrate to a test tube, add 2 mL of citric acid solution (2 in 10), 0.1 mL of thioglycolic acid, and mix. Add 10 N ammonium hydroxide until the solution is distinctly alkaline to litmus, dilute with water to 20 mL , and mix (Test Solution). Prepare a Standard Iron Solution containing the equivalent of $10 \mu \mathrm{~g}$ of iron per mL as directed under Iron $\langle 241\rangle$. Immediately before use, quantitatively dilute an accurately measured volume of this solution with water to obtain a Diluted Standard Iron Solution containing the equivalent of $1 \mu \mathrm{~g}$ of iron per
mL . Prepare the Standard Solution by transferring 10 mL of the Diluted Standard Iron Solution to a test tube and proceeding in the same manner as directed for the preparation of the Test Solution, beginning with "add 2 mL of citric acid solution (2 in 10)." After 5 minutes, any pink color in the Test Solution is not more intense than that in the Standard Solution, corresponding to a limit of $10 \mu \mathrm{~g}$ of iron per g .

Limit of oxidizing substances-Transfer 4.0 g to a glassstoppered, $125-\mathrm{mL}$ conical flask, and add 50.0 mL of water. Insert the stopper, and swirl for 5 minutes. Transfer to a glass-stoppered, $50-\mathrm{mL}$ centrifuge tube, and centrifuge to clarify. Transfer 30.0 mL of the clear supernatant to a glass-stoppered, $125-\mathrm{mL}$ conical flask. Add 1 mL of glacial acetic acid and 0.5 g to 1.0 g of potassium iodide. Insert the stopper, swirl, and allow to stand for 25 to 30 minutes in the dark. Add 1 mL of starch TS, and titrate with 0.002 N sodium thiosulfate VS to the disappearance of the starch-iodine color. Perform a blank determination, and make any necessary correction. Each mL of 0.002 N sodium thiosulfate is equivalent to $34 \mu \mathrm{~g}$ of oxidant, calculated as hydrogen peroxide. Not more than 1.4 mL of 0.002 N sodium thiosulfate is required ( $20 \mu \mathrm{~g}$ per g , calculated as $\mathrm{H}_{2} \mathrm{O}_{2}$ ).

Limit of sulfur dioxide: not more than $50 \mu \mathrm{~g}$ per g .

## REAGENTS-

Carbon dioxide - Use carbon dioxide, with a flow regulator that will maintain a flow of $100 \pm 10 \mathrm{~mL}$ per minute.

Bromophenol blue indicator solution-Dissolve 100 mg of bromophenol blue in 100 mL of dilute alcohol (1 in 5), and filter if necessary.

Hydrogen peroxide solution-Dilute 30\% hydrogen peroxide with water to obtain a $3 \%$ solution. Just before use, add 3 drops of Bromophenol blue indicator solution, and neutralize to a violet-blue endpoint with 0.01 N sodium hydroxide. Do not exceed the endpoint.

APPARATUS-In this test, the sulfur dioxide is released from the test specimen in a boiling acid medium and is removed by a stream of carbon dioxide. The separated gas is collected in a dilute hydrogen peroxide solution where the sulfur dioxide is oxidized to sulfuric acid and titrated with standard alkali. The apparatus consists essentially of a 500mL three-neck, round-bottom boiling flask, a separatory funnel having a capacity of 100 mL or greater, a gas inlet tube of sufficient length to permit introduction of the carbon dioxide within 2.5 cm of the bottom of the boiling flask, a reflux condenser having a jacket length of 200 mm , and a delivery tube connecting the upper end of the reflux condenser to the bottom of a receiving test tube. Apply a thin film of stopcock grease to the sealing surfaces of all of the joints, except the joint between the separatory funnel and the boiling flask, and clamp the joints to ensure tightness. PROCEDURE-Add 150 mL of water to the boiling flask. Close the stopcock of the separatory funnel, and begin the flow of carbon dioxide at a rate of $100 \pm 5 \mathrm{~mL}$ per minute through the Apparatus. Start the condenser coolant flow. Add 10 mL of Hydrogen peroxide solution to a receiving test tube. After 15 minutes, without interrupting the flow of carbon dioxide, remove the separatory funnel from the boiling flask, and transfer 25.0 g of test specimen into the boiling flask with the aid of 100 mL of water. Apply stopcock grease to the outer joint of the separatory funnel, and replace the separatory funnel in the boiling flask. Close the stopcock of the separatory funnel, and add 80 mL of 2 N
hydrochloric acid to the separatory funnel. Open the stopcock of the separatory funnel to permit the hydrochloric acid solution to flow into the boiling flask, guarding against the escape of sulfur dioxide into the separatory funnel by closing the stopcock before the last few mL of hydrochloric acid drain out. Pesition the Apparatus in a water bath, and Boil the mixture for 1 hour. Remove the receiving test tube, and transfer its contents to a $200-\mathrm{mL}$ wide-necked, conical flask. Rinse the receiving test tube with a small portion of water, add the rinsing to the $200-\mathrm{mL}$ conical flask, and mix. Heat on a water bath for 15 minutes, and allow to cool. Add 0.1 mL of Bromophenol blue indicator solution, and titrate the contents with 0.1 N sodium hydroxide VS until the color changes from yellow to violet-blue, with the color change lasting for at least 20 seconds. Perform a blank determination, and make any necessary correction (see Titrimetry $\langle 541\rangle$ ). Calculate the content, in $\mu \mathrm{g}$ per g , of sulfur dioxide in the test specimen taken by the formula:

$$
1000(32.03) \mathrm{VN} / \mathrm{W},
$$

in which 32.03 is the milliequivalent weight of sulfur dioxide; $V$ is the volume, in mL , of titrant consumed; $N$ is the normality of the titrant; and $W$ is the weight, in g , of test specimen taken.

Organic volatile impurities, Method $\Psi\langle(467)$ : meets the requirements._ANF23

## Identification-

A: Under a microscope, using a mixture of glycerin and water $(1: 1)$ as a mounting agent, it presents large and small granules, and very rarely, intermediate sizes. The large granules, usually $10 \mu \mathrm{~m}$ to $60 \mu \mathrm{~m}$ in diameter, are discoid or, more rarely, reniform when seen face-on. The central hilum and striations are invisible or barely visible and the granules sometimes show cracks on the edges. Seen in profile, the granules are elliptical and fusiform and the hilum appears as a slit along the main axis. The small granules, rounded or polyhedral, are $2 \mu \mathrm{~m}$ to $10 \mu \mathrm{~m}$ in diameter. Between crossed nicol prisms, the granules show a distinct black cross intersecting at the hilum.

B: Suspend 1 g of it in 50 mL of water, boil for $1 \mathrm{mi}-$ nute, and cool: a thin, cloudy mucilage is formed.

C: Te 1 mL of the murilage obtained in Itdentification test $B$, add 0.05 mL of iodine and potassium-iodide TS: a dark blue celor is produced, which disappears on heating.

C: To 1 mL of the mucilage obtained in Identification test $B$, add 0.05 mL of dine solution: ■iodine and potassium iodide TS 2: $\mathbf{I S ~ ( N F 2 3 ) ~}$ an orange-red to dark blue color is produced, which disappears on heating.

Iodine solution Dissolve 12.7g of iodine and 20gof po assitum iodide in water, and dillte with water to 1000.0 mL . Fe 10.0 mL of this selution, add 0.6 g of petassitum-iodide, and dilute with water to 100.0 mL . Prepare immediately before use.mis (NF23)

Microbial limits $\langle 61\rangle$ —The total aerobic microbial count does not exceed 1000 cfu per g , the total combined molds and yeasts count does not exceed 100 cfu per $g$, and it meets the requirements of the test for the absence of Escherichia coli.
$\mathbf{p H}\langle 791\rangle$ —Prepare a slurry by weighing 5.0 g of Wheat Starch, transfer to a suitable nonmetallic container, and add 25.0 mL of freshly boiled and cooled water. Agitate continuously at a moderate rate for 1 minute. Stop the agitation, and allow to stand for 15 minutes. Determine the pH to the nearest 0.1 unit: the pH , determined potentiometrically, is between 4.5 and 7.0.

Loss on drying $\langle 731\rangle$-Dry about 1 g , accurately weighed, at $130^{\circ}$ for 90 minutes: it loses not more than $15.0 \%$ of its weight.

## Change to read:

Residue on ignition $\langle 281\rangle$ : not more than $0.6 \%$, determined on a $1.0-\mathrm{g}$ test specimen. Ignition-temperature $600 \pm 50^{\circ} \cdot \square_{1 S}$ (NF23)

Total protein: not more than $0.3 \%$ of total protein (corresponding to $0.048 \%$ of nitrogen $\left[\mathrm{N}_{2}\right]$, conversion factor: 6.25).

Procedure-Accurately weigh 6.0 g of test substance containing about 2 mg of nitrogen, transfer to a combustion flask, and add 4 g of a powdered mixture of 100 g of potassium sulfate, 5 g of cupric sulfate, and 2.5 g of selenium, and three glass beads. Wash any adhering particles from the neck into the flask with 5 mL of sulfuric acid, allowing it to run down the sides of the flask, and mix the contents by rotation. Close the mouth of the flask loosely (e.g., by means of a glass bulb with a short stem) to avoid excessive loss of sulfuric acid. Heat gradually at first, then increase the temperature until there is vigorous boiling with condensation of sulfuric acid in the neck of the flask. [NOTE--Precautions should be taken to prevent the upper part of the flask from becoming overheated.] Continue the heating for 30 minutes, unless otherwise directed. Cool, dissolve the solid material by cautiously adding to the mixture 25 mL of water, cool again, and place in a steam distillation apparatus. Add 30 mL of sodium hydroxide solution (42 in 100), and distill immediately by passing steam through the mixture. Collect about 40 mL of distillate in 20.0 mL of 0.01 N hydrochloric acid and enough water to cover the tip of the condenser. Towards the end of the distillation, lower the receiver so that the tip of the condenser is above the surface of the acid. [NOTE-Take precautions to prevent any water on the outer surface of the condenser from reaching the contents of the receiver.] Titrate the distillate with 0.01 N sodium hydroxide, using methyl purple TS as indicator ( $n_{1} \mathrm{~mL}$ of 0.01 N sodium hydroxide).

Repeat the test using about 50 mg of glucose in place of the substance to be examined ( $n_{2} \mathrm{~mL}$ of 0.01 N sodium hydroxide).

$$
\text { Content of nitrogen }=\left[0.01401\left(n_{2}-n_{1}\right)\right] / m,
$$

Limit of iron-Shake 1.5 g of Wheat Starch with 15 mL of 2 N hydrochloric acid, and filter. Transfer 10 mL of the filtrate to a test tube, add 2 mL of citric acid solution (2 in 10), 0.1 mL of thioglycolic acid, and mix. Add 10 N ammonium hydroxide until the solution is distinctly alkaline to litmus, dilute with water to 20 mL , and mix (Test Solution). Prepare a Standard Iron Solution containing the equivalent of $10 \mu \mathrm{~g}$ of iron per mL as directed under Iron $\langle 241\rangle$. Immediately before use, quantitatively dilute an accurately measured volume of this solution with water to obtain a Diluted Standard Iron Solution containing the equivalent of $1 \mu \mathrm{~g}$ of iron per mL . ## PHARMACOPEIAL PREVIEWS

This section contains potential revisions not yet targeted for official adoption. These may include drafts for new monographs or chapters; drafts for standards that would require new or unusual technology; drafts for which more data are required; or changes that would affect numerous monographs, thus having a broad impact on individual products. Readers should review the drafts in this section and provide comments to the appropriate staff liaison whose name is cited in the Briefing (use the Staff Directory to find the contact information).

Briefings Each Preview is preceded by a Briefing in the following format:

## Briefing

Name of Item, citations of the most recent USP publications in which this item appeared. Rationale for the revision. Other relevant information. (For example, if a chromatographic method is being used, column specifications and retention times for compounds of interest.) Finally, the Committee designation (see How To Use PF), the name of the scientific staff liaison who handled this item, and the USP tracking correspondence number, as shown in the example below:
(PA5: K. Russo) RTS-55678-1

Symbols No symbols are used in this section, as Previews are not yet targeted for official adoption.

## STIMULI TO THE REVISION PROCESS

This section may contain the following:

- reports or statements of authoritative committees
- original research reports
- evaluations of new and existing pharmacopeial methods
- commentaries
- articles relevant to compendial issues

These items are published to stimulate discussion and continual review of Pharmacopeial standards. Generally, if an Expert Committee publishes an article on which they are specifically seeking comment, this will be clearly stated in the article. Readers may submit comments on issues raised in this section, but comment is not as critical as that for the In-Process Revision and Pharmacopeial Previews sections. Readers interested in submitting comments should see Instructions to Authors.
STIMULI TO THE REVISION PROCESS ..... 1873
Instructions to Authors ..... 1875
Changes to USP General Chapter Heavy Metals $\langle 231\rangle$, John T. Geary ..... 1876

## Instructions to Authors

Contributions in the form of original research reports, evaluations of new and existing compendial methods, and other commentaries and articles relevant to drug standards or to $U S P-N F$ revision will be considered for publication in the Pharmacopeial Forum under the section Stimuli to the Revision Process. Manuscripts are received with the explicit understanding that they have not been published previously and that they are not simultaneously under consideration by any other publication.

All manuscripts are subject to review by USP headquarters staff, Committee members, or qualified outside referees, and if accepted for publication will be subject to editing by USP staff. Accepted manuscripts become the property of the USP Convention, Inc., (USPC) and may not be published elsewhere without written permission from the USPC. Authors are also responsible for obtaining permission for reprinting any illustrations that have been published elsewhere.

Abstract-Include an abstract of not more than 250 words stating the purpose and the results or conclusions of the article.
References-Consult a current copy of the Pharmacopeial Forum and the ACS Style Guide for assistance with reference style.

Copyright - Copyright transfer documents will be sent to authors after manuscripts have been accepted for publication.
Contact Person-When submitting a manuscript, designate one author of the article as correspondent and include that author's full address, telephone number, fax number, and e-mail address.

Submission Instructions-Manuscripts must be submitted both as an electronic file and as a printed copy of the electronic file. Submit the text in Microsoff ${ }^{\mathbb{B}}$ Word or another current word-processing application. The preferred format for graphics submitted electronically is tagged image file format (TIFF). Graphics that cannot be submitted electronically must be cameraready, of easily reproducible quality and size, and clearly labeled. Photocopies are not acceptable. Manuscripts submitted for publication should be addressed to:

# Changes to USP General Chapter Heavy Metals $\langle 231\rangle$ 

John T. Geary ${ }^{*}$

#### Abstract

USP General Chapter Heavy Metals $\langle 231\rangle$ has been the subject of discussion within the industry for several years, and its deficiencies were discussed during a USP Open Conference that was convened in June, 2003 in Philadelphia, PA. This Stimuli article reviews a few of the problems with USP $\langle 231\rangle$ and outlines the changes USP is considering for a future proposal.

USP General Chapter Heavy Metals $\langle 231\rangle$ has been the subject of discussion within the industry for several years. Deficiencies of the method were recently the topic of the USP Open Conference on Analytical Methods and General USP Topics that was held in June 2003 in Philadelphia. The Basel Working Group on the Determination of Metal Traces presented a thorough discussion of the problems encountered using $\langle 231\rangle$ for heavy metals screening. To summarize their paper, "USP $\langle 231\rangle$ was never intended to be a universal test for heavy metals as it is currently applied."

Methods I, II, and III suffer to some degree from the lack of specificity using colorimetric detection. Not all heavy metals are detected by the procedure. The method is capable only of detecting metals precipitated by sulfide and those that produce a black or brown precipitate. The use of a $600{ }^{\circ} \mathrm{C}$ ignition temperature causes loss of analyte, especially mercury, and has been confirmed as a cause of false negative results.

USP is proposing the following changes to Heavy Metals $\langle 231\rangle$ : The Method II preparation using high-temperature ignition will be withdrawn. Methods $I$ and $I I I$ will be continued. Colorimetric detection for these preparations will be continued, but an alternative method of detection, Inductively Coupled Plasma/Atomic Emission Spectroscopy (ICP/AES), will be approved for both Method I and Method III, which will permit the user to choose either method of detection. USP intends to seek additional alternatives to colorimetric detection, such as x-ray fluorescence, atomic absorption, and electroanalytical methods. These alternatives will be proposed when sufficient data are available to attest to their effectiveness.

[^271]
# Development of a New Official Compendium, Separate from USP-NF, for Articles Not Legally Marketed in the U.S.* 

Council of Experts Executive Committee, ${ }^{\dagger}$ Ad Hoc Council of Experts Committee, $\ddagger$ and USP Staff ${ }^{\ddagger}$

#### Abstract

At a July 2003 meeting, the Council of Experts Executive Committee voted to include monographs in the United States Pharmacopeia and National Formulary for articles that are not legally marketed in the United States but are available in international commerce. Subsequently, the USP Board of Trustees formed a Task Force to monitor progression of this decision and related activities. The Board Task Force requested that USP develop a Stimuli article to solicit input related to how the decision of the Council of Experts Executive Committee might be implemented. This article (1) proposes that the clearest and most definitive way to effect the Council of Experts decision would be a separate official compendium, (2) provides additional information, and (3) requests comments.

## INTRODUCTION

Delegates representing regional medical societies from four regions of the country met in Washington, DC, in January 1820 to determine the contents of the first Pharmacopoeia of the United States of America (USP), which presented the best medicines, named them, and provided recipes for their preparation by practitioners of the day. Over time, with the rise in modern pharmaceutical manufacturing, the task of making a drug has shifted from practitioners to pharmaceutical manufacturers. A residuum of the original approach remains with practitioners who compound a medicine, using at times a $U S P$ preparation monograph pursuant to a physician's prescription. Today, only a relatively small fraction of prescriptions in the United States are compounded.

USP was incorporated in 1900 as the United States Pharmacopoeial Convention under federal law relating to the District of Columbia. It is now classified as a 501 (c)(3) nonprofit scientific corporation working in the public interest. Convention delegates meet at 5 -year intervals to elect the officers of the Convention, the Board of Trustees, and the Council of Experts, and to consider resolutions. With staff support, the Council of Experts creates content for two compendia, the original $U S P$ and, following its purchase in 1975, the National Formulary ( $N F$ ). $U S P$ and $N F$ are separate compendia but are published annually in a combined text with two Supplements. The USP is published as a continuing revision of the 1820 text, but each new $N F$ is a new edition. The current USP 27-NF 22 became official on Jan-

[^272]uary 1,2004 , and contains monographs for prescription and over-the-counter drugs, biologics, and allied therapeutic products (including some devices). In the current revision of $U S P$, a separate section is devoted to dietary supplements. Excipient monographs appear in $N F$. With some exceptions, all articles in $U S P-N F$ are legally marketed in the U.S. An example of such an exception is a dosage form containing four drugs to treat tuberculosis. Also, $U S P-N F$ contains ingredient and product monographs for many articles that have not undergone a regulatory approval in the U.S. These include drug products marketed in the U.S. prior to 1938, drug products marketed in the U.S. after 1938 without a regulatory filing, compounded preparations, dietary supplements, several positron emission tomography products, and some medical devices. Drug substances and excipients are reviewed but not formally approved as part of a regulatory filing for a dosage form in the U.S.
$U S P$ and $N F$ are unusual among compendia of the world because they are published independently from government. As an organization, USP depends for its success on many factors but certainly on its ability to evolve with the times. This Stimuli article postulates the need for a new compendium, separate from $U S P-N F$, to account for an increasing need for public monographs that serve a broad range of constituencies. This need is similar to, if not identical with, motivations that called delegates to the 1820 Convention.

## USP, FDA, AND THE U.S. MARKET

USP publishes $U S P-N F$ independently of statute under the authority of its charter and its Constitution and Bylaws. The original mandatory character of $U S P$, to the extent that it existed at all, devolved from practitioners who declared it to be their "official compendium" and agreed to abide by its standards. Over time, the two compendia have been adopted and made enforceable by various bodies, including both U.S. federal and state governments. Standards in USP $-N F$ also may be adopted by regulatory bodies and other parties
throughout the world when a local standard does not exist or requires modification. The U.S. Federal Food, Drug, and Cosmetic Act (FDCA), created in 1938, specifies what aspects of the USP FDA shall enforce. It does not empower or limit what USP can publish.

Various terms and words-at times confusing and subject to misinterpretation-are used to describe the character of $U S P-N F$ and the relationship of the two texts to the FDCA. USP uses the term official to describe the two compendia. For example, after the content of the USP is adopted by the Council of Experts, the USP Board of Trustees designates the date when the text becomes official. Use of the term in this context indicates that a standard emanating from the Council of Experts is authorized by the Board to be effective at a specified date. In Section 201(j) the FDCA designates the $U S P$, the $N F$, and the Homeopathic Pharmacopeia and their supplements as official compendia of the U.S. This designation in itself confers no enforcement authority. It is instead a drafting mechanism for making standards that appear in a supplement enforceable without having to adopt new regulations or legislation. Because monograph requirements are factual determinations made by USP's Council of Experts, USP functions as a fact-finding body, with conclusions based on these facts reflected in the decisions of the Council of Experts. Facts can change, but the law remains constant. That helps explain why changes appearing in $U S P-N F$ and its Supplements are enforceable without subsequent adoption by a legislature or agency. USP's continuous revision facilitates rapid updating to allow for advances in science and technology. These updates focus on new analytical procedures and acceptance criteria that generally improve over time. In contrast, antibiotic drug monographs, previously provided in the Code of Federal Regulations, were cumbersome to finalize and update and were eliminated in the 1997 Food and Drug Administration Modernization Act with deletion of Section $507 .{ }^{1}$

Other sections of the law indicate to FDA what aspects to enforce, e.g., Section 501(b). This section provides that an article that is a drug recognized in USP or $N F$ shall be deemed to be adulterated unless it complies with the standards of strength, quality, and purity contained therein. Noncompliance of a product with compendial requirements is to be determined in accordance with procedures defined in a monograph. USP can publish only information or facts upon which laws can operate. It has no enforcement authority, nor can it make legal requirements unilaterally.

Recognizing that certain aspects of the monograph are enforceable by FDA, USP has sought to clarify what parts of the two compendia are informational only. For example, USP has placed a chevron ( $>$ ) at the beginning of the Definition section in the monograph to separate informational items from enforceable items. The material above the chevron (e.g., the chemical structure and chemical formula) is informational and not enforceable. A similar approach has

[^273]been taken for General Chapters. Many General Chapters numbered below 1000 contain techniques or procedures, sometimes with acceptance criteria, that are referenced in a monograph as a means of conserving text space. USP has declared Chapters numbered above 1000 to be informational. To clarify this point, the following is stated in the General Notices section of the Second Supplement to USP 27-NF 22:

Articles recognized in this compendia must comply with the official standards and tests and assays in the General Notices, relevant monographs, and General Chapters numbered below 1000 .
General Chapters numbered above 1000 are considered to be interpretative of a subject. They contain no requirements unless specifically referenced in the monograph or elsewhere in the Pharmacopeia. As with any other parts of $U S P-N F$, other parties may recognize and incorporate these General Chapters above 1000 no matter what their subjects and make them enforceable. This is outside of USP's control. ${ }^{2}$
USP strives at all times to create the most complete, relevant, science-based standards for therapeutic articles and is under the direction of its Board of Trustees to do so. These standards arise from well-established processes that allow the standards to be authoritative, credible, and unbiased. Because the Council of Experts is an elected body and reaches its conclusions through majority-based balloting, it is not consensus based. Its character and the standards it creates are in and of themselves voluntary. They become mandatory and thus enforceable by action of other parties.
In the years of their existence, USP and FDA, together with pharmaceutical manufacturers and compounding professionals, have strived to work harmoniously in various ways that, in the aggregate, have resulted in a broad array of articles, both ingredients and preparations, that are among the best in the world. To the extent allowed by law, FDA representatives are welcomed in USP conclaves, either as representatives of the Agency or as members of the Expert Committees of the Council of Experts. FDA is constrained in working with USP to the extent that it is constrained in working with any non-U.S. government organization. However, unlike participation in voluntary consensus bodies, which is governed by the National Technology Transfer Act of 1995, FDA is specifically authorized to cooperate in the revision of USP pursuant to Circular OMB A-119 and 21 USC 377. This law was added by the Labor-Federal Security Appropriations Act of 1944 because USP standards are not considered voluntary but rather enforceable under the FDCA. Certain information available to FDA in regulatory filings may not be shared with USP, either because of laws protecting trade secret information or because of constraints on resources needed to fulfill provisions of the Freedom of Information Act.

[^274]FDA may not change a USP standard, but it can publish alternative methodology in a regulation if it believes that USP methodology is deficient. FDA has never resorted to this because of the cooperative relationship between the two bodies. If USP's analytical procedures are not suitable for a particular substance or product, a firm may submit alternative methodology to USP for incorporation in the relevant monograph. A firm may claim an article is not "USP" or " $N F$ " if it differs from the standards of strength, quality, or purity established for the article in USP and if the difference is stated on the product's label.

Both FDA and USP have executed different roles and responsibilities over the years. For example, taking advantage of the USP selection process to determine the "best drugs," the U.S. Government, turning to USP rather than FDA with passage of Medicare legislation in the 1960s, recognized articles included or approved for inclusion in the USP as a basis for certain types of reimbursement. ${ }^{3}$ More recently, the expansion of FDA's responsibilities-and perhaps in particular passage of the 1984 Drug Price Competition and Patent Term Restoration Act-has had a significant impact on USP.

Although the details of this impact are broad and certainly extend beyond USP, they relate, insofar as USP is concerned, to reduced incentives for manufacturers to voluntarily provide the information needed to support a public monograph, either because of the intensely competitive environment created by the 1984 law or because of a desire to avoid a dual review-an increasingly stringent one at FDA to achieve the private standard and, at times, a more protracted one with USP to achieve the public standard. In addition, with better control of an article's quality, the public monograph necessarily has moved beyond a "one size fits all" approach to a more accommodating one that accounts for different routes of synthesis and different dosage form performance characteristics. This results in what USP now terms the flexible monograph. Various aspects of a monograph are covered in a Guideline designed to assist sponsors in submitting Requests for Revision in support of a new monograph or a monograph revision (http://www.usp.org/ standards/revisionguideline/index.html). Further details about the complex relationship between FDA and USP are presented in an Appendix to this article.

## STATUS OF MONOGRAPHS

## New Monographs and Missing Monographs

Each year, FDA approves many new drugs, including biologics, with release in the market requiring conformance to private and/or public standards. Over time, the private standard may become public through USP processes. Despite the challenges and barriers discussed in the previous

[^275]section, USP continues to believe strongly in the value of public monographs for these articles and, when needed, associated official USP Reference Standards to support firstparty (manufacturer, compounding professional), secondparty (purchaser, distributor), and third-party (independent body) testing. In a world where counterfeit and substandard drugs are on the rise and control over market zones is either declining or nonexistent and where health professionals no longer have "hands-on" control over the quality of the medications they use, the value of a public science-based monograph appears as strong as, if not stronger than, the value perhaps perceived by the 1820 Convention delegates. The value may be even greater for therapeutic articles marketed outside the U.S., where regulatory control is diminished, a pharmacopeia may not be present, and the possibility of counterfeit and/or substandard drugs is more likely. In recognition of this value, delegates to the 1995 Quinquennial Meeting passed the following resolution:

USP is encouraged to determine the feasibility and advisability of providing upon request, authoritative standards for pharmaceuticals and related products, and health care technologies utilized by other countries that rely upon $U S P-N F$, where no national standard currently exists.
USP has always supported the activities of the World Health Organization (WHO) in creation of the International Pharmacopeia. To assist WHO, USP finalized a four-drug combination dosage form monograph for the treatment of tuberculosis. This monograph can assist manufacturers and public health authorities throughout the world in ensuring the availability of a good-quality fixed-combination dosage form to assist practitioners in treating patients with this dread disease. Note that this monograph now is part of official text in $U S P-N F$, but it has no implications for FDA or manufacturers marketing in the U.S., given that an article conforming to this monograph is not legally marketed in the U.S. Should such an article become available through FDA's new drug application process, the monograph might have to be adjusted based on the FDA regulatory review.

## Missing Monographs

In 1980, the USP Convention voted to change the scope of $U S P$ so that by 1990 it would include monographs for all drug entities (drug substances) and, to the extent possible, drug products marketed in the U.S. Because USP usually relies on voluntary donations of both information and reference standard candidate material to support $U S P-N F$ content and associated official USP Reference Standards, the two compendia over time-predominantly for the reasons discussed previously in this article-have failed, increasingly, to meet this goal. For example, USP is missing 323 non-complex drug substance monographs and approximately twice that number of dosage form monographs. Taken together, the total number of monographs missing from $U S P-N F$ is about a third; i.e., 2000 monographs of a potential cohort of about 6000 are not available to the public. The challenge is particularly acute for complex ingredi-
ents and dosage forms, in which cases creation of a public monograph is generally not deemed in the interest of some manufacturers.

## Monograph Updating

USP has requested the involved Council of Experts Expert Committees to review currently available monographs to determine how many contain outdated procedures. Reports received to date emphasize the need to modernize some test procedures and to include impurity tests in the monographs. New International Conference on Harmonization approaches to the USP tests, particularly the Impurity test, suggest that a drug substance monograph may need to have different Impurity test procedures to account for impurities arising from different routes of synthesis. For these reasons, many monographs need updating to better control ingredient and dosage form impurities. Again, the rationale for sponsors to submit these requests for revision is frequently lacking, given the resources needed to update a monograph and the lack of incentive to do so. This is a challenge also shared by FDA in maintaining private standards in an application. ${ }^{4}$

## A NEW APPROACH

For the various reasons delineated in this article, USP believes a new approach is needed not only to avoid an increasingly deficient monograph cohort in $U S P-N F$ but also for USP to better serve the international community. The approach will entail a search for sponsors of articles not legally marketed in the U.S.-i.e., sponsors who are willing to submit Requests for Revision for new monographs, with an increased emphasis on using USP's stan-dards-setting and laboratory capabilities to create the information needed to support a monograph. ${ }^{5}$ The overall approach was solidified by a formal decision of the Council of Experts in July 2003 to create monographs for articles not legally marketed in the U.S. ${ }^{6}$ This formal decision is extremely important, but it is also important to note that USP had already taken similar decisions in the past, including, as noted, the four-drug dosage form monograph to treat tuberculosis. In addition, the Preface to earlier editions of $N F$ indicated an intent to allow excipient monographs that were not part of FDA-approved dosage forms.

Working with the Council of Experts Executive Committee, USP has considered several ways to indicate the status of a monograph for an article not legally marketed in the U.S. Despite the overall complexity of the issue, the presen-

[^276]tation allows only a few possibilities. These include placing such monographs in (1) a separate section of Pharmacopeial Forum, (2) USP-NF with distinguishing marks, (3) $U S P-N F$ in a separate section, and (4) a separate compendium. Although the authors welcome comments on all possibilities, we believe that the most useful and clearest way would be to create a separate compendium. This would be an official compendium of USP but would not be an official compendium of the U.S. under the FDCA. The few monographs for articles not legally marketed in the U.S. that are currently in $U S P-N F$ would be transferred to the new compendium, as perhaps would General Chapters and other useful information.

## JUSTIFICATION

The new approach is justified by the support it provides, for both non-U.S. and U.S. constituencies. Non-U.S. constituencies who may benefit from a separate USP compendium include international public health officials, manufacturers marketing good-quality, safe and effective drugs, and the public at large.

- Public health officials throughout the world are expected to benefit from the proposed approach. The preface to the third edition of the International Pharmacopeia emphasizes the availability of monographs primarily for ingredients and dosage forms on the list of essential drugs, as determined by the WHO Expert Committee on the Selection of Essential Drugs. This list comprises 325 drug substances and 260 dosage forms, which leaves many hundreds of ingredients and dosage forms without modern monographs and associated reference standards. The proposed approach would allow USP thus to assist WHO in several ways. First, USP could aid WHO in providing monographs/ reference standards for medicines on the essential drug list. Second, USP would assist WHO in providing monographs/reference standards for articles moving in international commerce but not included in the essential drug list. In a separate compendium, USP might also follow WHO's lead in providing classical procedures (less demanding tests), as well as basic and screening tests, to help reduce the circulation of counterfeit and substandard drugs.
- For international regulatory agencies, the availability of modern ingredient and dosage form monographs in a separate USP compendium should facilitate review processes, given that validated analytical procedures and associated official USP Reference Standards would be available. The approach thus could alleviate constraints on regulatory resources, which in some locales is severe. The approach also would be useful to other government and nongovernment groups, including customs inspectors and international relief groups wishing to purchase good-quality drugs. Many of these groups engage in testing as a means of ensuring the quality of therapeutic articles. At this time, absence of
a monograph in any of the world's major pharmacopeias, including $U S P-N F$, means that such testing is either impeded or not possible. Although a separate compendium is proposed, USP intends to use Pharmacopeial Forum as a means of eliciting public comment on draft monographs for the separate compendium. Public comments would be encouraged from nonU.S. constituencies who might rely on tests, procedures, and acceptance criteria in a separate compendium.
- For manufacturers wishing to move ingredients and dosage forms in international commerce, the availability of modern ingredient and dosage form monographs in a separate USP compendium, coupled with the availability of official USP Reference Standards, will assist in applying the best, most appropriate procedures in support of work with regulatory agencies, international funding agencies, other manufacturers, and in country constituencies, including practitioners and patients.
U.S. constituencies who may benefit from the new approach include FDA, some manufacturers marketing or intended to market products in the U.S., and the U.S. public at large.
- For FDA, the value of the approach lies in the availability of validated analytical monograph procedures and associated official USP Reference Standards for articles moving in international commerce but not available on the U.S. market. Many of the articles in international commerce may have the same names and otherwise be similar to articles legally marketed in the U.S., with differences revealed perhaps only in certain testing, e.g., the USP Impurities test or the Performance test (dissolution, disintegration). If USP is able to publish monographs for these articles and make available official USP Reference Standards, FDA would have access to procedures/standards that would allow border control and detection of counterfeit and substandard medicines. The approach would facilitate efforts to keep such articles out of U.S. commerce rather than allowing safe harbors for articles legally marketed in the U.S. In addition, the proposed monographs/reference standards for international products and substances might be useful for legally marketed U.S. articles, given that many of the international monograph procedures would still be applicable for consideration as alternative methods for FDA-approved products. For example, if there were a question about strength, the official USP Reference Standard material might be used to test the U.S. product, even though the monograph was for an article not legally marketed in the U.S. Of course, due consideration would have to be given to the suitability of the method for this purpose. As a further advantage, it is also possible that the proposed approach would gener-
ate updates to USP monographs and private standards in FDA application files-a goal that FDA itself has championed. USP emphasizes, however, that the proposed approach is not intended to influence any product legally marketed in the U.S. Control of this market is entirely the responsibility of the U.S. government working through FDA and not that of USP.
- For U.S. manufacturers, the value of the proposed approach would be the ability to view modern specifications in ingredient and dosage form monographs, even though the article might not be legally marketed in the U.S. USP occasionally hears that manufacturers would like confirmed analytical procedures to test competing products. The proposed approach would fulfill that need. In addition, for U.S. generic manufacturers, the proposed approach offers the possibility of placing, with Council of Experts approval, ingredient and dosage form monographs in the separate compendium pending an FDA regulatory decision. With conclusion of a positive Agency decision and provision of regulatory judgments about acceptance criteria for impurities, dissolution, and other procedures, the monographs could move to $U S P-N F$. At present, a manufacturer is sometimes caught between FDA, which may wish to have final monographs in $U S P-N F$ for articles pending Agency approval, and USP, which states that it cannot conclude such a monograph pending receipt of final Agency decisions for acceptance criteria. [NOTEUSP's Council of Experts considered the possibility of keeping monographs for articles in Pharmacopeial Forum ( $P F$ ) pending an FDA decision. With FDA approval and availability of needed regulatory judgments, the monographs could move to $U S P-N F$. This approach, however, would detract from the finality of the monographs in that USP does not regard $P F$ to be an official compendium.]
- The U.S. public at large would benefit through increased assurance of good-quality products moving in U.S. commerce, avoidance of delays in regulatory approvals, and improved border control. Specifically, a separate compendium would indicate articles (and provide test procedures for them) that should not be in U.S. commerce. Legislative changes are under consideration to expand importation of ingredients and products. Should the approach be finalized, a separate compendium with public ingredient and dosage monographs would allow testing of possibly counterfeit or substandard imported drugs with modern analytical procedures, using associated official USP Reference Standards, subject to the conclusions of the USP Council of Experts.

## SPECIAL CONSIDERATIONS

A modern pharmacopeial monograph usually incorporates both regulatory and compendial decisions. For example, USP's Council of Experts now reviews extensive information in a Request for Revision that allows validated analytical procedures to appear in a monograph. It does not, as a rule, review isolation, characterization, and qualification data that support acceptance criteria (limits) for impurities. Similarly, USP does not usually review bioavailability and bioequivalence data to justify acceptance criteria used in a USP Performance test, such as dissolution or disintegration, for a dosage form. In addition, USP does not engage in extensive testing of candidate ingredient or dosage form material with a proposed monograph to ensure that the compendial procedures are adequate. These are left to manufacturers and FDA. ${ }^{7}$ To allow the new approach, USP might rely on information such as certain regulatory acceptance criteria, providing they were based on review by selected regulatory authorities, ${ }^{8}$ or USP could develop the necessary information itself. The new approach will require careful consideration of the information needed to support a monograph for articles not legally marketed in the U.S., coupled with an understanding of the resources needed to obtain this information.

## CONCLUSION

The international market for manufactured pharmaceuticals is changing at a rapid pace, leading to a global environment that is at least as challenging as that confronting Convention delegates in 1820. Like early practitioners in the U.S., modern practitioners in many parts of the world beyond the U.S. may confront a bewildering array of poorly named therapeutic ingredients and products with uncertain safety, efficacy, and quality. Yet unlike 1820, the possibility of uniform, good-quality, safe, and effective therapeutic agents today offers health care opportunities that could not be imagined by the practitioners who formed the early pharmacopeia. This Stimuli article is presented to further discuss how USP could-and perhaps should-evolve in the coming years to serve public health both nationally and internationally. The specific suggestion is to create a separate official USP compendium, clearly distinguished from USP, to support international needs and, as feasible, national interests as well. The approach offered has broad and complex underpinnings. At no point in the approach is it intended that the national relationship with FDA and manufacturers of articles legally marketed in the U.S. be al-

[^277]tered. Instead, the approach is designed to facilitate the availability of useful public analytical information to all constituencies of USP throughout the world. In an era of counterfeit drugs, substandard drugs, drugs with unclear names and quality, drugs with uncertain safety and efficacy, in an era when infectious diseases such as HIV, malaria, and tuberculosis threaten public health advances, in an era when therapeutic agents offer hope and promise to all the world's people, and in a world where therapeutic products move across national borders with increasing speed, there are overarching justifications for a separate compendium. We welcome comments.

## APPENDIX

## Drugs

The FD\&C Act defines drugs as "articles intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease in man or other animals" and "articles (other than food) intended to affect the structure or any function of the body of humans or other animals." USP's goal is to have substance and preparation (product) monographs for all FDA-approved drugs. USP also develops monographs for therapeutic products not approved by FDA, e.g., pre-1938 drugs and compounded preparations. The complex set of procedures that result in validation of private regulatory methods submitted in NDAs, ANDAs, NADAs, and ANADAs and the subsequent transition to a public official procedure in USP, coupled with availability of a verified reference standard material, have been described elsewhere. Although submission of information needed to develop a monograph by the Council of Experts is voluntary, compliance of an article bearing a USP name, with a $U S P-N F$ monograph, if available, is not.
Names for drug substances are established through the efforts of the United States Adopted Names (USAN) Council. USP participates in this activity together with the American Pharmacists Association, the American Medical Association, and the Food and Drug Administration. Drug product names can be established by FDA but more often are developed cooperatively with USP in activities of the Council of Experts Nomenclature and Labeling Expert Committee. Oversight of brand names is the responsibility of FDA, working with applicants.

## Biologics

Originating in 1938, the FDCA includes provisions of the Public Health Service Act (PHSA) and many subsequent amendments, e.g., the provisions of the Dietary Supplement Health and Education Act (DSHEA). As defined in the PHSA, biological products are any virus, therapeutic serum, toxin, antitoxin, vaccine, blood, blood component or derivatives, allergenic product, analogous product, arsphenamine or its derivatives, or any trivalent arsenic compound applicable to the prevention, treatment, or cure of diseases or injuries in humans. Through Intercenter agreements, many
macromolecules and mixtures manufactured through recombinant technology are regulated in CBER, except for hormone biologics, which are generally regulated in CDER. CDER also regulates small molecules manufactured through recombinant technology. Therefore, biologics regulated by CDER under NDAs are subject to the compendial standard requirements under the FDCA regarding adulteration and misbranding. Biologic products regulated under the PHSA are required to bear "proper" names, not "established" names like drugs. Provisions of the FDCA apply to biological products regulated under the PHSA-except that, if licensed, a biologic product does not need an approved application under Section 505 of the FDCA. For this reason, biological drug products approved under the PHSA should comply with the adulteration and misbranding provisions of the FDCA in Section 501(b) and 502(g) and, thus, should conform to official monographs if available.

## Medical Devices

Section 201(h) of the FDCA defines a device as an article/ instrument, apparatus, or component recognized in $U S P-$ NF. Section 502(e) defines the established name of a device in the absence of an FDA designation of the official name as the official title in an official compendium. Despite these statutory provisions, there is no comparable recognition of USP's standard-setting authority and ability to define the medical device as exists for other FDA-regulated therapeutic products. Under the Food and Drug Administration Modernization Act, CDRH recognizes national and international consensus standards, including some USP tests and assays for medical devices.

## Dietary Supplements

As with drugs and biologics, the FD\&C Act names $U S P$, $N F$, and the Homeopathic Pharmacopeia as official compendia for dietary supplements. Under section 403(s)(2)(D), a dietary supplement may be deemed misbranded if it is covered by the specification in an official compendium, is represented as conforming to its specification, and fails to conform. Therefore, unlike articles classified as drugs, the dietary supplement must assert conformance to the $U S P-N F$ monograph in order for the compendial standards to apply. Compliance with a $U S P-$ $N F$ monograph is thus voluntary on the part of a dietary supplement manufacturer. In contrast, a drug approved under the FDCA must conform to an "official compendium" if compendial standards exist, unless it declares nonconformance.

## Compounded Preparations

Preparation monographs may also provide information or standards applicable in compounding. Compounding means the preparation, mixing, assembling, packaging, or labeling of a drug or device or other article as the result of a practitioner's order or in anticipation of such an order based on routine regularly observed prescribing patterns. FDAMA defines the difference between pharmaceutical manufacturing and compounding. Statements in $U S P-N F$ for compounded preparations may be enforced both at the federal and state levels.

# Microbial Identification in the Pharmaceutical Industry 

Scott V.W. Sutton, Ph.D., and Anthony M. Cundell, Ph.D., USP Expert Committee on Analytical Microbiology*

#### Abstract

A review of the microbial identification methods that are available to support compendial testing was undertaken to determine the state of the art within the pharmaceutical industry and to stimulate the USP revision process. Emphasis was given to the preliminary screening of microbial isolates for cellular morphology, staining, and diagnostic biochemical reactions to either characterize the microorganisms or support decisions for using different microbial identification schema and the rapid microbial identification methods that are available. The relative advantages of phenotypic and genotypic microbial identification methods are discussed. Due to the complexity of the topic, the authors believe that treatment of alternative microbial identification systems warrants a guidance chapter separate from the proposed General Chapter $\langle 1227\rangle$ Validation of Alternative Microbiological Methods.

## INTRODUCTION

Microorganisms found in pharmaceutical ingredients, water for pharmaceutical use, the manufacturing environment, intermediates, and finished products are frequently identified to assist in product investigations. This is especially common if their numbers exceed alert and/or action levels for the material or process environment tested. Routine monitoring might include characterization by colony morphology, cellular morphology (rod, cocci, etc.), gram reaction, and key enzyme activities. This information may be sufficient to confirm that the bacteria found in the material are typical for that material or process environment or indicative of no change in the level of environmental control in an aseptic processing area. However, there may be a need for more precise identification methods during an investigation to assign a species name to the microorganism. Microbiological identification systems are based on different analytical techniques, and each has restrictions due to method and/or database limitations and each has inherent shortcomings in terms of accuracy, reproducibility, technical complexity, rapidity, and cost. A decision must be made regarding the appropriate technology to use in the routine pharmaceutical microbiological testing laboratory with these limits in mind as well as a thought to the need for the level of identification (genus, species, strain) needed for the particular situation.

## REGULATORY GUIDANCE ON MICROBIAL IDENTIFICATION

What is the status of microbial identification in the compendia and pharmaceutical regulations? There is no USP chapter that specifically addresses microbial identification. However, the need for microbial identification is specifically

[^278]cited in USP General Chapter $\langle 61\rangle$ Microbial Limit Tests, where it is recommended that microorganisms demonstrating characteristic cellular and colonial morphology on selective and/or diagnostic agar media in the absence of specified microorganisms tests be confirmed, if necessary, by other suitable cultural and biochemical tests.
The proposed Microbial Limit Tests harmonization document (1) does not include this specific text, but it does allow for the use of alternative microbiological tests. The Australian Therapeutic Goods Administration (TGA) recommends testing for the absence of all pseudomonads in topical preparations (2) but does not provide specific means for identification. FDA, in their 1993 Guide to Inspections of Microbiological Pharmaceutical Quality Control Laboratories, references the FDA Bacteriological Analytical Manual (3) for microbial identification techniques in reviewing microbial limits tests that relies heavily on selective and differential media.
USP General Chapter $\langle 71\rangle$ Sterility Tests (harmonized with the JP and Ph. Eur. January 1, 2004) allows for invalidation of the test if "after determination of the identity of the microorganisms isolated from the test, the growth of this species (or these species) may be ascribed unequivocally to faults with respect to the material and or the technique used in conducting the sterility test procedure." The TGA document contains similar wording (4) but has gone on record that this identification must be performed at the level of DNA (5). FDA has also argued that invalidation of a sterility test requires identification of microorganisms at the DNA level in its draft aseptic processing guideline (0).
The manufacturing area is also a concern for microbial identification. USP informational chapter $\langle 1116\rangle$ Microbiological Evaluation of Clean Rooms and Other Controlled Environments recommends that microbial isolates be identified at an appropriate level to support the environmental monitoring program. The recent FDA draft guidance document on aseptic processing (6) recommends the use of genotypic microbial identification methods because of the
increased accuracy and precision of these methods. The authors believe that this statement should be critically reviewed.

There is obviously a great deal of interest in microbial identification but little guidance about precisely how to conduct it. Although the draft USP informational chapter〈1223〉 Validation of Alternative Microbiological Methods provides some guidance (7), the treatment is not complete. There is very little guidance about precisely how to qualify different methods of microbial identification, and there are many methods to choose from.

## CHARACTERIZATION OF BACTERIA IN THE PHARMACEUTICAL ENVIRONMENT

## Historic Background

The pioneer in the classification of bacteria was the German biologist Cohn, who first suggested in 1870 the division of bacteria into groups based on their cellular morphology as determined by light microscopy. At the time it was a revolutionary idea that there are many different species of bacteria. Cohn recognized six genera without the advantages of pure culture and staining techniques, emphasizing that bacteria occur with different species. They were Micrococcus (ball or egg-shaped), Bacterium (short, rod-like), Bacillus (straight, fiber-like), Vibrio (wavy, curllike), Spirillum (short, screw-like), and Spirochete (long, flexible, spiral).

In 1884, the Danish microbiologist Christian Gram developed the differential staining of bacteria that is universally used to classify them as negatively or positively reactive to what is now called the Gram's stain. The established system of bacterial classification based on colony morphology and color, cellular morphology, differential staining, motility, physiology, biochemical reactions, and substrate utilization used by American microbiologists was systematized in the 1923 Bergey's Manual of Determinative Bacteriology. The routine identification methods employed in the food, clinical, and microbiology laboratory continue to be based on the determination of the morphology, differential staining, and physiology of a microbial isolate by means of miniaturized and automated substrate utilization screening methods to speciate the isolate, e.g., API, Vitek, and Biolog microbial identification systems (8-10).

## MICROBIAL ISOLATION

Microorganisms are present in a variety of milieux in the pharmaceutical manufacturing environment. The first step to identification is to isolate a pure colony for analysis. This purification is normally accomplished by subculturing one or more times on solid media to ensure purity, each time streaking for single colonies. This technique also allows full phenotypic expression and growth of sufficient inoculum for the identification.

It should be recognized that expressions of the microbial phenotype, i.e., cell size and shape, sporulation, cellular composition, antigenicity, biochemical activity, sensitivity to antimicrobial agents, etc. frequently depend on the media and growth conditions (Table 1). These conditions will include the better-known variables such as temperature, pH , redox potential, and osmolality and lesser-known variables such as nutrient depletion, vitamin and mineral availability, growth cycle, water activity of solid media, static or rotatory liquid culture, and solid versus liquid media culture, as well as colony density on the plate.

Table 1. Phenotypic characteristics that may be employed in microbial taxonomy

| Categories | Characteristics |
| :--- | :--- |
| Cultural | Colony morphology, colony color and <br> size, and pigment production |
| Morphological | Cellular morphology, cell size, flagella <br> type, reserve material, gram reaction <br> and spore, and acid-fast staining. |
| Physiological | Oxygen tolerance, pH range, tempera- <br> ture optimum and range, and salinity <br> tolerance |
| Biochemical | Carbon utilization, carbohydrate oxida- <br> tion or fermentation, and enzyme pat- <br> terns |
| Inhibition | Bile salt-tolerance, antibiotic suscep- <br> tibility, and dye tolerance |
| Serological | Agglutination <br> Chemo- |
| Taxty acid profile, microbial toxins, and |  |
| whole cell composition |  |

In contrast, the microbial genotype is highly conserved and is independent of the culture conditions, so the identifications may be conducted on uncultured test material-primary enrichments that increase the amount of nucleic acid available for analysis, the primary isolation cultures from microbial limit testing ( $\langle 61\rangle$ ), or environmental monitoring plates. For example, a recent publication (11) confirmed the stability of repetitive-sequence PCR patterns of the bacteria E. coli, P. aeruginosa, E. faecalis, S. epidermidis, and $A$. baumannii with respect to both the age of the culture and 5,10 , and 15 subcultures. Table 2 lists a number of genotypic characteristics that may be determined.

Table 2. Genotypic/phylogenic characteristics that may be employed in microbial taxonomy

| Categories | Characteristics |
| :--- | :--- |
| Genotypic | DNA base ratio $(G+C$ content $)$, restric- <br> tion fragment patterns, and DNA |
| phylogenic | probes <br> DNA-DNA hybridization, and 16S and <br> 23S rRNA codon sequences |

## PRELIMINARY SCREENING OF MICROBIAL ISOLATES

Microorganisms isolated from pharmaceutical ingredients, water for pharmaceutical use, the manufacturing environment, intermediates, and finished products on compendial media in all likelihood will be physiologically stressed. The microorganisms will go from a metabolic status suitable for slow or no growth for survival under adverse conditions to rapid growth under laboratory culture conditions. This transition can be managed by careful handling of the isolates. Individual representative colonies from the primary isolation media are streaked onto solid media as described above in preparation for identification. The first step is to determine the gram reaction and cellular morphology of the bacteria isolates. This is a critical step for phenotypic identification schemes. If the wrong gram reaction and/or cellular morphology are assigned to an isolate, subsequent testing may be conducted using the wrong microbial identification kit, resulting in an incorrect or nonsensical result. Several common preliminary screening tests are described below.

## Gram Staining

Gram staining methods employed include the four-step method: Crystal violet (primary stain); iodine (mordant); alcohol (decolorizer); safranin (counter stain) or the three-step method in which the decolorization and counter-staining step are combined. Done correctly, Gram-positive organisms retain the crystal violet stain and appear blue; Gramnegative organisms lose the crystal violet stain and contain only the counter-stain safranin and thus appear red. Common pitfalls in this method are that heat fixation may cause Gram-positive cells to stain Gram-negative and older cultures may give Gram-variable reaction; using too much decolorizer could result in a false Gram-negative result and not using enough decolorizer may yield a false Gram-positive result. One variation that has advantages in some situations is to perform a methanol fix of the bacterial smear on the microscope slide; this may be preferable to a heat fix for consistent results.

Because the Gram-staining reaction must be read under a microscope, this method provides two pieces of information: the Gram-staining characteristics and the cell morphology (i.e., rods or cocci, single cells or chains or clumps or clusters, etc.). The use of a semi-automated cell-staining device such as the Aerospray Gram-staining instrument (Wescor, Inc., Salt Lake City, UT) to give more consistent results is recommended.

## Spore Staining

Spore staining methods employed include a two-step method: malachite green (primary stain) and safranin (counter stain). The fixed bacterial smear is stained with 7.6\% aqueous malachite green solution for 10 minutes, rinsed, and counter stained with a $0.25 \%$ aqueous safranin solution
for 15 seconds, rinsed, and blotted dry. This procedure stains the spores green, but the rest of the bacterial cell is stained red.

## Biochemical Screening

Key biochemical screening tests are the oxidase test to separate Gram-negative rod-shaped bacteria into nonfermenters (oxidase positive) and enteric (oxidase negative) bacteria, the catalase test to separate Staphylococci (catalase positive) from Streptococci (catalase negative), and the coagulase test to separate staphylococci into coagulase negative (presumptively nonpathogenic) and coagulase positive (more likely pathogenic) staphylococci.
For many types of investigations, these few tests may provide enough information to trend data. However, there are much more definitive bacterial identification schemes or systems available to the pharmaceutical microbiologist.

## MICROBIAL IDENTIFICATION BY PHENOTYPIC METHODS

Phenotypic methods utilize expressed gene products to distinguish among different microorganisms. Generally, these require a large number of cells in pure culture. Disadvantages of culture methods for microbial enumeration and identification are well known and include the long incubation times, the inability of most environmental microorganisms to grow on artificial media, the specific growth requirements of many microorganisms, the unintentional selectiveness of culture methods, and the need to fully express phenotypic properties of recently isolated stressed microorganisms by subculture from primary isolation, selective, or diagnostic media prior to microbial identification. However, the carbon utilization and biochemical reaction patterns for microbial species in the database for a microbiological identification system are always based on inocula development for that identification system on specified culture media and incubation conditions to achieve consistency of identification. Despite these limitations, phenotypic microbial identification methods are successfully employed in the routine food, water, clinical, and pharmaceutical microbiological testing laboratory. An excellent overview of manual and automated systems for the detection and identification of microorganisms may be found in the 8th Edition of the ASM Manual of Clinical Microbiology (12).

## Carbon Utilization and Biochemical Reaction Methods

A compendial example of this approach is $\langle 61\rangle$ Microbial Limit Tests, which utilizes general and selective enrichment broth and diagnostic solid media to demonstrate the absence of specified microorganisms. These methods can be conducted in any microbiology laboratory.

There are several microbial identification kits based on carbon utilization and biochemical reactions that are readily available. The API strip takes what originally required racks of tubes and reduces them in size and complexity to several
small, prepackaged strips. The Vitek Microbial Identification System takes this concept a step further, miniaturizing the reaction tubes in cards and coupling the assay with automated incubation and reading. However, these traditional biochemical methods are not the only phenotypic test methods available to the pharmaceutical microbiologist.

The Biolog Microbial Identification System has an identification scheme based on carbohydrate utilization. A 96well microtiter plate holds a variety of media containing specified carbohydrates and a redox indicator. If growth occurs in a particular well, the reduced conditions within that well result in the redox dye tetrazolium turning dark, signifying catabolism of the substrate. This reaction is easily read manually or by a photometric plate reader, and the result is a semi-automated identification system that complements the traditional methods.

In addition to the carbohydrate utilization method, Biolog has also developed a "Phenotype MicroArrays" system that utilizes the same basic technology but can monitor, either directly or indirectly, a large number of different aspects of cell function. The range of phenotypes monitored includes cell-surface structure and transport functions, catabolism of carbon, nitrogen, phosphorus, and sulfur compounds, biosynthesis of small molecules, cellular respiratory functions, and finally, stress and repair functions. This offers the small lab an opportunity to delve into greater detail during an investigation and to provide finer differentiation among isolates.

In addition to the phenotypic methods used to identify microorganisms based on their gram reaction, cellular morphology, carbon utilization patterns, and biochemical reactions are methods based on the cellular composition of the microorganisms grown on specified media. These include the MIDI (gas-liquid chromatographic fatty acid ester analysis) Microbial Identification System and the MicroMass MALDI TOF mass spectrometry with the MicrobeLynx pattern recognition software.

## Fatty Acid Analysis

When bacteria are grown on defined and reproducible media, the fatty acid composition of their membranes is consistently expressed as a phenotypic characteristic. The MIDI Microbiological Identification System utilizes this characteristic. Fatty acids are extracted from cell cultures and es-
terified, and the patterns of fatty acid esters are then determined using gas-liquid chromatography. This system then identifies microorganisms based on the unique fatty acid pattern of each strain. The system uses gas chromatographs, proprietary microbial databases, and pattern recognition software to identify each strain.

## Mass Spectrometric Methods

Less well known than the fatty acid analysis (and far less utilized), MALDI TOF mass spectrometry has promise as a technique for the rapid identification of microorganisms. Whole bacterial cell analysis has yielded unique mass spectra from charged macromolecules from common species of bacteria. The absence of sample preparation, coupled with rapid analysis and high throughput make the technology attractive as a rapid microbial identification method. The method involves applying the bacterial cultures to the instrument plate wells, overlying the whole cells with a solvent matrix of alpha-cyano-4-hydroxycinnamic acid for Gram-negative bacteria and 5-chloro-2-mercaptobenzothiazole for Gram-positive bacteria. The wells are then bombarded with a nitrogen laser that causes desorption of ionized cellular components that travel down a tube toward a detector. The time for the charged components to reach the detector operated in a positive ion detection mode using an acceleration voltage of +15 kV is a function of their kinetic energy, i.e., mass and charge. The detector signal is captured as a unique fingerprint for different species/stains of microorganism in the acquisition mass range of 500 to 10,000 Daltons. The MicroMass MALDI TOF mass spectrome-try-MicrobeLynx database currently has approximately 3500 spectral entries covering more than 100 genera and more than 400 different species. The time to process a sample is on the order of 3 minutes, so the equipment could run at least 100 microbial identifications a day.

## Survey of Phenotypic Methods

Representative phenotypic microbial identification systems that are widely used in the pharmaceutical industry are listed in Tables 3 and 4. With the substrate utilization methods, the incubation time may be shortened from overnight to 2-4 hours by using higher inoculum levels.

Table 3. Representative phenotypic microbial identification methods for members of the family Enterobacteriacae

| Product | Manufacturer | Method | Incubation <br> Time |
| :--- | :--- | :--- | :--- |
| API 20E | bioMérieux, Durham, NC | Substrate utilization and <br> biochemical reactions | Overnight |
| BBL Crystal Enteric/ <br> Nonfermenter | BD Diagnostics, Sparks, DE | As above | 4 hours |
| GN Microplate <br> Vitek GNI Plus | Biolog, Hayward, CA <br> bioMérieux, Durham, NC | As above <br> As above | As above <br> 2 hours and/or <br> overnight |

Table 3. Representative phenotypic microbial identification methods for members of the family Enterobacteriacae (Continued)

## NUCLEIC ACID-BASED (GENOTYPIC) MICROBIOLOGICAL METHODS

## Historic Background

In 1953, Watson and Crick reported the chemical structure and the base pairing of the DNA molecule. Their Nobel prize-winning publication in the British scientific journal Nature was the beginning of the new field of molecular biology that revolutionized biology and medicine.

An important milestone in the development of molecular biology-based microbiological methods was the discovery by Kornberg in 1958 of the enzyme DNA polymerase, which is responsible for the replication of nucleic acid. This was followed by the use of DNA-DNA hybridization to show the DNA relatedness between enteric bacteria in 1969, as well as the discovery of restriction enzymes to cleave DNA into analyzable fragments (the basis of ribotyping) that same year. The first use of ribosomal 16S RNA gene homology in bacterial taxonomy was described by Woese in 1977, and that same year DNA sequencing was used in taxomony by Sanger. Eight years passed before polymerase chain reaction (PCR) was developed as a tool to rapidly amplify a DNA segment (Mullis in 1985), and the first complete DNA sequencing of the genome of a bacterium, Haemophilis influenzae, was achieved ten years later by Venter and his team in 1995. Additional information on these milestones may be found in the American Society for Microbiology website article titled "Significant Events of the Last 125 Years" (13).

By the end of 1999 there were 4313 validly named prokaryotic species and 849 validly named genera of Bacteria and Archaea reported in the second edition of Bergey's Manual of Systematic Bacteriology (14) based on 16S rRNA DNA sequence analysis. The phylogenetic organization, i.e., DNA relatedness at the species level of the manual is notable with references to the information contained in the species descriptions. The revolution in microbial taxonomy started by Woese in 1977 would seem to be complete.
The key to the whole field of nucleic acid-based identification of microorganisms was the introduction of the concept of molecular systematics using proteins and nucleic acids in 1965 by the American Nobel laureate, Linus Pauling. Because the sequence of nucleic acids in a particular microorganism is extremely conserved or constant, even over geological time, and the DNA and RNA molecules are relatively stable, they are excellent materials for the detection and identification of microorganisms. However, this is complicated by the fact that a single bacterial cell weighs $10^{-13} \mathrm{~g}$ and the nucleic acid sequences that are amplified by Polymerase Chain Reaction (PCR) may represent 100 to 100,000 times less than the weight of the bacterial cell. To analyze the nucleic acid from a microorganism one needs to culture the organism and/or amplify the nucleic acid.
More details of the historic development of microbiological methods can be found in a chapter by one of the authors in the book Rapid Microbial Methods in the Pharmaceutical Industry (14).

## Absence of Specified Microorganism Screening

To detect with a high probability a single Salmonella cell in 10 g of a pharmaceutical product as required by absence of specified microorganism screening, an enrichment culture would need to obtain at least $10^{3}$ cells per mL . The cells would be lyzed, the nucleic acid extracted, and a thermostable polymerase used to copy a nucleic acid strand using oligonucleotide primers specific for Salmonella. This is achieved using a set of cycling temperatures to denature the nucleic acid, hybridize it with the primers, and use poly-merase-mediated complementary-strand synthesis to produce more nucleic acid. Twenty to thirty thermocycles can increase the amount of target nucleic acid over a million times so it can be detected by its electrophoretic pattern after treatment with reverse transcriptase, reaction with chemiluminescent DNA probes, or rRNA base sequence. This technology has been commercialized for the detection of $E$. coli O157:H7, Listeria monocytogenes, and Salmonella spp. by Qualicon as the BAX Microbial Detection System; for the detection of E. coli O157:H7 by Applied Biosystems as the TaqMan Pathogenic E. coli Detection System; and for Salmonella spp. as the Roche LightCycler PCR Salmonella Detection System (see Table 5). With PCR technology it will be possible to develop a multiplex PCR system for the simultaneous detection of the USP indicator organisms $E$. coli, S. aureus, P. aeruginosa, and Salmonella spp. for absence of specified microorganism testing to meet microbial limits requirements for nonsterile pharmaceutical drug products as indicated in specific monographs.

## BAX Microbial Identification System

The BAX Microbial Detection System takes microbial enrichments according to standard protocols for the type of food to be examined. A heated lysis reagent solution ruptures the bacterial cell wall, thereby releasing the DNA that is added to a lyophilized PCR reagent, and the DNA is amplified in the thermocycler/detection instrumentation.

## Ribotyping

With the RiboPrinter Microbial Characterization System marketed by duPont Qualicon, DNA is extracted from the bacterial cell lysate of pure colonies picked from an agar plate; the cells are lyzed, and the DNA is cut into fragments by a restriction enzyme. The DNA fragments are separated by molecular size and charge using gel electrophoresis and are transferred to a membrane where they are hybridized with a labeled DNA probe. A chemiluminescent agent is added, and the emission of light is captured by a digitizing camera. The RiboPrint is compared to other patterns in a database, and the bacterium is identified or a stain comparison is made from the ribotyping patterns. The RiboPrinter has the capacity to identify on the order of 20 organisms daily.

## Bacterial Barcodes

Bacterial Barcodes developed a repetitive-sequence and PCR-based DNA fingerprinting (rep-PCR) technology that is combined with the Agilent 2100 Bioanalyzer and Caliper Technologies LabChip and the DiversiLab software to identify a range of bacterial stains of clinical significance. The rep-PCR technology is based on noncoding repetitive sequences that are found interspersed through bacterial DNA. When PCR is performed using primers complementary to these repetitive sequences, the DNA sequences lying between the repetitive sequences are amplified. These amplified sequences were initially separated by electrophoresis. The stained gel contains a banding pattern or barcode that is distinctive for the bacterial stain. Computer-based analyses of the digitized images of the banding generated dendrograms demonstrating the relatedness of the stains. The Bioanalyzer processes the LabChips DNA chips, replacing the standard gel electrophoresis with automated lab-on-a-chip microfluids. These components are capable of preparing samples, capturing DNA fingerprints, and analyzing the results within 5 hours.

## Ribosomal RNA Base Sequencing

The MicroSeq 500 16S rDNA Bacterial Sequencing Kit marketed by Applied Biosystems allows bacterial identification using the DNA sequence of the first 500 base pairs of the bacterium's 16 S rRNA gene, and the full-gene kit enables full characterization of the entire 16 S rRNA gene of the bacterium. The MicroSeq Bacterial Sequencing Kits have been validated for use on PCR thermal cyclers from Applied Biosystems. The nucleic acid is extracted from a loop of a bacterial colony and amplified. The amplification products are run on the capillary electrophoresis-based ABI PRISM 310 Genetic Analyzer for maximum automation or on the slab gel-based ABI PRISM 377 DNA Sequencer for maximum throughput. After sequencing, the MicroSeq system identifies a bacterium or its closest genetic relatives through dedicated software that compares the gene sequence of the sample against the MicroSeq 16S rDNA Database. This database includes the 16 S rDNA gene sequences of more than 1200 known organisms, and the microbial identification daily throughput ranges from 8 to 128 , depending on the sequencing instrumentation configuration.

## PCR Kit for the Detection of Salmonella in Food

The LightCycler Salmonella Detection Kit (RocheDiagnostics) was developed to detect low levels of Salmonella in food. Using sequence-specific primers in a PCR, the LightCycler amplifies and detects in real time, employing fluorescence hybridization probes, a fragment of the Salmonella DNA derived from an enrichment culture. This procedure, including PCR set and 36 - to 48 -cycle run, can be completed with 75 minutes with 30 samples included in the LightCycler run.

Table 5. Representative genotypic microbial identification methods

| Product | Manufacturer | Method | Processing Time |
| :---: | :---: | :---: | :---: |
| RiboPrinter Microbial Characterization System | DuPont Qualicon, Wilmington, DE | Ribotyping, i.e., restrictive enzyme cleavage, electrophoretic separation, and chemiluminescent probes | 8 hours |
| BAX Microbial Detection System | DuPont Qualicon, Wilmington, DE | Nucleic acid extraction, PCR amplification, and chemiluminescent probes | Overnight |
| MicroSeq 16S and 23S rRNA Gene Sequence Analysis | Applied Biosystems, Foster City, CA | Nucleic acid extraction, PCR amplification, and rRNA base sequencing | 2-4 hours |
| LightCycler PCR Salmonella Detection System | Roche Diagnostics, Indianapolis, IN | Nucleic acid extraction, PCR amplifica- tion, and chemiluminescent probes | 1-2 hours |

## IDENTIFICATION OF FUNGI

## Phenotypic Methods

Interest in fungal taxonomy has increased due the growing clinical importance of opportunistic fungal pathogens associated with immunocompromised patients due to the AIDS epidemic, leukemia, organ transplant, and invasive medical procedures. Fungi are classified and identified by their morphological features rather than their nutritional and biochemical differences. Fungal taxonomy is complicated by the existence of teleomorphs (sexual states) and anamorphs (asexual states) for the same fungus that develop at different times under different nutritional conditions, leading to dual species names (16). Clinical mycologists as well as pharmaceutical microbiologists are most familiar with Deuteromycetes (anamorphs) or, to use an older terminology, fungi imperfecti. Unfortunately, fungal taxonomy is
technically difficult and is usually limited to mycological specialists. Although classical identification methods based on morphology are generally applied to fungal identification, carbon utilization and biochemical reaction patterns have been successfully used to identify yeast, e.g., API 20C and the Biolog FF System. These methods are suitable for the routine microbiological testing laboratory. Table 6 presents a number of commercially available systems for phenotypic identification of fungi.
The Biolog Filamentous Fungi system employs redox chemistry similar to Biolog's other technology. Based on reduction of tetrazolium in response to metabolic activity, the reaction occurs in a 96 -well plate that allows the analysis of fungal growth via turbidimetric means. There is an option for workers to add their own patterns of carbon usage produced by new cultures outside of the Biolog database.

Table 6. Representative microbial phenotypic identification methods for fungi

| Product | Manufacturer | Method | Incubation <br> Time |
| :--- | :--- | :--- | :--- |
| API 20C (Yeast) | bioMérieux, Durham, NC | Substrate utilization and <br> biochemical reactions | $24-48$ hours |
| YT Microplate (Yeast) | Biolog, Hayward, CA <br> bioMérieux, Durham, NC | As above <br> Vitek YBC (Yeabove | As above |
| Biolog FF System (Filamentous <br> Fungi) | Biolog, Hayward, CA | As above | As above |
| Microbial Identification <br> System (MIS) | MIDI, Newark, DE | Fatty acid ester analysis | $4-14$ days |

## Genotypic Methods

rRNA gene sequencing and Ribotyping may also be applied to fungal identification. For example, recent studies using MicroSeq D2 ribosomal DNA sequencing to identify molds and yeasts found in a clinical setting determined that

58 and $93.9 \%$ of the molds and yeasts, respectively, that could be identified with those isolates were neither identified nor included in the MicroSeq or API microbial identification system libraries (17 and 18). Clearly the fungal MicroSeq library is inadequate for mold identification.

## THE RELATIVE MERITS OF PHENOTYPIC AND GENOTYPIC MICROBIAL IDENTIFICATION METHODS

Application in Clinical Microbiology

Whereas rRNA gene sequencing has had a profound effect on microbial taxonomy, it may be asked what are the appropriate applications of nucleic acid-based methods to pharmaceutical microbiology? In clinical microbiology genotypic identification methods have been successfully applied to the identification of fastidious organisms, e.g., Clamydia trachomatis and Neisseria gonorrhoeae, slowgrowing organisms, e.g., fungal pathogens, and Mycobacterium tuberculosis, rapid screening for pathogens e.g., group A Streptococcus confirmatory testing, and unculturable organisms, e.g., the Whipple's bacillus Tropheryma whippelii (19).

Because of medical reimbursement requirements, clinical microbiology is subject to greater cost controls than is pharmaceutical microbiology, and it is unlikely that rRNA gene sequencing will be a routine test method. However, in some instances the cost-effectiveness of the use of these methods can be demonstrated in better clinical outcomes, reduced hospital stays, or the prevention of future illness compared to conventional clinical microbiology testing. In contrast, it is difficult to justify genotypic identification methods for routine pathogen screening and identification, especially when the relatively few pathogens isolated from the screening of clinical samples that are usually sterile may be readily identified using phenotypic methods.

## Genotypic Methods

Genotypic microbial identification methods based on nucleic acid analyses may be less subjective, less dependent on the culture method, and theoretically more reliable because nucleic acid sequences are highly conserved by microbial species. These methods would include DNA-DNA hybridization, PCR, 16 S and 23 S rRNA gene sequencing, and analytical ribotyping. However, these methods are more technically challenging for the pharmaceutical microbiologist and are more expensive in terms of both equipment and current testing costs, and they often rely on a technology marketed by a single company. Their current use may be better suited to critical microbiological investigations associated with direct product failure or with the identifications conducted in a specialized research-oriented laboratory
within a pharmaceutical company or sent to a contract testing laboratory. The increased accuracy of identification with rRNA base sequencing and the ability to determine the strain of microorganism with ribotyping may be seen as molecular epidemiology tools that are best deployed to definitively determine the origin of the microbial contamination in media fill and sterility test failures and environmental monitoring excursions exceeding established action levels.

## Genotypic versus Phenotypic Methods

Phenotypic methods rely on the more subjective determination of cellular morphology, gram reaction, catalase, coagulase or oxidase activity, other biochemical reactions, and carbon utilization patterns for identification, which introduces some disadvantages in consistent identification. However, these are mature technologies that are marketed by multiple companies as consistent, prepackaged kits with well-established quality control procedures and mature instrumentation with extensive databases to identify the most commonly encountered microorganisms found in the pharmaceutical industry. Furthermore, their underlying technologies are familiar to microbiologists working in routine microbiological testing laboratories in both large and small pharmaceutical companies. In contrast, the technologies deployed in genotypic methods are not as well established and are better suited to a research environment. Typically a single company currently markets some technologies, and, in some cases, there is a lack of commercially available reagents, primers, and probes. In addition, the technology is unfamiliar to most pharmaceutical laboratories, and the tests may be subject to nucleic acid contamination if they are not run in an environment with suitable controls in place to eliminate such contamination. Also, the nucleic acid can be difficult to reliably extract from some organisms, and many of the systems lack validated and/or appropriate databases for environmental microorganisms encountered in the pharmaceutical industry. Additionally, the instrumentation is expensive, and the unit testing cost is greater than that for phenotypic methods, so the implementation of the technology may be limited to larger pharmaceutical companies. An important consideration with a microbial identification technology is the number and types of genera and species in the database compared to those in the public domain. A comparison of the database size of representative phenotypic and genotypic microbial identification methods is presented in Table 7.

Table 7. Comparison of the database size of representative phenotypic and genotypic microbial identification methods

| System | Classification | Database Size | Comments |
| :---: | :---: | :---: | :---: |
| Vitek Microbial Identification Systems | Phenotypic | 800+ species of bacteria and yeast | Stronger in clinical organisms |
| Microlog Microbial Identification Systems | Phenotypic | 1900 species of bacteria, yeast, and molds | Stronger in environmental organisms |
| Sherlock MIDI Microbial Identification System | Phenotypic | 2000 entries, including aerobic and anaerobic bacteria and yeasts | Wide applicability |
| MALDI TOF MS plus MicrobeLynx | Phenotypic | Approximately 3500 spectral entries covering more than 100 genera and more than 400 different species | Developed by a collaboration between Manchester Metropolitan University and NTTC |
| RiboPrinter | Genotypic | 6000 ribotypes consisting of 197 bacterial genera and 14,000 species | Type organisms and submitted isolates |
| MicroSeq 16S rRNA gene sequencing bacterial identification system | Genotypic | Bacterial full-gene and 500 basepair libraries have 1400+ entries | Includes an extensive coverage of Gram-negative nonfermenters, Bacillus, Coryneforms, Mycobacteria, and Staphylococcus |
| Microseq D2 LSU rDNA fungal identification system | Genotypic | 900 entries for yeast and filamentous fungi | Weak in both clinical and environmental fungi |
| Accugenix rRNA Gene Sequencing Systems | Genotypic | Accugenix bacterial database: 1607; Accugenix fungal database: 544 | Propriety database |
| Bergey's Manual of Systematic Bacteriology, 2nd ed. | Genotypic and Phenotypic | 849 genera and 4313 validly named prokaryotic species | Taxonomic authority |
| Ribosomal Database Release 2/06/04 | Genotypic | 87,860 aligned and annotated bacterial and archeal rRNA gene sequences | Extracted from primary sequence databases (DDBJ, EMBL, and GeneBank) |
| GeneBank (NCBI) | Genotypic | 1244 genera and 13,088 bacterial species | Public-domain database |

Driving the technology is the undisputed fact that these genotypic microbial identification methods, based on nucleic acid analyses, are less subjective, less dependent on the culture method, and theoretically more reliable because nucleic acids are highly conserved by microbial species. However, the microbiology laboratory cannot just buy the equipment, plug it in, and transfer a technician from performing other duties to running these methods. A significant investment in training, validation, and database development is required to successfully implement these methods.

The genotypic methods have some significant advantages; however their use should be limited to critical microbiological investigations associated with direct product failure, and identifications should be conducted in a specialized research-orientated laboratory within a pharmaceutical company (or sent to a qualified contact testing laboratory). The increased accuracy of identification with rRNA codon base sequencing and the ability to determine the strain of microorganism with ribotyping in some respects is a type of molecular epidemiology that seeks to more de-
finitively determine the origin of the microbial contamination in media fill and following sterility test failures and action level excursions during environmental monitoring.

## LITERATURE SURVEY

As stated earlier, in clinical microbiology genotypic identification methods have been successfully applied to the identification of fastidious organisms (e.g., Clamydia trachomatis and Neisseria gonorrhoeae), slow-growing organisms (e.g., fungal pathogens and Mycobacterium tuberculosis), rapid screening for pathogens (e.g., group A Streptococcus confirmatory testing), and unculturable organisms (e.g., the Whipple's bacillus Tropheryma whippelii) (19). Grazier et al. (20) looked at the ability of ribotyping to discriminate among Enterobacter cloacae isolates in comparison to a battery of conventional serological and biochemical assays and concluded that there was good agreement between identification by the genetic method and the combination of conventional methods. Clabouts et al. (21) performed a similar study with Clostridium difficile,

Martin et al. (22) with E. coli, Nielsen et al. (23) for Campylobacter jejuni, and Nadon et al. (24) for Listeria mono-cytogenes-all with similar results.

To date few publications have directly compared phenotypic and genotypic microbial identification methods. A study conducted at the Mayo Clinic reported using 72 unusual aerobic Gram-negative bacteria comparing the results achieved with the Sherlock MIDI system (cellular fatty acid profiles), MicroLog System (carbon utilization), and MicroSeq System (16S rRNA gene sequencing) against their clinical laboratory's conventional system (25). The agreement with the conventional system at the genus level was MicroSeq ( $97.2 \%$ ), MicroLog ( $87.5 \%$ ), and Sherlock ( $77.8 \%$ ). Drancourt et al. (26) demonstrated the need to accurately determine the gram reaction, oxidase and catalase activities, growth requirements, and appropriate biochemical profile determination to achieve accurate phenotypic identification; they used 16 S rDNA sequence analysis to identify previously unidentified environmental and clinical bacterial isolates. They also found that $10 \%$ of the environmental isolates could not be identified because they may be new species, and the sequencing could not separate Enterobacter and Pantoea isolates into species. In a poster at a recent ASM Annual Meeting, Waddington et al. compared genotypic and phenotypic methods for bacterial identification (27). They reported that with 18 ATCC cultures representing common environmental isolates the accuracy/reproducibility using MicroSeq DNA sequencing, Ribotyping, MIDI fatty acid ester analysis, Microlog substrate utilization, and Vitek 2 substrate utilization and biochemical reactions was $100 / 100 \%, 81 / 97 \%, 50 / 81 \%, 65 / 62 \%$, and $33 / 89 \%$, respectively. The selection of cultures readily identified by the DNA sequencing system may have unintentionally biased the outcome of the study.

Other studies using rRNA gene sequencing support the promise of the system for microbial identification but highlight the need to expand the database of the MicroSeq 500 16 S rRNA gene sequencing system. Furthermore, many microorganisms readily recognized by the phenotypic system do not require nucleic acid-based systems (28 and 29). However, a recent study by the National Reference Center for Mycology (Canada) shows that for difficult-to-cultivate mycobacteria these genetic approaches are actually more cost effective than conventional methods (30).

## DECISION MATRIX

Whereas rRNA gene sequencing has had a profound effect on microbial taxonomy, the appropriate role of nucleic acid-based identification methods in pharmaceutical microbiology is not yet clear. When companies are evaluating the suitability of microbial identification methods they are encouraged to consider a range of factors objectively in a decision matrix. Factors that must be considered and weighed are safety issues, breadth of application of the method, history of regulatory approval, equipment cost, unit-test cost, rapidity of the method, number of identification runs per day, number of vendors who can supply the equipment,
complexity of the method, ease of validation, training requirements, and potential cost savings. In addition, the use of the resultant information is a consideration. For example, there is no point to having highly detailed, expensive-to-obtain information to establish environmental trends in an aseptic manufacturing facility when identification to the genus level is sufficient to establish that the environment is in a state of control.
These considerations are common to all new microbiological methods. Recent publications discussing the adoption of new technology include the PDA Task Force Report (31), a recently published book on this topic (32), a USP Stimuli article discussing the relationship between rapid microbial methods and process analytical technology (33), and a recent In-Process Revision (7).

## VALIDATION OF MICROBIAL IDENTIFICATION METHODS

An excellent document that addresses both the selection and validation of microbial identification methods is Cumitech 31: Verification and Validation of Procedures in the Clinical Microbiology Laboratory (34). Another option is the AOAC International Official Methods program, which qualifies microbiological methods as official methods using interlaboratory collaborative studies (35). Additionally, USP has proposed a validation scheme (7). However, the proposed USP chapter is unsatisfactory in several regards, not least of which is that in an effort to address all aspects of the problem it has become so stilted and unwieldy that it is difficult to apply. The authors propose that the issue of microbial identification be removed from the draft general chapter $\langle 1223\rangle$ and be developed as a separate chapter utilizing available reference material.

# Proposal and Qualification of a Harmonized Anti-Factor Ila Assay for Unfractionated Heparin Potency Determination 

Patrick N. Shaklee,* USP Blood and Blood Products Expert Committee and BioCascade Incorporated; Elaine Gray, National Institute for Biological Standards and Control (UK); Peter Rigsby, National Institute for Biological Standards and Control (UK); Emmanuelle Charton, European Department for the Quality of Medicines; Toine Overbeeke, Diosynth bv; G.W.K van Dedem, Diosynth bv; Erwin Coyne, Loyola University Medical Center; Mette Schrøder, LEO Pharma A/S; and Kristian B. Johansen, LEO Pharma A/S

#### Abstract

In 1998, a working group was set up by the World Health Organization to address biological standardization of unfractionated heparin. The purpose of the working group was to examine the feasibility of replacing current pharmacopeial heparin assays with more modern test methods. A drafting group from within the working group was then given the task of testing and developing a suitable heparin assay, namely, the chromogenic Anti-Factor IIa (thrombin inhibition) method. The drafting group laboratories then conducted a multi-laboratory, multi-day qualification study of the proposed Anti-Factor IIa assay. In the present article, results of the drafting group qualification study are presented demonstrating the flexibility, precision, and robustness of the Anti-Factor IIa assay methodology. Based on the findings described herein, a proposal is put forth for conducting a larger collaborative study of the heparin Anti-Factor IIa assay. The larger collaborative study intends to assess suitability of the proposed Anti-Factor IIa method as a replacement for current pharmacopeial heparin assay methods involving animal plasmas.

## INTRODUCTION

The official USP monograph assay for measuring the potency of Unfractionated Heparin (heparin or UFH) has been in continuous, unchanged use since it was first introduced in 1949 (1). The USP heparin assay method is based on the ability of known amounts of heparin to inhibit the clotting of recalcified sheep plasma (2). The problems associated with the USP assay, including variability in sheep plasma sources, inability to automate the method, subjectivity in measuring the degree of clotting, and results being unsuitable for statistical evaluation, are well known and have been previously discussed (3). In a similar manner, the EP heparin potency assay involves measuring the extension of the clotting times when specified quantities of rabbit-brain cephalin and heparin are added to recalcified sheep plasma (widely known as the sheep plasma aPTT method; see refs. 4-6). No major difficulty has been reported with the EP assay, which has demonstrated robustness and reproducibility in two international collaborative studies (5, 6). However, the EP Assay relies on variable sheep-plasma and aPTT reagents that can, in turn, cause assay variability (3-5). Finally, the JP heparin assay procedure requires both sulfated bovine blood and bovine brain thrombokinase (8). Because of reports of bovine spongiphorm encephalopathy (BSE) in Europe, Japan, and the US, it is becoming increasingly difficult to obtain and/or import reagents for performing the assay using the JP procedure (9).

To circumvent the problems described above, a proposal for a new USP Heparin assay based on an Anti-Factor IIa (thrombin inhibition) procedure was put forth by Coyne et al. in a Pharmacopeial Forum Stimuli article in 1994 (3). A separate proposal was made by Johansen for an Anti-Factor IIa method as "a new pharmacopoeial assay for unfractionated heparin" during a 1998 meeting convened by the World Health Organisation (WHO) to establish the $5^{\text {th }}$ International Unfractionated Heparin Reference Standard (5, 10). Following the 1998 meeting, a Working Group (WG) was established consisting of representatives from WHO, the pharmacopoeias (i.e., USP, EP, and JP), industry, and national control authorities (11). The purpose of the WG was to examine the feasibility of using a chromogenic Anti-Factor IIa assay as a harmonized, global replacement assay for unfractionated heparin (11). A smaller Drafting Group was then established with a charge to "prepare a standard operating procedure for the proposed global Anti-Factor IIa chromogenic method" (11). During subsequent Drafting Group meetings (12,13), conditions were established for the harmonized Anti-Factor IIa method, and a validation study was designed and implemented by the Drafting Group members. One purpose of the present article is to present the design and findings of the Drafting Group Anti-Factor IIa method qualification study. A second purpose is to propose a future, larger collaborative study of the harmonized AntiFactor IIa procedure to assess suitability of the method as a replacement for current pharmacopeial heparin assays involving animal plasmas.

[^279]
## AIM OF STUDY

The aim of this study was to qualify the Anti-Factor IIa method finalized at the 2001 Drafting Group Meeting (13), using as reference and test materials the 5th International Standard for Unfractionated Heparin and a clinical preparation of unfractionated heparin, respectively (5). Six samples each of both reference and test heparin were sent to each of five participating laboratories for six separate days of AntiFactor IIa testing. Additionally, the study design required that participants use both common (provided) and in-house (local laboratory) antithrombin and thrombin assay components on each day of analysis and provide separate results for each set of reagents. Precision, robustness, and reagent effects were then assessed with a detailed statistical analysis of the results.

## SAMPLES

These two samples were sent to each of the participants:
S: The $5^{5 \mathrm{~h}}$ International Standard for Unfractionated Heparin, 97/578. Freeze-dried preparation. Potency 2031 IU/ampoule. T: A Clinical preparation of unfractionated heparin. Liquid preparation. Potency range $350-450 \mathrm{IU} / \mathrm{mL}$.
The participants were asked to use the potency range above as a guide and to adjust the initial dilutions of each heparin so that the responses for the dilutions in the assays were in a similar range.

In addition, a purified human antithrombin preparation (NIBSC, $95 / 808,5.0 \mathrm{IU} / \mathrm{ampoule})$ and a purified human thrombin preparation (NIBSC, $94 / 708$, specific activity $3400 \mathrm{IU} / \mathrm{mg}$, $20 \mathrm{IU} / \mathrm{ampoule}$ ) were also sent to participants. These were provided for use as common reagents in the overall study design (see below).

## PARTICIPANTS

The five laboratories listed in Appendix $A$ were the study participants. Each participating laboratory was arbitrarily assigned a number (see below), not necessarily representing the order of listing in Appendix $A$.

## ASSAY METHOD

Due to the fact that each laboratory utilized specialized equipment and technology, the assay method required only that certain time elements, as well as reagent and test article concentrations, be met by each participant's Anti-Factor IIa procedure. Thus, each participating laboratory was asked to perform the overall test method described, utilizing its own specific procedures in order to meet the assay requirements set forth below.

| Reagent | Method $^{\mathrm{A}}$ |
| :--- | :--- |
| Heparin, STD/Test | $0-10 \mathrm{mU}^{1}$ |
| Human AT | $0.075 \pm 0.025 \mathrm{IU} / \mathrm{mL}^{1}$ |
| Incubation | $37^{\circ} \mathrm{C} / 60 \mathrm{~s}$ |

| Reagent | Method $^{\mathrm{A}}$ |
| :--- | :--- |
| Thrombin | $0.56 \mathrm{IU} / \mathrm{mL}$ <br> (bovine/human) ${ }^{1, \mathrm{~B}}$ |
| Incubation <br> Substrate $\mathrm{B}^{\circ} \mathrm{C} / 60 \mathrm{~s}$ |  |
| Measurement | $0.278 \mathrm{mM}(\mathrm{S}-2238)^{2,3}$ |
| Kinetic/endpoint |  |

NOTE-Beyond meeting the assay requirements above, no further instructions were given to the participants. It should be noted that other chromogenic substrates for thrombin are commercially available and may be substituted for S-2238 (16).

## DESIGN AND NUMBER OF ASSAYS

All participants were requested to carry out 2 sets of 6 independent, daily assays ( 12 assays in total), one set using the common reagents provided and another set using inhouse (local) reagents. The same daily ampoules of standard and test article (and dilutions prepared from these) could be used for the assays performed using the different sets of reagents. An independent, daily assay was defined as one conducted with a completely fresh set of dilutions prepared from previously unopened ampoules of standard and test article.

## METHODS OF ANALYSIS

All assay results were analyzed using the principles of parallel line bioassay (14) comparing transformed assay response to log concentration. Here, an analysis of variance gives an assessment of the linearity and parallelism of the response lines, and tests for deviations from linearity and parallelism were performed at the $1 \%$ level of significance. For the majority of assays, the untransformed assay responses were found to give the best linearity with log concentration. In one laboratory, responses were transformed to percentages relative to the estimated upper and lower limits of the dose-response curve, and weighted regression of log response on $\log$ concentration was used.

All mean potencies were reported as unweighted geometric mean potencies. Variability between assays and laboratories were then expressed using geometric coefficients of variation (GCV; see ref. 15).

## RESULTS

Five laboratories presented results from 60 total assays. As previously mentioned, each laboratory was arbitrarily assigned a laboratory number. Lab 5 returned data for the
common reagents only. Lab 2 also provided data from an inhouse method (Method C) that was based on the proposed global method, using local in-house reagents. The Method C modifications to the final concentrations of the reagents were $0.06 \mathrm{IU} / \mathrm{mL}$ instead of $0.075 \mathrm{IU} / \mathrm{mL}$ of antithrombin; $0.48 \mathrm{IU} / \mathrm{mL}$ instead of $0.56 \mathrm{IU} / \mathrm{mL}$ of thrombin; 0.5 mM in-
stead of 0.28 mM of chromogenic substrate. Additionally, the incubation time between heparin and antithrombin was increased from 60 s to 90 s in Method C, and the incubation time of the heparin and antithrombin with thrombin was increased from 60 s to 180 s .

Table 1. Local in-house reagents

| Lab | Antithrombin | Thrombin | Readout | Instrumentation |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Octapharma | Diagnostic Stago | Kinetic | Automated analyser |
|  |  | (human) |  |  |
| 2 | Chromogenix | Kordia (human) | Kinetic | Microtitre plate, robotic dilution |
| 3 | Chromogenix | Sigma (human) | Endpoint | Microtitre plate |
| 4 | Chromogenix | Biofac (bovine) | Kinetic | Automated analyser |
| 5 | - | - | Endpoint | Microtitre plate |

Table 1 shows the commercial sources of the in-house antithrombin and thrombin reagents used by the participants. Three laboratories used antithrombin preparations from the same manufacturer. Only one lab used thrombin of bovine origin; all other participants used thrombin of human origin. Two laboratories used automated analysers; two laboratories used microtitre plates with manual dilutions of samples, and one laboratory used microtitre plate with robotic dilutions of samples.

All raw results were reported and analyzed by the parallel line method (14). Tables $2 a-2 e$ show the result summaries for laboratories 1 to 5 , respectively, comparing potency estimates obtained using the common reagents and the local in-house reagents. Linearity and parallelism were deemed satisfactory for all results; exceptions were noted (see Tables $2 a-2 e$ ) in only 4 of the 60 assays analysed ( 2 assays with nonlinearity, 2 assays with nonparallelism).

A summary of each laboratory's overall mean potency estimates for sample T, in IU $/ \mathrm{mL}$, is presented in Table 3 and shown in histogram format in Figure 1. All the potency estimates shown in both Table 3 and Figure 1 were based on the same statistical method (14).

Fig. 1. Histogram showing potency estimates obtained using common and in-house reagents. The number in the squares indicates the laboratory number.

[^282]Between-assay variability was low: GCVs were $<10 \%$ (mean GCV 5.0\%) in all but one case. The mean ratios were not significantly different from 1.0 , indicating excellent agreement between results using different reagents.

The inter-laboratory variability was also low: GCV values measured $4.5 \%$ and $5.6 \%$ for in-house and common reagents assays, respectively. These findings also take into account that the common reagent used by lab 5 was the in-house reagent for lab 5. When all results were analyzed as a group, the overall GCV value was determined to be 4.4\% (see Table 4).

Table 4. Inter-laboratory variability

|  | \% GCV |
| :---: | :---: |
| Common Reagents | $5.6(n=5)$ |
| In-House Reagents | $4.5(n=5)$ |
| Mean | $4.4(n=9)$ |

The sensitivity of the assay was then investigated by comparing the fitted slopes obtained using the common reagents and the in-house reagents (see Table 5). Due to the fact that different participants utilized different readouts (endpoint or kinetic), it was not possible to compare the responses between laboratories, but it was feasible to compare results within each laboratory. For labs 1 and 2, fitted slopes were noted to be consistently steeper when using the common reagents. This situation was reversed for lab 4 . No such patterns were noted for lab 3 . Comparison of sensitivity could not be made for lab 5, because this participant carried out only assays using the common reagents.

## ADDITIONAL STUDY RESULTS

Because of known differences between the unit values of the USP assay Unit (U) and the International Unit (IU) for unfractionated heparin ( $5,11,17$ ), lab 1 conducted an additional and separate arm of the Anti-Factor IIa validation study described above. Briefly, lab 1 included separate dilutions of the USP Heparin Sodium Reference Standard (Lot K-5) in each of the 12 sets of assays described above ( 2 sets of reagents, 6 independent assays). The purpose of this separate study arm was to investigate what effect, if any, different standards would have on the measured potency of the test article ( $\mathbf{T}$ ).
Results of the separate study conducted by lab 1 are presented in Table 6. The results in Table 6 demonstrate mean test article potencies with $6 \%$ to $8 \%$ lower values when USP K-5 was utilized as the reference standard. The percentage differences measured with the present Anti-Factor IIa procedure are similar in scale to previously reported discrepancies noted between the International and USP Units (5, 17).

| 2 | 399 | 395 | 374 | 361 |
| 3 | 402 | 397 | 368 | 374 |
| 4 | 404 | 402 | 377 | 366 |
| 5 | 408 | 414 | 379 | 375 |
| 6 | 394 | 403 | 383 | 373 |
| Mean | 401 | 405 | 378 | 371 |

## NOTES-

1. All unit values were determined utilizing the slope/ratio procedure, which accounts for the slight differences in $\mathbf{T}$ $\mathrm{IU} / \mathrm{mL}$ values (above) from those listed in Table $2 a$.
2. Comparing the common/common reagent determinations, $\mathbf{T}$ mean U/mL Anti-Factor IIa potencies were $94 \%$ of the measured IU/mL values. When in-house/in-house reagent results were compared, $\mathbf{T}$ mean $\mathrm{U} / \mathrm{mL}$ values were $92 \%$ of the measured $\mathrm{IU} / \mathrm{mL}$ values.

## DISCUSSION

Although the laboratories participating in the study were experienced with other chromogenic test methods, this was the first multi-laboratory qualification study of the harmonized Anti-Factor IIa assay procedure involving unfractionated heparin. Considering this fact, the performance of the proposed Anti-Factor IIa assay method was excellent. The between-assay variability for both common reagents and in-house reagents was low, and the majority of GCV values were below $10 \%$. Higher \% GCVs were obtained by laboratories using the manual-dilution, microtitre plate methods. The inter-laboratory variability was equally low; the overall GCV was found to be only $4.4 \%$. There was a lower between-laboratory variability with the in-house reagents assays compared to the common reagents, but this was not statistically significant. There was no significant difference between the potency estimates obtained using the two types of reagents as indicated by the close to " 1 " ratio obtained between potency estimates by the different reagents. There was also no significant difference in the potency estimates between the potency estimates obtained using the different in-house reagents. In addition, there was also no significant difference between potency estimates obtained using kinetic or endpoint readouts for the assays.

The data presented also suggest that the proposed AntiFactor IIa method is easy to set up and sufficiently flexible to allow for differences in reagents and equipment among participants. Further evidence of flexibility was seen with results from the modified procedure (Method C) used by Lab 2, which reported potency estimates that were similar to those obtained by the other participants. Although only
a small number of laboratories were involved in this study, the data presented suggest that the proposed Anti-Factor IIa assay is sufficiently precise and robust to warrant further evaluation. A larger collaborative study is therefore proposed in order to further evaluate the proposed Anti-Factor IIa method as a possible replacement for current pharmacopeial heparin assays.

# Sterilizing Filtrations with Microporous Membranes 

Maik W. Jornitz, Sartorius North America, and Theodore H. Meltzer, Capitola Consulting Co.

#### Abstract

By definition (FDA, 1987), a sterilizing filter is one that withstands organism challenges of $1 \times 10^{7} \mathrm{cfu}^{\text {per } \mathrm{cm}^{2}}$ of effective filter area. The confronting organism is Brevundimonas diminuta ATCC 19146 cultivated according to Leahy and Sullivan (1978). Until rather recently, it was believed that the sterilization of fluids could be ensured by their filtration through a sterilizing membrane whose proper and pertinent identity was confirmed by its pore size rating, which was itself determined by integrity testing.

Developments in filtration practices showed this belief to be too generally founded. As the folk wisdom has it, "the devil is in the details." It was discovered that the positive conclusions based on pore size ratings were subject to modification by the physicochemical specificity of the organism-suspending fluid; by the individuality of the organism type in its size-changing response to the suspending fluid; in the possible alteration in the filter's pore size induced by the fluid; and by the adsorptive qualities of the membrane resulting from its particular polymeric composition-all influenced by the filtration conditions in their numerous varieties. This article reviews the present status of and knowledge about sterilizing filtrations with microporous membranes.

## THE PRESENT STATUS

What had once seemed simple was recognized as being quite complex. The certainty of obtaining sterile effluent requires far more than the identification of a "sterilizing filter" by a pore size rating. The complex of influences governing the outcome of an intended sterilizing filtration necessitates a careful validation of the process, including that of the filter (PDA Special Report \#26). The very drug preparation of interest, the exact membrane type, the precise filtration conditions, and the specific organism type(s) of concern must be employed in the necessary validation.

Sterilization-meaning the absence of all (organism) life becomes severely restricted by the present view of "sterilizing filtration." The practice becomes limited to the organisms of concern, possibly only to those tested in the validation exercise (Agalloco, 1998). B. diminuta proves not to be a universal model for all types of microorganisms. Bioburden isolates are to be preferred. However, a necessary condition of any test organisms is their amenity to identification and culturing. A more general conclusion regarding other organism types under the same processing conditions involves assumptions. "Reasoned" extrapolations to other drug preparations, or to other filters, or to other filtration conditions involve a degree of risk.

The same filter may not sterilize the same preparation under different filtration conditions, especially under dissimilar differential pressures (Leahy and Sullivan, 1978). A given membrane may or may not retain a particular organism type suspended in a different drug vehicle (Bowman et al., 1967). The organism type need not remain constant in size, but may alter in response to its suspending fluid (Gould

[^283]et al., 1993; Leo et al., 1997). The effect of the vehicle upon the polymeric membrane may cause a change in the pore size (Lukaszewicz and Meltzer, 1980).
This newer version of sterilizing filtration is short of the (illusory) certainties that accompanied the earlier beliefs based on pore size ratings, absolute filters, and an exclusivity of particle retention by the sieve retention mechanism. Perhaps not surprisingly, its implementation has lagged somewhat. Be that as it may, the situation is as described. The application of validation to sterilizing filtrations can endow the practice with the seriousness it deserves and with the reliability it requires (Jornitz and Meltzer, 1998; PDA Special Report \#26).

## MECHANISMS OF ORGANISM RETENTIONS

The axiom of solid geometry that a particle too large to enter an opening (pore) cannot pass through it is so supported by common experiences that it is the usual view of the mechanism of particle retention. It is the straightforwardness of this logic that served so firmly to bolster a belief in an unquestionable correlation of filtrative sterilization with pore size ratings (Johnston and Meltzer, 1979). However, organism (particle) retentions need not derive only from sieving, from the size exclusion mechanism that results from the particle size / pore size relationship. Adsorptive effects, including filter-surface impactions, can also be effective in this regard.
The adsorptive fixation of organisms to solid surfaces is reported in the literature. Pertsovskaya and Zvyagintsev (1971) state that different groups of different bacteria are adsorbed by polymeric films composed of polyamides, polyacrylates, polyethylenes, or cellulose acetate. That various bacteria adsorb onto various surfaces was also disclosed
by Gerson and Zajic (1978). Hjertin et al. (1974) studied the adsorption of yeasts on nonionogenic, hydrophobic agarose and the column adsorption of S. typhimurium.

Zierdt and his associates in 1997 at the National Institutes of Health noted that both gram-negative and gram-positive organisms were retained on the surfaces of polycarbonate and cellulose acetate membranes of pore sizes much larger than the bacteria. The organisms involved in the studies were Escherichia coli and Staphylococcus aureus. The adsorptive bonding of the bacteria to the polymeric filter surface withstood the mechanical and desorptive actions of washings with buffer solutions (Zierdt et al., 1977). SEM photographic evidence of $0.8-\mu \mathrm{m}$ S. aureus organisms retained on the surfaces of (track-etched) polycarbonate membranes of $12 \mu \mathrm{~m}$-rated pore size is shown in Figure 1 (Zierdt, 1978).

Figure 1.
The adsorptive removal of $B$. diminuta by a glass fiber prefilter in circumstances unattributable to sieve retention is shown in Figure 2 (Leahy and Sullivan, 1978). Tanny et al. (1979) challenged the exclusivity of sieve retention as the mechanism of organism removal by membrane filters. It was postulated that the retention of B. diminuta by 0.45 $\mu \mathrm{m}$-rated mixed esters of cellulose membranes involved adsorptive sequestration. An initial reluctance by some to accept this view stemmed from the firmly stated belief of earlier investigators that membrane filters were so uniform in their pore sizes, a condition favorable to sieving, as to serve solely as screen filters. Pore size distribution of membranes had early on been explored by mercury porosimetry and had been reported to be a narrow $5 \%$. The $0.45 \mu \mathrm{~m}-$ rated membrane was said to be $0.02 \mu \mathrm{~m}$ in its distribution; "It reflects an extraordinary degree of uniformity." (Dwyer, 1966). Subsequently, Marshall and Meltzer (1978) demonstrated the actual value to be closer to $100 \%$.

Figure 2.
De-emphasis of membrane pore size distribution delayed explanation of the dependence of organism retention on the challenge density. The exaggerated report of pore size uniformity confused the meaning of the pore size rating by trivializing its difference from the largest pores. Meant to signal the mean pore size, it came also to identify the set of largest pores, those that are the concern in particle retentions. Consequently, experts in the membrane field advised, "The membrane filter functions primarily as a screen filter. It retains all particles larger than the pore size of the filter." (emphasis added) (Dwyer, 1966). This is now known not to be so; nor does the pore size rating value represent the pore dimensions.
The erroneous concepts sustained belief in the exclusivity of sieve retention and catered to the comforting reliance on absolute filters. The reluctance to abandon the certainty of sieve retention, where it applies, in favor of the conditional actions of the adsorptive effect is evident even todayhence, the drive to use membranes of lower pore size ratings, more assertive of size exclusions, where $0.2 / 0.22$ $\mu \mathrm{m}$-rated filters do not yield sterile effluent. Not surprisingly, some 20 cases of such occurrences have been noted, B. diminuta not being a universal model for all organisms (Sundaram et al., 2001). Thus, $0.1 \mu \mathrm{~m}$-ratings are championed as alternatives to the more conventional use of the $0.2 / 0.22-\mu \mathrm{m}$ variety despite the observation that the organisms escaping capture by the latter are not necessarily retained by the former and also despite the penalty in flows where the advocated substitution is unnecessary (Kawamura et al., 2000).

## THE CHALLENGE DENSITY

The origins of the $1 \times 10^{7} / \mathrm{cm}^{2}$ value are unclear. Thermal sterilizations are seen as capable as achieving fewer than one failure in one million. Because of sampling limitations, sterilizing filtrations cannot ensure fewer than one failure per thousand. It may be that the $1 \times 10^{7}$ number was se-
lected to elevate reliability of the sterilizing technique. The target of one in 10 million also represents an attempt to match the number of challenging organisms to the number of pores calculated to be present in an area of membrane. The calculations, which take into account the total porosity of a membrane area and assume each pore to have the volume of a sphere $0.2 \mu \mathrm{~m}$ in diameter, are too presumptuous. Nevertheless, some calculations suggest there are 10 million pores, $0.2 \mu \mathrm{~m}$-rated, per square centimeter of microporous membrane. The object of the challenge is to ensure that even an occasional, single large pore will be confronted by an organism. The goal is statistically flawed. The attainment of the hoped-for organism/pore confrontation would not be realized. The organism disposition over the membrane would not be uniform but would follow the laws of probability via the Poisson distribution. Some of the pores would go unchallenged while some would be multi-challenged (Juran, 1974).

The $1 \times 10^{7} / \mathrm{cm}^{2}$ challenge far exceeds the degree of organism loadings that characterizes pharmaceutical preparations presented to final filters. It is, however, justified by the belief that a filter capable of withstanding a severe trial will assuredly resist lesser confrontations. Indeed, Elford (1933) found and Wallhäusser (1985) confirmed that higher organism densities resulted in greater probabilities of organism passage.

It should be pointed out, however, that not the total organism count itself but its state of dilution may influence the filter's retention qualities as an expression of its pore size distribution. The matter has been little investigated with organism, but with silica particles it is found that diluter suspensions are initially retained quite thoroughly; progressively suffer poorer retentions over time; but ultimately undergo improved removal efficiency (Zahka and Grant, 1991). The changes in particle removal over time are explained as follows: Despite the hydrodynamic flow being preferentially directed to the fewer larger pores present in the filter, it engages the overwhelmingly larger of numbers of smaller pores. Complete particle removal results, and the smaller pores thus encountered become blocked. In consequence, the proportion of larger pores increases. This promotes particle passage. As the particles accumulate at the larger pores, they become increasingly clogged and blocked. Increased particle retention then results (Jornitz and Meltzer, 2001).

The implications of these findings to the selection of challenge densities appropriate to the testing of pharmaceutical preparations are intriguing. Validation of the sterilizing filtration operation using the very drug preparation of interest, whatever its actual organism concentration, may finesse the problem.

## THE MODEL ORGANISM

FDA (1987) defines a sterilizing filter as one that retains $1 \times 10^{7}$ cfu of Brevundimonas diminuta ATCC 19146/per $\mathrm{cm}^{2}$ of effective filtration area (EFA). FDA, although cognizant of smaller organisms (Howard and Duberstein, 1980),
selected $B$. diminuta as the model organism for sterile filtrations. Although not the smallest organism known, B. dimin$u t a$ was considered diminutive enough to represent whatever smaller size organisms were likely to be present in pharmaceutical preparations.

It was this organism, then called Pseudomonas diminuta, that Bowman et al. (1963) found could be removed from its suspension by $0.45 \mu \mathrm{~m}$-rated microporous membrane except, surprisingly, in the presence of penicillinase. The $0.2 / 0.22 \mu \mathrm{~m}$-rated membrane was devised for its removal. Until the $0.45 \mu \mathrm{~m}-$ rated membrane exhibited its inability to retain $B$. diminuta in that situation, it was considered the "sterilizing filter." This appellation was passed to the $0.2 /$ $0.22 \mu \mathrm{~m}$-rated membrane that did so retain the organism. However, the $0.45 \mu \mathrm{~m}$-rated membrane otherwise did perform as the sterilizing filter for $B$. diminuta, as well as in other circumstances (Tanny et al., 1979; Trotter et al., 2002). It depends upon the filtration process. The point being made is that the attainment of sterility is dependent upon more than the pore-size rating. Process conditions and fluid properties also influence the retentivity. A universal type "sterilizing filter" is unlikely, given the variety and complexities of sterile filtrations (Jornitz and Meltzer, 2001).

The filtrative sterilization by $0.45 \mu \mathrm{~m}$-rated membranes of solutions containing $B$. diminuta had conventionally been ascribed to sieve retention. This was brought into question by the interfering action of penicillinase. It seemed unreasonable that penicillinase in solution could interfere with sieve retention. That the $0.45 \mu \mathrm{~m}-$ rated pores were too large to sterilize by sieve retention became evident in that no sterile effluent resulted. In the absence of the protein, it was rationalized, organism removal was governed by adsorptive sequestration. In its presence, penicillinase preemptively saturated the adsorption sites to competitively prevent organism sequestration. To effect the sieve retention of the organisms the smaller pore sized $0.2 / 0.22 \mu \mathrm{~m}$-rated membrane was necessitated. The penicillinase did not interfere with sieve retention.

The earlier reliance on pore size as a guarantor of sterility, as defined by $1 \times 10^{7} \mathrm{cfu} / \mathrm{cm}^{2}$ EFA of $B$. diminuta, was based on a correlation of membrane integrity test values (which differ for membranes of different polymeric compositions) with the degrees of retention (Reti, 1977; Pall and Kirnbauer, 1978; Johnston and Meltzer, 1979). The experimental work largely utilized organism suspensions in water or in saline lactose broth. At the time, sieve retention was considered the exclusive mechanism of particle removal by filters. Consequently, the limitations imposed by factors such as vehicle effects, etc., were neither appreciated nor investigated.

## PORE SIZE RATINGS

The microporous membrane filters are available from several manufacturers in a series of pore sizes, each with a pore-size distribution that remains undefined (Marshall and Meltzer, 1978) despite its contribution to the retention pic-
ture (Zahka and Grant, 1991; Jornitz et al., 2001). The poresize ratings, upon which the sterilizing ability of membranes was believed to depend, have uncertain values. The ratings are assigned individually by each manufacturer; there is no industry standard. Consequently, the same pore size rating from different manufacturers may represent different pore dimensions (Meltzer and Lindenblatt, 2002). The designated pore sizes, as is by now widely understood, do not describe actual pore dimensions. They serve as manufacturer's parts numbers.

Pore size designations were early on assigned on the basis of mercury intrusion measurements (Rootare, 1970; Meltzer, 1987) or from mean flow-pore analyses (ASTM 1980), not by particle retentions. To attempt to use organism retentions invites, among other complications, those influencing adsorptive sequestrations. Retention ratings have been attempted using latex beads in the presence of surfactants that suppress adsorptions (Wrasidlo and Mysels, 1984; Emory et al., 1993). In one study the manufacturer of nylon membranes reported that on the basis of latex particle retention its $0.1 \mu \mathrm{~m}$ rating would be labeled $0.28 \mu \mathrm{~m}$; its $0.2 \mu \mathrm{~m}-$ rated counterpart would be rated $0.46 \mu \mathrm{~m}$ (Krygier, 1986). As stated, the filter ratings are not standardized, and the manufacturers do not ordinarily disclose their pore size rating systems.

The first "sterilizing membrane" manufactured in the USA, on the original German technology (Zsygmondy, 1909), was rated as having a pore size of $0.45 \mu \mathrm{~m}$. As stated above, it was found, however, that B. diminuta was not removed by this filter when protein was present in the drug preparation. The pore size was reduced by half to effect sterilization (Bowman et al., 1967). The resulting "sterilizing membrane" was labeled 0.20 or $0.22 \mu \mathrm{~m}$-rated, depending upon its fabricator.

FDA's defining of a "sterilizing filter" as one capable of retaining the $B$. diminuta burden of $1 \times 10^{7} /$ per cm $^{2}$ led filter makers to label such filters $0.2 / 0.22 \mu \mathrm{~m}-$ rated. The relevant bacteria testing is performed under specified conditions during the membranes' development and production stages (ASTM, 1988). The $0.1 \mu \mathrm{~m}$-rated filters, being tighter, require no qualification. Yet, neither of these ratings always retains all the organism types that are encountered in pharmaceutical processing. The $0.45 \mu \mathrm{~m}-$ rated filters do not meet this retention qualification. Nevertheless, as demonstrated by Tanny et al. (1979) and Trotter et al. (2002), they
do perform as sterilizing filters under specified conditions. The point being made is that pore size ratings do not guarantee the attainment of sterilizing filtrations, as had previously been believed. Considerations other than pore size are involved. The drug preparation can affect sieve retentions by altering the pore size and/or organism size. It can also influence the adsorptive sequestration mechanism by modifying the adsorptive tendencies of the filter polymer. Additionally, the filtration conditions, such as temperature and pressure differentials, exert their own influences.

## PORE ARCHITECTURE

The membrane analogy is that of a polymeric sponge. The filter pores are pictured as being irregular and tortuous capillaries composed of interconnected spaces within the polymer matrix. The structure derives from a polymer solution which is deposited (cast) in a very precise thickness. Being in solution, the long-chain polymer molecules are in motion in the coiled, convoluted, and tangled forms normal to their ambient temperature. The chain segments are separated from one another by distances fixed by the polymer dilution. It is these interstitial spaces that in their interconnections prefigure the pores of the finished membrane. Casting formulae of different polymer concentrations give rise to different intersegmental separations, ultimately to different porosities, when by proper manipulation the polymer is precipitated as a gel, to be washed and dried to its solid, microporous membrane state. There is an ineluctable pore size distribution, and some anisotropic pore shape formation is inevitable (Kesting, 1985).

Williams and Meltzer (1983) hypothesize the formation of the microporous membrane structure according to known soap bubble clustering and in accord with zeolitic compositions. The open areas were prefigured in the casting solution. They are of various polygonal shapes, framed by polymeric struts and walls. They are interconnected by openings in their common walls. It is these openings that are the metering and retaining pores of the membrane. Figure 3 is of a detergent foam confined between glass plates. The polygonal structure is obvious. Figure 4 is of a reticulated polyurethane foam demonstrating the same polygonal forms.

## Detergent Foam

 Between Two Glass Plates

Figure 3.

Figure 4. Reticulated polyurethane foam

Too little is actually known about the pore shapes and sizes. The total porosity of the filter can be assayed, but the number of pores, however defined (Johnston, 2003), is estimated on the basis of oversimplifying assumptions. The number of the all-important retentive pores, or of the largest pores, cannot be assessed with confidence.

## VALIDATION

Given the complexity of factors that govern the attainment of a sterilizing filtration, the achievement of the objective requires documented experimental evidence. The necessary validation protocol has been amply described in the literature. PDA Technical Report \#26, Sterilizing Filtration of Liquids, is an excellent and detailed source. Jornitz and Meltzer (2001) also deal with the subject. Figure 5. from PDA Technical Report \#26 illustrates in chart form the validation strategies that are involved in the exercise.

*Concurrence of the appropriate regulatory agency should be sought prior to using this methodology.

Figure 5.

## RESTATEMENT OF PRESENT SITUATION

Until recently, the $0.2 / 0.22 \mu \mathrm{~m}$-rated membranes were considered the "sterilizing filters" based on their retention of Brevundimonas diminuta in the amount of $1 \times 10^{7}$ cfu per $\mathrm{cm}^{2}$ of filter surface. However, $B$. diminuta is not a suitable model for organisms encountered in all pharmaceutical settings. Some type organisms penetrate $0.2 / 0.22 \mu \mathrm{~m}$-rated membranes. When the organisms are known to be smaller, as in water purification contexts, $0.1 \mu \mathrm{~m}$-rated membrane should be employed. The $0.1 \mu \mathrm{~m}$-rated membranes are tighter than their 0.2 or $0.22 \mu \mathrm{~m}$-rated counterparts. Their pores being more restricted, they better retain smaller organisms based on the size-exclusion principle. However, their
unnecessary use will needlessly penalize flow rates and possibly throughputs.

Filters retain organisms by other than by the sieve retention mechanism. In liquid filtrations, the main mechanisms of microbial retention are sieve retention and impact and surface adsorptions. Depending upon the fluid vehicle, the organism type, the membrane polymer type, and the filtration conditions, cells may adhere to the pore surfaces as they negotiate the "tortuous pores" through the membranes. For gas filtrations, the same phenomena are at work, but the adsorptive phenomenon is enhanced by additional electrostatic interactions. These electrostatic interactions are so strong that, for a given filter rating, particle retention is significantly more efficient in gas filtration than in liquid filtration.

It is now recognized that a pore size of whatever rating, however confirmed by integrity testing, whether $0.2 / 0.22$, 0.1 , or 0.45 , is not enough to ensure sterile effluent. Other factors can influence the microbial retentive properties of microporous membranes for fluid filtration applications. These include the physicochemistry of the fluid; pH , viscosity, and chemical composition, and its compatibility with the filtration matrix. The filtration conditions are also influential: the filtration velocity/flow rate, the differential pressure across the filter membrane, and the duration of the filtration. Additionally, the surface properties of the filtration matrix, particularly its propensity for adsorptions, and the size and surface properties of the particles being filtered are important. The validation of the filtration process is necessitated by the many variables. Its proper implementation requires the use of the actual membrane type and the specific drug preparation under the actual use conditions.

# The USP Perspective to Minimize the Potential Risk of TSE Infectivity in Bovine-Derived Articles Used in the Manufacture of Medical Products 

Ian DeVeau, ${ }^{*}$ USP, Roger Dabbah, USP, and Scott Sutton, USP Analytical Microbiology Expert Committee

#### Abstract

This Stimuli article on the potential risk of acquiring transmissible spongiform encephalopathy through the use of bovine-derived articles in the manufacture of medical products and on risk-reduction strategies to minimize this risk was prepared at the request of the USP Analytical Microbiology Expert Committee and USP Project Team 11. The article is divided into two major sections: a review of the illness and risk-reduction strategies. The review of the illness is intended to give the reader an overall view of the issues involved in transmissible spongiform encephalopathy and why it is a concern to the manufacturer, regulator, and consumer of health care products. The risk-reduction strategies are intended as a preliminary presentation of guidelines that may ultimately be included in a new general information chapter on the subject. Readers are invited to submit comments, suggested additions, changes, and revisions to the authors.

## INTRODUCTION

Articles of bovine origin are used extensively in the production of pharmaceuticals, biologics, medical devices, and dietary supplements; for many of these health care products, it is difficult to identify a single product from any one of the categories that does not contain or utilize in its production at least one component that can be derived from bovine sources. Bovine articles are used as active pharmaceutical ingredients, excipients, components of medical devices, or components of cell culture media used in the synthesis of biologics and biotechnological products. Since the first description and subsequent outbreaks of a transmissible spongiform encephalopathy (TSE) in cattle (bovine spongiform encephalopathy or BSE) capable of infecting other species, including humans, by the consumption of infected bovine products, there have been some concerns about the potential risk of TSE transmission through the use of health care products. Although there have been isolated reports of TSE transmission in domesticated animals linked to the use of vaccines (Agrimi et al., 1999; Caramelli et al., 2001), it is generally accepted that the TSE transmission risk through animal-derived articles used in the manufacture of health care products is very low (Bader et al., 1997; Cohen et al., 2003). Regardless of the very low risk potential, various US and international regulatory agencies have developed guidances to help manage and further reduce the potential transmission risks. The purpose of this article is to review the issues involved in TSE transmission risks and to outline general risk reduction strategies based upon current scientific studies and regulatory guidances.

## REVIEW OF THE ILLNESS

TSEs are a family of transmissible animal and human diseases characterized by spongy degeneration of the brain with severe neurological signs and symptoms. No treatments for TSEs are available, and the disease is fatal in all known cases. TSEs are also characterized by relatively long incubation periods of several years and, within the brain, are accompanied by activation of microglial cells, hypertrophy and proliferation of astrocytes, and degenerative neuronal vacuolation. Clinical features include mental changes, ataxia, and loss of fine motor control of body homeostasis (Koster et al., 2003).
The first description of a TSE was published in the mid1700s in Europe for scrapie, a neurological disorder in sheep and goats. A human TSE, Creutzfeldt-Jakob disease (CJD) was first described in the early 1900s (Creutzfeldt, 1920). Other human spongiform encephalopathies described prior to 1995 include Kuru, Gerstmann-SträusslerScheinker syndrome, and fatal familiar insomnia. Additional TSEs include chronic wasting disease of elk and deer, which is endemic in certain parts of the United States and Canada (Williams and Young, 1980) and Transmissible Mink Encephalopathy (Marsh et al., 1976).
The causative agent of TSE (including BSE) is still controversial (Narang, 2002; Priola et al., 2003; Manuelidis and $\mathrm{Lu}, 2003$ ), but most studies point to proteinaceous infectious particles devoid of any nucleic acid and termed prions (Prusiner, 1991; Uptain and Lindquist, 2002; Caughey and Lansbury, 2003; King and Diaz-Avalos, 2004). Evidence suggests that a prion is a modified form of a normal cellular protein $\left(\mathrm{PrP}^{\mathrm{c}}\right)$. This protein is found predominantly on the surface of neurons; however, it is also found on lymphoid, lung, liver, spleen, and kidney tissues (Brown et al., 1994). Small amounts of the protein have also been reported on skeletal muscle (Thomzig et al., 2003) and blood cells (Cervenakova et al., 2003). It is a soluble glycoprotein with a
secondary structure containing about 42 percent and about 3 percent alpha helix and beta sheet, respectively. The modified form of $\mathrm{PrP}^{\mathrm{c}}, \mathrm{PrP}^{\mathrm{sc}}$ (for scrapie), is the putative disease agent. $\mathrm{Pr}^{\mathrm{Pc}}$ is relatively insoluble, accumulates in cytoplasmic vesicles of diseased individuals, and has the primary structure identical to $\operatorname{PrP}^{\mathrm{c}}$, but its secondary structure is about 30 percent and about 43 percent alpha helix and beta sheet, respectively (Pan et al., 1993). PrPc can bind to each other, forming large aggregates. Furthermore, when it is present $\mathrm{PrP}^{\text {sc }}$ catalyzes the conversion of $\operatorname{PrP}^{\mathrm{c}}$ to $\operatorname{PrP}^{\mathrm{sc}}$; expression of $\mathrm{PrP}^{\mathrm{c}}$ is required for infection with a TSE (Brandner et al., 1996).

The two forms of the prion protein differ greatly in their reaction to various biochemical, chemical, and physical agents known to either hydrolyze or denature proteins. $\operatorname{PrP}{ }^{\mathrm{c}}$ is completely digested by hydrolysis with proteinase K , readily hydrolyzed by relatively weak acids and bases, and denatured by high heat and chaotropic agents. Proteinase K removes only the N -terminal 67 amino acids of $\mathrm{PrP}^{\text {sc }}$, leaving a residue that is still infectious. $\mathrm{PrP}^{\mathrm{sc}}$ is also resistant to acid hydrolysis and denaturation by heat and chaotropic agents.

BSE was unknown until the 1980s, when it was first described in the United Kingdom (Wells et al., 1987). Before the causative agent and means of transmission were known, an outbreak of BSE occurred within the UK leading to the death of approximately 200,000 head of cattle diagnosed with the disease. In order to contain the illness, more than 4.5 million head of asymptomatic cattle were destroyed, devastating the British cattle industry (DTZ Pieda Consulting, 1998). Although the UK has had the greatest number of reported cases of BSE, the illness has also been reported throughout Europe, Israel, Japan, Canada, and, as of December 2003, the United States (OIE, 2004). In the vast majority of these diagnosed cases, the source of the BSE has been identified as originating in the UK. Because the sole incidence of BSE in the United States was in a cow traced back to Canada, the US Department of Agriculture (USDA) and the Office International des Epizooties considers this as a nonindigenous case. The only regions still reporting no cases of BSE are South America (excluding the Falkland Islands), Australia, and New Zealand.

The origin of BSE also is controversial. Two theories have been proposed. The more favored theory is that it arose from sheep and goat scrapie; this theory is, in part, supported by the fact that scrapie is widespread and remains one of the more common TSEs in domesticated animals. This theory is further supported by the discovery of a strain of sheep scrapie that has chemical properties similar to those of BSE (Hope et al., 2000). However, there are still some strain differences between scrapie prion and the BSE prion. Furthermore, scrapie and BSE differ in the signs, symptoms, and progression of the respective diseases. The alternative theory is that BSE arose spontaneously in a few cows within UK herds (Bostok, 2000). This theory is, in part, supported by the belief that the human TSE, CJD, occurs spontaneously in one in every one to five million people. It is thought that the spontaneous rate of BSE in cattle may be
similar. Although the origin of BSE is controversial, the amplification and subsequent spread of the causative agent is believed to be fairly well established (Lindenbaum, 2001; Collinge, 2001).
Prions are stabilized by fatty material, and extraction of lipids tends to make them more susceptible to heat denaturation. It is an international agricultural practice to feed cattle, especially dairy cows, high-protein supplements derived from rendered animal by-products. In the past, these animal by-products included the remains of sheep and goats, as well as cattle. Prior to the 1980 s, it was common practice to extract and market tallow from rendered animals. As the demand for tallow declined around 1980, renderers switched to a less expensive rendering process, which used lower temperature without removing lipids. This produced animal feed of higher fat content. Some speculate that a few TSE-infected animals entered into the rendering process, the process failed to inactivate prions, and the subsequent infected feed was given to healthy animals. Prions were able to withstand normal digestion, passed into the animals' circulatory systems, and eventually were deposited into nervous tissues, where they became amplified. As the infected animals were recycled through the rendering process, an amplification of the infectious materials occurred, resulting in the epidemic that was experienced in the UK (Wilesmith et al., 1991; Taylor et al., 1995).
Beginning in 1988, measures to control BSE in the UK were put into place, and numerous countries began to ban the importation of cattle and bovine products from the UK. Eventually, bans on the feeding of ruminant-derived animal feed to ruminants were adopted worldwide. Statistics on the illness in the UK indicate that the regulations put into place after the BSE outbreak, following an initial lag period caused by the long incubation period of the illness, have significantly reduced the incidence within that country. Incidences of BSE are still being reported, primarily in animals that were born prior to the institution and enforcement of the feed band (MAFF, 1998). Regardless of whether BSE represents cross-species transmission of scrapie or spontaneous eruption within cattle herds, there is a potential risk of additional BSE outbreaks in cattle herds in the future if the feed ban described above, which appears to have broken the cycle of transmission and amplification, is rescinded or if its enforcement is lax.
In the years intervening between the detection of BSE in the UK and the institution of measures to control its spread, infected cattle entered into the human food chain. Although CJD had been first described in the 1920s, starting in 1994 a new form of CJD, variant CJD (vCJD), began to appear in persons residing or having resided in the UK. The signs and symptoms of CJD (Will et al., 1996) include a mean age of onset of about 65 years; mean onset of clinical signs before death of about 4 months; displays of degrees of confusion and ataxia without abnormal behavior, and, upon autopsy, "florid" amyloid plaques usually absent from brain tissue. In contrast, the signs and symptoms of vCJD include a mean age of onset of about 29 years, mean onset of clinical signs before death of about 12 months, displays of abnormal be-
havior, and, upon autopsy, "florid" amyloid plaques always present (Ironside et al., 1997). Another difference between vCJD and CJD is that, to date, $100 \%$ of all vCJD patients are homozygous at codon 129 of the prion protein gene for methionine, whereas no such distinction is present in cases of CJD. In addition, when the brain material from the vCJD patients was strain typed using the mouse system, vCJD and BSE were found to be the same strain (Bruce et al., 1997). Furthermore, the size and glycosylation pattern of the prion molecule from CJD and vCJD are different; prions from patients with vCJD are identical to those found in cattle with BSE (Collinge et al., 1996). It has also been shown that for transgenic mice containing the human prion protein and infected with BSE, the incubation times are very similar to those of mice containing the bovine prion protein (Korth et al., 2003). These last three characteristics, along with geography of both the BSE and vCJD outbreaks, indicate that the source of vCJD was from the consumption of human food products of bovine origin. This indication suggests there may be a potential risk of TSE transmission to humans from the use of bovine-derived medicinal products. Currently, fewer than 150 patients with vCJD have been diagnosed in the UK; however, recent examination of lymphoid tissues surgically removed from appendicitis and tonsillitis UK patients leads to estimates that UK residents may harbor the infectious TSE agent at a rate of $49-692$ per million (Hilton et al., 2004).

Prions at high titer are found primarily within tissue of the central nervous system of infected animals. This includes the brain, spinal cord, and dorsal root ganglia; these tissues are referred to as high-infectivity tissues (WHO, 1999). In infected cattle, lower titers have been found in cerebrospinal fluid, lung, lymph tissue, spleen, kidney, liver, and ileum (Brown et al., 2001; Terry et al., 2003); these tissues are referred to as low-infectivity tissues. In cattle, no detectable infectivity was found in skeletal muscle, cardiac muscle, prostate, adrenal glands, clotted blood, fat, gingiva, intestine (except for the ileum), testis, thyroid, milk, mucus, feces, saliva, semen, serous exudate, sweat, tears, and urine; these tissues are regarded as noninfectious. However, other studies of TSE-infected hamsters have found prions in skeletal muscle (Thomzig et al., 2003). Studies using rodents have demonstrated the presence of TSE infectivity associated with blood (Cervenakova et al., 2003). This infectivity is associated mostly with the leukocyte and plasma fractions, and residual infectivity is associated with red blood cells. The transfusion of blood from preclinical sheep infected with either BSE or scrapie can infect naive sheep (Hunter et al., 2002). Moreover, the December 2003 report of a case of a human vCJD fatality in the United Kingdom, purportedly from a blood transfusion, indicates a potential TSE-infection risk associated with blood and blood products (Matthews et al., 2003). In addition, studies have found prions in the urine of TSE-infected rodents, cattle, and humans as detected by immunological methods; however, in-
tracerebral inoculation of hamsters with urine-derived prions did not cause clinical signs of prion disease even after a prolonged incubation period, suggesting urine-derived prions may differ in pathogenic properties from brain-derived prions (Shaked et al., 2001).

Animals and humans are currently diagnosed with TSE post-mortem using several types of tests. The classic diagnostic test is histological examination of brain tissue, looking for the characteristic vacuolar degeneration. There are also immunohistochemical tests that can confirm the presence of $\mathrm{PrP}^{\mathrm{sc}}$ in the vacuolated regions of the brain (Haritani et al., 1994). In addition, there are other, immunologically based tests, such as Western blots (Oesch et al., 2000) and ELISA (Grassi et al., 2001), that can quantitate the PrPsc present in tissues having high or moderately high titers. These tests typically take less time to perform than histological examination (6-8 hours versus weeks, respectively) and can be partially or fully automated. Although most of these are post-mortem tests, some of them can be used as ante-mortem tests of lymphoid tissue samples from the tonsils (Schreuder, et al., 1998) or from the third eyelid (O'Rourke et al., 2000) of infected animals. However, the immunochemical tests still require extensive sample collection and preparation and are expensive, limiting their feasibility for routine testing and monitoring the disease state of large herds. Current tests lack the sensitivity to detect prions in certain tissues, such as blood, where infectivity has been demonstrated. Moreover, current tests may not be able to detect infectivity in infected animals not yet showing clinical signs; negative results do not ensure the absence of infectivity. In these cases, the detection of infectivity is possible if suspect tissue is inoculated intracranially into experimental animals where the prions can become amplified. The disadvantage of the intracranial inoculation approach for detection of low infectivity is that it can take months to years to obtain a positive result. Although other analytical methods are under development for the detection and quantitation of prions from low-infectivity tissues such as blood (Schmerr et al., 1999; Schmitt et al., 2002), no currently available and fully available method is sensitive enough for routine ante-mortem screening of asymptomatic animals. Other factors hampering method development include an unclear understanding of what constitutes an infectious dose, the lack of Biosafety level 3 laboratories necessary for carrying out method development and validation, sample matrix interferences, and the lack of readily available, standardized reference materials for validation. In this situation, the best current approach to reduce the risk of transmitting TSE either via foods or health care products is through the appropriate sourcing of the animal-derived articles and the use of practices and procedures that have been shown to eliminate or destroy the infectivity. The following section will address these issues.

## RISK-REDUCTION STRATEGIES

This section considers measures for minimizing the potential risk of TSE transmission during the use of animal-derived materials, especially if the animal is a ruminant. Such materials may be used for the preparation of:

- active substances
- excipients
- raw or source materials and reagents used in production (e.g., bovine serum albumin, enzymes, culture mediaincluding those used to prepare working cell banks or new master cell banks)
- fermentation culture media (media used in establishment of stock microbial cultures should be evaluated only for contribution to final fermentation volume)
- medical devices
- reagents used to clean manufacturing equipment
- media used for media fills on equipment used to manufacture sterile products.
It is recommended that alternative, nonanimal source ingredients be substituted for animal-source ingredients whenever possible. However, in some cases, nonanimal source ingredients may not be suitable for the intended purpose. In these situations, animal-source ingredients are a necessity, and the implementation and maintenance of riskreduction strategies are a requirement.

These risk-reduction strategies are also applicable to materials that come into direct contact with the equipment used in the manufacture (and therefore have the potential to allow contamination) of, for example, test media used in plant and equipment validation. The proposed measures are especially applicable for bovine and other ruminant-derived material and may be adapted to include other animals if they are later shown to have the potential risk of transmitting the TSE agent.

In light of the current scientific knowledge and regardless of the geographic origin, milk is unlikely to present any risk of TSE contamination (Bader et al., 1997; Cohen et al., 2003). Therefore, milk and materials derived only from milk may be excluded from the scope of these strategies, provided the milk is sourced from healthy animals under the same conditions as milk collected for human food consumption. Derivatives of milk from ruminants prepared with the use of other ruminant materials (such as pancreatic-enzyme digest of casein), are not excluded from the scope of this article because of the use of these other ruminant materials.

Derivatives of wool and hair of ruminants, such as lanolin, wool alcohol, and amino acids are also excluded from the scope of this article, provided the wool and hair are sourced from live animals, because hair by itself is considered to have no potential of infectivity (Bader et al., 1997). Derivatives of wool and hair from ruminants prepared with the use of other ruminant materials (such as pancreatic enzymes) are not excluded from the scope of this article because of the use of these other ruminant materials.

## Manufacturing (Including Collection of Source Materials)

Ideally, the sourcing of materials of ruminant origin should be established closed herds. A closed herd is maintained in such a way as to minimize contact with other domestic ruminants to reduce the risk of contracting diseases, such as TSE, that are transferable to humans. The animals in a closed herd have not been suspected of scrapie, BSE, or other herd-threatening diseases. Members of the closed herd have documented female lineage, and each animal is uniquely identified. Adequate steps are taken to ensure that the animals of a closed herd do not come in contact with other animals not of the closed herd, although exposure to animals not thought to be of high risk of being TSE infected, such as horses, cats, and dogs, may be acceptable. Food provided to the animals of the closed herd contains no rumi-nant-derived protein or offal, and, preferably, all animal feed is produced within the confines of the closed herd facility to help guard against accidental exposure to TSE-infected feed. Once established, all cattle in a closed herd should be born to that herd. Furthermore, because research indicates that semen does not transmit TSE (WHO, 1999), new genetic variation should be introduced into a closed herd only as semen. A herd should be maintained under the conditions stated above for at least 6 years to ensure no latent TSE is present before it can be declared a closed herd (ES, 2000). The lowest possible potential risks of TSE transmission are through the use of bovine-derived articles originating from animals from closed herds, especially for bovine-derived articles that do not undergo processing to reduce infectivity.
Currently, due to the relatively small number of closed herds, bovine and other ruminant-derived articles from closed herds are in limited supply and tend to be more expensive than articles derived from open herds. When using closed herd-derived material is not feasible, additional details should be sought about the source of the bovine-derived materials and other measures taken to minimize the risk of transmission of TSE agents (as well as other animal diseases); the remaining part of this discussion will focus on the use of open-herd, animal-derived material. The manufacturer of the medicinal product should audit the supplier of these materials to ensure that the latter are sourced and handled in conformity with the principles outlined in this article and appropriate quality control systems.
The risk of transmission of infectious agents can be greatly reduced by controlling a number of parameters. These parameters include:

- geographic source of animals
- nature of animal tissue used in manufacture
- production process(es).

It is unlikely that any single approach will establish the safety of a product, and therefore the three approaches cited above need to complement each other to minimize the risk of contamination.

## Animals as Sources of Materials

Careful selection of source materials is the most important criterion for the safety of medicinal products. The most satisfactory sources of materials are closed herds, followed by open herds from countries that have not reported cases of endogenous BSE and have (OIE, 2003):

- compulsory notification
- compulsory clinical and laboratory verification of suspected cases.
Official certification of the origin should be available from the supplier, obtained and kept on file. In addition, firms should ensure that a risk of BSE infection is not introduced from the following factors:
- the importation of cattle from countries where a high incidence of BSE has occurred
- the importation of progeny of affected females
- the use in ruminant feed of meat and bone meal containing any ruminant protein.
Current US FDA recommendations prohibit the use of any bovine-derived materials that originate from countries reporting indigenous cases of BSE in any FDA-regulated product (CBER, 2000), with the exception of gelatin. For veterinary biologics, current Center for Veterinary Biologics (USDA) regulations indicate that ingredients of animal origin should be sourced from countries whose BSE status is either no or low risk as defined by the US National Center for Import and Export and 9 CFR 94.18 (CVB, 2001). However, suppliers and manufacturers should not rely on country of origin alone to ensure the safety of the animal-derived materials when additional and reasonable practices and procedures are available to further reduce the potential risk. The absence of reports of indigenous cases of BSE should not be interpreted as evidence of complete absence of BSE within a country or region.

Source animals should be born after the feeding ban was imposed. If the date of birth of the animals is not known, both the implementation date of the ban and the incubation period of TSE should be considered to determine the safety of the sourcing.

Along with these measures, manufacturers of a medicinal product should justify their strategy for sourcing, in relation to the category of materials, the quantity of source material, and the intended use of the finished medicinal product. In supplying countries, source materials from well-monitored herds may provide an extra safety margin.

## Parts of Animal Bodies, Body Fluids, and Secretions as Starting Materials

Table 1 is a partial list of articles of bovine origin commonly used to manufacture medical products; the table also includes the common source tissue from which the articles are derived. In a TSE-infected animal, different organs and secretions have different levels of infectivity. On the basis of data on natural scrapie, organs, tissues and fluids have been classified into four main groups bearing different potential risks, as shown in Table 2 (EMEA, 2001). Although the dis-
tribution of infectivity in BSE-affected cattle may be different, the classification of tissues and body fluids in Table 2 can be a consideration for the selection of bovine-source materials; cross-referencing the information contained in Table 1 with Table 2 can yield some indications about the relative potential risk of a particular bovine-derived article to carry TSE infectivity. It is important to note the following points:

- the classification of tissues shown in Table 2 is based on titration of infectivity in mice inoculated by the intracerebral route. In experimental models using strains adapted to laboratory animals, higher titers and a slightly different classification of tissues may occur
- in certain situations there could be cross-contamination of tissues of different categories of infectivity. The potential risk will be influenced by the circumstances in which tissues were removed, especially contact of material of a low-risk group with that of a high-risk group. Thus, the cross-contamination of some tissues may be increased if infected animals are slaughtered by penetrative brain stunning or if the brain and/or spinal cord are sawed. The risk of cross-contamination will be decreased if body fluids are collected with minimal damage to tissue and cellular components are removed and if fetal blood is collected without contamination from other maternal or fetal tissues, including placenta or amniotic and allantoic fluids
- the risk posed by cross-contamination will be dependent on several complementary factors, including:
- precautions adopted to avoid contamination during collection of tissues (see above)
- level of contamination (amount of the contaminating tissue)
- amount of material to be used
- processes to which the material will be subjected during the manufacturing process
- no detectable infectivity does not necessarily mean no infectivity. Suppliers and manufacturers should not rely upon the tissue origin of the ruminant-derived article alone to ensure the lowest potential TSE risk when additional and reasonable practices and procedures also are available to reduce the risk even further
- the potential risk of a bovine-derived article carrying TSE infectivity is a function of both the potential risk associated with a particular tissue and the processes involved in the extraction and isolation of the article from the tissue. The potential risk of articles derived from high TSE infectivity tissue can be reduced by processes that can clear the TSE agent.
Suppliers and manufacturers of medicinal products should assess the potential risk and adjust their practices and procedures accordingly to minimize the potential risk of TSE infective to the lowest practical level.

Table 1. Partial list of articles of bovine origin used in the production of pharmaceuticals, biologics, medical devices, and dietary supplements

| Bovine Article | Tissue of Origin | Use | Alternatives Currently Available |
| :---: | :---: | :---: | :---: |
| Amino acids | Hair/skin | API and cell culture media | Yes |
| Aprotinin bovine | Lung | API | No |
| Bone and bone derivatives | Bone | Medical devices | Limited |
| Bovine colostrum | Colostrum | Colostrum | No |
| Bovine immunoglobulins | Blood, colostrum | Cell culture media | Limited |
| Bovine serum | Blood | Cell culture media | Limited |
| Bovine serum albumin | Blood | Cell culture media | Limited |
| Calf serum | Blood | Cell culture media | Limited |
| Casein derivatives | Milk | Excipients and cell culture media | Limited |
| Cholesterol | Brain | Excipient | Yes |
| Chondroitin sulfate sodium | Bones | API and dietary supplement | Yes |
| Creatine | Muscle | Dietary supplement | Yes |
| Chymotrypsin | Pancreas | API and cell culture media | Limited |
| Collagen | Bone/hide | Medical device and cell culture media | Yes |
| Corticotropin | Pituitary | API | Yes |
| Diglycerides | Tallow | Excipient | Yes |
| Fatty acids | Tallow | Excipient | Yes |
| Fetal bovine serum | Bone | Cell culture media | Limited |
| Fibroblast growth factors | Multiple (including brain) | Cell culture media | Limited |
| Fibronectin | Blood | Cell culture media | Yes |
| Gelatin | Bone and hide | Excipient and cell culture media | Limited |
| Glucagon | Pancreas | API | Yes |
| Glycerin | Tallow | Excipient and cell culture media | Yes |
| Hard fat | Tallow | Excipient | Yes |
| Hemoglobin | Blood | Blood replacement | Limited |
| Heparin | Intestine | API | Limited |
| Hyaluronidase | Testis | API | Yes |
| Insulin | Pancreas | API | Yes |
| Lactitol | Milk | Excipient | No |
| Lactoferrin | Milk | Excipient | Limited |
| Lactose | Milk | Excipient | Limited |
| Lactulose | Milk | API | Limited |
| Levothyroxine sodium | Thyroid | API | Limited |
| Monoglycerides | Tallow | Excipient | Yes |
| Oxytocin | Pituitary | API | Yes |
| Pancreatin | Pancreas | API | Yes |
| Pancrelipase | Pancreas | API | Yes |
| Pegademase bovine | Intestine | API | No |
| Pepsin | Stomach | API and cell culture media | Yes |
| Peptone | Muscle | Cell culture media | Limited |
| Phospholipids | Brain | Excipient | Yes |
| Pituitary gland extract | Pituitary gland | Cell culture media | Limited |
| Polysorbate 80 | Tallow | Excipient and cell culture media | Yes |
| Smallpox vaccine | Living skin | Live vaccine | No |
| Stearates | Tallow | Excipients and cell culture media | Yes |
| Thrombin | Blood | API | No |
| Thyroid | Thyroid | API | Yes |
| Trypsin | Pancreas | API and cell culture media | Limited |
| Vasopressin | Pituitary | API | Yes |

Table 2. Relative scrapie infectivity titers in tissues and body fluids from naturally infected sheep and goats with clinical scrapie ${ }^{1}$

| Category I | High infectivity <br> Brain, spinal cord, (eye) <br> Category II <br> Medium infectivity |
| :---: | :---: |
| Category III | Ileum, lymph nodes, proximal colon, spleen, tonsil (dura mater, pineal gland, placenta), <br> cerebrospinal fluid, pituitary, adrenal gland <br> Low infectivity |
| Category IV | Distal colon, nasal mucosa, peripheral nerves, bone marrow, liver, lung, pancreas, thymus, <br> blood <br> No detectable infectivity |
|  | Clotted blood, feces, heart, kidney, mammary gland, milk, ovary, saliva, salivary gland, <br> seminal vesicle, serum, skeletal muscle, testis, thyroid, uterus, fetal tissue, (bile, bone), car- <br> tilaginous tissue, connective tissue, hair skin, urine) |

${ }^{1}$ Tissues in parentheses were not titrated in the original studies, but their relative infectivity is indicated by other data on spongiform encephalopathies. On the basis of their composition, materials not listed may be classified by analogy to those mentioned.
${ }^{2}$ No infectivity was transmitted in bioassays involving inoculation of up to 5 mg of tissue into rodent brains.

## Process Validation

Due to the documented resistance of TSE agents to most inactivation procedures, controlled sourcing is the most important criterion in achieving acceptable product safety. However, whenever possible, validation studies of processes developed to reduce or eliminate prions from potentially infected materials should be performed.

Caveats to performing such studies are that validation studies of removal/inactivation procedures may be difficult to interpret because it is necessary to take into consideration the nature of the spiked material and its relevance to the natural situation, the design of the study (including scalingdown of processes), and the method of detection of the agent (in vitro or in vivo assay), after spiking and after the treatment. Further research is needed to develop an understanding of the most appropriate methodology for validation studies. An additional problem in performing prion clearance validation studies is the lack of readily available, suitably well-characterized and standardized reference materials for spiking. Regardless, if claims are made for the ability of a specific manufacturing process to remove or inactivate TSE agents, these claims will have to be substantiated by appropriate validation studies with suitably characterized reference material. Because there are currently no validated analytical methods for the detection of small amounts of the TSE agent, TSE clearance validation studies typically employ the intracranial injection of in-processed material into rodents for amplification and detection of potential residual infectivity (Blum et al., 1998). Analysts should consult USP general chapter Design and Analysis of Biological Assays $\langle 111\rangle$ when developing their validation studies.

Beyond the particular limitations that apply to TSE validation studies and their interpretation, the major hurdle is identifying steps that will effectively remove or inactivate TSE agents during the manufacture of biological medicinal
products. Manufacturers are encouraged to continue their investigations into removal and inactivation methods to identify steps/processes that will have benefit in ensuring the removal or inactivation of TSE agents. In any event, a production process whenever possible should be designed taking note of available information about methods that are thought to inactivate or remove TSE agents. For example, certain production procedures such as those used in the manufacture of tallow, tallow derivatives, and gelatin may contribute considerably to the reduction of the risk of TSE contamination.

## TSE Reference Materials

As indicated previously, there are no readily available, well-characterized, and standardized TSE reference materials with which to perform TSE clearance validation studies. However, the acquisition of some forms of TSE reference materials, most frequently TSE-infected brain homogenate, is sometimes possible via academic sources. Within the United States, the possession, use, and transfer of TSE agents are regulated by USDA ( 9 CFR Part 121, 2002). Potential users of TSE reference materials should consult and comply with the regulations. When selecting materials to be used in validation studies, researchers should consider the relative resistance of the TSE reference materials to be cleared by a given procedural step. For example, certain TSE strains, such as mouse-adapted BSE strain 301 V , appear to be the most resistant to heat inactivation (Bostock, 2000). It is recommended that this strain, or a strain showing similar resistance to heat, be used to validate a heat treatment step. Although TSE-infected brain homogenate appears to be the most available type of TSE reference material, such material may not be the best for all situations. The brain matrix in which the TSE agent is found may promote or prevent the inactivation of a given procedural step. In such cases, the use of isolated prion protein may be more appropriate.

## Age of Animals

Because the accumulation of TSE infectivity occurs during an incubation period of several years, sourcing from young animals may be prudent. Because this consideration will be lot specific, the audit of the raw material supplier should include a review of records establishing this fact. In addition, the purchase contract should stipulate the maximum age of the source animals.

## Specific Products

Tallow. Tallow used as the starting material for the manufacture of tallow derivatives should be produced by a method at least as robust and rigorous as those referred to in international regulations (EMEA, 2001 and APAG, 2003). Tallow derivatives such as glycerol and fatty acids that are manufactured from tallow by rigorous processes have been the subject of specific consideration and are thought unlikely to be infectious. Examples of rigorous processes are:

- transesterification or hydrolysis at not less than $200^{\circ} \mathrm{C}$ for not less than 20 minutes under pressure (glycerol, fatty acids, and fatty acid ester production)
- saponification with 12 M NaOH (glycerol and soap production)
- batch processes: at not less than $95^{\circ} \mathrm{C}$ for not less than 3 hours
- continuous processes: at not less than $140^{\circ} \mathrm{C}$, at a pressure of 2 bars ( 2000 hPA ) for not less than 8 minutes, or equivalent.
Gelatin. Current US FDA guidance for industry on the use and sourcing of gelatin for health care products (FDA, 1997) allows for the use of bovine-derived gelatin from cattle from countries reporting BSE or from countries not meeting the latest international BSE-related standards (OIE, 2003) provided:
- importers, manufacturers, and suppliers of bovine materials determine the tissue, species, and country source of all such materials to be used in processing gelatin for human use. This requires thorough record keeping with a clear indication of chain of custody
- bones and hides from cattle, from any country, that show signs of neurological disease are not to be used as raw material for the manufacture of gelatin
- the slaughterhouse removes the heads, spines, and spinal cords immediately after slaughter and that the heads, spines, and spinal cords are not used in gelatin production
- the gelatin produced from the above countries is not to be used either in injectable, ophthalmic, or implanted FDA-regulated products, or in their manufacture. The gelatin may be used for oral dosage forms and cosmetics.
In order to reduce the potential risk of transmitting the TSE agent in gelatin produced from cattle originating and residing in BSE-free countries, it is recommended that the practice described in the third item above - the removal
of heads, spines, and spinal cord immediately after slaughter and the nonuse of heads, spines, and spinal cords in gelatin production - also be followed. Regardless of the country of origin of the bovine material, it is recommended that the alkaline process of manufacturing gelatin be performed, because this method has been shown to clear the TSE agent (Inveresk Research International, 1998a, 1998b, and 1999). Systems should be in place for monitoring of the production process and for batch delineation (i.e., definition of batch, separation of batches, cleaning between batches, etc.). The potential for cross-contamination with possible infectious material is to be avoided.

Other bovine-derived articles. The extraction and production of both tallow and gelatin from bovine tissues involve the prolonged exposure of the tissues to high moist heat and/or high pH , agents that have been shown to inactivate the TSE agent. However, such treatments are inappropriate for the extraction of many other types of bovinederived articles because those treatments will lead to the destruction of the article of interest. In these cases, other means to remove or destroy the TSE agents must be employed. In some situations, conventional chemical and biochemical extraction and isolation procedures may be sufficient to remove the infectious agent. For example, it has been shown that an extraction and isolation procedure involving multiple ammonium sulfate fractionation steps and ion-exchange chromatography, plus other conventional techniques, were sufficient to significantly reduce the TSE infectivity from an aprotinin preparation derived from bovine lungs that had been spiked with TSE-infected brain homogenate (Blum et al., 1998). Similar techniques may be effective for other bovine-derived articles.

## CONCLUDING REMARKS

The assessment of the risks associated with TSE requires careful consideration of all of the parameters cited, and the preferred option should be to avoid the use of material derived from animals known to be susceptible (other than by experimental challenge) to TSEs in the products produced by the pharmaceutical industry. The acceptability of a particular medicinal product containing the materials, or which as a result of manufacture could contain these materials, will be influenced by a number of factors, including:

- documented and recorded source of animals
- nature of animal tissue used in manufacture
- production process(es)
- route of administration
- quantity of tissue used in the medicinal products
- maximum therapeutic dosage (daily dosage and duration of treatment)
- intended use of the product.

Manufacturers of medicinal articles containing ingredients of animal origin are responsible for the selection and justification of adequate measures to reduce the potential risk of TSE infectivity. The state of science and technology must be taken into consideration. Notwithstanding the points and considerations raised above, it should be empha-
sized that the potential risks associated with a given medicinal product should be considered individually in the light of specific circumstances and any new development in the current understanding of TSEs. The various steps to be taken by USP should provide an additional and complementary prospective to the strategies developed in this Stimuli article, with the ultimate goal of benefiting the patient.

## USP's BSE-TSE Initiative

In 2002, USP initiated the formation of a Project Team to advise the USP Council of Experts on steps that USP could initiate to help ensure the safety of pharmaceutical products in terms of BSE-TSE contamination. The Project Team includes the following national and international experts:

Brian Nunnally - Eli Lilly and Co.
Byron Rippke - US Department of Agriculture
Chuck Filburn - Nutramax Laboratories, Inc
David Schoneker - Colorcon
Everett Flanigan - Advanced ChemTech
Hannelore Wilkommen -Clearant GmbH
James Akers - Akers, Kennedy and Associates
Jordi Ruiz-Combalia - BIOIBERICA, S.A.
Joseph Knapp - University of Pittsburgh, School of Pharmacy
Judd Aiken - University of Wisconsin, School of Veterinary Medicine
Kristen Blancard - Nutramax Laboratories, Inc.
Louis Blecher - International Specialty Products
Mary Jo Schmerr - Iowa State University, College of Veterinary Medicine
Peter Ganz - Health Canada
Ralph Gomez - Hoffmann-La Roche Inc.
Richard Moreton - Penwest Pharmaceuticals Co.
Scott Sutton - Vectech Consulting
Susan Schniepp - Abbott Laboratories
Taryn Rogalski-Salter - Merck \& Company
Thomas Kreil - Baxter BioScience
Ana Padilla - WHO
Debbie Cooper - Wyeth
The Project Team discussed the role of USP and highlighted the need for standardized methods and reference materials. USP is investigating the elaboration of reference materials, including brain homogenate, reagents, and analytical procedures, that could be useful in the manufacture of bovine-derived articles and medical products. USP recognizes that the next step could be the development of an information chapter based on this Stimuli article and the need to monitor the new analytical procedures in order to be able to standardize those procedures in the future. Furthermore, USP is developing two new general information chapters, Glycoprotein and Glycan Analysis $\langle 1084\rangle$ and Biological Assay Validation $\langle 1033\rangle$, which will provide additional framework for the standardization and validation of biological assays and glycoprotein analysis. These general information chapters should assist suppliers and medical
product manufacturers in the development and validation of procedures to minimize the potential risk of TSE contamination of bovine-derived articles.

## NOMENCLATURE

This section includes supplements to the latest edition of the USP Dictionary of USAN and International Drug Names that incorporate new United States Adopted Names (USAN) and revisions to existing Dictionary names. Also listed are Proposed and Recommended International Nonproprietary Names (INN) when they have been announced by the World Health Organization.

Possible names suggested for use as USAN and INN are listed for public review and comment along with information on how nonproprietary names are devised. In addition, readers may find articles relevant to current compendial nomenclature issues that also occasionally report on related matters pertaining to USAN and INN.

## USP Dictionary of USAN and International Drug Names 2004 USP DICTIONARY SUPPLEMENT 3

IMPORTANT-Save this Supplement. This and all supplements appearing in $P F$ are needed to keep the 2004 edition of the USP Dictionary (USPD) up-to-date. The cumulative contents of the supplements to the current (2004) edition will be included in the next complete edition of the Dictionary.

## New United States Adopted Names (USAN)

The following are newly established United States Adopted Names (USAN). These names will not be listed cumulatively; see preceding and succeeding numbers of $P F$ for other new USAN to supplement the Dictionary main volume.

Alagebrium Chloride [2004] ( $\mathrm{al} \mathrm{a}^{\prime \prime}$ je bree ${ }^{\prime}$ um). $\mathrm{C}_{13} \mathrm{H}_{14}$ ClNOS. 267.78. (1) Thiazolium, 4,5-dimethyl-3-(2-oxo-2-pheny-lethyl)-, chloride; (2) 4,5-Dimethyl-3-(2-oxo-2-phenylethyl)thiazolium chloride. CAS-341028-37-3. Prevention and treatment of cardiovascular complications of aging, diabetes, and end stage renal disease; diabetic multisymptom pathology (other than cardiovascular) including retinopathy, neuphropathy, neuropathy, and ulcers (advanced glycosylation endproduct $(A G E)$ crosslink inhibitor). (Alteon) $\diamond A L T$ 711

$\mathrm{Cl}^{-}$

Atilmotin [2004] ( $\mathrm{a}^{\prime \prime}$ til moe' tin). $\mathrm{C}_{86} \mathrm{H}_{135} \mathrm{~N}_{20} \mathrm{O}_{19}{ }^{+}$. 1753.00. (1) LLysinamide, $N$-[(2S)-1-oxo-3-phenyl-2-(trimethylammonio)-propyl]-L-valyl-L-prolyl-L-isoleucyl-L-phenylalanyl-L-threo-nyl-L-tyrosylglycyl-L- $\alpha$-glutamyl-L-leucyl-L-glutaminyl-D-ar-ginyl-L-leucyl-; (2) $N-[(2 S)-3-$ Phenyl-2-(trimethylammonio)propanoyl]-L-valyl-L-prolyl-L-isoleucyl-L-phenylalanyl-L-threonyl-L-tyrosylglycyl-L-glutamyl-L-leu-cyl-L-glutaminyl-D-arginyl-L-leucyl-L-lysinamide. CAS-533927-56-9. Intended for use in the stimulation of gastrointestinal motility (GI prokinetic agent)(motilin receptor agonist). (Baxter Anesthesia and Critical Care) $\diamond M O T-288$; OHM-11638; BAX-ACC-1638

Becatecarin [2004] (be" ka tek' ar in). $\mathrm{C}_{33} \mathrm{H}_{34} \mathrm{Cl}_{2} \mathrm{~N}_{4} \mathrm{O}_{7}$. 669.60. (1) $5 H$-Indolo[2,3-a]pyrrolo[3,4-c]carbazole-5,7(6H)-dione, 1,11-dichloro-6-[2-(diethylamino)ethyl]-12,13-dihydro-12-(4-O-methyl- $\beta$-D-glucopyranosyl)-; (2) 1,11-Dichloro-6-[2-(diethylamino)ethyl]-12-(4-O-methyl- $\beta$-D-glucopyranosyl)-12,13-dihydro- 5 H -indolo [2,3-a]pyrrolo[3,4-c]carbazole-5,7(6H)-dione. CAS-119673-08-4. Antineoplastic (rebeccamycin analogue). (Exelixis) $\diamond X L 119 ; B M S-181176 ; B M Y-$ 27557; NSC-655649

Cariporide Mesylate [2004] (kar ee por' ide).
$\mathrm{C}_{12} \mathrm{H}_{17} \mathrm{~N}_{3} \mathrm{O}_{3} \mathrm{~S} . \mathrm{CH}_{4} \mathrm{O}_{3} \mathrm{~S} .379 .46$. [Cariporide is INN.] (1) Benzamide, $N$-(aminoiminomethyl)-4-(1-methylethyl)-3-(methylsulfonyl)-, monomethanesulfonate; (2) $N$-(Diamino-methylene)-4-isopropyl-3-(methylsulfonyl)benzamide monomethanesulfonate; (3) N -(4-Isopropyl-3-methanesulfonyl-benzoyl)-guanidine.CAS-159138-81-5; CAS-159138-80-4 [cariporide]. Reduction of death and non-fatal myocardial infarction in patients undergoing CABG surgery. (Aventis Pharma Deutschland GmbH$) \stackrel{\rightharpoonup}{ } \stackrel{\text { HOE }}{ } 642$

Ciclesonide [2004] (sik le son' ide). $\mathrm{C}_{32} \mathrm{H}_{44} \mathrm{O}_{7}$. 540.69. (1) Pregna-1,4-diene-3,20-dione, 16,17-[[( $R$ )-cyclohexylmethylene] bis-(oxy)]-11-hydroxy-21-(2-methyl-1-oxopropoxy)-, ( $11 \beta, 16 \alpha$ ); (2) $2 H$-Naphth [ $\left.2^{\prime}, 1^{\prime}: 4,5\right]$ indeno [1,2-d] [1,3] dioxole, pregna-1,4-diene-3,20-dione deriv. $C A S$-126544-47-6; CAS-141845-82-1. INN. Treatment of asthma as prophylactic therapy in adults and adolescents. Alvesco (Dynamit Nobel $\mathrm{GmbH}) \diamond R P R 251526$

Disufenton Sodium [2004] (dye soo fen' ton). $\mathrm{C}_{11} \mathrm{H}_{13} \mathrm{NNa}_{2} \mathrm{O}_{7} \mathrm{~S}_{2}$. 381.30. (1) 1,3-Benzenedisulfonic acid, 4-[[(1,1-dimethy-lethyl)oxidoimino]methyl]-, disodium salt; (2) Disodium 4-tert-butyliminomethyl)benzene-,3-disulfonate $N$-oxide; (3) Disodium 4-[[(1,1-dimethylethyl)imino]methyl]benzene-1,3disulfonate $N$-oxide. CAS-168021-79-2. INN. Neuroprotective agent used to treat ischemic stroke. (AstraZeneca) $\checkmark N X Y-059$

Eritoran Tetrasodium [2004] ( $\mathrm{er}^{\prime \prime}$ i tore' an). $\mathrm{C}_{66} \mathrm{H}_{122} \mathrm{~N}_{2} \mathrm{Na}_{4} \mathrm{O}_{19} \mathrm{P}_{2}$. 1402.00. (1) $\alpha$-D-Glucopyranose, 3- O-decyl-2-deoxy-6-O-[2-deoxy-3-O-[(3R)-3-methoxydecyl]-6-O-methyl-2-[[(11Z)-1-oxo-11-octadecenyl]amino]-4- $O$-phosphono- $\beta$-d-glucopyra-nosyl]-2-[(1,3-dioxotetradecyl)amino]-, 1-(dihydrogen phosphate), tetrasodium salt; (2) 3-O-Decyl-2-deoxy-6-O-[2-deoxy-3-O-[(3R)-3-methoxydecyl]-6-O-methyl-2-[(11Z)-oc-tadec-11-enoylamino]-4- $O$-phosphonato- $\beta$-D-glucopyrano-syl]-2-[(3-oxotetradecanoyl)amino]- $\alpha$-D-glucopyranosyl tetrasodium phosphate. CAS-185954-98-7. Treatment of sepsis and other diseases due to reaction to bacterial endotoxin (endotoxin antagonist). (Eisai Medical Research) $\diamond$ E5564; B1287

Lenalidomide [2004] (le na lid' oh mide). $\mathrm{C}_{13} \mathrm{H}_{13} \mathrm{~N}_{3} \mathrm{O}_{3}$. 259.30. (1) 2,6-Piperidinedione, 3-(4-amino-1,3-dihydro-1-oxo- 2 H -iso-indol-2-yl)-; (2) 3-(4-Amino-1-oxo-1,3-dihydro-2H-isoin-dol-2-yl)piperidine-2,6-dione. CAS-191732-72-6. Immunomulator intended for use in the treatment of multiple myeloma, myelodysplastic syndromes, solid tumors including glioma and metastatic melanoma, Crohn's disease, and heart failure. Revlimid (Celgene) $\diamond C C-5013 ; C D C-501$

Levalbuterol Tartrate [2004] (lev al byoo' ter ol).
$2\left(\mathrm{C}_{13} \mathrm{H}_{21} \mathrm{NO}_{3}\right) . \mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{6}$. 628.71. 1,3-Benzenedimethanol, $\alpha^{1}$ [ [(1,1-dimethylethyl)amino]methyl]-4-hydroxy-, ( $\left.\alpha^{1} \mathrm{R}\right)$-, (2R,3R)-2,3-dihydroxybutanedioate (2:1) (salt). CAS-661464-94-4. Anti-asthmatic and bronchodilator ( $\beta_{2}$-adrenergic receptor agonist). Xopenex HFA (Sepracor)

Midostaurin [2004] (mi doe stor' in). $\mathrm{C}_{35} \mathrm{H}_{30} \mathrm{~N}_{4} \mathrm{O}_{4}$. 570.64. (1) Benzamide, $N-[(9 S, 10 R, 11 R, 13 R)-2,3,10,11,12,13$-hexahy-dro-10-methoxy-9-methyl-1-oxo-9,13-epoxy- $1 \mathrm{H}, 9 \mathrm{H}$-diindolo [1,2,3-gh:3', $\left.2^{\prime}, 1^{\prime}-l m\right]$ pyrrolo[3,4-j][1,7]benzodiazonin-11-yl]-N-methyl-; (2) $N$-[(9S,10R,11R,13R)-10-methoxy-9-methyl-1-oxo-2,3,10,11,12,13-hexahydro-9,13-epoxy$1 H, 9 H$-diindolo [1,2,3-gh:3', 2', 1'-lm]pyrrolo[3,4-j][1,7]ben-zodiazonin-11-yl]-N-methylbenzamide. CAS-120685-11-2. INN. Antineoplastic; protein kinase C inhibitor. (Novartis) $\checkmark C G P 41251$; PKC 412

Paliperidone [2004] (pal ee per' i done). $\mathrm{C}_{23} \mathrm{H}_{27} \mathrm{FNH}_{4} \mathrm{O}_{3} .388 .50$. (1) $4 H$-Pyrido [1,2-a]pyrimidin-4-one, 3-[2-[4-(6-fluoro-1,2-benzisoxazol-3-yl)-1-piperidinyl]ethyl]-6,7,8,9-tetrahydro-9-hydroxy-2-methyl-; (2) (9RS)-3-[2-[4-(6-Fluoro-1,2-benzi-soxazol-3-yl)piperidin-1-yl]]ethyl]-9-hydroxy-2-methyl-6,7,8,9-tetrahydro-4H-pyrido[1,2-a]pyrimidin-4-one.CAS-144598-75-4. INN. Treatment of schizophrenia. (Johnson \& Johnson) $\triangleleft R O 76477$

Paliperidone Palmitate [2004]. $\mathrm{C}_{39} \mathrm{H}_{57} \mathrm{FN}_{4} \mathrm{O}_{4}$. 664.90. (1) Hexadecanoic acid, 3-[2-[4-(6-fluoro-1,2-benzisoxazol-3-yl)-1-pi-peridinyl]ethyl]-6,7,8,9-tetrahydro-2-methyl-4-oxo-4H-pyri-do[1,2-a]pyrimidin-9-yl ester; (2) (9RS)-3-[2-[4-(6-Fluoro-1,2-benzisoxazol-3-yl)piperidin-1-yl]ethyl]-2-methyl-4-oxo-6,7,8,9-tetrahydro-4H-pyrido[1,2-a]pyrimidin-9-yl hexadecanoate. CAS-199739-10-1. Treatment of schizophrenia. (Johnson \& Johnson) $\triangleleft R O 92670$

Radafaxine Hydrochloride [2004] (rad a fax' een).
$\mathrm{C}_{13} \mathrm{H}_{18} \mathrm{ClNO}_{2}$. HCl . 292.20. (1) 2-Morpholinol, 2-(3-chloro-phenyl)-3,5,5-trimethyl-, hydrochloride, $(2 S, 3 S)-;(2)(+)-$ ( $2 S, 3 S$ )-2-(3-Chlorophenyl)-3,5,5-trimethylmorpholin-2-ol hydrochloride. CAS-106083-71-0. Antidepressant; antianxiety. (GlaxoSmithKline) $\diamond G W 353162 A$

Selegiline [2004] (se lé ji leen). $\mathrm{C}_{13} \mathrm{H}_{17} \mathrm{~N} .187 .30$. (1) Benzeneethanamine, $N, \alpha$-methyl- $N$-2-propynyl-, $(\alpha R)-;(2)(-)-(N)$ -Methyl- $N$-[(1R)-1-methyl-2-phenylethyl]prop-2-yn-1-amine. CAS-14611-51-9. Antidepressant (MAO inhibitor). (BASF); (Abbott)

Trodusquemine [2004] (troe doo' skwe meen). $\mathrm{C}_{37} \mathrm{H}_{72} \mathrm{~N}_{4} \mathrm{O}_{5} \mathrm{~S}$. 685.10. (1) Cholestane-7,24-diol, 3-[[3-[[4-[(3-aminopropy-1)amino]butyl]amino]propyl]amino]-, 24-(hydrogen sulfate), $(3 \beta, 5 \alpha, 7 \alpha, 24 R)-;(2)(24 R)-3 \beta-[[3-[[4-[(3-a m i n o p r o p y l) a m i-$ no]butyl]amino]propyl]amino]-7 $\alpha$-hydroxy-5 $\alpha$-cholestan-24yl hydrogen sulfate. CAS-186139-09-3. Treatment of medically significant obesity. (Genaera) $\diamond M S I-1436$

Vestipitant Mesylate [2004] (ves tee pit' ant). $\mathrm{C}_{23} \mathrm{H}_{24} \mathrm{~F}_{7} \mathrm{~N}_{3} \mathrm{O}$.$\mathrm{CH}_{4} \mathrm{O}_{3} \mathrm{~S}$. 587.60. (1) 1-Piperazinecarboxamide, $N-[(1 R)$-1-[3,5-bis(trifluoromethyl)phenyl]ethyl]-2-(4-fluoro-2-methyl-phenyl)- $N$-methyl-, (2S)-, monomethanesulfonate; (2) ( + )-(2S)- $N$-[(1R)-1-[3,5-bis(trifluoromethyl)phenyl]ethyl]-2-(4-fluoro-2-methylphenyl)- $N$-methylpiperazine-1-carboxamide methanesulfonate. CAS-334476-64-1. Antidepressant/antianxiety; prevention of nausea and vomiting; used in the treatment of functional dyspepsia, irritable bowel syndrome and $G E R D$. (GlaxoSmithKline) $>G W 597588 B$

## Proposed and Recommended International Nonproprietary Names

International Nonproprietary Names (INN) are devised by the World Helath Organization (WHO).

Under its charter, the WHO is empowered simply to recommend specific actions or procedures to its Member States. This limitation is incorporated into the WHO program concerned with the selection of international nonproprietary names for pharmaceutical substances, in that the WHO first publishes the selected names as proposals ("Proposed International Nonproprietary Names"). A period of four months from the date of publication in WHO Drug Information is allowed for entering comments on, or objections to, any proposal on the part of Member States or other interested par-
ties. In general, an objection reflects a belief that the proposal concerned is confusingly close to (i.e., conflicts with) a name already in use, perhaps in only a restricted area in which the party has a proprietary interest in the form of trademark rights. In the event that no objection is received, the WHO proceeds with listing and publishing the names so devised as recommendations ("Recommended International Nonproprietary Names"), which many Member States then recognize as the sole or preferred nonproprietary name for use within their respective territories.

## Proposed International Nonproprietary Names

The following 55 names have been selected by the World Health Organization (WHO) as Proposed International Nonproprietary Names. This list, with chemical names or descriptions and the molecular formulae, appears in WHO Drug Information, Vol 17, No. 3, 2003.

| Proposed INN | Therapeutic Indication |
| :--- | :--- |
| Adargileukin Alfa | Antiviral; antineoplastic |
| Alamifovir | Antiviral |
| Aprinocarsen | Antineoplastic |
| Belimumab | Immunomodulator |
| Cantuzumab Mertansine | Treatment of tumors that |
|  | express C242 antigen |
| Cimicoxib | Cycloxygenase-2 inhibitor |
| Dabuzalgron | Alfarl-adrenoreceptor agonist |
| Dacinostat | Antitumor agent, inhibitor of |
|  | histone deacetylase |
| Deligoparin Sodium | Anticoagulant |
| Desvenlafaxine | Antidepressant |
| Dibotermin Alfa | Growth factor |
| Diquafosol | P2Y receptor agonist |
| Disermolide | Antineoplastic |
| Edifoligide | Oligonucleotide |
| Edratide | Treatment of systemic lupus |
|  | erythematosus |
| Elsilimomab | Immunomodulator |
| Elvucitabine | Antiviral |
| Epitumomab Cituxetan | Immunomodulator |
| Eptotermin Alfa | Growth factor |
| Exatecan Alideximer | Antineoplastic |
| Exenatide | Antidiabetic |
| Firocoxib | Cycloxygenase-2 inhibitor |
| Fispemifene | Antiestrogen |
| Fluorescein Lisicol | Diagnostic aid |
| Freselestat | Elastase inhibitor |
| Galiximab | Immunomodulator |
| Hemoglobin Raffimer | Oxygen carrier |
| Icofungipen | Antifungal |
| Icrocaptide | Anti-inflammatory |
| Iferanserin | Serotonin receptor antagonist |
|  |  |

Any comments or formal objections to the proposed names should be addressed to Sandra Van Laan, Assistant Secretary, USAN Council, American Medical Association, 515 North State Street, Chicago, Illinois 60610.

| Proposed INN | Therapeutic Indication |
| :--- | :--- |
| Istradefylline | Antiparkinsonian |
| Ixabepilone | Antineoplastic |
| Ladostigil | Cholinesterase and monamine |
| Lapatinib | oxidase inhibitor |
| Lomeguatrib | Antineoplastic |
| Odiparcil | Alkylluavanine alkyltransferase |
| Omiganan | inhibitor |
| Pactimibe | Antithrombotic |
| Patupilone | Antimicrobial |
| Pertuzumab | Antiatherosclerotic |
| Pixantrone | Antineoplastic |
| Pritumumab | Immunomodulator |
| Ralfimamide | Antineoplastic |
|  | Antineoplastic |
| Rebimastat | Analgesic, sodium channel |
| Segestrone | blocker |
| Semapimod | Matrix metalloproteinase |
| Sufugolix | inhibitor |
|  | Contraceptive |
|  | Immunomodulator |
| Tafluprost | Luteinizing hormone-releas- |
| Talizumab | ing-hormone (LHRH) |
| Technetium (99m Tc) | antagonist |
| Nitridocade | Antiglaucoma |
| Tesofensine | Immunomodulator |
| Tifenazoxide | Radiodiagnostic agent |
| Tisocalcitate | Antiparkinsonian |
| Ulifloxacin | Antidiabetic |
| Varenicline | Vitamin D analog |
|  | Antibacterial |
|  | Nicotinic acetylcholine |
|  | receptor agonist |

## Suggested United States Adopted Names

The United States Adopted Names (USAN) program is the specifically organized effort in the United States directed to producing simple and useful nonproprietary names for drugs while the drugs are still in the investigational stages. The American Medical Association (AMA), the American Pharmaceutical Association (APhA), and the United States Pharmacopeial Convention (USPC) jointly sponsor the USAN program with representation from the FDA.

Each U.S. Adopted Name is chosen with the expectation that it will be suitable for prescribing and dispensing purposes and for designation as the title of the monograph, should the article be recognized in the official United States Pharmacopeia or National Formulary. A measure of the prestige and recognition of the value of the USAN program can be found in the following regulations published by the Commissioner of Food and Drugs and the Secretary of Health and Human Services in the Federal Register of February 1988.

All who are concerned with the prescription, dispensing, use, sale or manufacture of drugs may, in the absence of the designation of an official name by the FDA, rely on the current compendial name or the U.S. Adopted Name (USAN) listed in this volume as being the established name in accordance with the Federal Food, Drug, and Cosmetic Act.
A formal procedure ${ }^{1}$ is followed by the USAN Council in selecting an established name for a drug. The USAN Council Secretary is also an ex officio member of the International Nonproprietary Names (INN) Committee. USAN Guiding Principles are concordant with World Health Organization (WHO) principles, and all USANs for substances also named by the INN Committee are sys-

| Suggested USAN | Category |
| :---: | :---: |
| Aerofilcon | Hydrophilic contact lens |
| Hyperfilcon | material |
| Oxsilfilcon |  |
| Silfilcon |  |
| Afboximab | Anti-angiogenic agent to treat |
| Afociximab | solid tumors and age-related |
| Afotuximab | macular degeneration |
| Boxatuximab |  |
| Valiximab |  |
| Volociximab |  |
| Volotuximab |  |
| Alkarginine Acetate | Treatment of cardiogenic shock |
| Arloginine Acetate | complicating acute myocardial |
| Marginine Acetate | infarction |
| Monarginine Acetate |  |
| Targinine Acetate |  |
| Tilarginine Acetate |  |
| Aloglustratide Hydrochloride | Antineoplastic [activated by |
| Canfosfamide Hydrochloride | gluathione S-transferase |
| Canglustrac Hydrochloride | (GST) P1-1] |
| Canglustrafos Hydrochloride |  |
| Canglustramide Hydrochloride Canglustratide Hydrochloride |  |
|  |  |
| Ampaglufuran | Treatment of schizophrenia |
| Ampaxazole |  |
| Farampator |  |

tematically processed through the INN Committee. This ensures that, with very rare exceptions, USANs are identical to INNs and available for world-wide use.

A suggestion for a USAN originates usually from a firm or an individual who has developed a substance of potential therapeutic utility to the point where there is a distinct possibility of its being marketed in the United States of America. Occasionally, the initiative is taken by the USAN Council in the form of a request to parties interested in a substance for which a nonproprietary name appears to be lacking.
Submissions to the USAN Council are expected to conform to the established Guiding Principles ${ }^{2}$ and to be reasonably free from conflict with other names, including both trademarks and nonproprietary names. An effort is made to discourage the occasional, undesirable practice of incorporating in trademarks the syllables used in an established nonproprietary name, or syllables recommended for USAN. Such trademarks may act as a bar to the subsequent adoption of appropriate nonproprietary names for closely related drugs.

The suggested nonproprietary names for the drugs described in the following list are under consideration by the USAN Council. The name(s) being considered for each drug substance, and the applicable category, are separated by double spacing from the name(s) and category for the next listed drug substance. Where two or more names are being considered for the same drug substance, the names are single-spaced, and the applicable category term is written only once to the right of the single-spaced group of names.

Any comments or protests should be addressed to Sandra Van Laan, Assistant Secretary, USAN Council, American Medical Association, 515 North State Street, Chicago, Illinois 60610.

## Suggested International Nonproprietary Names

International Nonproprietary Names (INN) are devised by the World Health Organization (WHO). INNs for substances originating within the United States are applied for through the USAN Council. INN and USAN Guiding Principles are concordant, which assures that, with very few exceptions, INNs and USANs are identical.

Under its charter, the WHO is empowered simply to recommend specific actions or procedures to its Member States. This limitation is incorporated into the WHO program concerned with the selection of international nonproprietary names for pharmaceutical substances, in that the WHO first publishes the selected names as proposals ("Proposed International Nonproprietary Names"). A period of four months from the date of publication in WHO Drug Information is allowed for entering comments on, or objections to, any proposal on the part of Member States or other interested parties. In general, an objection reflects a belief that the proposal concerned is confusingly close to (i.e., conflicts with) a name already in use, perhaps in only a restricted area in which the party has a proprietary interest in the form of trademark rights. In the event
that no objection is received, the WHO proceeds with listing and publishing the names so devised as recommendations ("Recommended International Nonproprietary Names"), which many Member States then recognize as the sole or preferred nonproprietary name for use within their respective territories.

The names for the drugs that are categorized in the following list are under consideration for the selection of new Proposed International Nonproprietary Names. The name(s) being considered for each drug substance, and the applicable category, are separated by double spacing from the name(s) and category for the next listed drug substance. Where two or more names are being considered for the same drug substance, the names are single-spaced, and the applicable category term is written only once to the right of the single-spaced group of names.

Any comments or protests should be addressed to Sandra Van Laan, Assistant Secretary, USAN Council, American Medical Association, 515 North State Street, Chicago, Illinois 60610.

| Suggested INN | Category |
| :---: | :---: |
| Acetaxel Exetaxel | Anti-tumor, especially those that overexpress P-glycoproteins |
| Ampaglufaran <br> Ampaneopion <br> Ampaxazole <br> Farampator | Treatment of schizophrenia |
| Aplindore Palindore | Antischizophrenic |
| Azifloxacin Bazofloxacin Endofloxacin | Antibacterial agent |
| Benzcapone Nibenzcapone Nibicapone | Treatment of Parkinson's disease |
| Canfosfamide Canglustratide | Antineoplastic agent |
| Dalbavancin | Antibiotic |
| Etemucret Icomucret | Treatment of dry eye (stimulates glycoprotein secretion) |
| Glicidelin Indacidelin Indantin | Treatment of neuropathic pain |
| Iboctadekin | Antineoplastic |
| Iloprost | Treatment of pulmonary arterial hypertension |
| Levotofisopam Levtofisopam | Anxiolytic, treatment of autonomic instability |
| Manitlimus | Immunosuppressive |
| Padorporfin Topadiporfin | Photosensitizer used in the treatment of prostate cancer |

| Suggested INN | Category |
| :---: | :---: |
| Pancarcinomab Nafenatox <br> Pancarcinomab Optimotox <br> Pantumomab Nafenatox <br> Pantumomab Optimotox <br> Ultimomab Nafenatox <br> Ultimomab Optimotox | Treatment of cancer |
| Parexyprisnil Pontiprisnil Spetoxyprisnil | Contraceptive (selective progesterone receptor modulator) |
| Pentadol <br> Tapentadol | Analgesic |
| Petaprost <br> Rivenprost <br> Voluprost | Treatment of fractures resulting from osteoporosis |
| Recamline <br> Ricamfoline <br> Ricamline | Anti-inflammatory, anti-rheumatic |
| Sapavaptan | Treatment of congestive heart failure, SIADH, liver cirrhosis with ascites and water retention, brain edema, nephritic syndrome associated with generally high AVP plasma levels and hyponatremia |
| Targinine Acetate Tilarginine Acetate | Treat cardiogenic shock complicating acute myocardial infarction (MI) |
| Tovelamer | Treatment and prevention of Clostridium difficile associated diarrheal disease |
| Transferrin Difitox | Treatment of glioblastoma multiform and high grade glioma |
| Volociximab | Anti-angiogenic agent to treat solid tumors and age-related macular degeneration |

## INDEX

This is a cumulative directory for the content of all issues of $P F$ beginning with $P F$ 30(1).
[Note-This index covers Vol. 30 No. 1, pp. 1-381, Vol. 30, No. 2 pp. 383-755, Vol. 30, No. 3 pp. 757-1114, Vol. 30 No. 4, pp. 1115-1530, Vol. 30 No. 5, pp.1533-1939]

GENERAL NOTICES AND REQUIREMENTS (USP)
Significant Figures and Tolerances (USP) . . . . . . . . . . . 424, 794

## REAGENTS，INDICATORS，AND SOLUTIONS

## Reagent Specifications

Acetal（USP） ..... 644
Ammonium Hydroxide，6N（USP） ..... 1388
Ammonium pyrrolidinedithiocarbamate（USP） ..... 1043
Anion－exchange Resin，Styrene－Divinylbenzene（USP） ..... 1043
Bacterial Alkaline Protease Preparation（USP） ..... 644
Benzamidine Hydrochloride Hydrate（USP） ..... 644
Bromofluoromethane（USP） ..... 1388
Calf Thymus DNA（USP） ..... 1389
Cation－exchange Resin，Styrene－Divinylbenzene（USP） ..... 1043
4－Chlorophenol（USP） ..... 1044
p－Chlorophenol（USP） ..... 1045
Chromotrope 2R（USP） ..... 1389
Citric Acid（USP） ..... 1044
Citric Acid，Anhydrous（USP） ..... 1044
Collagen（USP） ..... 1389
Collagenase（USP） ..... 1389
Bovine Collagen（USP） ..... 644
Rat Tail Collagen（USP） ..... 644
Cyclohexylmethanol（USP） ..... 644
Dicyclohexyl（USP） ..... 645
1，5－Dimethyl－1，5－diazaundecamethylene Polymethobromide （USP） ..... 315
1，9－Dimethyl－Methylene Blue（USP） ..... 645
Dimethyl Sulfoxide（USP） ..... 1045
Direct Red 80 （USP） ..... 1390

## INDEX

This is a cumulative directory for the content of all issues of $P F$ beginning with $P F$ 30(1).

Amoxicillin and Clavulanate Potassium for Oral Suspension
(USP) . . . . . . . . . . . . . . . . . . . . . . .
Amphetamine Sulfate (USP)

| (USP) . . . . . . . . . . . . . . . . . . . . . . . . . . . . | 53 |
| :--- | :--- |
| Amphetamine Sulfate (USP) |  |
| Amphetamine Sulfate Tablets (USP) | $\ldots$ |

Amphotericin B Lotion (USP) . . . . . . . . . . . . . . . . . . 444
Amphotericin B Topical Emulsion (USP) . . . . . . . . . . . . 445
Ampicillin Capsules (USP) . . . . . . . . . . . . . . . . . . . . 55
Ampicillin Tablets (USP) . . . . . . . . . . . . . . . . . . . . . 56
Anecortave Acetate (USP) . . . . . . . . . . . . . . . . . . . . 445
Anecortave Acetate Injectable Suspension (USP) . . . . . . . 447
Anticoagulant Citrate Dextrose Solution (USP) . . . . . . . . 1583
Antithrombin III Human (USP) . . . . . . . . . . . . . . . . . 56
Arginine Hydrochloride (USP) . . . . . . . . . . . . . . . . . . 449
Ascorbic Acid Tablets (USP) . . . . . . . . . . . . . . . . . . . 60
L-Asparagine (NF) . . . . . . . . . . . . . . . . . . . . . . . . . 205
Aspartic Acid (USP) . . . . . . . . . . . . . . . . . . . . . . . . 1163
Aspirin (USP) . . . . . . . . . . . . . . . . . . . . . . . . . . . 1164
Aspirin, Caffeine, and Dihydrocodeine Bitartrate Capsules
(USP) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 60
$\begin{array}{ll}\text { (USP) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . } & 60 \\ \text { Atovaquone Oral Suspension (USP) . . . . . . . . . . . . . . } & 449\end{array}$
Atracurium Besylate Injection (USP) . . . . . . . . . . . . . . 450, 808
Avobenzone (USP) . . . . . . . . . . . . . . . . . . . . . . . . 1164
Azithromycin (USP) . . . . . . . . . . . . . . . . . . . . . . . . 450
Aztreonam (USP) . . . . . . . . . . . . . . . . . . . . . . . . . 61
Baclofen Tablets (USP) . . . . . . . . . . . . . . . . . . . . . . 61
BCG Live (USP) . . . . . . . . . . . . . . . . . . . . . . . . . . 452
Benzocaine (USP) . . . . . . . . . . . . . . . . . . . . . . . . . 809
Benzoyl Peroxide Gel (USP) . . . . . . . . . . . . . . . . . . . 455, 1165
Benzoyl Peroxide Lotion (USP) . . . . . . . . . . . . . . . . . 456
Benzoyl Peroxide Topical Emulsion (USP) . . . . . . . . . . . 456
Benzyl Alcohol (NF) . . . . . . . . . . . . . . . . . . . . . . . 690
Benzyl Benzoate Lotion (USP) . . . . . . . . . . . . . . . . . 457
Benzyl Benzoate Topical Emulsion (USP) . . . . . . . . . . . 457
Betadex (NF) . . . . . . . . . . . . . . . . . . . . . . . . 206, 595, 1323
Betahistine Hydrochloride (USP) . . . . . . . . . . . . . . . . 1584
Betamethasone Dipropionate Lotion (USP) . . . . . . . . . . . 458
Betamethasone Dipropionate Topical Emulsion (USP) . . . . 459
Betamethasone Sodium Phosphate (USP) . . . . . . . . . . . . 1166
Betamethasone Oral Solution (USP) . . . . . . . . . . . . . . . 460
Betamethasone Syrup (USP) . . . . . . . . . . . . . . . . . . . 460
Betamethasone Tablets (USP) . . . . . . . . . . . . . . . . . . 62
Betamethasone Valerate Lotion (USP) . . . . . . . . . . . . . 461
Betamethasone Valerate Topical Emulsion (USP) . . . . . . . 461
Bethanechol Chloride (USP) . . . . . . . . . . . . . . . . . . . 1586
Bethanechol Chloride Tablets (USP) . . . . . . . . . . . . . . 1587
Bethanechol Chloride (USP erratum) . . . . . . . . . . . . . . 1155
Biological Indicators for Moist Heat, Dry Heat, and Gaseous
Modes of Sterilization, Metal, or Plastic Carriers (USP) . . 63
Biological Indicators for Moist Heat, Dry Heat, and Gaseous
Modes of Sterilization, Liquid Spore Suspensions (USP) . . 66
Bismuth Subsalicylate Oral Suspension (USP) . . . . . . . . . 1166
Bismuth Subsalicylate Tablets (USP) . . . . . . . . . . . . . . 1167
Bisoprolol Fumarate (USP erratum) . . . . . . . . . . . . . . . 417
Bisoprolol Fumarate Tablets (USP) . . . . . . . . . . . . . . . 1588
Bisoprolol Fumarate and Hydrochlorothiazide Tablets (USP
erratum) . . . . . . . . . . . . . . . . . . . . . . . . . . 1155
1155
Red Blood Cells (USP) . . . . . . . . . . . . . . . . . . . . . . 69
Whole Blood (USP) . . . . . . . . . . . . . . . . . . . . . . . . 76
Bretylium Tosylate in Dextrose Injection (USP) ........... . . . . . 1589
Brompheniramine Maleate and Pseudoephedrine Sulfate Oral
Solution (USP) 9
Brompheniramine Maleate and Pseudoephedrine Sulfate Syrup
(USP) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 80
Bupivacaine Hydrochloride (USP) . . . . . . . . . . . . . . . . 1589
Bupivacaine Hydrochloride in Dextrose Injection (USP) .... 1590
Bupropion Hydrochloride Extended-Release Tablets
(USP) . . . . . . . . . . . . . . . . . . . . . . . . . . . . 810, 1562
Butalbital, Acetaminophen, and Caffeine Tablets (USP) . . . . . . . . . . . . . 810,1562
Butylparaben (NF) . . . . . . . . . . . . . . . . . . . . . . . . . 1431
Caffeine (USP) . . . . . . . . . . . . . . . . . . . . . . . . . . . 1168
Caffeine Citrate Injection (USP) . . . . . . . . . . . . . . . . 462, 1590

## EXCIPIENTS

Excipients，USP and NF Excipients，Listed by Ca 587，961，1317， 1659
GENERAL CHAPTERS
Acid－neutralizing Capacity $\langle 301\rangle$（USP）．．．．．．．．．．．． 1006
Aerosols，Metered Dose Inhalers，and Dry Powder Inhalers $\langle 601\rangle$
（USP）．．．．．．．．．．．．．．．．．．．．．．．．．．．． 1342

Analytical Data－Interpretation and Treatment $\langle 1010\rangle$
（USP）．．．．．．．．．．．．．．．．．．．．．．．．．．．．． 236

Antibiotics－Microbial Assays $\langle 81\rangle$（USP）．．．．．．．．．．． 1002
Antimicrobial Agents－Content $\langle 341\rangle$（USP）．．．．．．．．． 1678
Application of Water Activity Determination to Nonsterile
Pharmaceutical Products $\langle 1112\rangle$（USP）．．．．．．．．．． 1709
Biological Indicators－Resistance Performance Tests $\langle 55\rangle$
（USP）．．．．．．．．．．．．．．．．．．．．．．．．．．．．

Cleaning Glass Apparatus $\langle 1051\rangle$（USP）．．．．．．．．．．．． 264
Dissolution $\langle 711\rangle$（USP）．．．．．．．．．．．．．．．．．．．．． 234
The Dissolution Procedure：Development and Validation $\langle 1092\rangle$
（USP）．．．．．．．．．．．．．．．．．．．．．．．．．．．．． 351
Effusivity $\langle 1073\rangle$（USP）．．．．．．．．．．．．．．．．．．．．． 1489
Elastomeric Closures for Injections $\langle 381\rangle$（USP）．．．．．．． 220

Emergency Medical Services Vehicles and Ambulances－
Storage of Preparations $\langle 1070\rangle$（USP）．．．．．．．．．． 1706
Environmentally Sensitive Preparations $\langle 386\rangle$（USP）．．．．． 1680
Genotoxicity Testing $\langle 1082\rangle$（USP）．．．．．．．．．．．．．．． 264
Heavy Metals $\langle 231\rangle$（USP）．．．．．．．．．．．．．．．．217，614， 1004
Impurities in Official Articles $\langle 1086\rangle$（USP erratum）．．．．． 787
Inductively－Coupled Plasma $\langle 730\rangle$（USP）．．．．．．．．．．． 1022
Instrumentation for Analysis of High Purity Pharmaceutical
Waters $\langle 1232\rangle$（USP）
303， 1806
Insulin Assays $\langle 121\rangle$（USP）．．．．．．．．．．．．．．．．．．． 1675
Microbial Enumeration Tests－Nutritional and Dietary
Supplements $\langle 2021\rangle$（USP erratum）
1566
Microbiological Attributes of Nonsterile Nutritional and Dietary
Supplements $\langle 2023$（USP）．．．．．．．．．．．．．．．．． 1818
Microbiological Best Laboratory Practices $\langle 1117\rangle$（USP）．．． 1713
Optical Rotation $\langle 781\rangle$（USP erratum）．．．．．．．．．．．．． 787
Osmolality and Osmolarity $\langle 785\rangle$（USP）．．．．．．．．．．．． 1702
Packaging—Unit of Use 〈1136（USP）．．．．．．．．．．．．． 1722
Pharmacopeial Harmonization $\langle 1196\rangle$（USP）．．．．．．．．．． 1151
Powder Fineness $\langle 811\rangle$（USP erratum）．．．．．．．．．．．．． 417
Sensitization Testing $\langle 1184\rangle$（USP）．．．．．．．．．．．．．．． 289
Specific Surface Area $\langle 846\rangle$（USP）．．．．．．．．．．．．．．．． 1465
Spectrophotometry and Light－Scattering 〈851〉（USP）．．．．． 1703
Sterilization and Sterility Assurance of Compendial Articles
$\langle 1211\rangle$（USP）．．．．．．．．．．．．．．．．．．．．．．．．． 1729
$\begin{aligned} &\langle 1211\rangle(\text { USP ）} \\ & \text { Tablet Friability }\langle 1216\rangle \text {（USP）} \text { ．．．．．．．．．．．．．．．．．．．．．．．．．} \\ & 1740\end{aligned}$
Terminally Sterilized Pharmaceutical Products—Parametric
Release $\langle 1222\rangle$（USP）．．．．．．．．．．．．．．．．．．．． 1741
Release
Total Organic Carbon $\langle 643\rangle$（USP）

## USP CATALOG

## New Items at a Glance

See what's new in USP Reference Standards. For your convenient and quick reference, here's a list of Reference Standards released by USP over the past year.

This list is continuously updated with the newest Reference Standards released within the past 12 months.

| Cat. No. | Description | Curr. <br> Lot | Price |
| :---: | :---: | :---: | :---: |
| 1012699 | Alcohol Determination-Acetonitrile ( $5 \mathrm{~mL} /$ ampule; 5 ampules) | F0C419 | \$156 |
| 1012688 | Alcohol Determination-Alcohol ( $5 \mathrm{~mL} /$ ampule; 5 ampules) | F0C399 | \$156 |
| 1048619 | Benazepril Hydrochloride (125 mg) | F0C250 | \$156 |
| 1048641 | Benazepril Related Compound C $(50 \mathrm{mg})$ | F0C425 | \$487 |
| 1071439 | Positive Bioreaction (3 strips; $10 \mathrm{~cm} \times 1$ cm) | F0D014 | \$325 |
| 1076206 | Powdered Black Cohosh Extract (1.5 g) | F0D086 | \$520 |
| 1076341 | Boric Acid (1 g) (AS) | F0D036 | \$200 |
| 1082708 | Butylated Hydroxytoluene ( 500 mg ) (AS) | F0D122 | \$156 |
| 1086334 | Calcium Acetate (1 g) (AS) | F0D156 | \$156 |
| 1086403 | Calcium Carbonate (1 g ) (AS) | F0D099 | \$156 |
| 1086436 | Calcium Chloride (1 g) (AS) | F0D153 | \$156 |
| 1086855 | Calcium Hydroxide (1 g) (AS) | F0D168 | \$156 |
| 1087701 | Candelilla Wax ( 250 mg ) | F0D123 | \$156 |
| 1091505 | Caprylocaproyl Polyoxylglycerides $(200 \mathrm{mg})$ | F0C312 | \$175 |
| 1098118 | Cefpiramide ( 300 mg ) | F0C203 | \$156 |
| 1098027 | Cefpodoxime Proxetil ( 350 mg ) | F0C192 | \$156 |
| 1105009 | Powdered Chaste Tree Extract (1.5 g) | F0C406 | \$520 |
| 1111001 | Chlorhexidine ( 200 mg ) | F0C306 | \$156 |
| 1111103 | Chlorhexidine Acetate ( 500 mg ) | F0C281 | \$156 |
| 1111307 | Chlorhexidine Related Compounds $(50 \mathrm{mg})$ | F0D017 | \$487 |
| 1115545 | Chlorogenic Acid ( 50 mg ) | F0C420 | \$156 |
| 1140349 | Clonazepam Related Compound C $(25 \mathrm{mg})$ | F0C340 | \$487 |
| 1140393 | Clonidine ( 200 mg ) | F0C401 | \$156 |
| 1140418 | Clonidine Related Compound A ( 25 mg ) | F0C373 | \$487 |
| 1140429 | Clonidine Related Compound B ( 25 mg ) | F0C403 | \$487 |
| 1152701 | Cyclandelate ( 200 mg ) | F0C384 | \$156 |
| 1187080 | Dibutyl Phthalate ( 200 mg ) | F0D125 | \$156 |
| 1224959 | Dolasetron Mesylate ( 200 mg ) | F0C319 | \$156 |
| 1224960 | Dolasetron Mesylate Related Compound A $(25 \mathrm{mg})$ | F0C321 | \$487 |
| 1231728 | Powdered Echinacea Purpurea Extract (1 g) | F0D018 | \$520 |
| 1231706 | Powdered Echinacea Angustifolia Extract (1 g) | F0D019 | \$520 |
| 1234704 | Powdered Eleuthero Extract (1.5 g) | F0C291 | \$520 |
| 1269414 | Fenbendazole Related Compound A ( 30 mg ) | F0D009 | \$487 |
| 1269425 | Fenbendazole Related Compound B ( 30 mg ) | F0D008 | \$487 |
| 1272204 | Fludarabine Phosphate ( 300 mg ) | F0C374 | \$156 |
| 1279837 | Fluoxetine Related Compound C ( 15 mg ) | F0C352 | \$487 |
| 1288317 | Ganciclovir Related Compound A $(15 \mathrm{mg})$ | F0C288 | \$624 |

| Cat. No. | Description | Curr. <br> Lot | Price |
| :---: | :---: | :---: | :---: |
| 1288463 | Gemcitabine Hydrochloride ( 200 mg ) | F0D037 | \$156 |
| 1294207 | Glucosamine Hydrochloride ( 200 mg ) | F0C363 | \$156 |
| 1305507 | 2E, 4E-Hexadienoic Acid Isobutylamide $(25 \mathrm{mg})$ | F0C353 | \$540 |
| 1311306 | Homopolymer Polypropylene (3 Strips) | F0C096 | \$156 |
| 1349014 | Isoflurane Related Compound A (0.1 mL ) | F0C232 | \$487 |
| 1349025 | Isoflurane Related Compound B (0.1 mL ) | F0C233 | \$487 |
| 1356836 | Lamivudine ( 200 mg ) | F0C361 | \$156 |
| 1356847 | Lamivudine Resolution Mixture A ( 10 mg ) | F0D024 | \$487 |
| 1356950 | Lauroyl Polyoxylglycerides ( 500 mg ) (AS) | F0D020 | \$156 |
| 1358503 | Leuprolide Acetate (200 mg) | F0C430 | \$1,525 |
| 1367708 | Linoleoyl Polyoxylglycerides (100 mg) | F0C283 | \$156 |
| 1370270 | Loratadine (200 mg) | F0C414 | \$260 |
| 1374260 | Magnesium Hydroxide (1 g) (AS) | F0D158 | \$156 |
| 1375127 | Manganese Chloride (1 g) (AS) | F0D150 | \$156 |
| 1375149 | Manganese Sulfate (1 g) (AS) | F0D151 | \$156 |
| 1378012 | Medroxyprogesterone Acetate Related Compound A ( 25 mg ) | F0C427 | \$500 |
| 1434011 | Methylphenidate Hydrochloride Erythro Isomer Solution ClI ( 0.5 mL ) | F0C368 | \$560 |
| 1441232 | Metoprolol Related Compound A $(20 \mathrm{mg})$ | F0C343 | \$520 |
| 1441243 | Metoprolol Related Compound B ( 50 mg ) | F0C377 | \$520 |
| 1441254 | Metoprolol Related Compound C $(20 \mathrm{mg})$ | F0C344 | \$520 |
| 1441265 | $\underset{(50 \mathrm{mg})}{\substack{\text { Metoprolol Related Compound D }}}$ | F0C378 | \$520 |
| 1441298 | Metoprolol Succinate ( 200 mg ) | F0C415 | \$156 |
| 1444279 | Mirtazapine ( 350 mg ) | F0D155 | \$800 |
| 1445211 | Mitoxantrone System Suitability Mixture ( 0.3 mg ) | F0D010 | \$500 |
| 1449530 | Nabumetone Related Compound A $(15 \mathrm{mg})$ | F0D165 | \$487 |
| 1457469 | Naratriptan Hydrochloride (125 mg) | F0C360 | \$208 |
| 1460703 | Nevirapine Anhydrous ( 100 mg ) | F0D159 | \$156 |
| 1460714 | Nevirapine Hemihydrate (100 mg) | F0D034 | \$156 |
| 1460725 | Nevirapine Related Compound A ( 15 mg ) | F0D035 | \$487 |
| 1460736 | Nevirapine Related Compound B $(15 \mathrm{mg})$ | F0D033 | \$487 |
| 1478152 | Oleoyl Polyoxylglycerides (100 mg) | F0C313 | \$156 |
| 1485125 | Oxybutynin Related Compound B ( 20 mg ) | F0D061 | \$487 |
| 1485136 | Oxybutynin Related Compound C $(20 \mathrm{mg})$ | F0D062 | \$487 |
| 1535020 | Phenytoin Related Compound B ( 50 mg ) | F0C157 | \$487 |
| 1547925 | Polysorbate 20 (2 g) (AS) | F0D130 | \$156 |
| 1547947 | Polysorbate $60(2 \mathrm{~g})$ (AS) | F0D131 | \$156 |
| 1547969 | Polysorbate 80 (2 g) (AS) | F0D132 | \$156 |
| 1548101 | Potassium Benzoate (1 g) (AS) | F0D161 | \$156 |
| 1548134 | Potassium Bicarbonate (1 g) (AS) | F0D074 | \$156 |
| 1548167 | Potassium Carbonate (1 g) (AS) | F0D075 | \$156 |
| 1548190 | Potassium Chloride (1 g) (AS) | F0D127 | \$156 |
| 1548280 | Potassium Iodide (1 g) (AS) | F0D078 | \$156 |

## New Items at a Glance (Continued)

| Cat. No. | Description | Curr. Lot | Price |
| :---: | :---: | :---: | :---: |
| 1572208 | Propionic Acid (1.5 mL/ampule; 3 ampules) (AS) | F0D029 | \$156 |
| 1601102 | Residual Solvents Mixture - Class 1 ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C407 | \$156 |
| 1601146 | Residual Solvent Class 1 - Benzene ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C408 | \$156 |
| 1601168 | Residual Solvent Class 1 - Carbon Tetrachloride ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C409 | \$156 |
| 1601180 | Residual Solvent Class 1-1,2Dichloroethane ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C412 | \$156 |
| 1601204 | Residual Solvent Class 1-1,1Dichloroethene ( $1.2 \mathrm{~mL} / \mathrm{ampule}$; 3 ampules) | F0C411 | \$156 |
| 1601226 | Residual Solvent Class 1-1,1,1Trichloroethane ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0C410 | \$156 |
| 1601340 | Residual Solvent Class 2 - Acetonitrile ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0D049 | \$156 |
| 1601361 | Residual Solvent Class 2 Chlorobenzene ( $1.2 \mathrm{~mL} / \mathrm{ampule}$; 3 ampules) | F0D048 | \$156 |
| 1601420 | Residual Solvent Class 2-1,2Dichloroethene ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0D040 | \$156 |
| 1601521 | Residual Solvent Class 2-1,4-Dioxane ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0D050 | \$156 |
| 1601623 | Residual Solvent Class 2 - Methanol ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0D045 | \$156 |

| Cat. No. | Description | Curr. Lot | Price |
| :---: | :---: | :---: | :---: |
| 1601689 | Residual Solvent Class 2 - <br> Methylcyclohexane ( 1.2 mL /ampule; 3 ampules) | F0D044 | \$156 |
| 1601441 | Residual Solvent Class 2 - Methylene Chloride ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0D046 | \$156 |
| 1601770 | Residual Solvent Class 2 - <br> Tetrahydrofuran ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0D043 | \$156 |
| 1601805 | Residual Solvent Class 2 - Toluene ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0D042 | \$156 |
| 1601849 | Residual Solvent Class 2 - Xylenes ( $1.2 \mathrm{~mL} /$ ampule; 3 ampules) | F0D041 | \$156 |
| 1604508 | Rimantadine Hydrochloride ( 300 mg ) | F0C266 | \$156 |
| 1610090 | Scopoletin ( 20 mg ) | F0C329 | \$156 |
| 1613407 | Sodium Acetate (1 g) (AS) | F0D083 | \$156 |
| 1613757 | Sodium Carbonate Anhydrous (1 g) (AS) | F0D100 | \$156 |
| 1614396 | Sodium Metabisulfite (1 g) (AS) | F0D111 | \$156 |

| 1724769 | Zinc Sulfate (1 g) (AS) | F0D133 | \$156 |

## USING AND ORDERING USP REFERENCE STANDARDS

## Official Reference Standards

USP Reference Standards are required for use in pharmacopeial assays and tests in the official standards publication, the United States Pharmacopeia-National Formulary (USP-NF). USP Reference Standards help to ensure compliance with the official, FDA-enforceable quality requirements in the $U S P-N F$. The Reference Standards also lend themselves to many other applications, including measurements required to attain accurate and reproducible results in modern chromatographic and spectrophotometric methods.

## Rigorous Testing and Quality Control

USP Reference Standards are selected for their high purity, critical characteristics, and suitability for the intended purpose. Unless a USP Reference Standard label states a specific potency or content, the USP Reference Standard is taken as being $100 \%$ pure for the USP purposes for which it is provided. As a service to our customers, labeled purity values for Reference Standards and Authentic substances released after January 1, 2004 are listed in this catalog. See p. 9 for explanation of how values are calculated.

Heterogeneous substances, of natural origin, are also designated "Reference Standards" where needed. Usually these are the counterparts of international standards.

USP Reference Standards are established through a process of rigorous testing, evaluation, and quality control. They are independently tested in three or more laboratories-USP, FDA, and academic and industrial laboratories throughout the United States. The Reference Standards are released under the authority of USP's Board of Trustees, on the recommendation of the USP Reference Standards Expert Committee, which approves selection and suitability of each lot.

## Reference Standards Categories

USP offers more than 1,560 Reference Standards for pharmaceuticals, excipients, and dietary supplements. On pages $12-57$ of this catalog, you'll find a full list of available USP and NF Reference Standards, with information updated through May 2004. The list includes:

- Reference Standards required by the current official edition of $U S P-N F$.
- Reference Standards not required in the current $U S P-N F$, but for which sufficient demand remains.
- Reference Standards specified in the current edition of the Food Chemicals Codex (FCC).
- Authentic Substances (AS)—highly purified samples of chemicals, including substances of abuse, required by analytical, clinical, pharmaceutical, and research laboratories.

The distribution of controlled substances is subject to the regulations and licensing provisions of the Drug Enforcement Administration (DEA) of the U.S. Department of Justice.

USP also collaborates with the World Health Organization in its program to provide international biological standards and chemical reference materials for antibiotics, biologicals, and chemotherapeutic agents. Some USP Reference Standards are standardized in terms of the corresponding international standards.

## Proper Use of USP Reference Standards

USP Reference Standards are provided primarily for quality control use in conducting the pharmacopeial assays and tests described in the $U S P-N F$. Neither Reference Standards nor Authentic Substances are intended for use as drugs, dietary supplements, or medical devices.

To serve its intended purpose, each USP Reference Standard must be properly stored, handled, and used. Users of USP Reference Standards should refer to General Chapter $\langle 11\rangle$ in the $U S P-N F$ :

## Listing and directions in USP-NF

- Refer to the list of revisions, additions, and deletions of individual USP Reference Standards in USP 27-NF 22. Individual $U S P$ or $N F$ monographs specify the USP Reference Standard(s) required for assay and test procedures. The USP 27-NF 22 General Test Chapter $\langle 11\rangle$ USP Reference Standards provides additional information and instructions for proper use and storage. Note that if specific instructions for use appearing on the label of a USP Reference Standard differ from the instructions in Chapter $\langle 11\rangle$, the instructions on the label take precedence.
- Consult the cumulative updates to Reference Standards information provided in $U S P-N F$ Supplements and also in $U S P-N F$ Interim Revision Announcements, which are published in USP's bimonthly journal, Pharmacopeial Forum.

## Suitability for use

- The user must ascertain that the Reference Standards they are using are an official lot.

## USING AND ORDERING USP REFERENCE STANDARDS

- The user must determine the suitability of Reference Standards for applications and uses not in the $U S P-N F$.

## Storing

- Ensure that the USP Reference Standards are stored in their original stoppered containers, according to any special label directions, away from heat and humidity, and protected from light.

## Weighing

- Ensure that Reference Standard substances are accurately weighed-taking due account of relatively large errors potentially associated with weighing small masses-where it is directed that a standard solution or a standard preparation be prepared for a quantitative determination. See USP 27-NF 22 General Chapters $\langle 41\rangle$ Weights and Balances and $\langle 31\rangle$ Volumetric Apparatus, and USP-NF General Notices, for information regarding appropriate use of USP Reference Standards.

## Drying

- Use a clean and dry vessel, and not the original container, as the drying vessel where a USP Reference Standard is required to be dried before use.
- Make sure not to dry a specimen repeatedly at temperatures above 25 degrees.
- Follow any special drying requirements specified on the Reference Standards label or in specific sections of USP or NF monographs (note that any specific instructions on the label or in the monograph supersede the usual instructions in Procedures under Tests and Assays in $U S P-N F$ General Notices).
- Follow Method I under USP-NF General Chapter $\langle 921\rangle$ Water Determination where the titrimetric determination of water is required at the time a Reference Standard is to be used. Instrumental or microanalytical methods are acceptable for this purpose. When using typical amounts, users must titrate about 50 mg of the Reference Standard with a fourfold dilution of the reagent.

## ORDERING USP REFERENCE STANDARDS

## Four convenient ways to order

1. Phone: Call USP with your requirements: (800) 227-8772 from the U.S. or Canada and (301) 881-0666 from other countries. Please note that DEA controlled substances cannot be placed over the phone.

Hours of operation:

Monday-Friday
8:30AM-5:00PM
Fax: Fax your orders to (301) 816-8148.
Online: Order through the World Wide Web at http://store.usp.org. Please note that DEA controlled substances cannot be ordered online.
Mail: Send all mail orders to:
USP
Customer Service Department
12601 Twinbrook Parkway
Rockville, MD 20852, USA

## Important Order/Policy Information

For fax and mail orders, please use the order form at the back of this catalog. Official purchase orders on company letterhead may also be used to order USP Reference Standards. The purchase orders must have billing and shipping addresses and should include the catalog number, the name of the official Reference Standard, and the number of units ordered. Lot numbers need not be specified on written purchase orders as USP only ships current official lots. Confirmation orders may be sent and must clearly be designated as such. The USP does not assume responsibility for duplication of orders not clearly marked as confirmation orders.

## Pricing

USP Reference Standards must be ordered in whole units. Please note that one unit may include several individual containers.

Reference Standards unit prices included in the product listings from pages 12-57 of this catalog are effective until December 31, 2004. Please note that prices and package sizes are subject to change without notice.

## No Returns or Exchanges

USP Reference Standards may not be returned or exchanged for refund.

## Quantity Discounts

A 5\% discount is allowed for 5-24 units of any one Reference Standard in a single order, and a $10 \%$ discount for 25 or more units of any one Reference Standard in a single order. These discounts are subject to change without notice.

## USING AND ORDERING USP REFERENCE STANDARDS

## Shipping

- Reference Standards orders can only be shipped to a street address and not to P.O. boxes.
- Orders to the U.S. and Ontario, Canada are shipped via air courier of USP's choice at a charge of $\$ 11$ or via air courier of the customer's choice at an additional $\$ 25$ charge.
- Non-controlled substance orders to Canadian provinces other than Ontario are shipped via air courier of USP's choice at a charge of U.S. $\$ 70$. Carriers of the customer's choice incur an additional $\$ 25$ charge.
- Non-controlled substance orders to be shipped outside the U.S. and Canada are accepted directly by USP only when customs forms related to export are not required. They are shipped via air courier of USP's choice at a charge of U.S. $\$ 70$. Carriers of the customer's choice incur an additional $\$ 25$ charge.
- Shipping in cold pack can be done at customer request for an extra charge of \$25.
- Controlled substance orders to anywhere outside the U.S. are shipped via air courier of USP's choice with a charge of U.S. $\$ 220$.
- An additional shipping charge may be assessed for dangerous goods shipments.
- An additional shipping charge of $\$ 75$ will be assessed for rush/ same-day shipments.
- Customers may provide their shipping account numbers to have shipping charged directly.

## Payment

- Full payment in advance, in U.S. dollars, is required for all U.S. orders unless open account status has been granted by USP's Finance Department. To apply for open account status, an application can be requested by calling (301) 816-8177.
- Full payment in advance, in U.S. dollars, is required for all non-U.S. orders.
- Payment may be made by check, money orders, credit cards (VISA, MasterCard, American Express), and electronic wire transfer (please call (301) 816-8177 to get bank information for wire transfers). The customer is responsible for any bank fees and must include it in the payment. The customer is also responsible for any other fees such as customs duties, taxes, or tariffs.

## List Chemicals

The following Reference Standards are "List Chemicals": Dihydroergotamine Mesylate
*Ephedrine Sulfate
Ergonovine Maleate
Ergotamine Tartrate
Methylergonovine Maleate
Phenylpropanolamine Bitartrate
Phenylpropanolamine HCl
Pseudoephedrine HCl
Pseudoephedrine Sulfate

An organization in the United States seeking to purchase a List Chemical Reference Standard for resale to another customer must have a DEA registration (either a controlled substance or List Chemical registration). If an organization in the United States is purchasing the List Chemical Reference Standard for its own analytical use, it must provide USP with a letter on company letterhead describing the reason for the purchase.

## CONTROLLED DRUG SUBSTANCE ORDER

## DEA Requirements (U.S. Orders)

For all orders for controlled drug substances-regulated by the U.S. Drug Enforcement Administration (DEA)-to be shipped within the U.S., a copy of the customer's current DEA Registration Certificate must be on file with USP. To order Schedule I and II standards, customers must submit, with their order forms or purchase orders, a DEA Form 222-C, properly completed. In addition, customers ordering DEA Schedules III and IV must provide appropriate DEA registration numbers for those schedules on their order forms or purchase orders.

## DEA Requirements (International Orders)

For all international controlled drug substance orders, please contact Julie Smith at (301) 816-8164 or foreigncontrols@ usp.org.

All orders for controlled drug substances-regulated by the U.S. Drug Enforcement Administration (DEA)-to be shipped outside the U.S. must be accompanied by:

1. Full payment.

## USING AND ORDERING USP REFERENCE STANDARDS

2. An import permit (in English or with an English translation attached) valid at least 6 months from the date of its receipt by USP Customer Service.
3. A statement of non-reexport and use for medical or scientific purposes (in English or with an English translation attached).
4. Purchase Order or Price Quote given by USP.

On receiving the order, USP takes 2-3 business days to:

- Review all documents to make sure they are adequate and appropriate.
- Complete and legally approve the required DEA forms.
- Forward the forms to the DEA office to obtain the necessary Export Permits.

USP cannot ship items without an Export Permit. While it typically takes 6-10 weeks to get the permit from the DEA, USP has no control over the time in which permits are issued. On receiving the Export Permit, USP completes processing of the order in 1-3 days and ships out the materials through its freight forwarder.

Controlled substances (CI, CII, CIII, CIV, CV) and List Chemicals shipped to an international address, including Canada, add $\$ 25$ per unit.

For controlled substance orders to be shipped to Mexico, in addition to the DEA processing period, an additional week is required to obtain a certificate from the Mexican Embassy, authorizing the shipment to enter the country. Customers will pay an additional $\$ 114$ to cover the fee charged by the Mexican Embassy per import permit.

## Back Orders

USP will ship a back-ordered item if that item becomes available within 30 days of the date the order is placed if there is a valid open P.O. or payment for the item. If the order is more than 30 days old when the item becomes available, the customer will receive a Notice of Availability (NOA), indicating that the item is available. Such items will be shipped only after USP receives written authorization by the customer. The order will be canceled if the Reference Standard does not become available within six months of the original order. NOAs not replied to within 45 days of generation will be cancelled, and the customer account will be credited appropriately.

Customers may send confirmation orders for back-ordered Reference Standards that subsequently become available. They must clearly designate the confirmation orders as such-USP is not responsible for duplication of orders not clearly designated.

[^286]
## HOW TO READ PRODUCT LISTINGS

Column 1 (Catalog Number): Catalog number currently assigned to each Reference Standard and Authentic Substance. Please include this number in your orders.

Column 2 (Description): Product description as designated in $U S P-N F$, the product label, and / or the Drug Enforcement Administration Control Schedule, as applicable. The quantity of material per container follows the name in parentheses (all materials are in single containers unless otherwise specified).

Column 3 (Current Lot): Current lot designation of each official item being distributed as of the date of this catalog. If the current lot is blank, the item is not in distribution.

Column 4 (Purity Values) Assigned purity value as it appears on the RS or AS label. Code interpretations for the basis of purity assignments are as follows:
Basis Interpretation

## Code

| (ai) | as is |
| :--- | :--- |
| (dr) | dried |
| (an) | anhydrous |
| (fb) | free base |

Column 5 (Change Code): Codes that identify any change in USP Reference Standards status or information since the July/Aug. 2004, official Catalog. Code interpretations are as follows:

| Change <br> Code | Interpretation |
| :---: | :--- |
| 1 | New Reference Standard |
| 2 | New lot |
| 3 | Change in package size or description |
| 4 | Correction of typographical error |
| 5 | New catalog number-use for all orders |
| 6 | Previous lot no longer official; only <br> current lot to be used |
| 7 | Valid use date of previous lot extended <br> Change in catalog number and / or name, <br> 8 |
| see cross-reference section <br> Discontinued |  |

Column 6 (Previous Lot/Valid Use Date): Lot designations for recent lots no longer being distributed. The indicated month and year in parenthesis indicates the date (last day of the month) through which that lot was valid as an official USP Reference Standard. (e.g. "F-1 (06/00)" means lot F-1 is no longer being distributed, but was considered official through June 30, 2000.)

Column 7 (CAS Number) ${ }^{*}$ : Chemical Abstracts Service number, when available, for USP Reference Standards and Authentic Substances. In case of mixtures, typically, the CAS number of the analyte of interest is listed.

Column 8 (Price) List price of the reference standard.
