Identify any peaks due to dihydroequilenin, 17β-dihydroequilenin, 3-*O*-methylestrone, and equilenin in the chromatogram of the *Sample solution.* Calculate the quantities, in percentage, of 17α-dihydroequilenin, 17β-dihydroequilenin, and equilenin as their sodium sulfate salts in the portion of Conjugated Estrogens taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times F \times 100$$

- R_U = ratio of the peak response of the appropriate analyte to that of the internal standard from the *Sample solution*
- R_S = ratio of the peak response of estrone to that of the internal standard from the *Standard solution*
- C_S = concentration of USP Estrone RS in the *Stock solution* (µg/mL)
- C_U = concentration of the *Sample solution* (µg/mL)
- F = conversion factor (ratio of molecular weight of sodium salts to free estrogen), 1.381

Acceptance criteria: NMT 3.25%, NMT 2.75%, and NMT 5.5% of the labeled content of Conjugated Estrogens for 17α-dihydroequilenin, 17β-dihydroequilenin, and equilenin, respectively, as their sodium sulfate salts.

- **PROCEDURE 2: LIMITS OF 17β-ESTRADIOL AND $\Delta^{8,9}$-DEHYDROESTRONE**

Internal standard solution, Stock solution, Solution A, System suitability solution, Standard solution, Sample solution, and **Chromatographic system:** Proceed as directed in the *Assay*.

[NOTE—The relative retention times of 17β-estradiol, 3-*O*-methylestrone, and $\Delta^{8,9}$-dehydroestrone are about 0.29, 1.0, and 0.9, respectively.]

Analysis:

Samples: *Standard solution* and *Sample solution*

Identify any peaks due to 17β-estradiol, 3-*O*-methylestrone, and $\Delta^{8,9}$-dehydroestrone in the chromatogram of the *Sample solution.* Calculate the quantities, in percentage, of 17β-estradiol and $\Delta^{8,9}$-dehydroestrone as their sodium sulfate salts in the portion of Conjugated Estrogens taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times F \times 100$$

- R_U = ratio of the peak response of the appropriate analyte to that of the internal standard from the *Sample solution*
- R_S = ratio of the peak response of estrone to that of the internal standard from the *Standard solution*
- C_S = concentration of USP Estrone RS in the *Stock solution* (µg/mL)
- C_U = concentration of the *Sample solution* (µg/mL)
- F = conversion factor (ratio of molecular weight of sodium salts to free estrogen), 1.381

Acceptance criteria: NMT 2.25% and NMT 6.25% of the labeled content of Conjugated Estrogens for 17β-estradiol and $\Delta^{8,9}$-dehydroestrone, respectively, as their sodium sulfate salts.

- **PROCEDURE 3: LIMIT OF ESTRONE, EQUILIN, AND 17α-DIHYDROEQUILIN** (free steroids)

Internal standard solution, Solution A, Stock solution, System suitability solution, and Chromatographic system: Proceed as directed in the *Assay*.

Free steroids standard solution: Dilute the *Stock solution* tenfold. Pipet 1.0 mL of the resulting solution and 1.0 mL of the *Internal standard solution* into a suitable centrifuge tube fitted with a tight screw cap or stopper. Proceed as directed for *Standard solution* in the *Assay*, beginning with "Evaporate the mixture…".

Sample solution: Proceed as directed for *Sample solution* in the *Assay* with the following exceptions: do not add the sulfatase enzyme solution, and transfer 6.0 mL of the solution instead of 3.0 mL to the centrifuge tube. Prepare a reagent blank in the same manner.

System suitability: Proceed as directed in the *Assay* with the additional requirement that the relative standard deviation for the ratio of the peak response of estrone to that of the internal standard in the *Free steroids standard solution* is NMT 5.5%, on the basis of NLT two replicate injections.

Analysis:

Samples: *Free steroids standard solution* and *Sample solution*

Calculate the ratio, R_U, of the combined peak areas of estrone, equilin, and 17α-dihydroequilin relative to the area of the internal standard in the *Sample solution*, correcting for any reagent blank peaks.

Acceptance criteria: NMT 0.65 (1.3% of free steroids), for the ratio R_U/R_S, where R_S is the peak response ratio of estrone to that of the internal standard of the *Free steroids standard solution*

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in well-closed containers. Store at 25°, excursions permitted between 15° and 30°.
- **LABELING:** Label it to state the content of Conjugated Estrogens on a weight-to-weight basis.
- **USP REFERENCE STANDARDS** ⟨11⟩

USP 17α-Dihydroequilin RS
USP Equilin RS
USP Estradiol RS
USP Estrone RS

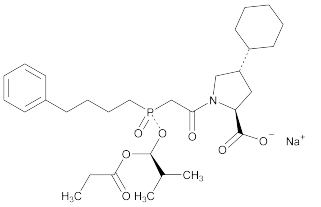
In-Process Revision

BRIEFING

Fosinopril Sodium, *USP 32* page 2449 and page 4059 of the *First Supplement*. On the basis of comments and supporting validation data received, in *Procedure 1* of the test for *Organic Impurities* it is proposed to add a new impurity, Impurity 3, that is well resolved from fosinopril and all other known impurities described in *Impurity Table 1*.

(MD-CV: S. Ramakrishna.) RTS—C73793

Fosinopril Sodium



$C_{30}H_{45}NNaO_7P$ 585.64

L-Proline, 4-cyclohexyl-1-[[[2-methyl-1-(1-oxopropoxy)propoxy](4-phenylbutyl)phosphinyl]acetyl]-, sodium salt, [1[*S**(*R**)],2α,4*β*]-; (4*S*)-4-Cyclohexyl-1-[(*R*)-[(*S*)-1-hydroxy-2-methylpropoxy](4-phenylbutyl)phosphinyl]acetyl-L-proline propionate (ester), sodium salt [88889-14-9].

DEFINITION

Fosinopril Sodium contains NLT 97.5% and NMT 102.0% of $C_{30}H_{45}NNaO_7P$, calculated on the anhydrous basis.

IDENTIFICATION

• **INFRARED ABSORPTION** ⟨**197**⟩

ASSAY

Procedure

Mobile phase: Acetonitrile, phosphoric acid, and water (2000:1:10)

System suitability solution: 0.1 mg/mL of USP Fosinopril Sodium RS and 0.01 mg/mL of USP Fosinopril Related Compound B RS in *Mobile phase*

Standard solution: 0.10 mg/mL of USP Fosinopril Sodium RS in *Mobile phase*

Sample solution: 0.10 mg/mL of Fosinopril Sodium in *Mobile phase*

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

Mode: LC

Detector: UV 214 nm

Column: 3.9-mm × 15-cm; packing L3

Temperature: 33°

Flow rate: 1.2 mL/min

Injection size: 20 µL

System suitability

Sample: *System suitability solution*

Suitability requirements

Resolution: NLT 2.0 between fosinopril related compound B and fosinopril sodium

Relative standard deviation: NMT 2.0%

Analysis

Samples: *Sample solution* and *Standard solution*

Calculate the percentage of $C_{30}H_{45}NNaO_7P$ in the portion of Fosinopril Sodium taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*

r_S = peak response from the *Standard solution*

C_S = concentration of USP Fosinopril Sodium RS in the *Standard solution* (mg/mL)

C_U = nominal concentration of Fosinopril Sodium in the *Sample solution* (mg/mL)

Acceptance criteria: 97.5%–102.0% on the anhydrous basis

IMPURITIES

Inorganic Impurities

• **HEAVY METALS,** *Method II* ⟨**231**⟩**:** 20 ppm

Change to read:

Organic Impurities

Procedure 1

Mobile phase and **Chromatographic system:** Proceed as directed in the *Assay*.

System suitability solution: 0.1 mg/mL of USP Fosinopril Sodium RS and 0.01 mg/mL each of USP Fosinopril Related Compound A RS and USP Fosinopril Related Compound B RS in *Mobile phase*

Sample solution: Use the *Sample solution* as directed in the *Assay*.

Analysis

Sample: *Sample solution*

Proceed as directed in the *Assay*, and measure the areas for each component in the chromatogram obtained, carrying out the chromatography to four times the retention time of the fosinopril sodium peak.

Calculate the percentage of each individual related compound:

$$\text{Result} = (r_U/r_T) \times 100$$

r_U = individual peak response, other than the fosinopril sodium peak

r_T = sum of all the peak responses

[NOTE—If present, two more diastereomers may not be resolved from fosinopril related compound B by this method. These peaks, appearing at a relative retention time of 0.7, should be integrated together to determine conformance with the limit in *Impurity Table 1*.]

Acceptance criteria

Individual impurities: See *Impurity Table 1*.

BRIEFING

Galantamine Tablets, *USP 32* page 2478, *Interim Revision Announcement* on page 253 of *PF* 35(2) [Mar.–Apr. 2009], and page 1452 of *PF* 34(6) [Nov.–Dec. 2008]. On the basis of comments received, it is proposed to revise the relative response factor value for *N*-Desmethylgalantamine and 6α-Hexahydrogalantamine from 1.0 to 1.1. It is also proposed to delete the specified impurity *O*-Desmethylgalantamine from *Impurity Table 1* as this is a process impurity in the drug substance.

(MD-PP: R. Ravichandran.) RTS—C73352

Galantamine Tablets

DEFINITION
Galantamine Tablets contain an amount of Galantamine Hydrobromide equivalent to NLT 90.0% and NMT 110.0% of the labeled amount of galantamine ($C_{17}H_{21}NO_3$).

In-Process Revision

IDENTIFICATION

- **A. ULTRAVIOLET ABSORPTION ⟨197U⟩:** The spectrum of the *Sample solution* corresponds to that of the *Standard solution,* as obtained in the test for *Uniformity of Dosage Units.*
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution,* as obtained in the *Assay.*

ASSAY

- **PROCEDURE**

Buffer solution: 5.34 g/L of dibasic sodium phosphate dihydrate in water. Adjust with phosphoric acid to a pH of 6.5.
Solution A: Methanol and *Buffer solution* (1:19)
Solution B: Acetonitrile and methanol (19:1)
Mobile phase: See the gradient table below.

Time (min)	Solution A (%)	Solution B (%)
0	100	0
40.0	75	25
45.0	60	40
46.0	40	60
55.0	40	60
56.0	100	0
61.0	100	0

Diluent: Dissolve 35.4 g of edetate disodium in 950 mL of water, and add 50 mL of methanol. [NOTE—First dissolve in water, then add methanol.]
Standard solution: 0.62 mg/mL of USP Galantamine Hydrobromide RS in *Diluent*
Sample solution: 0.48 mg/mL of galantamine from powdered Tablets (NLT 10) in *Diluent*. Pass through a PTFE filter having a porosity of 0.45 µm or finer.
Chromatographic system
(See *Chromatography* ⟨621⟩*, System Suitability*.)
Mode: LC
Detector: UV 230 nm
Column: 4.6-mm × 10-cm; 3-µm L1 packing
Temperature: 35°
Flow rate: 1.5 mL/min
Injection size: 20 µL
System suitability
Sample: *Standard solution*
Suitability requirements
Relative standard deviation: NMT 2.0%
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the quantity, as a percentage of the label claim, of $C_{17}H_{21}NO_3$ in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of USP Galantamine Hydrobromide RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of galantamine in the *Sample solution* (mg/mL)
M_{r1} = molecular weight of galantamine, 287.35
M_{r2} = molecular weight of galantamine hydrobromide, 368.27

Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS

- **DISSOLUTION ⟨711⟩**

Medium: Water; 500 mL
Apparatus 2: 50 rpm
Time: 20 min
Sample solution: Pass portions of the solution under test through a suitable 0.2-µm filter.
Standard solution: Dissolve USP Galantamine Hydrobromide RS in *Medium*, and dilute quantitatively, and stepwise if necessary, to obtain concentrations as follows: 8 µg/mL of galantamine for Tablets labeled to contain 4 mg; 16 µg/mL of galantamine for Tablets labeled to contain 8 mg; and 24 µg/mL of galantamine for Tablets labeled to contain 12 mg.
Spectrometric conditions
Mode: UV
Analytical wavelength: 288 nm
Cell: 5-cm cell for 4-mg and 8-mg Tablets; 1-cm cell for 12-mg Tablets
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_{17}H_{21}NO_3$ dissolved:

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

A_U = absorbance of the *Sample solution*
A_S = absorbance of the *Standard solution*
C_S = concentration of USP Galantamine Hydrobromide RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of galantamine in the *Sample solution* (mg/mL)
M_{r1} = molecular weight of galantamine, 287.35
M_{r2} = molecular weight of galantamine hydrobromide, 368.27

Tolerances: NLT 80% (Q) of the labeled amount of galantamine is dissolved.

- **UNIFORMITY OF DOSAGE UNITS ⟨905⟩:** Meet the requirements for coated Tablets

Procedure for content uniformity
Standard solution: 0.05 mg/mL of USP Galantamine Hydrobromide RS in 0.1 N hydrochloric acid
Sample solution: Add 1 Tablet to each appropriately sized volumetric flask to obtain a final galantamine concentration of 0.04 mg/mL, add an appropriate amount of 0.1 N hydrochloric acid, equivalent to 75% of the total volume of the volumetric flask, and mechanically shake for 45 min. Dilute with 0.1 N hydrochloric acid to volume. Pass a portion of this solution through a filter having a 0.2-µm or finer porosity, and use the filtrate.
Spectrometric conditions
Mode: UV
Analytical wavelength: Absorption maximum at about 289 nm
Analysis
Samples: *Standard solution* and *Sample solution*
Determine the amount of $C_{17}H_{21}NO_3$ dissolved in filtered portions of the *Sample solution* in comparison with the *Standard solution.*
Calculate the quantity, as a percentage of the label claim, of $C_{17}H_{21}NO_3$ dissolved:

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

A_U = absorbance of the *Sample solution*
A_S = absorbance of the *Standard solution*
C_S = concentration of USP Galantamine Hydrobromide RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of the *Sample solution* (mg/mL)
M_{r1} = molecular weight of galantamine, 287.35
M_{r2} = molecular weight of galantamine hydrobromide, 368.27

In-Process Revision

BRIEFING

Glucagon, *USP 32* page 2504. The following revisions are proposed.

1. The Glucagon source (see the chemical name) has been changed.
2. The *Definition* has been revised to define Glucagon of a recombinant DNA origin, and potency is to be determined by a validated bioassay approved by a competent authority.
3. *Identification* test *A* has been revised to use the *Assay* retention times. *Identification* test *B*, which uses peptide mapping, has been added.
4. The animal-based *Assay* has been replaced with an HPLC *Assay*. The LC method has been validated using a 3-mm × 15-cm column containing 3-µm packing L1.
5. In *Other Components,* the test for *Nitrogen Determination* has been deleted.
6. The *Inorganic Impurities* section has been deleted (includes *Residue on Ignition* and *Zinc Determination)*.
7. The *Organic Impurities* test has been replaced with a test based on the chromatographic procedure used in the *Assay*.
8. In *Specific Tests,* the *Water Determination* test has been revised, and a *Bacterial Endotoxins* test has been added.
9. The current USP Reference Standards have been deleted, and USP rGlucagon RS and USP Endotoxin RS have been added for use in the revised text. As noted in item 2 above, USP intends to release a USP rGlucagon RS of recombinant origin.

DEFINITION

Change to read:

~~Glucagon is a polypeptide hormone that has the property of increasing the concentration of glucose in the blood. It is obtained from porcine and bovine pancreas glands.~~

■Glucagon is a polypeptide hormone that has the property of increasing the concentration of glucose in the blood. It has the same structure (29 amino acids) as the hormone produced by the α-cells of the human pancreas. Glucagon is produced by microbial processes using recombinant DNA (rDNA) technology. The host cell–derived protein content and/or the host cell–derived or vector-derived DNA content are determined by validated methods. During the course of product development, it must be demonstrated that the manufacturing process produces Glucagon having a biological activity of NLT 1 USP unit/mg, using a validated bioassay approved by a competent authority. It contains NLT 90% and NMT 105% of $C_{153}H_{225}N_{43}O_{49}S$, calculated on the anhydrous basis.■2S *(USP33)*

IDENTIFICATION

Delete the following:

■~~• The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution,* as obtained in the *Procedure* for *Inorganic Impurities.*~~■2S *(USP33)*

Add the following:

■**A:** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.■2S *(USP33)*

Add the following:

■**B:** Determine the peptide fragments, using the following peptide mapping procedure.

Ammonium bicarbonate buffer: Prepare a 1 M solution of ammonium bicarbonate, and adjust the pH with ammonia to 10.3. Prepare a mixture of 1 M ammonium bicarbonate and water (1:9).

Enzyme solution: 2 mg/mL α-chymotrypsin (peptide mapping grade) in *Ammonium bicarbonate buffer*.

Solution A: Prepare a degassed mixture of 0.5 mL of trifluoroacetic acid and 1000 mL of water.

Solution B: Prepare a degassed mixture of 0.5 mL of trifluoroacetic acid, 600 mL of ethanol, and 400 mL of water.

Mobile phase: See *Gradient Table 1* below.

Gradient Table 1

Time (min)	Solution A (%)	Solution B (%)
0	100	0
35	53	47
45	0	100
46	100	0
75	100	0

Standard digest solution: Prepare a 5 mg/mL solution of USP rGlucagon RS in 0.01 M hydrochloric acid. Mix 200 µL of this solution with 800 µL of *Ammonium bicarbonate buffer*. To this solution add 25 µL of *Enzyme solution*, and place in a closed vial at about 37° for 2 h. Remove the vial, and stop the reaction immediately by the addition of 120 µL of glacial acetic acid.

Sample digest solution: Prepare a 5 mg/mL solution of Glucagon in 0.01 M hydrochloric acid. Proceed as directed for *Standard digest solution*, beginning with "Mix 200 µL of this solution".

Chromatographic system
(See *Chromatography* ⟨621⟩*, System Suitability*.)
Mode: LC
Detector: UV 215 nm
Column: 4.0-mm × 5-cm; 5-µm or less packing L1
Flow rate: 1 mL/min
Injection volume: 20 µL

System suitability
Samples: *Standard digest solution*
Suitability requirement: The chromatogram of the *Standard digest solution* corresponds to the chromatogram provided with USP rGlucagon RS.

Analysis
Samples: *Standard digest solution* and *Sample digest solution*
Acceptance criteria: The chromatographic profile of the *Sample digest solution* corresponds to that of the *Standard digest solution*.■2S *(USP33)*

In-Process Revision

ASSAY

Change to read:

- **PROCEDURE**

[NOTE—All buffers have a final pH of 7.4, unless otherwise indicated. The concentration range of the *Standard solutions* and the *Sample solutions* may be modified to fall within the linear range of the *Assay*. The calculations should be adjusted accordingly. Alternatively, full curve analysis using validated nonlinear statistical methods can be used, provided that similarity is demonstrated when comparing the responses of the *Standard solutions* and the *Sample solutions*.]

Hepatocyte Preparation

Calcium-free perfusion buffer with dextrose: Prepare a solution containing, in each L, 7.92 g of sodium chloride, 0.35 g of potassium chloride, 1.80 g of dextrose, 0.19 g of edetic acid, and 2.38 g of *N*-2-hydroxyethylpiperazine-*N*′-2-ethanesulfonic acid. Oxygenate prior to circulation.

Collagenase buffer: Prepare a solution containing, in each L, 3.62 g of sodium chloride, 23.83 g of *N*-2-hydroxyethylpiperazine-*N*′-2-ethanesulfonic acid, 0.35 g of potassium chloride, 0.52 g of calcium chloride, and 1.8 g of dextrose. Adjust to a pH of 7.6, and oxygenate. Immediately before perfusion, dissolve a quantity of collagenase in this solution to obtain a concentration of 0.02% to 0.05%.

Wash buffer: Prepare a solution containing, in each L, 7.92 g of sodium chloride, 0.35 g of potassium chloride, 0.19 g of edetic acid, 2.38 g of *N*-2-hydroxyethylpiperazine-*N*′-2-ethanesulfonic acid, 0.22 g of calcium chloride, and 0.12 g of magnesium sulfate.

Incubation buffer: Prepare a solution containing, in each L, 6.19 g of sodium chloride, 0.35 g of potassium chloride, 0.22 g of calcium chloride, 0.12 g of magnesium sulfate, 0.16 g of monobasic potassium phosphate, 11.915 g of *N*-2-hydroxyethylpiperazine-*N*′-2-ethanesulfonic acid, and 1% bovine serum albumin (BSA). Adjust to a pH of 7.5.

Test animals: Male Sprague-Dawley rats are maintained on a standard rat chow diet and freely given water. On the morning of the test, select a healthy rat weighing approximately 300 g, and administer 100 Units of Heparin Sodium subcutaneously.

Method

[NOTE—Conduct this *Method* in the morning to ensure that the rat has optimal glycogen in its liver.]

Anesthetize the rat with an appropriate anesthetic. Open the abdominal cavity, and isolate the portal vein. Insert an angiocatheter connected to a perfusion pump, and tie into the portal vein at the general location of the lienal branch. Start the perfusion (25 mL/min) in situ with *Calcium-free perfusion buffer with dextrose,* equilibrated with oxygen, at a temperature of 37°. As the liver enlarges, cut the inferior vena cava to allow pressure equilibrium.

[NOTE—300 mL of the perfusate is needed to clear the liver of red blood cells at a flow rate of 30–60 mL/min.]

Then circulate *Collagenase buffer* at a flow rate of 30–60 mL/min for 10 min. The exact concentration of collagenase (within the range of 0.02%–0.05%) is determined empirically for each lot of enzyme. The concentration of collagenase is that necessary to consistently cause a breakdown of the liver 10 min after initial entry of the *Collagenase buffer* into the liver. When the liver significantly increases in size, changes color and consistency, and starts to leak perfusate out of the lobes, change the system to the oxygenated prewarmed *Wash buffer.* 100 mL of *Wash buffer* is needed to wash the liver of collagenase at a flow rate of 25 mL/min. Surgically remove the liver from the animal, and place it in a prewarmed tray containing oxygenated *Wash buffer* (37°). Gently comb the liver with a stainless steel, fine-toothed comb to free the hepatocytes. Wash the hepatocytes with *Wash buffer,* and filter through cheesecloth (or a 150-µm mesh polyethylene net) into a plastic beaker. Centrifuge the cell suspension for 2 min at 25 × g to form a loosely packed pellet. Discard the supernatant, and resuspend the pellet in *Wash buffer.* Repeat the washing procedure twice for a total of three washes. Resuspend the final pellet in 100–200 mL of *Incubation buffer,* depending on cell yield.

[NOTE—If the *Analysis* is interrupted, cool the cells by collecting them in a beaker placed in ice. The cells are washed with ice-cold *Wash buffer,* and stored on ice until ready for use. At that point the cells are pelleted once more, and resuspended in ice-cold *Incubation buffer.*]

Suitability: The concentrations of cells may vary due to the collagenase activity and the viability of the hepatocytes. To check cell viability and to determine viable cell concentration, dilute duplicate 100-µL aliquots of cell suspension with 400 µL of *Wash buffer* and 500 µL of isotonic 0.4% trypan blue. The aliquots are counted in a hemocytometer. The cells are suspended in *Incubation buffer* to obtain a viable cell concentration of NLT 3×10^6/mL. Count several distinct fields.

[NOTE—Viable cells are those cells that exclude the trypan blue.]

Negative control solution: Prepare a solution containing 0.5% BSA in sterile water.

Incubation flasks: Use 25-mL conical flasks, the bottoms of which have been heated and pushed inward to form a conically raised center.

Standard solutions: In duplicate, dissolve a suitable quantity of USP Glucagon RS in 0.01 N hydrochloric acid or other suitable diluent to obtain a solution containing 1.0 USP Glucagon Unit/mL. All dilutions thereafter are made using 0.5% BSA (w/v) in water. Accurately dilute measured volumes of each solution with *Negative control solution* to obtain five concentrations (200, 100, 50, 25, and 12.5 micro-Units/mL) of each solution (*Standard solutions*). Pipet 0.2 mL of each *Standard solution* into separate *Incubation flasks.* Pipet 0.2 mL of *Negative control solution* into each of two flasks (*Negative control solutions 1* and *2*). Then add the hepatocytes into each of the 12 flasks.

Sample solutions: Using quantities of Glucagon, proceed as directed for *Standard solutions.*

D-Glucose Determination

Standard stock solution: Transfer 2.0 g of USP Dextrose RS to a 200-mL volumetric flask, and dissolve in and dilute with saturated benzoic acid solution to volume.

Standard solutions: Transfer suitable quantities of *Standard stock solution* to three flasks, and dilute with saturated benzoic acid solution to obtain solutions having known concentrations of 0.5, 1.0, and 1.5 times the typical sample glucose concentration.

Potassium ferrocyanide solution: Dissolve 1.25 g of trihydrate potassium ferrocyanide in 125 mL of *Sterile Water for Injection* (see *Water for Pharmaceutical Purposes* ⟨1231⟩).

System suitability: Analyze the *Potassium ferrocyanide solution,* the *Standard solutions,* and five replicates of the middle *Standard solution.* Prepare a standard curve using the *Standard solutions* as directed for *Analysis*: the relative standard deviation of the standard curve is NMT 2.0%; the response of the *Potassium ferrocyanide solution* is NMT 30 mg/L; and the relative standard deviation is NMT 2.0% for the replicate analyses of the middle *Standard solution.*

Analysis: Dispense 5 mL of *Hepatocyte Preparation* into the special incubation flasks in sequence from high glucagon concentration to low glucagon concentration, alternating the *Standard solutions* with the *Sample solutions.* The flasks are swirled in an orbiting water bath at 125 rpm at 30° for approximately 30–60 min.

[NOTE—The exact incubation time must be determined to optimize the signal-to-noise ratio.]

Following incubation, place 0.5- to 1.0-mL aliquots, in duplicate, from each incubation flask into labeled tubes, and centrifuge at 12,500 × g. Determine the percentage of glucose concentration in each flask's supernatant.

To conform to the linear range of the instrument being used, it may be necessary to adjust by dilution each of the preparations. Use a glucose analyzer that has demonstrated appropriate specificity, accuracy, precision, and linear response over the range of concentrations being determined.

In-Process Revision

[NOTE—A suitable analyzer may use an immobilized, oxidase-enzyme membrane or jacket-generating hydrogen peroxide, which is then detected at the electrode.]

Perform the glucose analysis in the following sequence: *Negative control solution 1, Standard solutions, Sample solutions,* and *Negative control solution 2*.

Determine the percentage of glucose against the *Negative control solution* for each preparation.

Linearity test: Use an analysis of variance (ANOVA) with one sample assayed against a standard, and using two replicates each, construct a table (see *Table 1*). Compare the value of the ratio $MSNL/MSRES_T$ to a critical value obtained from a table for an F distribution with $m-2$ and $3m-3$ degrees of freedom, where m is the number of dose levels for each preparation. If the ratio $MSNL/MSRES_T$ does not indicate the presence of significant nonlinearity (ratio value is lower than the critical value), then proceed to the test for parallelism. If the ratio exceeds the critical value (significance level of 0.025), the nonlinearity is statistically significant and the test is repeated, discarding the results from either the highest or lowest dose of both the *Standard solutions* and the *Sample solutions* (four dose levels). If the ratio $MSNL/MSRES_T$ does not indicate the presence of significant nonlinearity, then proceed to the test for parallelism.

Parallelism test: Compare the ratio $MSNP/MSRES_2$ to a critical value obtained from an F distribution having 1 and $4m-5$ degrees of freedom. If the ratio $MSNP/MSRES_2$ does not indicate the presence of significant nonparallelism, then the assay is considered valid. Use the appropriate dose levels for the estimation of the relative potency.

Relative potency: Calculate the relative potency, R, of the *Sample solutions* as compared with the *Standard solutions* as follows:

(1) X_j is defined as the $\log_{10}$ of the j^{th} dose of the *Standard solutions* or the *Sample solutions*. The glucagon dose varies from 12.5 to 200×10^{-6} USP Glucagon Units/mL. For ease in the subsequent calculations, these doses are respectively represented by 1 through 5, as shown in the table below:

j	1	2	3	4	5
Dose	12.5	25	50	100	200
X_j	1.10	1.40	1.70	2.00	2.30

(2) To differentiate between the *Standard solutions* and the *Sample solutions* in the calculations, the subscript i will be used, with $i = 1$ to designate the *Standard solutions* and $i = 2$ to designate the *Sample solutions*. Y_{ijk} will denote the glucose concentration associated with the k^{th} replicate of the j^{th} dose of the i^{th} preparation. For example, Y_{1jk} is the glucose concentration associated with the k^{th} replicate of the j^{th} dose of the appropriate *Standard preparation,* Y_{11k} is the glucose concentration associated with the k^{th} replicate of dose 1 of the *Standard preparation,* and Y_{21k} is the glucose concentration associated with the k^{th} replicate of dose 1 of the *Sample solution.* Dose 1 represents a glucose dose of 12.5×10^{-6} USP Glucagon Units/mL. Finally, Y_{132} represents the glucose concentration associated with the 2nd replicate of dose 3 for the *Standard solution.*

(3) Y_S and Y_t denote the average glucose concentrations for the *Standard solutions* and the *Sample solutions,* respectively.

(4) Calculate the least-squares slope estimate, b, for a linear regression relating the Y_{ijk}'s to the X_j's as follows: $b = S_{xy} / S_{xx}$, with S_{xy} and S_{xx} calculated using the equations in *Table 2*.

(5) The log potency, M, is calculated using $M = -1[(Y_S - Y_t)/b]$.

(6) R = antilog (M).

(7) Calculate the confidence limits (upper and lower) for the relative potency, R, using the value $s^2 = MSRES_3$ (see *Table 1* and *Table 2*) as follows. Obtain t from a table for a t distribution having $4m - 4$ degrees of freedom. For the 95% limits, the t values can be obtained from *Design and Analysis of Biological Assays* ⟨111⟩, *Table 9*.

[NOTE—For confidence limits having other probability levels (i.e., 100(1 − a)%), the right tail t critical value having a/2 area to its right is used.]

Calculate $g = t^2 S^2 / b^2 S_{xx}$

and $F = (ts/b)\sqrt{(1/m)(1-g) + (M^2/S_{xx})}$

and calculate

$$M_L = (M - F)/(1 - g)$$

and

$$M_U = (M + F)/(1 - g)$$

where M is the log potency and M_L and M_U are the log potency lower and upper confidence limits. The lower and upper confidence limits for the relative potency, R, are given by:

RL = antilog (M_L)

RU = antilog (M_U)

It meets the requirements if the potency is 0.8–1.25 USP Glucagon Units/mg, and the confidence interval width at P = 0.95 does not exceed 45% of the computed potency. Repeat the assay if the confidence interval width exceeds 45% of the computed potency.

Table 1. ANOVA for the Rat Hepatocyte Assay for Glucagon

Source	Degrees of Freedom	SS (Sum of Squares)	MS (Mean Square)
Preparations	1	SSPREP	MSPREP
Replicates	1	SSREP	MSREP
Linear Slope	1	SSLIN	MSLIN
$Residual_3$	$4m-4$	$SSRES_3$	$MSRES_3$
Nonparallelism	1	SSNP	MSNP
$Residual_2$	$4m-5$	$SSRES_2$	$MSRES_2$
Nonlinearity	$m-2$	SSNL	MSNL
$Residual_T$	$3m-3$	$SSRES_T$	$MSRES_T$
TOTAL	$4m-1$	SST	

[NOTE—This analysis pertains to one sample assayed against a standard, using two replicates each.]

The number of dose levels for each preparation is denoted by *m*.

Table 2 gives the equations for calculating the SS terms.

In each row of the ANOVA table, the MS is obtained by dividing the SS term by the degrees of freedom.

$$SSNL = \frac{\sum_j Y_{.j.}^2}{4} - SSLIN - CF$$

$$SSRES_1 = SSRES_2 - SSNL$$

*Refer to *D-Glucose Determination* for the section on *Relative Potency* for the definitions of x_j and x_{ijk}.

■**Solution A:** Dissolve 16.3 g of potassium phosphate, monobasic in 750 mL of water, adjust the pH with phosphoric acid to 2.7 (±0.05), add water to 800 mL, add 200 mL of acetonitrile, and degas.

Solution B: Prepare a degassed solution of acetonitrile and water (4:6).

System suitability solution: Reconstitute a vial of USP rGlucagon RS in 0.01 N hydrochloric acid to obtain a solution having a concentration of about 0.5 mg/mL. Let stand at 50° for 48 h. At least 7% total of all four desamido glucagons should be present in the solution.

Standard solution: Reconstitute a vial of USP rGlucagon RS in 0.01 N hydrochloric acid to obtain a solution having a concentration of about 0.5 mg/mL.

Sample solution: 0.5 mg/mL of Glucagon in 0.01 N hydrochloric acid

Mobile phase: See *Gradient Table 2* below. [NOTE—The ratio of *Solution A* to *Solution B* can be adjusted to obtain a retention time of about 21 min for the main peak.]

Gradient Table 2

Time (min)	Solution A (%)	Solution B (%)
0	61	39
25[a]	61	39
29	12	88
30	12	88
31	61	39
70	61	39

[a] The end time of the isocratic elution can be adjusted so that the gradient begins after the fourth desamido peak elutes (relative retention time about 1.4). The rest of the program is then adjusted accordingly with this offset.

Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 214 nm
Column: 3-mm × 15-cm; 3-µm packing L1
Column temperature: 45°
Flow rate: 0.5 mL/min
Injection volume: 15 µL

System suitability
Samples: *System suitability solution* and *Standard solution*
Suitability requirements
Resolution: *System suitability solution*: four peaks eluting after the glucagon peak that correspond to the desamido glucagons are clearly visible. The resolution between the main peak and the first eluting desamido peak is NLT 1.5.
Tailing factor: NMT 1.8 for the glucagon peak, *Standard solution*
Relative standard deviation: NMT 2.0%, *Standard solution*

Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_{153}H_{225}N_{43}O_{49}S$ in the portion of Glucagon taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of the *Standard solution* (mg/mL)
C_U = concentration of the *Sample solution* (mg/mL)

Acceptance criteria: NLT 90% and NMT 105% on the anhydrous basis■2S *(USP33)*

BRIEFING

Glucagon for Injection, *USP 32* page 2507. It is proposed to replace the animal-based assay with an HPLC assay. The LC method has been validated using a 3-mm × 15-cm column containing 3-µm packing L1. USP intends to release USP rGlucagon RS of a recombinant origin. The following changes are also proposed:

1. The *Definition* range has been revised to NLT 65% and NMT 110% of the labeled amount.
2. *Identification* test *A* has been added to use the *Assay* retention time comparison.
3. The test for *Chromatographic Purity* has been deleted and replaced with an *Organic Impurities* test based on the same chromatographic procedure as that of the *Assay*.
4. A *Labeling* section has been added to state that the material is of recombinant DNA origin.

(BB PP: T. Sigambris.) RTS—C54723

In-Process Revision

Glucagon for Injection

DEFINITION

Change to read:

~~Glucagon for Injection is a mixture of the hydrochloride of Glucagon with one or more suitable dry diluents. It contains NLT 80.0% and NMT 125.0% of the labeled amount of glucagon ($C_{153}H_{225}N_{43}O_{49}S$).~~

■Glucagon for Injection is a sterile lyophilized mixture of the hydrochloride of glucagon with one or more suitable buffering and stabilizing agents. It contains NLT 65% and NMT 110% of the labeled amount of glucagon.■2S *(USP33)*

IDENTIFICATION

Add the following:

■• The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.■2S *(USP33)*

• **PROCEDURE**

~~[NOTE—All buffers have a final pH of 7.4, unless otherwise indicated. The concentration range of the *Standard solutions* and the *Sample solutions* may be modified to fall within the linear range of the *Assay*. The calculations should be adjusted accordingly. Alternatively, full curve analysis using validated nonlinear statistical methods can be used, provided that similarity is demonstrated when comparing the responses of the *Standard solutions* and the *Sample solutions*.]~~

~~**Hepatocyte preparation**~~

~~**Calcium-free perfusion buffer with dextrose:** Prepare a solution containing, in each L, 7.92 g of sodium chloride, 0.35 g of potassium chloride, 1.80 g of dextrose, 0.19 g of edetic acid, and 2.38 g of *N*-2-hydroxyethylpiperazine-*N*′-2-ethanesulfonic acid. Oxygenate prior to circulation.~~

~~**Collagenase buffer:** Prepare a solution containing, in each L, 3.62 g of sodium chloride, 23.83 g of *N*-2-hydroxyethylpiperazine-*N*′-2-ethanesulfonic acid, 0.35 g of potassium chloride, 0.52 g of calcium chloride, and 1.8 g of dextrose. Adjust to a pH of 7.6, and oxygenate. Immediately before perfusion, dissolve a quantity of collagenase in this solution to obtain a concentration of 0.02%–0.05%.~~

~~**Wash buffer:** Prepare a solution containing, in each L, 7.92 g of sodium chloride, 0.35 g of potassium chloride, 0.19 g of edetic acid, 2.38 g of *N*-2-hydroxyethylpiperazine-*N*′-2-ethanesulfonic acid, 0.22 g of calcium chloride, and 0.12 g of magnesium sulfate.~~

~~**Incubation buffer:** Prepare a solution containing, in each L, 6.19 g of sodium chloride, 0.35 g of potassium chloride, 0.22 g of calcium chloride, 0.12 g of magnesium sulfate, 0.16 g of monobasic potassium phosphate, 11.915 g of *N*-2-hydroxyethylpiperazine-*N*′-2-ethanesulfonic acid, and 1% bovine serum albumin (BSA). Adjust to a pH of 7.5.~~

~~**Test animals:** Male Sprague-Dawley rats are maintained on a standard rat chow diet and freely given water. On the morning of the test, select a healthy rat weighing approximately 300 g, and administer 100 Units of Heparin Sodium subcutaneously.~~

~~**Analysis**~~

~~[NOTE—Conduct this Analysis in the morning to ensure that the rat has optimal glycogen in its liver.]~~

~~Anesthetize the rat with an appropriate anesthetic. Open the abdominal cavity, and isolate the portal vein. Insert an angiocatheter connected to a perfusion pump, and tie into the portal vein at the general location of the lienal branch. Start the perfusion (25 mL/min) in situ with a *Calcium-free perfusion buffer with dextrose*, equilibrated with oxygen, at a temperature of 37°. As the liver enlarges, cut the inferior vena cava to allow pressure equilibrium.~~

~~[NOTE—300 mL of the perfusate is needed to clear the liver of red blood cells at a flow rate of 30–60 mL/min.]~~

~~Circulate the *Collagenase buffer* at a flow rate of 30–60 mL/min for 10 min. The exact concentration of collagenase (within the range of 0.02%–0.05%) is determined empirically for each lot of enzyme. The concentration of collagenase is that necessary to consistently cause a breakdown of the liver 10 min after initial entry of the *Collagenase buffer* into the liver. When the liver significantly increases in size, changes color and consistency, and starts to leak perfusate out of the lobes, change the system to the oxygenated prewarmed *Wash buffer*. Use 100 mL of *Wash buffer* to wash the liver of collagenase at a flow rate of 25 mL/min. Surgically remove the liver from the animal and place in a prewarmed tray containing oxygenated *Wash buffer* (37°). Gently comb the liver with a stainless steel, fine-toothed comb to free the hepatocytes. Wash the hepatocytes with *Wash buffer*, and filter through cheesecloth (or a 150-µm mesh polyethylene net) into a plastic beaker. Centrifuge the cell suspension for 2 min at 25 × g to form a loosely packed pellet. Discard the supernatant, and resuspend the pellet in *Wash buffer*. Repeat the washing *Analysis* twice for a total of three washes. Resuspend the final pellet in 100–200 mL of *Incubation buffer*, depending on cell yield.~~

~~[NOTE—If the *Assay Analysis* is interrupted, cool the cells by collecting the cells in a beaker placed in ice. The cells are washed with ice-cold *Wash buffer*, and stored on ice until ready for use. At that point the cells are pelleted once more, and resuspended in ice-cold *Incubation buffer*.]~~

~~**Suitability:** The concentrations of cells may vary due to the collagenase activity and the viability of the hepatocytes. To check cell viability and to determine viable cell concentration, dilute duplicate 100-µL aliquots of cell suspension with 400 µL of *Wash buffer* and 500 µL of isotonic 0.4% trypan blue. The aliquots are counted in a hemocytometer. The cells are suspended in *Incubation buffer* to obtain a viable cell concentration of not less than 3×10^6 per mL. Count several distinct fields.~~

~~[NOTE—Viable cells are those cells that exclude the trypan blue.]~~

~~**Negative control solution:** Prepare a solution containing 0.5% BSA in sterile water.~~

~~**Incubation flasks:** Use 25-mL conical flasks, the bottoms of which have been heated and pushed inward to form a conically raised center.~~

~~**Standard solutions:** In duplicate, dissolve a suitable quantity of USP Glucagon RS in 0.01 N hydrochloric acid or other suitable diluent to obtain a solution containing 1.0 USP Glucagon Unit/mL. All dilutions thereafter are made using 0.5% BSA (w/v) in water. Dilute measured volumes of each solution with *Negative control solution* to obtain five concentrations: 200, 100, 50, 25, and 12.5 micro-Units/mL of each solution (*Standard solutions*). Pipet 0.2 mL of each *Standard solution* into separate *Incubation flasks*. Pipet 0.2 mL of *Negative control solution* into each of two flasks (*Negative control solutions* 1 and 2). Then add the hepatocytes into each of the 12 flasks.~~

~~**Sample solutions:** Using weighed quantities of Glucagon, proceed as directed for *Standard solutions*.~~

~~**D-Glucose determination**~~

~~**Standard stock solution:** Transfer 2.0 g of USP Dextrose RS to a 200-mL volumetric flask, and dissolve in and dilute with saturated benzoic acid solution to volume.~~

~~**Standard solutions:** Transfer suitable quantities of *Standard stock solution* to three flasks, and dilute with saturated benzoic acid solution to obtain solutions having known concentrations of 0.5, 1.0, and 1.5 times the typical sample glucose concentration.~~

In-Process Revision

Potassium ferrocyanide solution: Dissolve 1.25 g of trihydrate potassium ferrocyanide in 125 mL of Sterile Water for Injection.

System suitability: Analyze the *Potassium ferrocyanide solution*, the *Standard solutions*, and five replicates of the middle *Standard solution*. Prepare a standard curve using the *Standard solutions* as directed for the *Analysis*.

Suitability requirements: The relative standard deviation of the standard curve is NMT 2.0%; the response of the *Potassium ferrocyanide solution* is NMT 30 mg/L; and the relative standard deviation is NMT 2.0% for the replicate analyses of the middle *Standard solution*.

Analysis: Dispense 5 mL of *Hepatocyte preparation* into the special *Incubation flasks* in sequence from high glucagon concentration to low glucagon concentration, alternating the *Standard solutions* with the *Sample solutions*. The flasks are swirled in an orbiting water bath at 125 rpm at 30° for approximately 30–60 min.

[NOTE—The exact incubation time must be determined to optimize the signal-to-noise ratio.]

Following incubation, place 0.5- to 1.0-mL aliquots, in duplicate, from each *Incubation flask* into labeled tubes, and centrifuge at 12,500 × g. Determine the percentage of glucose concentration in each flask's supernatant.

To conform to the linear range of the instrument being used, it may be necessary to adjust by dilution each of the preparations. Use a glucose analyzer that has demonstrated appropriate specificity, accuracy, precision, and linear response over the range of concentrations being determined.

[NOTE—A suitable analyzer may use an immobilized, oxidase-enzyme membrane or jacket-generating hydrogen peroxide, which is then detected at the electrode.]

Perform the glucose analysis in the following sequence: *Negative control solution 1*, *Standard solutions*, *Sample solutions*, and *Negative control solution 2*.

Determine the percentage of glucose against the *Negative control solution* for each preparation.

Calculations

Linearity test: Use an analysis of variance (ANOVA) with one sample assayed against a standard, and using two replicates each, construct a table (see *Table 1*). Compare the value of the ratio $MSNL/MSRES_T$ to a critical value obtained from a table for an F distribution with $m - 2$ and $3m - 3$ degrees of freedom, where m is the number of dose levels for each preparation. If the ratio $MSNL/MSRES_T$ does not indicate the presence of significant nonlinearity (ratio value is lower than the critical value), then proceed to the *Parallelism test*. If the ratio exceeds the critical value (significance level of 0.025), the nonlinearity is statistically significant and the test is repeated, discarding the results from either the highest or lowest dose of both the *Standard solutions* and the *Sample solutions* (four dose levels). If the ratio $MSNL/MSRES_T$ does not indicate the presence of significant nonlinearity, then proceed to the *Parallelism test*.

Parallelism test: Compare the ratio $MSNP/MSRES_2$ to a critical value from an F distribution having 1 and $4m - 5$ degrees of freedom. If the ratio $MSNP/MSRES_2$ does not indicate the presence of significant nonparallelism, then the assay is considered valid. Use the appropriate dose levels for the estimation of the *Relative potency*.

Relative potency: Calculate the *Relative potency*, R, of the *Sample solutions* as compared with the *Standard solutions* as follows.

(1) X_j is defined as the $\log_{10}$ of the j^{th} dose of the *Standard solutions* or the *Sample solutions*. The glucagon dose varies from 12.5 to 200 × 10^{-6} USP Glucagon Units/mL. For ease in the subsequent calculations, these doses are represented by 1 through 5, as shown in the table below.

j	1	2	3	4	5
Dose	12.5	25	50	100	200
X_j	1.10	1.40	1.70	2.00	2.30

(2) To differentiate between the *Standard solutions* and the *Sample solutions* in the calculations, the subscript i will be used, with i = 1 to designate the *Standard solutions* and i = 2 to designate the *Sample solutions*. Y_{ijk} will denote the glucose concentration associated with the k^{th} replicate of the j^{th} dose of the i^{th} preparation. For example, Y_{1jk} is the glucose concentration associated with the k^{th} replicate of the j^{th} dose of the appropriate *Standard solution*; Y_{11K} is the glucose concentration associated with the k^{th} replicate of dose 1 of the *Standard solution*; and Y_{21K} is the glucose concentration associated with the k^{th} replicate of dose 1 of the *Sample solution*. Dose 1 represents a glucose dose of 12.5 × 10^{-6} USP Glucagon Units per mL. Finally, Y_{132} represents the glucose concentration associated with the 2nd replicate of dose 3 for the *Standard solution*.

(3) Y_S and Y_T denote the average glucose concentrations for the *Standard solutions* and the *Sample solutions*, respectively.

(4) Calculate the least-squares slope estimate, b, for a linear regression relating the Y_{ijk}'s to the X_j's as follows: $b = S_{XY}/S_{XX}$, with S_{XY} and S_{XX} calculated using the equations in *Table 2*.

(5) The log potency, M, is calculated using $M = -1[(Y_S - Y_T)/b]$.

(6) R = antilog (M).

(7) Calculate the confidence limits (upper and lower) for the relative potency, R, using the value $s^2 = MSRES_3$ (see *Table 1* and *Table 2*) as follows. Obtain t from a table for a t distribution having 4m −4 degrees of freedom. For the 95% limits, the t values can be obtained from *Table 9* under *Design and Analysis of Biological Assays* ⟨111⟩.

[NOTE—For confidence limits having other probability levels (i.e., 100(1 - a)%), the right tail t critical value having a/2 area to its right is used.]

Calculate $g = t^2 S^2 / b^2 S_{xx}$

and $F = (ts/b)\sqrt{(1/m)(1-g) + (M^2/S_{xx})}$

and calculate

$$M_L = (M - F)/(1 - g)$$

and

$$M_U = (M + F)/(1 - g)$$

M = log potency
M_L = log potency lower confidence limit
M_U = log potency upper confidence limit

The lower and upper confidence limits for the *Relative potency*, R, are as follows:

RL = antilog (M_L)
RU = antilog (M_U)

Acceptance criteria: The potency is NLT 80.0% and NMT 125.0% of the labeled amount of glucagon, and the confidence interval width at *P* equals 0.95 does not exceed 45% of the computed potency.

[NOTE—Repeat the *Assay* if the confidence interval width exceeds 45% of the computed potency, or if the potency is less than 80.0% or more than 125.0% of the labeled amount of glucagon.]

Table 1. ANOVA for the Rat Hepatocyte Assay for Glucagon

Source	Degrees of Freedom	SS (Sum of Squares)	MS (Mean Square)

TOTAL	4m −1	SST	

In-Process Revision

~~[NOTE—This analysis pertains to one sample assayed against a standard, using two replicates each.~~
~~The number of dose levels for each preparation is denoted by *m*.~~
~~*Table 2* gives the equations for calculating the SS terms.~~
~~In each row of the ANOVA table, the MS is obtained by dividing the SS term by the degrees of freedom.~~]

Table 2. Equations for Calculating the Sums of Squares in the Analysis of Variance*

$$Y_{i..} = \sum_{jk} \sum y_{ijk}$$

$$Y_{.j.} = \sum_{ik} \sum y_{ijk}$$

$$Y_{..k} = \sum_{ij} \sum y_{ijk}$$

$$CF = \frac{\left(\sum_{ijk} \sum\sum y_{ijk}\right)^2}{4m}$$

$$S_{xy}^S = \sum_{jk} \sum x_j y_{1jk} - \frac{\left(\sum_j x_j\right)(Y_{1..})}{m}$$

$$S_{xy}^T = \sum_{jk} \sum x_j y_{2jk} - \frac{\left(\sum_j x_j\right)(Y_{2..})}{m}$$

$$S_{xy} = S_{xy}^S + S_{xy}^T$$

$$S_{xx}^S = 2\sum_j x_j^2 - \frac{2\left(\sum_j x_j\right)^2}{m}$$

$$S_{xx}^T = S_{xx}^S$$

$$S_{xx} = S_{xx}^S + S_{xx}^T$$

$$SSPREP = \frac{\sum_i Y_{i..}^2}{2m} - CF$$

$$SSREP = \frac{\sum_k Y_{..k}^2}{2m} - CF$$

$$SSLIN = \frac{\left(S_{xy}\right)^2}{S_{xx}}$$

$$SST = \sum_{i\,j\,k} \sum\sum y_{ijk}^2 - CF$$

$$SSRES_3 = SST - SSPREP - SSREP - SSLIN$$

$$SSNP = \frac{\left(S_{xy}^S\right)^2}{S_{xx}^S} + \frac{\left(S_{xy}^T\right)^2}{S_{xx}^T} - SSLIN$$

$$SSRES_2 = SSRES_3 - SSNP$$

$$SSNL = \frac{\sum_j Y_{.j.}^2}{4} - SSLIN - CF$$

$$SSRES_1 = SSRES_2 - SSNL$$

*Refer to the *Calculations* for section on *Relative Potency* for the definitions of x_j and x_{ijk}.

■**Solution A:** Dissolve 16.3 g of monobasic potassium phosphate in 750 mL of water, adjust with phosphoric acid to a pH of 2.7 (± 0.05), add water to 800 mL, add 200 mL of acetonitrile, and degas.

Solution B: Prepare a degassed solution of acetonitrile and water (4:6).

Standard solution: Reconstitute a vial of USP rGlucagon RS in 0.01 N hydrochloric acid to obtain a solution having a concentration of about 0.5 mg/mL.

System suitability solution: Reconstitute a vial of USP rGlucagon RS in 0.01 N hydrochloric acid to obtain a solution having a concentration of about 0.5 mg/mL. Let stand at 50° for 48 h. At least 7% total of all four desamido glucagons should be present in the solution.

Sample solution: Dissolve an adequate amount of Glucagon for Injection in order to obtain a 0.5-mg/mL concentration of glucagon in 0.01 N hydrochloric acid.

Mobile phase: See the gradient table below. [NOTE—The ratio of *Solution A* to *Solution B* can be adjusted to obtain a retention time of about 21 min for the main peak.]

Time (min)	Solution A (%)	Solution B (%)	Elution
0	61	39	isocratic
25[a]	61	39	isocratic
29	12	88	linear gradient
30	12	88	isocratic
31	61	39	linear gradient
70	61	39	re-equilibration

[a] The end time of the isocratic elution can be adjusted so that the gradient begins after the 4th desamido peak elutes (relative retention time about 1.4). The rest of the program is then adjusted accordingly with this offset.

Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 214 nm
Column: 3-mm × 15-cm; 3-µm or less packing L1
Column temperature: 45°
Flow rate: 0.5 mL/min
Injection volume: 15 µL

System suitability
Samples: *Standard solution* and *System suitability solution*
Suitability requirements
Relative standard deviation: NMT 2.0%, *Standard solution*
Tailing factor: NMT 1.8 for the glucagon peak, *Standard solution*
Resolution: NLT 1.5 between the main peak and the first eluting desamido peak. Four peaks eluting after the glucagon peak that correspond to the desamido glucagons are clearly visible, *System suitability solution*

Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_{153}H_{225}N_{43}O_{49}S$ in the amount of Glucagon for Injection taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of the *Standard solution* (mg/mL)
C_U = concentration of the *Sample solution* (mg/mL)

Acceptance criteria: 65%–110%■2S (*USP33*)

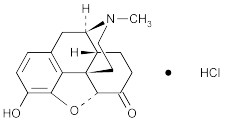
BRIEFING

Hydromorphone Hydrochloride. *USP 32* page 2588. It is proposed to replace the *Ordinary Impurities* chromatographic test with an *Organic Impurities* procedure which uses a validated HPLC method. The liquid chromatographic procedure is based on analyses performed with a Waters Symmetry brand of L1 column. The typical retention time for hydromorphone hydrochloride is about 21 min. The USP Reference Standards section has also been updated appropriately to reflect the addition of USP Hydromorphone Related Compound A RS.

(MD-CCA: C. Anthony.) RTS—C44976

Hydromorphone Hydrochloride



$C_{17}H_{19}NO_3 \cdot HCl$ 321.80
Morphinan-6-one, 4,5-epoxy-3-hydroxy-17-methyl-, hydrochloride, (5α)-;
4,5α-Epoxy-3-hydroxy-17-methylmorphinan-6-one hydrochloride [71-68-1].

DEFINITION
Hydromorphone Hydrochloride, dried at 105° for 2 h, contains NLT 98.0% and NMT 101.0% of $C_{17}H_{19}NO_3 \cdot HCl$.

IDENTIFICATION
• **A. INFRARED ABSORPTION** ⟨**197K**⟩
• **B. ULTRAVIOLET ABSORPTION** ⟨**197U**⟩
Sample solution: 100 µg/mL
Analytical wavelength: 280 nm
Acceptance criteria: Absorptivities, calculated on the dried basis, do not differ by more than 3.0%.
• **C. IDENTIFICATION TESTS—GENERAL,** *Chloride* ⟨**191**⟩**:** Meets the requirements
Sample solution: 1 in 20

ASSAY
• **PROCEDURE**
Sample: 225 mg, previously dried
Analysis: Transfer the *Sample* to a 250-mL conical flask. Dissolve in 80 mL of glacial acetic acid, warming, if necessary. Cool, and add 5 mL of acetic anhydride and 10 mL of mercuric acetate TS. Add 1 drop of crystal violet TS, and titrate with 0.1 N perchloric acid VS to a blue endpoint. Perform a blank determination, and make any necessary correction (see *Titrimetry* ⟨541⟩). Each mL of 0.1 N perchloric acid is equivalent to 32.18 mg of $C_{17}H_{19}NO_3 \cdot HCl$.
Acceptance criteria: 98.0%–101.0%, dried at 105° for 2 h

IMPURITIES
Inorganic Impurities
• **RESIDUE ON IGNITION** ⟨**281**⟩**:** NMT 0.3%
• **SULFATE**
Sample solution: 100 mg in 5 mL of water
Analysis: To the *Sample solution,* add 0.5 mL of 3 N hydrochloric acid and 1 mL of barium chloride TS.

In-Process Revision

Acceptance criteria: No turbidity is produced.

Change to read:

Organic Impurities

• **~~PROCEDURE: ORDINARY IMPURITIES ⟨466⟩~~**
~~Sample solution:~~ ~~Prepare in water.~~
~~Standard solution:~~ ~~Prepare in water.~~
~~Eluant:~~ ~~Methylene chloride, methanol, and ammonium hydroxide (80:20:1)~~
~~Visualization:~~ ~~3, followed by overspraying with hydrogen peroxide TS and immediate exposure of the plate to iodine vapors for 30 min.~~

■• **PROCEDURE**

Diluent: Phosphoric acid and water (1:1000)

Solution A: 1.0 mg/mL of sodium 1-heptanesulfonate monohydrate in 1000 mL of methanol and water (1:9). Add 1.0 mL of triethylamine and adjust with phosphoric acid to a pH of 2.5 ± 0.1.

Solution B: 1.0 mg/mL of sodium 1-heptanesulfonate monohydrate in 1000 mL of methanol and water (1:1). Add 1.0 mL of triethylamine, and adjust with phosphoric acid to a pH of 2.5 ± 0.1.

Mobile phase: See the gradient table below.

Time (min)	Solution A (%)	Solution B (%)
0	94	6
25	94	6
40	20	80
70	20	20
75	94	6
90	94	6

Standard solution: 4 µg/mL USP Hydromorphone Hydrochloride RS in *Diluent*.

System suitability solution: 0.8 mg/mL each of USP Hydromorphone Hydrochloride RS and USP Hydromorphone Related Compound A RS in *Diluent*. [NOTE—The solution should be kept in a cool place protected from light.]

Sample solution: 0.8 mg/mL of Hydromorphone Hydrochloride in *Diluent*.

Chromatographic system:
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 220 nm
Column: 3.9-mm × 15-cm; 5-µm packing L1
Temperature: 45°
Flow rate: 1.0 mL/min
Injection size: 20 µL

System suitability
Sample: *Standard solution* and *System suitability solution*
Suitability requirements
Resolution: NLT 1.0 between hydromorphone related compound A and hydromorphone peaks, *System suitability solution*
Tailing factor: NMT 1.5 for hydromorphone peak, *Standard solution*
Relative standard deviation: NMT 5.0%, *Standard solution*

Analysis
Samples: *Diluent*, *Standard solution*, and *Sample solution*
Calculate the percentage any specified or unspecified impurity in the portion of Hydromorphone Hydrochloride taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 1/F \times 100$$

r_U = peak response for each degradation found, including those in *Impurity Table 1*, from the *Sample solution*
r_S = peak response of hydromorphone from the *Standard solution*
C_S = concentration of USP Hydromorphone Hydrochloride RS in the *Standard solution* (mg/mL)
C_U = concentration of Hydromorphone Hydrochloride in the *Sample solution* (mg/mL)
F = relative response factor for the corresponding individual specified or unspecified impurity from *Impurity Table 1*.

Acceptance criteria
See *Impurity Table 1*. [NOTE—Disregard peaks corresponding to those obtained from the *Diluent*.]

Impurity Table 1

Name	Relative Retention Time	Relative Response Factor	Acceptance Criteria, NMT (%)
8-Hydroxyhydromorphone[a]	0.50	1.0	0.15
Dihydromorphine (DHM)[b]	0.61	1.0	0.5
Morphine[c]	0.65	1.8	0.15

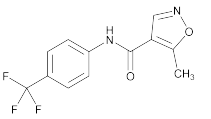
BRIEFING

Leflunomide, *USP 32* page 2754. On the basis of comments received, it is proposed to increase the *Loss on Drying* specifications from 0.3% to 0.5% and increase the limit for leflunomide related compound A from 0.01% to 0.02% to be consistent with approved products.

(MD-CCA: C. Anthony.) RTS—C75413; C77281

Leflunomide



$C_{12}H_9F_3N_2O_2$ 270.21

4-Isoxazolecarboxamide, 5-methyl-*N*-[4-(trifluoromethyl)-phenyl]-;

α,α,α-Trifluoro-5-methyl-4-isoxazolecarboxy-*p*-toluidide [75706-12-6].

DEFINITION

Leflunomide contains NLT 98.0% and NMT 102.0% of $C_{12}H_9F_3N_2O_2$, calculated on the dried basis.

IDENTIFICATION

- **A. INFRARED ABSORPTION ⟨197K⟩**
  Sample: Dry the substance for 10 min at 130°.
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

ASSAY

- **PROCEDURE**
  Mobile phase: Acetonitrile, triethylamine, and water (70:1:130). Adjust with phosphoric acid to a pH of 4.
  Standard solution: 0.5 mg/mL of USP Leflunomide RS in *Mobile phase*. [NOTE—Dissolve USP Leflunomide RS in 5 mL of acetonitrile, and dilute with *Mobile phase*.]
  System suitability solution: 0.5 mg/mL of USP Leflunomide RS, 0.15 mg/mL of USP Leflunomide Related Compound B RS, and 0.05 mg/mL of USP Leflunomide Related Compound C RS in *Mobile phase*. [NOTE—Dissolve the Reference Standards in acetonitrile and dilute with *Mobile phase*.]
  Sample solution: 0.5 mg/mL of Leflunomide in acetonitrile and *Mobile phase* (1:9). [NOTE—First dissolve in acetonitrile. Protect solutions from light.]
  Chromatographic system
  (See *Chromatography* ⟨621⟩, *System Suitability*.)
  Mode: LC
  Detector: UV 210 nm
  Column: 4-mm × 12.5-cm; packing L1
  Flow rate: 1 mL/min
  Injection size: 20 µL
  System suitability
  Sample: *System suitability solution*
  [NOTE—The relative retention times for leflunomide related compound B and leflunomide related compound C are 0.2 and 0.9, respectively.]
  Suitability requirements
  Resolution: NLT 1.0 between the leflunomide and leflunomide related compound C peaks
  Analysis
  Samples: *Standard solution* and *Sample solution*
  Calculate the percentage of $C_{12}H_9F_3N_2O_2$ in the portion of Leflunomide taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of USP Leflunomide RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of Leflunomide in the *Sample solution* (mg/mL)

Acceptance criteria: 98.0%–102.0% on the dried basis

BRIEFING

Leflunomide Tablets, *USP 32* page 2755. On the basis of comments received, it is proposed to delete the test for *Water Determination*. The water content of dosage forms is highly dependent on excipients and may vary widely between formulations. In addition, the excipients used in the formulation are individually limited for water content in their respective *NF* monographs, and this should be sufficient for moisture control.

(MD-CCA: C. Anthony.) RTS—C75414

Leflunomide Tablets

DEFINITION
Leflunomide Tablets contain NLT 90.0% and NMT 110.0% of the labeled amount of leflunomide ($C_{12}H_9F_3N_2O_2$).

IDENTIFICATION
• **A. ULTRAVIOLET ABSORPTION ⟨197U⟩**
Analytical wavelength: 220–360 nm
Sample solution: 0.01 mg/mL in methanol
• **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

ASSAY
• **PROCEDURE**
Mobile phase: Acetonitrile, triethylamine, and water (70:1:130). Adjust with phosphoric acid to a pH of 4.0.
System suitability solution A: 10 µg/mL of USP Leflunomide Related Compound A RS, 1 mg/mL of USP Leflunomide Related Compound B RS, and 100 µg/mL of USP Leflunomide Related Compound C RS in a minimum amount of acetonitrile, and diluted with *Mobile phase*
System suitability solution B: Transfer 100.0 mg of USP Leflunomide RS to a 100-mL volumetric flask. Dissolve in 2 mL of acetonitrile, add 1 mL of *System suitability solution A* and 80 mL of *Mobile phase*, and shake by mechanical means for 10 min. Dilute with *Mobile phase* to volume.
Standard solution: 1 mg/mL of USP Leflunomide RS in a minimum volume of acetonitrile, and diluted in *Mobile phase*
Sample solution: Equivalent to 100 mg of leflunomide from Tablets (finely powder NLT 20 Tablets), to a 100-mL volumetric flask. Add 20 mL of acetonitrile, dilute with *Mobile phase* to volume, and shake by mechanical means for 10 min. Pass through a membrane filter.
Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 210 nm
Column: 4.0-mm × 12.5-cm; packing L1
Flow rate: 1 mL/min
Injection size: 10 µL
System suitability
Samples: *Standard solution* and *System suitability solution B*
[NOTE—The relative retention times for leflunomide related compound A, leflunomide related compound B, leflunomide related compound C, and leflunomide are 0.4, 0.2, 0.9, and 1.0, respectively.]
Suitability requirements
Resolution: NLT 1.5 between leflunomide related compound C and leflunomide
Tailing factor: NMT 3.0 for leflunomide
Relative standard deviation: NMT 2.0%
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_{12}H_9F_3N_2O_2$ in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of USP Leflunomide RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of leflunomide in the *Sample solution* (mg/mL)
Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS
• **DISSOLUTION ⟨711⟩**
Medium:
For Tablets labeled to contain 10 mg or 20 mg: Water, 1000 mL, deaerated
For Tablets labeled to contain 100 mg: Water containing 0.6% of polyoxyethylene lauryl ether; 1000 mL, deaerated
Apparatus 2: 100 rpm
Time: 30 min
Determine the amount of $C_{12}H_9F_3N_2O_2$ dissolved employing one of the following methods:

In-Process Revision

Spectrometric method
Mode: UV
Analytical wavelength: 262 nm
Standard solution: USP Leflunomide RS in *Medium*. [NOTE—A volume of methanol not exceeding 2% of the final volume of the *Standard solution* may be used to dissolve leflunomide.]
Sample solutions: Sample per *Dissolution* ⟨711⟩. Dilute with *Medium* to a concentration that is similar to *Standard solution*. Pass through a 0.45-µm filter.
Chromatographic method
Mobile phase: Acetonitrile and water (1:1)
Standard solution: Transfer 22 mg of USP Leflunomide RS to a 100-mL volumetric flask. Add 40 mL of acetonitrile, and sonicate until dissolved. Add 40 mL of water, and cool to room temperature. Dilute with water to volume. Transfer 10.0 mL of this solution to a 100-mL volumetric flask, and dilute with water to volume.
Sample solution: Use portions of the solution under test passed through a suitable 0.45-µm filter.
Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 260 nm
Column: 4.6-mm × 15-cm; 5-µm packing L1
Flow rate: 1.5 mL/min
Injection size: 40 µL
System suitability
Sample: *Standard solution*
Suitability requirements
Tailing factor: NMT 2.0
Relative standard deviation: NMT 2.0%
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_{12}H_9F_3N_2O_2$ dissolved:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of USP Leflunomide RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of leflunomide in the *Sample solution* (mg/mL)
Tolerances: NLT 80% (Q) of the labeled amount of $C_{12}H_9F_3N_2O_2$ is dissolved.

• **UNIFORMITY OF DOSAGE UNITS** ⟨905⟩**:** Meet the requirements
Procedure for content uniformity
Mobile phase, Standard solution, System suitability solutions, and **Chromatographic system:** Prepare as directed in the *Assay*.
Sample solution: Transfer 1 Tablet to a suitable volumetric flask, and prepare a solution having a concentration of 1 mg/mL of leflunomide. Add *Mobile phase* 50% by volume, and shake to disintegrate the Tablet. After the Tablet is completely disintegrated, add acetonitrile 20% by volume, dilute with *Mobile phase* to volume, and shake again. Pass through a membrane filter.
Analysis: Proceed as directed in the *Assay*.

IMPURITIES
Organic Impurities
• **PROCEDURE**
Mobile phase, System suitability solutions, Standard solution, Sample solution, and **Chromatographic system:** Proceed as directed in the *Assay*.
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of each individual impurity in the portion of Tablets taken:

$$\text{Result} = (r_U/r_T) \times 100$$

r_U = peak response of each individual impurity from the *Sample solution*
r_T = sum of all the related compounds and the leflunomide peak responses from the *Sample solution*

Acceptance criteria
Leflunomide related compound A: NMT 0.1%
Leflunomide related compound B: NMT 3.5%
Leflunomide related compound C: NMT 0.2%
Individual impurities: NMT 0.2%
Total impurities: NMT 4.0%

In-Process Revision

BRIEFING

Methylphenidate Hydrochloride Extended-Release Tablets. *USP 32* page 2950. On the basis of comments received, a test for *Organic Impurities* is being added to the monograph. The proposed liquid chromatographic procedure in the test for *Organic Impurities* is based on analyses performed with a Water Symmetry C18, brand of L1 column. The typical retention times are 11.5 min for methylphenidate hydrochloride, 5.4 min for methylphenidate related compound A, and 7.5 min for methylphenidate hydrochloride erythro isomer. *Identification* test *B*, with an HPLC retention time comparison of the major peak in the chromatograms of the *Standard solution* and *Sample solution* in the test for *Organic Impurities* is also proposed.

(MD-PP: H. Ramanathan, R. Ravichandran.) RTS—C42825

Methylphenidate Hydrochloride Extended-Release Tablets

DEFINITION

Methylphenidate Hydrochloride Extended-Release Tablets contain NLT 90.0% and NMT 110.0% of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$).

IDENTIFICATION

• **INFRARED ABSORPTION**

Sample specimen: Place a portion of powdered Tablets, equivalent to 100 mg of methylphenidate hydrochloride, into a 100-mL beaker. Add 20 mL of chloroform, stir for 5 min, and filter, collecting the filtrate. Evaporate the filtrate to about 5 mL. Add ethyl ether slowly, with stirring, until crystals form. Filter the crystals, wash with ethyl ether, and dry at 80° for 30 min.

Acceptance criteria: The IR absorption spectrum of a mineral oil dispersion of the crystals obtained exhibits maxima only at the same wavelengths as that of a similar preparation of USP Methylphenidate Hydrochloride RS.

Add the following:

■• **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the test under *Organic Impurities*.■2S (*USP33*)

ASSAY

• **PROCEDURE**

Acetate buffer: Dissolve 1.64 g of anhydrous sodium acetate in 900 mL of water. Adjust with acetic acid to a pH of 4.0, and dilute with water to 1000 mL.

Mobile phase: Methanol, acetonitrile, and *Acetate buffer* (4:3:3)

Internal standard solution: 0.4 mg/mL of phenylephrine hydrochloride in *Mobile phase*

Standard stock solution: 0.2 mg/mL of USP Methylphenidate Hydrochloride RS in *Mobile phase*

Standard solution: Transfer 10.0 mL of *Standard stock solution* to a glass-stoppered, 25-mL conical flask, add 5.0 mL of *Internal standard solution*, and mix.

Sample stock solution: 0.2 mg/mL of methylphenidate hydrochloride from powdered Tablets (NLT 20 Tablets) in *Mobile phase*. [NOTE—Sonicate for 15 min.] Cool to room temperature. Dilute with *Mobile phase* to volume, and mix. Pass a portion of this solution through a suitable membrane filter, discarding the first portion of the filtrate. [NOTE—Avoid the use of glass filters. Polypropylene filters are suitable for use.]

Sample solution: Transfer 10.0 mL of the clear filtrate to a glass-stoppered, 25-mL conical flask, and add 5.0 mL of *Internal standard solution*.

Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 210 nm
Column: 4.6-mm × 25-cm; packing L10
Flow rate: 1.5 mL/min
Injection size: 50 µL

System suitability
Sample: *Standard solution*
[NOTE—The relative retention times for phenylephrine hydrochloride and methylphenidate hydrochloride are 0.8 and 1.0, respectively.]
Suitability requirements
Resolution: NLT 2.0 between the analyte and internal standard peaks
Relative standard deviation: NMT 2.0% from the peak response ratios of the analyte to the internal standard

Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_{14}H_{19}NO_2 \cdot HCl$ in the portion of Tablets taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

R_U = peak response ratio of the analyte to the internal standard from the *Sample solution*
R_S = peak response ratio of the analyte to the internal standard from the *Standard solution*
C_S = concentration of the *Standard solution* (mg/mL)
C_U = nominal concentration of the *Sample solution* (mg/mL)

Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS

• **DISSOLUTION,** *Procedure for a Pooled Sample* ⟨**711**⟩

Test 1
Medium: Water; 500 mL
Apparatus 2: 50 rpm
Times: 1, 2, 3.5, 5, and 7 h
Sample solution: Use portions of the solution under test passed through suitable 0.45-µm filter. [NOTE—Do not use glass fiber filters.]
Analysis: Determine the amount of $C_{14}H_{19}NO_2 \cdot HCl$ dissolved by using the procedure in the *Assay*, and make any necessary volumetric adjustments.
Tolerances: The percentages of the labeled amount of $C_{14}H_{19}NO_2 \cdot HCl$ dissolved at the times specified conform to *Acceptance Table 2*.

Time (h)	Amount Dissolved
1	25%–45%
2	40%–65%
3.5	55%–80%
5	70%–90%
7	NLT 80

Test 2 (for products labeled for dosing every 24 h): If the product complies with this test, the labeling indicates that it meets USP *Dissolution Test 2*.
Medium: Acidified water, adjust with phosphoric acid to a pH of 3; 50 mL, at 37 ± 0.5°
Apparatus 7: (see *Drug Release* ⟨724⟩)
30 cycles/min; 2–3 cm amplitude
Use *Sample Preparation A* with a metal coil sample holder (*Figure 4d*). Place 1 Tablet in the holder with the Tablet orifice facing down, and cover the top of the holder with Parafilm™. At the end of each specified test interval, the systems are transferred to the next row of new test tubes containing 50 mL of fresh *Medium*.

In-Process Revision

Times: 1 h intervals for a duration of 10 h
Determine the percentages of the labeled amount of $C_{14}H_{19}NO_2 \cdot HCl$ dissolved by using the following method.
Dilution medium: Mixture of acetonitrile and *Medium* (1:3)
Standard stock solution: 0.3 mg/mL USP Methylphenidate Hydrochloride RS in *Dilution medium*
Standard solutions: Prepare at least six solutions by making serial dilutions of the *Standard stock solution* in *Dilution medium* to bracket the expected drug concentration range.
Solution A: Dissolve 2.0 g of 1-octanesulfonic acid sodium salt in 700 mL of water, mix well, and adjust with phosphoric acid to a pH of 3.0.
Mobile phase: Acetonitrile and *Solution A* (3:7)
Chromatographic system
(See *Chromatography* ⟨621⟩*, System Suitability*.)
Mode: LC
Detector: UV 220 nm
Column: 3.2-mm × 5-cm; 5-µm packing L1
Flow rate: 1 mL/min
Column temperature: 30°
Injection size: 25 µL
System suitability
Sample: *Standard solution*
Suitability requirements
Tailing factor: NMT 2
Capacity factor: NMT 2
Relative standard deviation: NMT 2% from the peak response of the analyte; NMT 2% of retention time of the analyte
Analysis
Samples: *Standard solutions* and the solution under test
Construct a calibration curve by plotting the peak response versus the concentration of the *Standard solutions*. Determine the amount of $C_{14}H_{19}NO_2 \cdot HCl$ in each interval by linear regression analysis of the standard curve.
Tolerances: The percentages of the labeled amount of $C_{14}H_{19}NO_2 \cdot HCl$ dissolved at the times specified conform to *Acceptance Table 2*.

Time (h)	Amount Dissolved
1	12%–32%
4	40%–60%
10	NLT 85%
Average from 3 to 6	9%–15%/h

Calculate the average percentage released from 3 to 6 h:

$$\text{Result} = (Y - X)/3$$

Y = cumulative drug released from 0 to 6 h
X = cumulative drug released from 0 to 3 h

• **UNIFORMITY OF DOSAGE UNITS ⟨905⟩:** Meet the requirements

IMPURITIES

Add the following:

■Organic Impurities

• **PROCEDURE**

Mobile phase: Dissolve 2 g of 1-octanesulfonic acid in 730 mL of water. Adjust with phosphoric acid to a pH of 2.7. Mix with 270 mL of acetonitrile.
Solution A: Acidified water. Adjust with phosphoric acid to a pH of 3.
Diluent A: Acetonitrile and *Solution A* (1:3)
Diluent B: Acetonitrile and methanol (1:1)
System suitability solution: 80 µg/mL of USP Methylphenidate Hydrochloride RS, 1 µg/mL of methylphenidate hydrochloride erythro isomer from USP Methylphenidate Hydrochloride Erythro Isomer Solution RS and 2 µg/mL of USP Methylphenidate Related Compound A RS, in *Diluent A*
Standard solution: 0.2 µg/mL of USP Methylphenidate Hydrochloride RS, 0.5 µg/mL of methylphenidate hydrochloride erythro isomer from USP Methylphenidate Hydrochloride Erythro Isomer Solution RS and 1.5 µg/mL of USP Methylphenidate Related Compound A RS, in *Diluent A*
Sample stock solution: Dissolve 10 Tablets in 20% of total volume in *Diluent B*. Stir for 4 h. Dilute with *Solution A* to volume.
Sample solution: 0.1 mg/mL of methylphenidate hydrochloride in *Solution A,* from *Sample stock solution.* [NOTE—Centrifuge before chromatographic analysis.]
Chromatographic system
(See *Chromatography* ⟨621⟩*, System Suitability*.)
Mode: LC
Detector: UV 210 nm
Column: 3.9-mm × 15-cm column; 5-µm packing L1
Flow rate: 1 mL/min
Injection size: 25 µL
Temperature: 30°
Run time: 2 times the retention time of methylphenidate
System suitability
Sample: *System suitability solution*
Suitability requirements
Tailing factor: NMT 2.0 for methylphenidate peak
Resolution: NLT 6.0 between methylphenidate and erythro isomer peaks
Relative standard deviation: NMT 2.0% for methylphenidate peak and NMT 4.0% each for methylphenidate related compound A and erythro isomer peaks
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of methylphenidate related compound A or erythro isomer in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = response of methylphenidate related compound A or erythro isomer from the *Sample solution*
r_S = response of methylphenidate related compound A or erythro isomer from the *Standard solution*
C_S = concentration of USP Methylphenidate Related Compound A RS or methylphenidate hydrochloride erythro isomer, in the *Standard solution* (mg/mL)
C_U = nominal concentration of methylphenidate hydrochloride in the *Sample solution* (mg/mL)

Calculate the percentage of any unspecified degradation product in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = response of each impurity from the *Sample solution*
r_S = response of USP Methylphenidate Hydrochloride RS from the *Standard solution*
C_S = concentration of USP Methylphenidate Hydrochloride RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of methylphenidate hydrochloride in the *Sample solution* (mg/mL)

Acceptance criteria
Individual impurities: See *Impurity Table 1.*
Total impurities: NMT 2.5%

Impurity Table 1

Name	Relative Retention Time	Acceptance Criteria, NMT (%)
Methylphenidate related compound A[a]	0.47	1.5
Erythroisomer[b]	0.65	0.5

[a] α-Phenyl-2-piperidineacetic acid.
[b] Methyl (*RS,SR*)-2-phenyl-2-(piperidin-2-yl) acetate.

Impurity Table 1 *(Continued)*

Name	Relative Retention Time	Acceptance Criteria, NMT (%)
Methylphenidate hydrochloride	1.0	—
Any unspecified degradation product	—	0.2

[a] α-Phenyl-2-piperidineacetic acid.
[b] Methyl (*RS,SR*)-2-phenyl-2-(piperidin-2-yl) acetate.

BRIEFING

Morphine Sulfate Extended-Release Tablets. Because there is no existing *USP* monograph for this drug product, a new monograph based on validated methods of analysis is proposed. The liquid chromatographic procedures in the test for *Organic Impurities* and in the *Assay* are based on analyses performed with the Keystone ODS/B brand of L1 column. Typical retention times are about 2.8 min for morphine sulfate related compound A, about 3.7 min for morphine sulfate, and about 5.0 min for morphine sulfate related compound B.

(MD-CCA: C. Anthony. BPC: M. Marques.) RTS—C34840

Add the following:

■Morphine Sulfate Extended-Release Tablets

DEFINITION
Morphine Sulfate Extended-Release Tablets contain NLT 90.0% and NMT 110.0% of the labeled amount of morphine sulfate $(C_{17}H_{19}NO_3)_2 \cdot H_2SO_4 \cdot 5H_2O$.

IDENTIFICATION
- **A. IDENTIFICATION TESTS—GENERAL,** *Sulfate* ⟨**191**⟩
  Analysis: Triturate a portion of the composite powder from the *Assay* equivalent to about 250 mg of morphine sulfate with 25 mL of alcohol, sonicate for 10 min, and centrifuge the mixture. Decant the supernatant through a glass-fiber filter. Wash the residue with 15 mL of alcohol, centrifuge, and decant the supernatant through the same filter. Evaporate the combined filtrates to dryness, digest the residue in 10 mL of warm water, and pass through another glass-fiber filter.
  Acceptance criteria: The filtrate (1-mL portions) meets the requirements.
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

ASSAY
- **PROCEDURE**
  Buffer: 20.8 mg/mL of monobasic sodium phosphate and 0.87 mg/mL of sodium octanesulfonate in water
  Mobile phase: Methanol, triethylamine, and *Buffer* (150:1:350). Adjust with phosphoric acid to a pH of 4.5. Pass through a 0.45-µm polyvinylidene fluoride membrane filter.
  Solvent: Methanol and water (19:1)
  Diluent: Methanol and water (1:1)
  Standard stock solution A: 0.06 mg/mL of USP Morphine Sulfate Related Compound A RS in *Mobile phase*
  Standard stock solution B: Dissolve a quantity of USP Morphine Sulfate Related Compound B RS in a suitable quantity of 0.1 N sodium hydroxide, and dilute quantitatively, and stepwise if necessary, with *Mobile phase* to obtain a solution having a known concentration of about 0.06 mg/mL.
  Standard solution: Weigh a quantity of USP Morphine Sulfate RS, and measure quantities of USP Morphine Sulfate Related Compound A RS stock solution and USP Morphine Sulfate Related Compound B RS stock solution. Dissolve in *Mobile phase* to obtain a solution having known concentrations of about 0.12 mg/mL of morphine sulfate, and about 2.4 µg/mL each of morphine sulfate related compound A and morphine sulfate related compound B. Mix well, and pass through a 0.45-µm polyvinylidene fluoride membrane filter, discarding the first 3 mL of solution.
  Sample solution: Weigh and finely powder NLT 20 Tablets. Transfer a portion of the powder, equivalent to about 30 mg of morphine sulfate, to a 100-mL volumetric flask. Add about 20 mL of *Solvent* and gently swirl to disperse. Allow to stand for 5 min. Add, while swirling, 50 mL of *Diluent.* Sonicate for at least 5 min, and shake mechanically for at least 30 min. Dilute with *Diluent* to volume, mix, and then transfer 4.0-mL into a 10.0-mL volumetric flask. Dilute with *Mobile phase* to volume, and mix. Pass through a 0.45-µm polyvinylidene fluoride membrane filter, and discard the first 3 mL.
  Chromatographic system
  (See *Chromatography* ⟨621⟩, *System Suitability.*)
  Mode: LC
  Detector: UV 240 nm
  Column: 4.6-mm × 15-cm column; 5-µm packing L1
  Flow rate: 1.2 mL/min
  Injection size: 20 µL
  System suitability
  Sample: *Standard solution*
  Suitability requirements
  Tailing factor: NMT 2.0 for the morphine sulfate peak
  Resolution: NLT 2 between any two major peaks
  Relative standard deviation: NMT 2.0% for morphine sulfate from replicate injections
  Analysis
  Samples: *Standard solution* and *Sample solution*
  Calculate the percentage of $(C_{17}H_{19}NO_3)_2 \cdot H_2SO_4 \cdot 5H_2O$ in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of morphine sulfate, calculated on anhydrous basis, in the *Standard solution* (mg/mL)
C_U = nominal concentration of of morphine sulfate in the *Sample solution* (mg/mL)
M_{r1} = molecular weight of morphine sulfate, 758.83
M_{r2} = molecular weight of anhydrous morphine sulfate, 668.77

In-Process Revision

Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS

• **DRUG RELEASE** ⟨**724**⟩
Medium: Water; 500 mL
Apparatus 1: 100 rpm
Times: 2, 4, and 8 h
Standard solution: 30 µg/mL of USP Morphine Sulfate RS in *Medium*
Sample solution: Pass a portion of the solution under test through a 0.8-µm mixed cellulose ester filter, discarding the first few mL. Replace the volume withdrawn with the same volume of warmed *Medium*.
Detector: UV 286 nm
Blank: *Medium*
Percentage of morphine sulfate dissolved at 2 h:

$$(A_{U2}/A_S) \times (C_S \times V) \times 100/L$$

Percentage of morphine sulfate dissolved at 4 h:

$$(A_{U4}/A_S) \times (C_S \times V) \times 100 + A/L$$

Percentage of morphine sulfate dissolved at 8 h:

$$(A_{U8}/A_S) \times (C_S \times V) \times 100 + A + B/L$$

Amount of morphine sulfate (mg) removed at 2 h (A):

$$A = A_{U2}/A_S \times C_S \times V_2$$

Amount of morphine sulfate (mg) removed at 4 h (B):

$$B = A_{U4}/A_S \times C_S \times V_4$$

A_{U2} = absorbance of the *Sample solution* at 2 h
A_{U4} = absorbance of the *Sample solution* at 4 h
A_{U8} = absorbance of the *Sample solution* at 8 h
A_S = absorbance of the *Standard solution*
C_S = concentration of the *Standard solution* (mg/mL)
V = volume of morphine sulfate, 500 mL
L = Tablet label claim (mg)
V_2 = volume of sample withdrawn at 2 h (mL)
V_4 = volume of sample withdrawn at 4 h (mL)
Tolerances: The percentages of the labeled amount of $(C_{17}H_{19}NO_3)_2 \cdot H_2SO_4 \cdot 5H_2O$ dissolved at the times specified conform to *Acceptance Table 2*.

Time (h)	Amount Dissolved
2	30%–50%

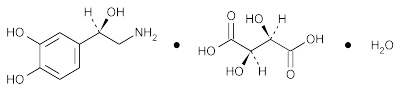
BRIEFING

Norepinephrine Bitartrate, *USP 32* page 3103. On the basis of comments received from FDA, it is proposed to revise the *Residue on Ignition* test under *Inorganic Impurities* by replacing the currently stated limit of "Negligible" with a quantitative limit of NMT 1.0%.

(MD-CV: S. Ramakrishna.) RTS—C68836

Norepinephrine Bitartrate



$C_8H_{11}NO_3 \cdot C_4H_6O_6 \cdot H_2O$ 337.28

$C_8H_{11}NO_3 \cdot C_4H_6O_6$ 319.27

1,2-Benzenediol, 4-(2-amino-1-hydroxyethyl)-, (*R*)-,[*R*-(*R**,*R**)]-2,3-dihydroxybutanedioate (1:1) (salt), monohydrate;
(–)-α-(Aminomethyl)-3,4-dihydroxybenzyl alcohol tartrate (1:1) (salt), monohydrate [69815-49-2].
Anhydrous [51-40-1].

DEFINITION
Norepinephrine Bitartrate contains NLT 97.0% and NMT 102.0% of $C_8H_{11}NO_3 \cdot C_4H_6O_6$, calculated on the anhydrous basis.

In-Process Revision

IDENTIFICATION
- **A. Infrared Absorption** ⟨197K⟩
- **B. Procedure**
  Sample solution: Dissolve 10 mg in 2 mL of water.
  Analysis: Add 1 drop of ferric chloride TS.
  Acceptance criteria: An intensely green color develops.
- **C. Procedure**
  Sample solution: 0.01 µg/mL
  Analysis: Add 1.0 mL of 0.10 N iodine to 10 mL of the *Sample solution*. Allow to stand for 5 min, and add 2.0 mL of 0.10 N sodium thiosulfate.
  Acceptance criteria: The solution is colorless, or has at most a slight pink or slight violet color (epinephrine and isoproterenol at the same pH, about 3.5, give a strong red-brown or violet color).

ASSAY
- **Procedure**
  Sample solution: Dissolve 500 mg of Norepinephrine Bitartrate in 20 mL of glacial acetic acid, warming slightly if necessary to effect solution.
  Analysis: Add 2 drops of crystal violet TS to the *Sample solution*, and titrate with 0.1 N perchloric acid VS. Perform a blank determination, and make any necessary correction (see *Titrimetry* ⟨541⟩). Each mL of 0.1 N perchloric acid is equivalent to 31.93 mg of $C_8H_{11}NO_3 \cdot C_4H_6O_6$.
  Acceptance criteria: 97.0%–102.0% on the anhydrous basis

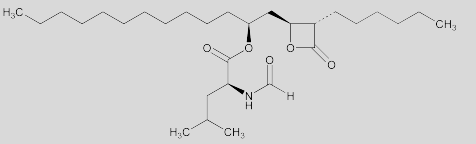
Briefing

Orlistat. Because there is no existing *USP* monograph for this article, a new monograph is being proposed. The liquid chromatographic procedures in the *Assay* and in the test for *Organic Impurities, Procedure 3* are based on analyses performed with a Nova-Pak brand of L1 column. The typical retention time for orlistat is about 10.5 min. The gas chromatographic procedure in the test for *Limit of Orlistat Related Compound B* is based on analyses performed with a DB-1 brand of column. The typical retention time for orlistat related compound B is about 22 min. The liquid chromatographic procedure in the test for *Limit of Orlistat Related Compound D* is based on analyses performed with a Superspher 60-RP Select B brand of L7 column. The typical retention time for orlistat related compound D is about 35 min. The liquid chromatographic procedure in the test for *Limit of Orlistat Related Compound E* is based on analyses performed with an aminoquant column. The typical retention time for orlistat related compound E is about 15.5 min.

(MD-CCA: C. Anthony.) RTS—C44029

Add the following:

■Orlistat



$C_{29}H_{53}NO_5$ 495.73

L-Leucine, *N*-formyl-, 1-[(3-hexyl-4-oxo-2-oxetanyl)methyl]dodecyl ester, [2*S*-[2α(*R**), 3β]]-;
N-Formyl-L-leucine, ester with (3*S*,4*S*)-3-hexyl-4-[(2*S*)-2-hydroxytridecyl]-2-oxetanone [96829-58-2].

DEFINITION
Orlistat contains NLT 98.0% and NMT 101.5% of $C_{29}H_{53}NO_5$, calculated on the anhydrous, solvent-free basis.

IDENTIFICATION
- **A. Infrared Absorption** ⟨197M⟩
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution,* as obtained in the *Assay.*

ASSAY
- **Procedure**
  [Note—Avoid the use of plastic flasks for the preparation or containment of any solution in this analysis.]
  Mobile phase: Acetonitrile, water, and phosphoric acid (860:140:0.05)
  Standard solution: 0.5 mg/mL of USP Orlistat RS in *Mobile phase*. Inject immediately after preparation or store at 5°.
  Sample solution: 0.5 mg/mL of Orlistat in *Mobile phase*. Inject immediately after preparation or store at 5°.
  Chromatographic system
  (See *Chromatography* ⟨621⟩, *System Suitability*.)

In-Process Revision

Mode: LC
Detector: UV 195
Column: 3.9-mm × 15-cm column; 4-µm packing L1
Flow rate: 1.0 mL/min
Injection size: 20 µL
System suitability
Sample: *Standard solution*
Suitability requirements
Relative standard deviation: NMT 2.0%
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_{29}H_{53}NO_5$ in the portion of Orlistat taken:

$$\text{Result} = 100(r_U/r_S)(C_S/C_U)$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of USP Orlistat RS in the *Standard solution* (mg/mL)
C_U = concentration of Orlistat in the *Sample solution* (mg/mL)

Acceptance criteria: 98.0%–101.5% on the anhydrous, solvent-free basis

IMPURITIES

Inorganic Impurities

- **RESIDUE ON IGNITION ⟨281⟩:** NMT 0.1%
- **HEAVY METALS,** *Method II* ⟨**231**⟩**:** 20 ppm

Organic Impurities

- **PROCEDURE 1: LIMIT OF ORLISTAT RELATED COMPOUND A**

Standard solution: 0.1 mg/mL of USP Orlistat Related Compound A RS in acetone
Sample solution: 50 mg/mL of Orlistat in acetone
Chromatographic system
(See *Chromatography* ⟨621⟩*, Thin-Layer Chromatography*.)
Mode: TLC
Adsorbent: 0.25-mm layer of chromatographic silica gel mixture
Application volume: 10 µL
Developing solvent system: Toluene and ethyl acetate (4:1)
Detection solution: Transfer 2.5 g of phosphomolybdic acid and 1 g of cerric sulfate into a 100-mL volumetric flask, dissolve in and dilute with methanol to volume.
Analysis
Samples: *Standard solution* and *Sample solution*
Remove the plate, and air-dry it thoroughly. Spray the dried plate with *Detection solution*, and place the plate in an oven at 120° for 30 min.
Acceptance criteria: Any secondary spot from the *Sample solution* corresponding to orlistat related compound A is not more intense than the corresponding spot from the *Standard solution* (0.2%).

- **PROCEDURE 2: LIMIT OF ORLISTAT RELATED COMPOUND B**

Standard solution: 0.025 mg/mL of USP Orlistat Related Compound B RS in methylene chloride
Sample solution: 50 mg/mL of Orlistat in methylene chloride
Spiked sample solution: 50 mg/mL of Orlistat in *Standard solution*
Chromatographic system
(See *Chromatography* ⟨621⟩*, System Suitability*.)
Mode: GC
Detector: Flame ionization
Column: 0.32-mm x 30-m fused silica column coated with a 0.25-µm G27 stationary phase
Column temperature: See the temperature program table below.

Initial Temperature (°)	Temperature Ramp (°/min)	Final Temperature (°)	Hold Time at Final Temperature (min)
50	4	170	—
170	30	300	30

Injector temperature: 270°
Detector temperature: 280°
Carrier gas: Helium
Flow rate: 30 mL/min
Split ratio: 10:1
Injection size: 2 µL
System suitability
Sample: *Standard solution*
Suitability requirements
Relative standard deviation: NMT 10.0%
Analysis
Samples: *Sample solution* and *Spiked sample solution*
Calculate the percentage of orlistat related compound B in the portion of Orlistat taken:

$$\text{Result} = 100(r_U/(r_{SP} - r_U))(C_S/C_T)$$

r_U = peak response of orlistat related compound B from the *Sample solution*
r_{SP} = peak response of orlistat related compound B from the *Spiked sample solution*
C_S = concentration of USP Orlistat Related Compound B RS in the *Standard solution* (mg/mL)
C_T = concentration of Orlistat in the *Spiked sample solution* (mg/mL)

Acceptance criteria: NMT 0.05% of orlistat related compound B is found.

- **PROCEDURE 3**

[NOTE—Avoid the use of plastic flasks for the preparation or containment of any solution in this analysis.]
Mobile phase, Standard solution, Sample solution, and **Chromatographic system:** Proceed as directed in the *Assay*.
System suitability solution: 10 µg/mL of USP Orlistat RS, 0.1 µg/mL of USP Orlistat Related Compound C RS, and 0.25 µg/mL of USP Orlistat Related Compound D RS in *Mobile phase*
Chromatographic system
(See *Chromatography* ⟨621⟩*, System Suitability*.)
Proceed as directed in the *Assay* except to chromatograph the *System suitability solution*.
System suitability
Sample: *System suitability solution*
Suitability requirements
Signal-to-noise ratio: NLT 3 for the orlistat related compound C and orlistat related compound D peaks
Relative standard deviation: NMT 10.0% for the orlistat peak
Analysis
Samples: *Sample solution* and *Standard solution*
Calculate the percentage of each impurity in the portion of Orlistat taken:

$$\text{Result} = 100(r_U/(r_S)(C_S/C_U)(1/F)$$

r_U = peak response for each individual impurity from the *Sample solution*
r_S = peak response of USP Orlistat RS from the *Standard solution*
C_S = concentration of USP Orlistat RS in the *Standard solution* (mg/mL)
C_U = concentration of Orlistat in the *Sample solution* (mg/mL)
F = relative response factor as given in *Impurity Table 1*

Acceptance criteria: See *Impurity Table 1*.

Impurity Table 1

Name	Relative Retention Time	Relative Response Factor	Acceptance Criteria, NMT (%)
Formylleucine[a]	0.10	4.0	0.2
Orlistat related compound C	0.13	33	0.05
Orlistat open ring epimer[b]	0.44	1.0	0.2

- **PROCEDURE 4: LIMIT OF ORLISTAT RELATED COMPOUND D**

Mobile phase: Methanol and water (83:17)
System suitability solution: 4 mg/mL of USP Orlistat RS and 2.4 µg/mL of USP Orlistat Related Compound D RS in acetonitrile, respectively
Standard solution: 5.0 mg/mL of USP Orlistat RS in acetonitrile
Sample solution: 5.0 mg/mL of Orlistat in acetonitrile
Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: 205 nm
Column: 4.0-mm × 25-cm column; 5-µm packing L7
Flow rate: 0.6 mL/min
Injection size: 20 µL
System suitability
Sample: *System suitability solution*
Suitability requirements
Signal-to-noise ratio: NLT 3 for the orlistat related compound D peak
Relative standard deviation: NMT 10.0% for the orlistat peak
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of each impurity in the portion of Orlistat taken:

$$\text{Result} = 100(r_U/(r_S)(C_S/C_U)(1/F)$$

r_U = peak response for each individual impurity from the *Sample solution*
r_S = peak response for USP Orlistat RS from the *Standard solution*
C_S = concentration of USP Orlistat RS in the *Standard solution* (µg/mL)
C_U = concentration of Orlistat in the *Sample solution* (µg/mL)
F = relative response factor as obtained in *Impurity Table 2*

Acceptance criteria: See *Impurity Table 2*.

Impurity Table 2

Name	Relative Retention Time	Relative Response Factor	Acceptance Criteria, NMT (%)
Orlistat related compound D	0.94	1.0	0.2
Orlistat	1.00	—	—
Orlistat open ring amide[e]	1.25	4.3	0.1

[e]*N*-Formyl-L-leucine (*S*)-1-[(2*S*,3*S*)-2-hydroxy-3-[1-phenyl-*R*-ethyl-carbomoyl]nonyl]-dodecyl ester.

- **PROCEDURE 5: LIMIT OF ORLISTAT RELATED COMPOUND E**

Solution A: Transfer 4.1 g of sodium acetate trihydrate and 40 mg of ethylenediaminetetraacetic acid (EDTA) into a 1-L volumetric flask, dissolve in 950 mL of water, and adjust the pH to 7.2 with 0.1 N sodium hydroxide. Dilute with water to volume, add 2.5 mL of tetrahydrofuran, and mix. Filter and degas.
Solution B: Transfer 2.7 g of sodium acetate trihydrate and 40 mg of EDTA into a 1-L volumetric flask, dissolve in 200 mL of water, and adjust the pH to 7.2 with 0.1 N sodium hydroxide. Add 800 mL of acetonitrile, filter, and degas.
Mobile phase: See the gradient table below.

Time (min)	Solution A (%)	Solution B (%)
0	96.7	3.3
20	60	40
24	0	100
38	96.7	3.3
45	96.7	3.3

Standard stock solution: Prepare a 2.6 µg/mL solution by dissolving a weighed amount of USP Orlistat Related Compound E RS into a suitable volumetric flask, using a volume of 4 N sodium hydroxide equal to 10% of the volume of the flask. Dilute with water to volume, and mix.
Standard solution: 0.13 µg/mL of USP Orlistat Related Compound E RS in water from *Standard stock solution*
Sample solution: Transfer a weighed quantity of about 50 mg of Orlistat into a 20-mL head-space vial, add 20 mL of 4 N sodium hydroxide, and close the vial. Heat the vial to 100° for 1 h. Allow the solution to cool slowly at room temperature. Transfer 2 mL of the resulting solution into a 50-mL volumetric flask, and dilute with water to volume.
Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: Fluorescence 340 nm (excitation); 450 nm (emission)
Column: 2.1-mm × 20-cm column; packing L1 and 2.1-mm × 2-cm guard column; 50-µm packing L1
Flow rate: 0.5 mL/min
Injection size: 20 µL
System suitability
Sample: *Standard solution*
Suitability requirements
Relative standard deviation: NMT 6.0% for the orlistat peak
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of this impurity in the portion of Orlistat taken:

$$\text{Result} = 100(r_U/(r_S)(C_S/C_U)$$

r_U = peak response for orlistat related compound E in the *Sample solution*
r_S = peak response for USP Orlistat Related Compound E RS in the *Standard solution*

In-Process Revision

C_S = concentration of USP Orlistat Related Compound E RS in the *Standard solution* (mg/mL)
C_U = concentration of Orlistat in the *Sample solution* (mg/mL)

Acceptance criteria
Individual impurity: NMT 0.2% of orlistat related compound E is found.
Total impurities: NMT 1.0% of total impurities is found, the results for *Procedures 1, 2, 3, 4,* and *5* being added.

SPECIFIC TESTS
- **OPTICAL ROTATION,** *Specific Rotation* ⟨**781**⟩**:** Between –48.0° and –51.0°, at 20°
- **WATER DETERMINATION,** *Method Ic* ⟨**921**⟩**:** NMT 0.2%

ADDITIONAL REQUIREMENTS

BRIEFING

Orlistat Capsules. The previous proposal for this *USP* dosage form monograph (see page 1739 of *PF* 32(6) [Nov.–Dec. 2007]) is being canceled, and the monograph is being republished in the new Monograph Redesign format. The liquid chromatographic procedures in the *Assay* and in the tests for *Dissolution* and *Organic Impurities* are based on analyses performed with the Nova-Pak C18 brand of L1 packing. The typical retention time for orlistat is about 10.2 min.

(MD-CCA: C. Anthony, BPC: M. Marques.) RTS—C44029

Add the following:

■Orlistat Capsules

DEFINITION
Orlistat Capsules contains NLT 90.0% and NMT 110.0% of the labeled amount of orlistat ($C_{29}H_{53}NO_5$).

IDENTIFICATION
- The retention time of the major peak from the *Sample solution* corresponds to that from the *Standard solution,* as obtained in the *Assay.*

ASSAY
- **PROCEDURE**
  Mobile phase: Acetonitrile, water, and phosphoric acid (860:140:0.05)
  Standard solution: 0.6 mg/mL of USP Orlistat RS in *Mobile phase*
  Sample solution: Transfer the contents of not fewer than 10 Capsules into a suitable container, weigh, and mix. Transfer an accurately weighed portion of the powder, equivalent to 120 mg of orlistat into a 200-mL volumetric flask. Add 140 mL of *Mobile phase*, and sonicate for 1 min. Shake the resulting solution mechanically for 15 min, and dilute with *Mobile phase* to volume. Pass a portion of this solution through a filter having a 0.45-µm or finer porosity, discarding the first few mL of filtrate.
  Chromatographic system
  (See *Chromatography* ⟨621⟩*, System Suitability.*)
  Mode: LC
  Detector: 195-nm
  Column: 3.9-mm × 15-cm column; packing L1
  Flow rate: 1.0 mL/min
  Injection size: 20 µL
  System suitability
  Sample: *Standard solution*
  System suitability requirements
  Relative standard deviation: NMT 2.0%
  Analysis
  Samples: *Standard solution* and *Sample solution*
  Calculate the percentage of $C_{29}H_{53}NO_5$ in the portion of Capsules taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of USP Orlistat RS in the *Standard solution* (mg/mL)
C_U = concentration of orlistat in the *Sample solution* (mg/mL)

Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS
- **DISSOLUTION** ⟨**711**⟩
  Medium: 3% sodium lauryl sulfate and 0.5% sodium chloride in water. To each 10 L of media, add 1–2 drops of *n*-octanol, and adjust with phosphoric acid to a pH of 6.0; 900 mL.
  Apparatus: 75 rpm, with coil wire sinker
  Time: 45 min
  Mobile phase: Proceed as directed in the *Assay*.
  Standard solution: Transfer about 13 mg of USP Orlistat RS to a 100-mL volumetric flask, dissolve in 2 mL of acetonitrile, and dilute with *Medium* to volume.
  Sample solution: Pass a portion of the solution under test through a suitable 0.2-µm filter.
  Chromatographic system
  (See *Chromatography* ⟨621⟩*, System Suitability.*)
  Mode, detector, and **column:** Proceed as directed in the *Assay*.
  Flow rate: 2.0 mL/min
  Injection size: 50 µL
  System suitability
  Sample: *Standard solution*
  System suitability requirements
  Relative standard deviation: NMT 2.0%
  Calculate the percentage of $C_{29}H_{53}NO_5$ dissolved:

$$\text{Result} = (r_U/r_S) \times (C_S/L) \times V \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of the *Standard solution* (mg/mL)
L = capsule label claim (mg)
V = volume of *Medium*, 900 mL

Tolerances: NLT 75% of the labeled amount of orlistat is dissolved.
- **UNIFORMITY OF DOSAGE UNITS** ⟨**905**⟩**:** Meet the requirements

IMPURITIES
Organic Impurities
- **PROCEDURE**
  Mobile phase: Proceed as directed in the *Assay*.
  Standard solution: Proceed as directed for *Standard solution* in the *Assay.*
  Sample solution: Proceed as directed for *Sample solution* in the *Assay.*
  System suitability solution: Transfer 0.025 mg/mL of USP Orlistat Related Compound D RS in *Mobile phase.* Transfer 1 mL of this solution to a 50-mL volumetric flask, and dilute with *Standard solution* to volume.
  Chromatographic system
  (See *Chromatography* ⟨621⟩*, System Suitability.*)

In-Process Revision

System suitability
Sample: *System suitability solution*
System suitability requirements
Resolution: NLT 1.4 between USP Orlistat RS and USP Orlistat Related Compound D RS
Relative standard deviation: NMT 2.0% for the orlistat peak
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of each impurity in the portion of Capsules taken:

$$\text{Result} = (r_U/(r_S) \times (C_S/C_U) \times (1/F) \times 100$$

r_U = peak response for the individual impurity in the *Sample solution*
r_S = peak response for orlistat in the *Standard solution*
C_S = concentration of USP Orlistat RS in the *Standard solution* (mg/mL)
C_U = concentration of orlistat in the *Sample solution* (mg/mL)
F = the relative response factor (see *Impurity Table 1* for values)

Acceptance criteria: See *Impurity Table 1*.
The limits of impurities are specified in the table below.

Impurity Table 1

Name	Relative Retention Time	Relative Response Factor	Acceptance Criteria, NMT (%)
Orlistat open-ring epimer[a]	0.45	1.0	1.5
Orlistat open ring[b]	0.5	1.0	0.3
Orlistat related compound D	0.9	1.0	1.0
Orlistat	1.0	—	—

BRIEFING

Oxazepam Capsules, *USP 32* page 3154. As part of *USP* monograph modernization efforts, it is proposed to replace the UV-based *Assay* with a stability-indicating HPLC-based method. A test for *Organic Impurities* is also introduced. The proposed HPLC method for the *Assay* and the test for *Organic Impurities* is based on analyses performed with a Zorbax SB-C18 brand of L1 column. The retention time of the oxazepam peak is 6 min.

(MD-PP: H. Ramanathan, R. Ravichandran.) RTS—C53348

Oxazepam Capsules

DEFINITION
Oxazepam Capsules contain NLT 90.0% and NMT 110.0% of the labeled amount of $C_{15}H_{11}ClN_2O_2$.

IDENTIFICATION
- The solution prepared for measurement of absorbance in the *Assay* exhibits a maximum at 229 ± 2 nm.

ASSAY

Delete the following:

■• ~~**PROCEDURE**~~
~~**Standard solution:** 4 µg/mL USP Oxazepam RS in alcohol~~
~~**Sample solution:** Remove, as completely as possible, the contents of NLT 20 Capsules, and weigh. Transfer a portion of the mixed powder, nominally equivalent to 50 mg of oxazepam, to a medium-porosity, sintered-glass funnel that is fitted into a small suction flask. Add 25 mL of alcohol, mix with the aid of a stirring rod, and after about 5 min apply gentle suction to remove the extract. Repeat the extraction with four additional 25-mL portions of alcohol, transfer the extracts to a 250-mL volumetric flask, and dilute with alcohol to volume. Transfer 2.0 mL of this solution to a 100-mL volumetric flask, and dilute with alcohol to volume.~~
~~**Spectrometric conditions**~~
~~**Detector:** UV 229 nm~~
~~**Cell:** 1 cm~~
~~**Blank:** Alcohol~~
~~**Analysis**~~
~~**Samples:** *Standard solution* and *Sample solution*~~
~~Calculate the percentage of $C_{15}H_{11}ClN_2O_2$ in the portion of Capsules taken:~~

~~$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times 100$$~~

~~A_U = absorbance of the solution from the Capsules~~
~~A_S = absorbance of the solution from the *Standard solution*~~
~~C_S = concentration of the *Standard solution* (µg/mL)~~
~~C_U = concentration of the *Sample solution* (µg/mL)~~
~~**Acceptance criteria:** 90.0%–110.0%~~■2S (*USP33*)

Add the following:

■• **PROCEDURE**
Diluent: Methanol and water (9:1)
Buffer: 8.5 g/L potassium phosphate, monobasic in water. Adjust with 1 N sodium hydroxide to a pH of 6.5.
Mobile phase: Methanol and *Buffer* (3:2)
Standard solution: 0.1 mg/mL of USP Oxazepam RS in *Diluent*
Sample solution: 0.1 mg/mL of oxazepam in *Diluent*, from contents of NLT 20 capsules. [NOTE—Sonicate for 15 min and shake for 15 min. Pass through a 0.45–µm filter.]

USP Oxazepam RS

BRIEFING

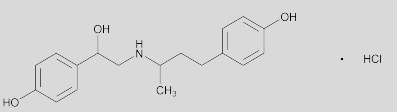
Ractopamine Hydrochloride Suspension. Because there is no *USP* monograph for this drug substance, a new monograph, based on validated methods of analysis, is being proposed. The liquid chromatographic procedures in the *Assay* are based on analyses performed with a Supecosil LC 18-DB brand of L1 column. The typical retention time for ractopamine is about 13 min. The liquid chromatographic procedures in the test for *Organic Impurities* are based on analyses performed with a Supecosil LC 18-DB brand of L1 column. The typical retention time for ractopamine is about 19 min. The liquid chromatographic procedures in the test for *Diastereomer Ratio* are based on analyses performed with a Jones Apex ODS brand of L1 column. Typical retention times for the *RS,SR* diastereoisomer and the *RR,SS* diastereoisomer are about 20 and 21 min, respectively.

(VET: E. Gonikberg.) RTS—C62987

In-Process Revision

Add the following:

▪Ractopamine Hydrochloride Suspension



$C_{18}H_{23}NO_3 \cdot HCl$ 337.84

Benzenemethanol, 4-hydroxy-α-[[[3-(4-hydroxyphenyl)-1-methylpropyl]amino]methyl]-, hydrochloride;
(±)-all-*rac*-*p*-Hydroxy-α-[[[3-(*p*-hydroxyphenyl)-1-methylpropyl]amino]methyl]benzyl alcohol, hydrochloride [90274-24-1].

DEFINITION

Ractopamine Hydrochloride Suspension contains NLT 10% and NMT 20%, by weight, of ractopamine hydrochloride ($C_{18}H_{23}NO_3 \cdot HCl$) in water. [NOTE—The material partially precipitates out at room temperature to form a slurry, and redissolves to form a clear solution when heated to 50°–60°.]

IDENTIFICATION

• **INFRARED ABSORPTION ⟨197K⟩**

Sample: Dry a portion of Ractopamine Hydrochloride Suspension under vacuum for 3 h at 60°.

ASSAY

• **Procedure**

Solution A: 5.75 mg/mL solution of monobasic ammonium phosphate adjusted to a pH of 4.0 ± 0.1 with 10% phosphoric acid

Solution B: 1.1 mg/mL solution of 1-heptanesulfonic acid sodium salt in *Solution A*

Mobile phase: Stabilizer-free tetrahydrofuran and *Solution B* (3:17)

Diluent: Stabilizer-free tetrahydrofuran and water (3:17).

[NOTE—The *Standard solutions* and *System suitability solution* are stable for up to 72 h at room temperature. The *Sample solution* is stable for up to 90 h at room temperature.]

System suitability solution: 100 µg/mL of USP Ractopamine Hydrochloride RS and 10 µg/mL of USP Raspberry Alcohol RS in *Diluent*

Standard solution A: 0.08 mg/mL of USP Ractopamine Hydrochloride RS in *Diluent*

Standard solution B: 0.1mg/mL of USP Ractopamine Hydrochloride RS in *Diluent*

Standard solution C: 0.12 mg/mL of USP Ractopamine Hydrochloride RS in *Diluent*

Sample stock solution: Stir Ractopamine Hydrochloride Suspension in a 50°–60° water bath for up to 1 h, to ensure complete dissolution. While hot, transfer 700 mg of the Ractopamine Hydrochloride Suspension dropwise to a 100-mL volumetric flask, and dilute with *Diluent* to volume.

Sample solution: Dilute a portion of the *Sample stock solution* with *Diluent* (1:10).

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*).

Mode: LC

Detector: UV 226 nm

Column: 4.6-mm × 15-cm; 5-µm packing L1

Flow rate: 1 mL/min

Injection size: 20 µL

System suitability

Samples: *System suitability solution* and *Standard solution B*

Suitability requirements

Resolution: NLT 1.5 between raspberry alcohol and ractopamine, *System suitability solution*

Tailing factor: NLT 0.7 and NMT 2.0, for the ractopamine peak, *Standard solution B*

Relative standard deviation: NMT 2.0%, three replicate injections, *Standard solution B*

Analysis

Samples: *Standard solutions* and *Sample solution*

Prepare a calibration curve using the three ractopamine peak responses from *Standard solutions A, B,* and *C* and their corresponding concentrations. From the graph so obtained determine the concentration, C, in mg/mL, of ractopamine hydrochloride in the *Sample solution*.

Calculate the percentage (w/w) of $C_{18}H_{23}NO_3 \cdot HCl$ in the portion of Ractopamine Hydrochloride Suspension taken :

$$\text{Result} = (V/W) \times C \times D \times 100$$

V = volume of the *Sample stock solution*, 100 mL
W = weight of Ractopamine Hydrochloride Suspension taken (mg)
C = as determined above
D = dilution factor to prepare the *Sample solution*, 10

Acceptance criteria: 10%–20% of $C_{18}H_{23}NO_3 \cdot HCl$

IMPURITIES

Organic Impurities

• **PROCEDURE**

Solution A: 5.75 mg/mL of monobasic ammonium phosphate in water; pH NLT 4.4

Solution B: 1.1 mg/mL of 1-heptanesulfonic acid sodium salt in *Solution A*

Solution C: Acetonitrile and *Solution B* (1:9)

Solution D: Acetonitrile and *Solution B* (17:33)

Mobile phase: See the gradient table below.

Time (min)	Solution C (%)	Solution D (%)
0	100	0
22	0	100
32	0	100
37	100	0
55	100	0

Diluent: Acetonitrile and water (1:4)

System suitability solution: 9 µg/mL each of USP Raspberry Ketone RS and USP Ractopamine Hydrochloride RS in *Diluent*

Blank: *Diluent*

Sample solution A: Stir Ractopamine Hydrochloride Suspension in a 50°–60° water bath for up to 1 h, to ensure complete dissolution. While hot, transfer 200 mg of the Ractopamine Hydrochloride Suspension dropwise into a 50-mL volumetric flask, and dilute with *Diluent* to volume.

Sample solution B: Dilute a portion of *Sample solution A* with *Diluent* (1:100).

[NOTE—The *Sample solutions* are stable for up to 48 h if stored at 5°.]

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

Mode: LC

Detector: UV 226 nm

Column: 4.6-mm × 25-cm; 5-µm packing L1

Flow rate: 1 mL/min

Injection size: 20 µL

System suitability

Sample: *System suitability solution*

Suitability requirements

Resolution: NLT 2.0 between raspberry ketone and ractopamine

Analysis

Samples: *Blank*, *Sample solution A*, and *Sample solution B*

[NOTE—Disregard any peaks that correspond to those in the *Blank*. Correct the response of the ractopamine peak in *Sample solution B* by subtracting the peak response at the retention time of ractopamine in the *Blank*.]

Calculate the percentage of each individual impurity in the portion of Ractopamine Hydrochloride Suspension taken:

$$\text{Result} = (r_A/r_B) \times 100/D$$

In-Process Revision

r_A = peak response of each individual impurity from *Sample solution A*
r_B = corrected response for the ractopamine peak from *Sample solution B*
D = dilution factor to prepare *Sample solution B,* 100

SPECIFIC TESTS
- **DIASTEREOMER RATIO**

Solution A: 5.75 mg/mL of monobasic ammonium phosphate in water
Solution B: Add 10 mL of triethylamine to 950 mL of *Solution A,* and adjust with phosphoric acid to a pH of 4.5.
Mobile phase: Acetonitrile and *Solution B* (3:22)
Diluent: Acetonitrile and *Solution A* (1:4)
System suitability solution: 0.4 mg/mL of USP Ractopamine Hydrochloride RS in *Diluent*
Sample solution: Stir Ractopamine Hydrochloride Suspension in a 50°–60° water bath for up to 1 h to ensure complete dissolution. While hot, transfer 275 mg of it dropwise into a 100-mL volumetric flask, and dilute with *Diluent* to volume. [NOTE—The *Sample solution* is stable for up to 36 h when stored at ambient conditions.]
Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 226 nm
Column: 4.6-mm × 25-cm; 5-µm packing L1
Flow rate: 1 mL/min
Injection size: 20 µL
System suitability
Sample: *System suitability solution*
[NOTE—The elution order is *RS,SR* diastereoisomer followed by *RR,SS* diastereoisomer.]
Suitability requirements
Resolution: NLT 1.25 between the diastereomers
Analysis
Sample: *Sample solution*
Calculate the *RS,SR* diastereomer content, in percentage:

$$\text{Result} = r_A/(r_A + r_B) \times 100$$

r_A = peak area response of the *RS,SR* diastereoisomer from the *Sample solution*
r_B = peak area response of the *RR,SS* diastereoisomer from the *Sample solution*

Acceptance criteria: 45%–49%

ADDITIONAL REQUIREMENTS
- **PACKAGING AND STORAGE:** Store at a temperature not exceeding 70°.
- **LABELING:** Label it to indicate that it is for veterinary use only.
- **USP REFERENCE STANDARDS** ⟨11⟩
USP Ractopamine Hydrochloride RS
USP Raspberry Alcohol RS
USP Raspberry Ketone RS■2S *(USP33)*

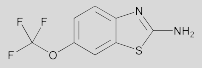
BRIEFING

Riluzole. Because there is no existing *USP* monograph for this drug substance, a new monograph is being proposed. The liquid chromatographic procedures in the *Assay* and the test for *Organic Impurities* were validated with a Waters Symmetry brand of L1 column, in which riluzole elutes at about 3 min.

(MD-PP: D. Vicchio, R. Ravichandran.) RTS—C61270

Add the following:

■Riluzole



$C_8H_5F_3N_2OS$ 234.20
2-Benzothiazolamine, 6-(trifluoromethoxy)-;
2-Amino-6-(trifluoromethoxy)benzothiazole [1744-22-5].

DEFINITION
Riluzole contains NLT 98.0% and NMT 102.0% of the labeled amount of $C_8H_5F_3N_2OS$, calculated on the anhydrous basis.

IDENTIFICATION
- **A. INFRARED ABSORPTION** ⟨197K⟩
- **B:** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

USP Riluzole Related Compound A RS■2S *(USP33)*

BRIEFING

Sodium Fluoride Gel. Because there is no existing *USP* monograph for this dosage form, a new monograph is being proposed.

(MD-GRE: E. Gonikberg.) RTS—C70458

Add the following:

■Sodium Fluoride Gel

DEFINITION

Sodium Fluoride Gel contains NLT 90.0% and NMT 110.0% of the labeled amount of NaF, in an aqueous medium containing a suitable viscosity-inducing agent. It may contain a suitable buffering agent.

IDENTIFICATION

• **PROCEDURE**

Sample solution: Amount of Gel, equivalent to 500 mg of fluoride ion

Analysis: Place the *Sample solution* in a platinum crucible in a well-ventilated hood, and add 15 mL of sulfuric acid. Cover the crucible with a piece of clear, polished glass, and heat on a steam bath for 1 h. Remove the glass cover, rinse it in water, and dry.

Acceptance criteria: The glass surface exposed to vapors from the crucible is etched.

In-Process Revision

ASSAY

- **PROCEDURE**

[NOTE—Store all solutions, except the *Buffer*, in plastic containers.]

Buffer: Dissolve 57 mL of glacial acetic acid, 58 g of sodium chloride, and 4 g of (1,2-cyclohexylenedinitrilo)tetraacetic acid in 500 mL of water. Adjust with 5 N sodium hydroxide to a pH of 5.25 ± 0.25, and dilute with water to 1000 mL.

Standard solution A: 420 µg/mL of USP Sodium Fluoride RS, equivalent to 190 µg/mL of fluoride ion (10^{-2} M)

Standard solution B: 19 µg/mL of fluoride ion (10^{-3} M), from *Standard solution A*

Standard solution C: 1.9 µg/mL of fluoride ion (10^{-4} M), from *Standard solution B*

Sample solution: Equivalent to 20 µg/mL of fluoride from the Gel in water

Analysis

Samples: *Standard solution A*, *Standard solution B*, *Standard solution C*, and *Sample solution*

Pipet 20 mL of each *Standard solution* and the *Sample solution* into separate plastic beakers each containing a plastic-coated stirring bar. Pipet 20 mL of *Buffer* into each beaker. Concomitantly measure the potentials (see *pH* ⟨791⟩), in mV, of the solutions from the *Standard solutions* and of the solution from the *Sample solution*, with a pH meter capable of a minimum reproducibility of ±0.2 mV and equipped with a fluoride-specific, ion-indicating electrode and a suitable reference electrode.

[NOTE—When taking measurements, immerse the electrodes in the solution, stir on a magnetic stirrer having an insulated top until equilibrium is attained (1–2 min), and record the potential. Rinse and dry the electrodes between measurements, taking care to avoid damaging the crystal of the specific-ion electrode.]

Plot the logarithms of the fluoride-ion concentrations, in µg/mL, of the diluted *Standard solutions* versus potential, in mV. From the measured potential of the *Sample solution* and the standard response line, determine the concentration, C, in µg/mL, of fluoride ion in the *Sample solution.*

Calculate the quantity, as a percentage of label claim, of fluoride ion in the portion of Gel taken:

$$\text{Result} = (C/C_U) \times 100$$

C = defined above

C_U = nominal concentration of fluoride ion in the *Sample solution* (µg/mL)

Calculate the quantity, as a percentage of label claim, of sodium fluoride in the portion of Gel taken:

$$\text{Result} = (C/C_U) \times (M_r/A_r) \times 100$$

C = defined above

C_U = nominal concentration of sodium fluoride (NaF) in the *Sample solution* (µg/mL)

M_r = molecular weight of sodium fluoride, 41.99

A_r = atomic weight of fluoride, 19.00

Acceptance criteria: 90.0%–110.0%

SPECIFIC TESTS

- **pH ⟨791⟩:** 6.0–8.0

Place about 40 mL in a plastic beaker, and determine the pH using a suitable electrode system.

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in tight, plastic containers.
- **LABELING:** Label the Gel in terms of the content of sodium fluoride (NaF) and in terms of the content of fluoride ion.
- **USP REFERENCE STANDARDS ⟨11⟩**

USP Sodium Fluoride RS■2S *(USP33)*

BRIEFING

Valsartan and Hydrochlorothiazide Tablets, *USP 32* page 3843. On the basis of comments received, it is proposed to revise the calculations in the test for *Organic Impurities* and to clarify that the other impurities are quantitated based on the valsartan peak as per the approved NDA.

(MD-CV: S. Ramakrishna.) RTS—C70461

Valsartan and Hydrochlorothiazide Tablets

DEFINITION

Valsartan and Hydrochlorothiazide Tablets contain NLT 90.0% and NMT 110.0% of the labeled amounts of valsartan ($C_{24}H_{29}N_5O_3$) and hydrochlorothiazide ($C_7H_8ClN_3O_4S_2$).

IDENTIFICATION

- **A. THIN-LAYER CHROMATOGRAPHIC IDENTIFICATION TEST ⟨201⟩**

Sample solution: To an amount of ground Tablets, equivalent in weight to a single Tablet, add 2.0 mL of acetone, sonicate for 15 min, and centrifuge.

Application volume: 2 µL

Developing solvent system: Ethyl acetate, dehydrated alcohol, and 3.6 M of ammonium hydroxide (8:2:1)

Analysis: Proceed as directed in the chapter, except to develop the plate in a paper-lined chromatographic chamber equilibrated with *Developing solvent system* for 15 min before use. Allow the chromatogram to develop until the solvent front has moved at least 7 cm. After removing the plate and marking the solvent front, dry the plate under a current of warm air. The R_F values of the principal spots obtained from the *Sample solution* correspond to those from the *Standard solution*.

- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution,* as obtained in the *Assay.*

ASSAY

- **PROCEDURE**

Diluent: Acetonitrile and water (1:1)

Solution A: Acetonitrile, water, and trifluoroacetic acid (10:90:0.1)

Solution B: Acetonitrile, water, and trifluoroacetic acid (90:10:0.1)

Mobile phase: See the gradient table below.

Time (min)	Solution A (%)	Solution B (%)
0	90	10
25	10	90
27	90	10
40	90	10

Standard solution: Transfer 12.5 mg of USP Hydrochlorothiazide RS to a 200-mL volumetric flask, and add 12.5J mg of USP Valsartan RS, J being the ratio of the labeled amount, in mg, of valsartan to the labeled amount, in mg, of hydrochlorothiazide/Tablet. Add 100 mL of *Diluent*, sonicate for 15 min, dilute with *Diluent* to 250 mL, and mix. Transfer 25.0 mL of this solution to a 50-mL volumetric flask, dilute with *Diluent* to volume, and mix. Dilute with *Diluent* to obtain a solution having a concentration of 0.2 mg/mL of USP Valsartan RS in *Diluent*.

Sample stock solution: To the equivalent of 62.5 mg of hydrochlorothiazide from a number of Tablets add 5 mL of water, and allow to stand for 5 min. Then add 100 mL of *Diluent*, sonicate for 15 min, and shake for 30 min. Dilute with

In-Process Revision

Diluent to 250 mL, and centrifuge a portion of this solution at 3000 rpm. Dilute 25.0 mL of the clear supernatant with *Diluent* to 200.0 mL.
Sample solution: 0.2 mg/mL of valsartan, from *Sample stock solution* in *Diluent*
Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 265 nm
Column: 3.0-mm × 12.5-cm; 5-µm packing L1
Flow rate: 0.4 mL/min
Injection size: 10 µL
System suitability
Sample: *Standard solution*
Suitability requirements
Relative standard deviation: NMT 2.0%
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_{24}H_{29}N_5O_3$ and $C_7H_8ClN_3O_4S_2$ in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response of valsartan or hydrochlorothiazide from the *Sample solution*
r_S = peak response of the appropriate USP Reference Standard from the *Standard solution*
C_S = concentration of the appropriate USP Reference Standard in the *Standard solution* (mg/mL)
C_U = nominal concentration of the corresponding analyte in the *Sample solution* (mg/mL)
Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS

• **Dissolution** ⟨**711**⟩
Medium: pH 6.8 phosphate buffer; 1000 mL
Apparatus 2: 50 rpm
Time: 30 min
Detector: UV
Analytical wavelength: 250 nm for valsartan and 272 nm for hydrochlorothiazide
Sample solutions: Sample per *Dissolution* ⟨711⟩. Dilute with *Medium* to a concentration that is similar to that of the *Standard solution.*
Analysis: Determine the amounts of $C_{24}H_{29}N_5O_3$ and $C_7H_8ClN_3O_4S_2$ dissolved by using UV absorption on portions of the *Sample solution* passed through a 1-µm glass fiber filter, diluted with *Medium* if necessary, using a 0.2-cm quartz cell.
Calculate the amount of $C_{24}H_{29}N_5O_3$ dissolved in percentage:

$$\text{Result} = [(A_{UT2} \times \alpha H_{272}) - (A_{UT1} \times \alpha H_{250})/(\alpha V_{250} \times \alpha H_{272}) - (\alpha V_{272} \times \alpha H_{250})] \times 12{,}500$$

Calculate the amount of $C_7H_8ClN_3O_4S_2$ dissolved in percentage:

$$\text{Result} = [(A_{UT1} \times \alpha V_{250}) - (A_{UT2} \times \alpha V_{272})/(\alpha H_{272} \times \alpha V_{250}) - (\alpha H_{250} \times \alpha V_{272})] \times 80{,}000$$

A_{UT1} = absorbance of the *Sample solution* at 272 nm
αV_{250} = absorptivity (1%, 0.2 cm, 250 nm) of valsartan in *Medium*
A_{UT2} = absorbance of the *Sample solution* at 250 nm
αV_{272} = absorptivity (1%, 0.2 cm, 272 nm) of valsartan in *Medium*
αH_{272} = absorptivity (1%, 0.2 cm, 272 nm) of hydrochlorothiazide in *Medium*
αH_{250} = absorptivity (1%, 0.2 cm, 250 nm) of hydrochlorothiazide in *Medium*
Tolerances: NLT 80% (Q) of the labeled amounts of $C_{24}H_{29}N_5O_3$ and $C_7H_8ClN_3O_4S_2$ is dissolved.

• **Uniformity of Dosage Units** ⟨**905**⟩
Procedure for content uniformity
Diluent, Solution A, Solution B, Mobile phase, Standard solution, and **Chromatographic system:** Proceed as directed in the *Assay*.
Sample solution: Transfer 1 Tablet to a 200-mL volumetric flask, add 5 mL of water, and allow to stand for 5 min. Add 100 mL of *Diluent*, and sonicate for 15 min. Dilute with *Diluent* to 250 mL, mix, and centrifuge a portion of this solution at 3000 rpm. Dilute a volume of the clear supernatant with *Diluent* to obtain a solution having a concentration of 0.2 mg/mL of valsartan.
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_{24}H_{29}N_5O_3$ and $C_7H_8ClN_3O_4S_2$ in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times L$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of the appropriate USP Reference Standard in the *Standard solution* (mg/mL)
C_U = nominal concentration of the corresponding analyte in the *Sample solution* (mg/mL)
L = labeled quantity of the relevant analyte (mg/Tablet)
Acceptance criteria: Meets the requirements

IMPURITIES

■Calculate the percentage of benzothiadiazine related compound A in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

In-Process Revision

r_U = peak response of benzothiadiazine related compound A from the *Sample solution*
r_S = peak response of benzothiadiazine related compound A from the *Standard solution*
C_S = concentration of benzothiadiazine related compound A in the *Standard solution* (mg/mL)
C_U = nominal concentration of hydrochlorothiazide in the *Sample solution* (mg/mL)

Calculate the percentage of each other impurity in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response of each other impurity from the *Sample solution*
r_S = peak response of valsartan from the *Standard solution*
C_S = concentration of valsartan in the *Standard solution* (mg/mL)
C_U = nominal concentration of valsartan (for calculating other impurities) in the *Sample solution* (mg/mL)

■2S (*USP33*)

Acceptance criteria: NMT 1.0% of benzothiadiazine related compound A; NMT 0.2% of any other impurity, excluding valsartan related compound A; NMT 1.3% of total impurities, excluding valsartan related compound A. [NOTE—Valsartan related compound A is the enantiomer of valsartan and coelutes with valsartan in this test.]

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in tight containers, and store at 25°; excursions are permitted between 15° and 30°. Protect from moisture and heat.

BRIEFING

Sterile Water for Inhalation, *USP 32* page 3871 and page 883 of *PF* 35(4) [July–Aug. 2009]. In *Water Conductivity* ⟨645⟩, the name of the section for testing this article has been changed from *Packaged Water* to *Sterile Water*. There is no change to the monograph requirements. For a description of companion changes, see the briefings in the chapters *Water Conductivity* ⟨645⟩ and *Water for Pharmaceutical Purposes* ⟨1231⟩, appearing elsewhere in this issue of *PF*.

(PW: A. Hernandez-Cardoso.) RTS—C76228

Sterile Water for Inhalation

DEFINITION

Change to read:

Sterile Water for Inhalation is prepared from Water for Injection that is sterilized and suitably packaged. It contains no ~~antimicrobial agents, except where used in humidifiers or other similar devices and where liable to contamination over a period of time, or other added substances~~■ added antimicrobial agents.■2S (*USP33*)

[NOTE—Do not use Sterile Water for Inhalation for parenteral administration or for other sterile compendial dosage forms.]

SPECIFIC TESTS

[NOTE—For microbiological guidance, see *Water for Pharmaceutical Purposes* ⟨1231⟩.]

- **OXIDIZABLE SUBSTANCES**
  Sample: 100 mL
  Analysis: Add 10 mL of 2 N sulfuric acid, and heat to boiling. For Sterile Water for Inhalation in containers having a fill volume less than 50 mL, add 0.4 mL of 0.02 M potassium permanganate, and boil for 5 min; where the fill volume is 50 mL or more, add 0.2 mL of 0.02 M potassium permanganate, and boil for 5 min. If a precipitate forms, cool in an ice bath to room temperature, and pass through a sintered-glass filter.
  Acceptance criteria: The pink color does not completely disappear.

Change to read:

- **WATER CONDUCTIVITY,** ~~*Packaged*~~■ *Sterile*■2S (*USP33*) *Water* ⟨**645**⟩**:** Meets the requirements
- **STERILITY TESTS** ⟨**71**⟩**:** Meets the requirements
- **BACTERIAL ENDOTOXINS TEST** ⟨**85**⟩**:** Less than 0.5 USP Endotoxin Unit/mL

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in glass or plastic containers. Glass containers are preferably of Type I or Type II glass.
- **LABELING:** Label it to indicate that it is for inhalation therapy only and that it is not for parenteral administration.
- **USP REFERENCE STANDARDS** ⟨**11**⟩
  USP Endotoxin RS

BRIEFING

Sterile Water for Injection, *USP 32* page 3871, and page 803 of *PF* 31(3) [May–June 2005]. - **PACKAGING AND STORAGE:** Preserve in suitable tight containers.
- **LABELING:** Label it to indicate the method for preparation, and to indicate that it is not for parenteral administration.

BRIEFING

Zidovudine Oral Solution, *USP 32* page 3890. It is proposed to use a flexible monograph approach to indicate that manufacturers may perform either *Organic Impurities, Procedure 1* or *Procedure 2*, based on labeling instructions and the impurity profile. The HPLC procedure in *Organic Impurities, Procedure 2* is based on analysis performed with a Hypersil BDS 3-µm brand of L1 column. Two reference standards are added as required to perform *Organic Impurities, Procedure 2*. The typical retention time for zidovudine is 21.6 min. Additionally, it is proposed to omit *Identification* test *A* from the monograph because the procedure was not orthogonal to *Identification* test *B*. An editorial change is proposed for the remaining *Identification* test to provide clarity.

(MD-AA: L. Santos, B. Davani.) RTS—C45529

Zidovudine Oral Solution

DEFINITION
Zidovudine Oral Solution contains NLT 90.0% and NMT 110.0% of the labeled amount of zidovudine ($C_{10}H_{13}N_5O_4$).

DIETARY SUPPLEMENTS—MONOGRAPHS

BRIEFING

Andrographis; Powdered Andrographis; Powdered Andrographis Extract. *USP* Dietary Supplement monographs are being proposed. The liquid chromatographic procedure in the test for *Content of Diterpene Lactones* is based on analyses performed with the LiChrosphere or Luna C18(2) brand of L1 column, with 5-µm packing. The typical retention times for andrographolide, neoandrographolide, 14-deoxy-11,12-didehydroandrographolide, and andrograpanin are about 14.3, 17.2, 19.5, and 23.1 min, respectively.

(DSB: M. Sharaf.) RTS—C66623

Add the following:

▪Andrographis

DEFINITION

Andrographis consists of the dried stems and leaves of *Andrographis paniculata* Nees. (Fam. Acanthaceae). It contains NLT 1.0% of diterpene lactones, calculated on the dried basis as the sum of andrographolide, neoandrographolide, 14-deoxy-11,12-didehydroandrographolide and andrograpanin.

IDENTIFICATION

• **A. THIN-LAYER CHROMATOGRAPHIC IDENTIFICATION TEST ⟨201⟩**

Standard solution 1: Use *Standard solution A*, prepared as directed in the test for *Content of Diterpene Lactones*.

Standard solution 2: Sonicate an amount of USP Powdered Andrographis Extract RS, equivalent to about 15 mg of diterpene lactones, for 10–15 min in 25 mL of methanol, centrifuge, and use the supernatant.

Sample solution: Use *Sample stock solution*, prepared as directed in the test for *Content of Diterpene Lactones*.

Adsorbent: Chromatographic silica gel mixture with an average particle size of 10–15 µm (TLC plates)

Application volume: 10 µL, as 5–10 mm bands

Developing solvent system: Chloroform, acetone, and toluene (2:2:1)

Spray reagent: A mixture of 1% vanillin in alcohol and 10% sulfuric acid in alcohol (1:1)

Analysis

Samples: *Standard solution 1*, *Standard solution 2* and *Sample solution*

Use a saturated chamber. Develop the chromatograms until the solvent front has moved about 90% of the length of the plate. Remove the plate from the chamber, dry, spray with the *Spray reagent*, heat for 5–10 min at 100°, and examine under visible light.

Acceptance criteria: The *Sample solution* exhibits three main grayish blue zones with R_F values of approximately 0.4, 0.6, and 0.8 that correspond in position and color to zones in *Standard solution 2*. *Standard solution 1* exhibits a grayish blue zone due to andrographolide at an R_F of about 0.4. The *Sample solution* exhibits a zone similar in color and R_F value to that due to andrographolide in *Standard solution 1*.

• **B.** The retention time of the main peak of the *Sample solution* obtained in the test for *Content of Diterpene Lactones* corresponds to that of andrographolide in *Standard solution A*. Identify other diterpene lactone peaks in the *Sample solution* by comparison with *Standard solution B* and the reference chromatogram provided with the lot of USP Powdered Andrographis Extract RS. *Sample solution* shows additional peaks corresponding to neoandrographolide, 14-deoxy-11,12-didehydroandrographolide, and andrograpanin.

COMPOSITION

• **CONTENT OF DITERPENE LACTONES**

Solution A: Dissolve 0.14 g of potassium dihydrogen phosphate in 900 mL of water, add 0.5 mL of phosphoric acid, dilute with water to 1000 mL, mix, filter, and degas.

Solution B: Use filtered and degassed acetonitrile.

Standard solution A: Dissolve a weighed quantity of USP Andrographolide RS in methanol to obtain a solution having a known concentration of about 1.0 mg/mL. Transfer 5.0 mL of this solution to a 10-mL volumetric flask, dilute with acetonitrile to volume, and mix.

Standard solution B: Transfer an amount of USP Powdered Andrographis Extract RS, equivalent to about 25 mg of diterpene lactones, to a 50-mL volumetric flask, add 25 mL of methanol, heat gently for 15–20 min, dilute with acetonitrile to volume, and mix. Before injection, pass through a membrane filter having a 0.45-µm or finer porosity, discarding the first 5 mL of the filtrate.

Sample stock solution: Transfer about 2.0 g of finely powdered Andrographis to a 250-mL flask fitted with a reflux condenser. Add 50 mL of methanol, reflux on a water bath for 15 min, cool to room temperature, and decant the supernatant. Repeat until the last extract is colorless. Combine the extracts, filter, concentrate under vacuum, and adjust the volume to 50.0 mL using methanol.

Sample solution: Transfer 25.0 mL of *Sample stock solution* to a 50-mL volumetric flask, dilute with acetonitrile to volume, and mix. Before injection, pass through a membrane filter having a 0.45-µm or finer porosity, discarding the first 5 mL of the filtrate.

Mobile phase: See the gradient table below.

Time (min)	Solution A (%)	Solution B (%)
0	95	5
18	55	45
25	20	80
28	20	80
35	55	45

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

Mode: LC

Detector: UV 223 nm

Column: 4.6-mm × 25-cm; 5-µm packing L1

Flow rate: 1.5 mL/min

Injection size: 20 µL

System suitability

Samples: *Standard solution A* and *Standard solution B*

Suitability requirements

[NOTE—The chromatogram from *Standard solution B* is similar to the Reference chromatogram provided with the lot of USP Powdered Andrographis Extract RS.]

Column efficiency: NLT 5000 theoretical plates, *Standard solution A*

Tailing factor: NMT 1.5 for the andrographolide peak, *Standard solution A*

Relative standard deviation: NMT 2.0%, determined from the andrographolide peak for replicate injections, *Standard solution A*

In-Process Revision

Resolution: NLT 5 between neoandrographolide and 14-deoxy-11,12-didehydroandrographolide peaks, *Standard solution B*

Analysis

Samples: *Standard solution A*, *Standard solution B*, and *Sample solution*

Using the chromatogram of *Standard solution A*, *Standard solution B*, and the reference chromatogram provided with the lot of USP Powdered Andrographis Extract RS, identify the retention times of the peaks corresponding to the different diterpene lactones. The approximate relative retention times of the different diterpene lactones are provided in the following table:

Analyte	Relative Retention Time
Andrographolide	1.00
Neoandrographolide	1.16
14-Deoxy-11,12-didehydroandrographolide	1.31
Andrograpanin	1.50

Separately calculate the percentages of andrographolide, neoandrographolide, 14-deoxy-11,12-didehydroandrographolide, and andrograpanin in the portion of Andrographis taken:

$$\text{Result} = (C_S/W) \times (r_U/r_S) \times 10F$$

C_S = concentration of USP Andrographolide RS in *Standard solution A* (mg/mL)

W = weight of Andrographis taken to prepare the *Sample solution* (g)

r_U = peak response for each diterpene lactone from the *Sample solution*

r_S = peak response for andrographolide from *Standard solution A*

F = conversion factor for each analyte (1.00 for andrographolide, 3.90 for neoandrographolide, 1.45 for 14-deoxy-11,12-didehydroandrographolide, and 2.65 for andrograpanin)

Acceptance criteria: NLT 1.0%, on the dried basis, of the sum of the percentages of andrographolide, neoandrographolide, 14-deoxy-11,12-didehydroandrographolide, and andrograpanin

IMPURITIES

Inorganic Impurities

- **PROCEDURE 2: ARTICLES OF BOTANICAL ORIGIN,** *General Method for Pesticide Residues Analysis* ⟨**561**⟩**:** Meets the requirements

SPECIFIC TESTS

- **BOTANIC CHARACTERISTICS**

Macroscopic: Stem is dark green, woody, 2–6 mm in diameter, bearing numerous branches, showing slightly swollen nodes, the upper part is distinctly quadrangular with four bulges in the four corners, and the lower part is somewhat rounded; texture fragile, easily broken; branches quadrangular, often narrowly winged in the upper part. Leaves are simple, opposite, short petiolated or nearly sessile; lamina crumpled and easily broken, when whole, lanceolate or ovate-lanceolate, 2–7 cm long, 1–3 cm wide, with acuminate apex, reticulate venation and cuneate-decurrent base, margin entire or undulate; the upper surface green, the lower surface grayish green; both surfaces are glabrous. Pharmacopeial article consists of dry mixtures of crisp, dark-green broken leaves and quadrangular stems; leaves brittle; stems fracture short, fibrous.

Histology

Transverse section of stems: Epidermal layer showing cells containing round, long-elliptical or clavate calcium carbonate deposits (cystoliths), 1–4 celled nonglandular hairs and multicellular, disk-shaped glandular hairs; collenchyma below the epidermis and in the bulges; endodermis is distinct; vascular bundles surround the parenchyma of the central pith; small acicular crystals of calcium oxalate present in the cortex and pith.

Transverse section of leaves: Subsquare or rectangular upper and lower epidermal cells; lower epidermal cells are relatively smaller; both epidermal layers show cells containing cystoliths, nonglandular hairs and glandular hairs similar to those of the stem; mesophyll composed of 1–2 layers of palisade parenchyma and spongy parenchyma; loosely arranged spongy parenchyma appear across the upper part of the midrib; vascular bundles of midrib are collateral and grooved; cells containing cystoliths appear above the xylem.

- **LOSS ON DRYING** ⟨**731**⟩**:** Dry 1.0 g of finely powdered Andrographis at 105° for 3 h: it loses NMT 12.0% of its weight.
- **ARTICLES OF BOTANICAL ORIGIN,** *Total Ash* ⟨**561**⟩**:** NMT 15%, determined on 1.0 g of finely powdered Andrographis
- **ARTICLES OF BOTANICAL ORIGIN,** *Alcohol-Soluble Extractives, Method 2* ⟨**561**⟩**:** NLT 8.0%
- **MICROBIAL ENUMERATION TESTS—NUTRITIONAL AND DIETARY SUPPLEMENTS** ⟨**2021**⟩**:** The total aerobic bacterial count does not exceed 10^5 cfu/g; the total combined molds and yeasts count does not exceed 10^3 cfu/g; and the bile-tolerant Gram-negative bacteria does not exceed 10^3 cfu/g.
- **ABSENCE OF SPECIFIED MICROORGANISMS—NUTRITIONAL AND DIETARY SUPPLEMENTS** ⟨**2022**⟩**:** Meets the requirements of the tests for absence of *Salmonella* species and *Escherichia coli*

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in well-closed containers, protected from light and moisture, and store at room temperature.
- **LABELING:** The label states the Latin binomial and, following the official name, the parts of the plant contained in the article.

USP Andrographolide RS

USP Powdered Andrographis Extract RS■2S (*USP33*)

BRIEFING

Powdered Andrographis. A new *USP* Dietary Supplement monograph is proposed—See briefing under *Andrographis* published elsewhere in this issue of *PF*.

(DSB: M. Sharaf.) RTS—C66624

Add the following:

■Powdered Andrographis

DEFINITION

Powdered Andrographis is Andrographis reduced to a fine or very fine powder.

IDENTIFICATION

- **A. THIN-LAYER CHROMATOGRAPHIC IDENTIFICATION TEST** ⟨**201**⟩

Standard solution 1: Use *Standard solution A*, prepared as directed in the test for *Content of Diterpene Lactones*.

Standard solution 2: Sonicate an amount of USP Powdered Andrographis Extract RS, equivalent to about 15 mg of

In-Process Revision

diterpene lactones, for 10–15 min in 25 mL of methanol, centrifuge, and use the supernatant.

Sample solution: Use *Sample stock solution*, prepared as directed in the test for *Content of Diterpene Lactones*.

Adsorbent: Chromatographic silica gel mixture with an average particle size of 10–15 µm (TLC plates)

Application volume: 10 µL, as 5–10 mm bands

Developing solvent system: Chloroform, acetone, and toluene (2:2:1)

Spray reagent: A mixture of 1% vanillin in alcohol and 10% sulfuric acid in alcohol (1:1)

Analysis

Samples: *Standard solution 1*, *Standard solution 2*, and *Sample solution*

Use a saturated chamber. Develop the chromatograms until the solvent front has moved about 90% of the length of the plate. Remove the plate from the chamber, dry, spray with the *Spray reagent*, heat for 5–10 min at 100°, and examine under visible light.

Acceptance criteria: The *Sample solution* exhibits three main grayish blue zones with R_F values of approximately 0.4, 0.6, and 0.8 that correspond in position and color to the main zones of *Standard solution 2*. *Standard solution 1* exhibits a grayish blue zone due to andrographolide at an R_F of about 0.4. The *Sample solution* exhibits a zone similar in color and R_F value to that due to andrographolide in *Standard solution 1*.

• **B.** The retention time of the main peak of the *Sample solution* obtained in the test for *Content of Diterpene Lactones* corresponds to that of andrographolide in *Standard solution A*. Identify other diterpene lactone peaks in the *Sample solution* by comparison with *Standard solution B* and the reference chromatogram provided with the lot of USP Powdered Andrographis Extract RS. The *Sample solution* shows additional peaks corresponding to neoandrographolide, 14-deoxy-11,12-didehydroandrographolide, and andrograpanin.

COMPOSITION

• **CONTENT OF DITERPENE LACTONES**

Solution A: Dissolve 0.14 g of potassium dihydrogen phosphate in 900 mL of water, add 0.5 mL of phosphoric acid, dilute with water to 1000 mL, mix, filter, and degas.

Solution B: Use filtered and degassed acetonitrile.

Standard solution A: Dissolve a weighed quantity of USP Andrographolide RS in methanol to obtain a solution having a known concentration of about 1.0 mg/mL. Transfer 5.0 mL of this solution to a 10-mL volumetric flask, dilute with acetonitrile to volume, and mix.

Standard solution B: Transfer an amount of USP Powdered Andrographis Extract RS, equivalent to about 25 mg of diterpene lactones, to a 50-mL volumetric flask, add 25 mL of methanol, heat gently for 15–20 min, dilute with acetonitrile to volume, and mix. Before injection, pass through a membrane filter having a 0.45-µm or finer porosity, discarding the first 5 mL of the filtrate.

Sample stock solution: Transfer about 2.0 g of Powdered Andrographis to a 250-mL flask fitted with a reflux condenser. Add 50 mL of methanol, reflux on a water bath for 15 min, cool to room temperature, and decant the supernatant. Repeat until the last extract is colorless. Combine the extracts, filter, concentrate under vacuum, and adjust the volume to 50.0 mL using methanol. Transfer 25.0 mL of this solution to a 50-mL volumetric flask, dilute with acetonitrile to volume, and mix. Before injection, pass through a membrane filter having a 0.45-µm or finer porosity, discarding the first 5 mL of the filtrate.

Sample solution: Transfer 25.0 mL of *Sample stock solution* to a 50-mL volumetric flask, dilute with acetonitrile to volume, and mix. Before injection, pass through a membrane filter having a 0.45-µm or finer porosity, discarding the first 5 mL of the filtrate.

Mobile phase: See the gradient table below.

  USP Andrographolide RS

  USP Powdered Andrographis Extract RS■2S *(USP33)*

BRIEFING

Powdered Andrographis Extract. A new *USP* Dietary Supplement monograph is proposed. See briefing under *Andrographis* published elsewhere in this *PF*.

(DSB: M. Sharaf.) RTS—C66625

Add the following:

■Powdered Andrographis Extract

DEFINITION

Powdered Andrographis Extract is prepared from Andrographis by extraction with methanol or alcohol. The ratio of plant material to extract is between 15:1 and 10:1. It contains NLT 90.0% and NMT 110.0% of the labled amount of diterpene lactones, calculated on the dried basis as the sum of andrographolide, neoandrographolide, 14-deoxy-11,12-didehydroandrographolide, and andrograpanin. The content of 14-deoxy-11,12-didehydroandrographolide is NMT 15% of the total diterpene lactones. It may contain suitable added substances as carriers.

IDENTIFICATION

- **A. THIN-LAYER CHROMATOGRAPHIC IDENTIFICATION TEST** ⟨**201**⟩

  Standard solution 1: Use *Standard solution A*, prepared as directed in the test for *Content of Diterpene Lactones*.

  Standard solution 2: Sonicate for 10–15 min a quantity of USP Powdered Andrographis Extract RS, equivalent to about 15 mg diterpene lactones, in 25 mL of methanol, centrifuge, and use the supernatant.

  Sample solution: Sonicate for 10–15 min a quantity of Powdered Andrographis Extract, equivalent to about 15 mg diterpene lactones, in 25 mL of methanol. Centrifuge, and use the supernatant.

  Adsorbent: Chromatographic silica gel mixture with an average particle size of 10–15 µm (TLC plates).

  Application volume: 10 µL, as 5–10 mm bands.

  Developing solvent system: Chlorofom, acetone, and toluene (2:2:1).

  Spray reagent: A mixture containing 1% vanillin in alcohol and 10% sulfuric acid in alcohol (1:1).

  Analysis

  Samples: *Standard solution 1*, *Standard solution 2*, and *Sample solution*

  Use a saturated chamber. Develop until the solvent front has moved up about 90% of the plate. Remove the plate from the chamber. Dry, and spray with the *Spray reagent*. Heat for 5–10 min at 100°, and examine under visible light.

  Acceptance criteria: The *Sample solution* exhibits three main grayish blue zones with R_F values of approximately 0.4, 0.6, and 0.8 that correspond in position and color to zones in *Standard solution 2*. *Standard solution 1* exhibits a grayish blue zone due to andrographolide at an R_F of about 0.4. The *Sample solution* exhibits a zone similar in color and R_F value to that due to andrographolide in *Standard solution 1*.
- **B.** The *Sample solution* in the test for *Content of Diterpene Lactones* shows a main peak at a retention time corresponding to that of andrographolide in *Standard solution A*. Identify other diterpene lactone peaks in the *Sample solution* by comparison with *Standard solution B* and the Reference chromatogram provided with the lot of USP Powdered Andrographis Extract RS. The *Sample solution* shows additional peaks corresponding to neoandrographolide, 14-deoxy-11,12-didehydroandrographolide, and andrograpanin.

BRIEFING

***Cryptheconidinium cohnii* Oil Capsules.** Because there is no existing *USP* Dietary Supplement monograph for this article, the following new monograph is being proposed. The *Content of DHA* is conducted using the same chromatographic procedure in the USP general test chapter *Fats and Fixed Oils, Omega-3 Fatty Acids Determination and Profile* ⟨401⟩ that became official in the *First Supplement* to *USP 32*.

(DSN: C. Phinney.) RTS—C55686

Add the following:

■*Cryptheconidinium cohnii* Oil Capsules

DEFINITION
Cryptheconidinium cohnii Oil Capsules contain NLT 95.0% and NMT 105.0% of the labeled amount of docosahexaenoic acid (DHA, $C_{22}H_{32}O_2$) (C22: 6 n-3).

In-Process Revision

IDENTIFICATION

• **FATTY ACID PROFILE**

Fatty Acids as Methyl Esters	Shorthand Notation	Lower Limit Area, (%)	Upper Limit Area, (%)
Polyunsaturated fatty acids			
Linoleic acid	18:2 n-6	0	1.0
Eicosapentanoic acid	20:5 n-3	0	0.1
Docosapentaenoic acid	22:5 n-6	0	0.1
Docosahexanoic acid	22:6 n-3	39.0	47.0

Acceptance criteria: The oil contained in the Capsules meets the following requirements: The area percent for each methyl ester of the fatty acids of the *Test Solution* as obtained in the test for *Content of EPA and DHA* in *Fats and Fixed Oils* ⟨401⟩, *Omega-3 Fatty Acids Determination and Profile* meet the requirements for each fatty acid indicated in the table above; and the methyl esters have a common elution order as described in *Fats and Fixed Oils, Fatty Acid Composition* ⟨401⟩.

OTHER COMPONENTS

• **CONTENT OF *Crypthecodinium cohnni* OIL:** Weigh NLT 10 Capsules in a tared weighing bottle. With a sharp blade or other appropriate means, carefully open the Capsules, without loss of the shell material, and transfer the combined Capsule contents to a 100-mL beaker. Remove any adhering substance from the emptied capsules by washing with several small portions of isooctane. Discard the washings, and allow the empty capsules to dry in a current of dry air until the isooctane is completely evaporated. Weigh the empty capsules in the original tared weighing bottle, and calculate the average net weight of *Crypthecodinium cohnni* oil/Capsule.

• **CONTENT OF DHA**

Analysis: Proceed as directed in *Fats and Fixed Oils* ⟨401⟩, *Omega-3 Fatty Acids Determination and Profile*.

Acceptance criteria: NLT 40.0% docosahexaenoic acid (DHA)

IMPURITIES

Inorganic Impurities

• **LIMIT OF ARSENIC**

[NOTE—For the preparation of all aqueous solutions and for the rinsing of glass, polytef, and plastic vessels before use, employ water that has been passed through a strong-acid, strong-base, mixed-bed ion-exchange resin before use. Select all reagents to have as low a content of arsenic as practicable, and store all reagent solutions in containers of borosilicate glass. Cleanse glass, polytef, and plastic vessels before use by soaking in warm 8 N nitric acid for 30 min and by rinsing with deionized water.]

Solution A: Transfer 1 g of ultrapure palladium metal into a Teflon beaker. Add 20 mL of water and 10 mL of nitric acid, and warm on a hot plate to dissolve. Allow the solution to cool to room temperature, transfer it into a 100-mL volumetric flask, and dilute with deionized water to volume.

Solution B: Transfer 1 g of ultrapure magnesium nitrate into a Teflon beaker. Add 40 mL of water and 1 mL of nitric acid, and warm on a hot plate to dissolve the solids. Allow the solution to cool to room temperature, transfer it into a 100-mL volumetric flask, and dilute with deionized water to volume.

Solution C: *Solution A*, *Solution B*, and 2% nitric acid (3:2:5). A volume of 5 µL provides 0.015 mg of palladium and 0.01 mg of magnesium nitrate.

Blank: Nitric acid and water (1:19)

Standard stock solution: Transfer 10.0 mL of *Standard Arsenic Solution*, prepared as directed in the test for *Arsenic* ⟨211⟩, to a 100-mL volumetric flask, add 40 mL of water and 5 mL of nitric acid, and dilute with water to volume. This solution contains 0.10 µg/mL of arsenic.

Standard solutions: Dilute the *Standard stock solution* with the *Blank* to obtain concentrations of 0.002, 0.005, 0.010, 0.025, and 0.050 µg/mL of arsenic.

Sample solution: For preparation of the *Sample solution*, use a microwave oven with a magnetron frequency of 2455 MHz and a selectable output power of 0–950 watts in 1% increments, equipped with advanced composite vessels with 100-mL polytef liners. Use rupture membranes to vent vessels should the pressure exceed 125 psi. The vessels fit into a turntable, and each vessel can be vented into an overflow container. Equip the microwave oven with an exhaust tube to ventilate fumes. [**CAUTION—**Wear proper eye protection and protective clothing and gloves.] Transfer approximately 500 mg of *Crypthecondinium cohnii* oil from Capsules, weighed to the nearest 0.1 mg, into a Teflon digestion vessel liner. Prepare samples in duplicate. Add 15 mL of nitric acid, and swirl gently. Cover the vessels with lids, leaving the vent fitting off. Predigest overnight under a hood. Place the rupture membrane in the vent fitting, and tighten the lid. Place all vessels on the microwave oven turntable. Connect the vent tubes to the vent trap, and connect the pressure-sensing line to the appropriate vessel. Initiate a two-stage digestion procedure by heating the microwave at 15% power for 15 min, followed by 25% power for 45 min. Remove the turntable of vessels from the oven, and allow the vessels to cool to room temperature. [NOTE—A cool water bath may be used to speed the cooling process.] Vent the vessels when they reach room temperature. Remove the lids, and slowly add 2 mL of 30% hydrogen peroxide to each. Allow the reactions to subside, and seal the vessels. Return the vessels on the turntable to the microwave oven, and heat for an additional 15 min at 30% power. Remove the vessels from the oven, and allow them to cool to room temperature. Transfer the cooled digests into 25-mL volumetric flasks, and dilute with water to volume.

Analysis: Program the graphite furnace as follows. Dry at 115°, using a 1-s ramp, a 65-s hold, and an argon flow of 300 mL/min. Char the sample at 1000°, using a 1-s ramp, a 20-s hold, and an airflow of 300 mL/min. Cool down, and purge the air from the furnace for 10 s, using a 20° set temperature and an argon flow of 300 mL/min. Atomize at 2400°, using a 0-s ramp and a 5-s hold with the argon flow stopped. Clean out at 2600° with a 1-s ramp and a 5-s hold. Separately inject equal volumes (20 µL) of the *Standard solutions*, the *Sample solution*, and the *Blank*, followed by an injection of 5 µL of *Solution C* for each of the samples, into the graphite tube of a suitable graphite furnace atomic absorption spectrometer equipped with a hollow-cathode lamp for arsenic. Determine the peak area at the arsenic emission line at 193.7 nm, corrected for background absorption. Plot the corrected peak areas of the *Standard solutions* versus their contents of arsenic, in µg/mL, and calculate the regression line best fitting the points. Determine the concentration, C, in µg/mL, of arsenic in each mL of the *Sample solution* by interpolation from the regression line.

Calculate the content of arsenic in the portion of Capsules taken:

$$\text{Result} = 25 \times (C/W)$$

C = concentration as obtained above

W = weight of Capsules content taken to prepare the *Sample solution* (g)

Acceptance criteria: NMT 0.1 µg/g

• **LIMIT OF LEAD**

[NOTE—For the preparation of all aqueous solutions and for the rinsing of glass, polytef, and plastic vessels before use, employ water that has been passed through a strong-acid, strong-base, mixed-bed ion-exchange resin before use. Select all reagents to have as low a content of lead as practicable, and store all reagent solutions in containers of borosilicate glass. Cleanse glass, polytef, and plastic vessels before use by soaking in warm 8 N nitric acid for 30 min and by rinsing with deionized water.]

Solution A: 10 g of ultrapure monobasic ammonium phosphate in 1 mL of nitric acid and 40 mL of water to dissolve the phosphate. Dilute with deionized water to 100 mL.

In-Process Revision

Solution B: Transfer 1 g of ultrapure magnesium nitrate to a Teflon beaker. Add 40 mL of water and 1 mL of nitric acid, and warm on a hot plate to dissolve the solids. Allow the solution to cool to room temperature, transfer it to a 100-mL volumetric flask, and dilute with deionized water to volume.
Solution C: *Solution A*, *Solution B*, and 2% nitric acid (2:1:2). A volume of 5 µL provides 0.2 mg of phosphate plus 0.01 mg of magnesium nitrate.
Blank: Nitric acid and water (1:19)
Standard stock solution: Transfer 10.0 mL of *Lead Nitrate Stock Solution*, prepared as directed in the test for *Heavy Metals* ⟨231⟩, to a 100-mL volumetric flask, add 40 mL of water and 5 mL of nitric acid, and dilute with water to volume. Transfer 1.0 mL of this solution to a second 100-mL volumetric flask, add 50 mL of water and 1 mL of nitric acid, and dilute with water to volume. This solution contains 0.10 µg/mL of lead.
Standard solutions: Dilute the *Standard stock solution* with the *Blank* to obtain concentrations of 0.002, 0.005, 0.010, 0.025, and 0.050 µg/mL of lead.
Sample solution: Prepare as directed for *Sample solution* in the test for *Limit of Arsenic.*
Analysis: Program the graphite furnace as follows. Dry at 120°, using a 1-s ramp, a 55-s hold, and an argon flow of 300 mL/min. char the sample at 850°, using a 1-s ramp, a 30-s hold, and an airflow of 300 mL/min. Cool down, and purge the air from the furnace for 10 s, using a 20° set temperature and an argon flow of 300 mL/min. Atomize at 2100°, using a 0-s ramp and a 5-s hold with the argon flow stopped. Clean out at 2600° with a 1-s ramp and a 5-s hold. Separately inject equal volumes (20 µL) of the *Standard solutions*, the *Sample solution*, and the *Blank*, followed by an injection of 5 µL of the *Solution C* for each of the samples, into the graphite tube of a suitable graphite furnace atomic absorption spectrometer equipped with a hollow-cathode lamp for lead. Determine the peak area at the lead emission line at 283.3 nm, corrected for background absorption. Plot the corrected peak areas of the *Standard solutions* versus their contents of lead, in µg/mL, and calculate the regression line best fitting the points. Determine the concentration, C, in µg/mL, of lead in each mL of the *Sample solution* by interpolation from the regression line.
Calculate the content of lead in the portion of Capsules taken:

$$\text{Result} = 25 \times (C/W)$$

C = concentration, as obtained above
W = weight of Capsules content taken to prepare the *Sample solution* (g)

Acceptance criteria: NMT 0.1 µg/g

- **LIMIT OF CADMIUM**

[NOTE—For the preparation of all aqueous solutions and for the rinsing of glass, polytef, and plastic vessels before use, employ water that has been passed through a strong-acid, strong-base, mixed-bed ion-exchange resin before use. Select all reagents to have as low a content of cadmium as practicable, and store all reagent solutions in containers of borosilicate glass. Cleanse glass, polytef, and plastic vessels before use by soaking in warm 8 N nitric acid for 30 min and by rinsing with deionized water.]
Solution A: 10 g of ultrapure monobasic ammonium phosphate in 40 mL of water and 1 mL of nitric acid to dissolve the phosphate. Dilute with deionized water to 100 mL.
Solution B: Transfer 1 g of ultrapure magnesium nitrate to a Teflon beaker. Add 40 mL of water and 1 mL of nitric acid, and warm on a hot plate to dissolve the solids. Allow the solution to cool to room temperature, transfer it to a 100-mL volumetric flask, and dilute with deionized water to volume.
Solution C: *Solution A*, *Solution B*, and 2% nitric acid to volume (2:1:2). A volume of 5 µL provides 0.2 mg of phosphate and 0.01 mg of magnesium nitrate.
Blank: Nitric acid and water (1:19)
Standard stock solution A: 0.1372 mg/mL of cadmium nitrate
Standard stock solution B: *Standard stock solution A*, nitric acid, and water (2:1:97). This solution contains 0.10 µg/mL of cadmium. [NOTE—Before make up to final volume dissolve in a portion of water and nitric acid.]
Standard solutions: Dilute *Standard stock solution B* with the *Blank* to obtain concentrations of 0.002, 0.005, 0.010, 0.025, and 0.050 µg/mL of cadmium.
Sample solution: Prepare as directed for *Sample solution* in the test for *Limit of Arsenic.*
Analysis: Program the graphite furnace as follows. Dry at 120°, using a 1-s ramp, a 55-s hold, and an argon flow of 300 mL/min. Char the sample at 850°, using a 1-s ramp, a 30-s hold, and an airflow of 300 mL/min. Cool down, and purge the air from the furnace for 10 s, using a 20° set temperature and an argon flow of 300 mL/min. Atomize at 2400°, using a 0-s ramp and a 5-s hold with the argon flow stopped. Clean out at 2600° with a 1-s ramp and a 5-s hold. Separately inject equal volumes (20 µL) of the *Standard solutions*, the *Sample solution*, and the *Blank*, followed by an injection of 5 µL of the *Solution C* for each of the samples, into the graphite tube of a suitable graphite furnace atomic absorption spectrometer equipped with a hollow-cathode lamp for cadmium. Determine the peak area at the cadmium emission line at 228.8 nm, corrected for background absorption. Plot the corrected peak areas of the *Standard solutions* versus their contents of cadmium, in µg/mL, and calculate the regression line best fitting the points. Determine the concentration, C, in µg/mL, of cadmium in each mL of the *Sample solution* by interpolation from the regression line. Calculate the content of cadmium in the Capsules taken:

$$\text{Result} = 25 \times (C/W)$$

C = concentration, as obtained above
W = weight of Capsules content taken to prepare the *Sample solution* (g)

Acceptance criteria: NMT 0.1 µg/g

- **LIMIT OF MERCURY:** Proceed as directed for *Mercury* ⟨261⟩, *Method IIa*, except to use a *Standard Mercury Solution* having the equivalent of 0.1 µg/mL of mercury.
Sample solution: Prepare as directed for the *Sample solution* in the test for *Limit of Arsenic* combining the two duplicate cooled digests into 1.0 mL of *Potassium Permanganate Solution.*
Acceptance criteria: NMT 0.1 µg/g

SPECIFIC TESTS

- **FATS AND FIXED OILS,** *Anisidine Value* ⟨**401**⟩**:** NMT 20.0, determined on the contents of the Capsules
- **FATS AND FIXED OILS,** *Free Fatty Acids* ⟨**401**⟩**:** The free fatty acids in 10 g require for neutralization NMT 1.42 mL of 0.1 N sodium hydroxide.
- **FATS AND FIXED OILS,** *Peroxide Value* ⟨**401**⟩**:** NMT 5.0, determined on the contents of the Capsules
- **FATS AND FIXED OILS,** *Total Oxidation Value (TOTOX)* ⟨**401**⟩**:** NMT 26 (determined on the contents of the Capsules), calculated:

$$\text{Result} = (2 \times PV) + AV$$

PV = the peroxide value
AV = the anisidine value

- **FATS AND FIXED OILS,** *Unsaponifiable Matter* ⟨**401**⟩**:** NMT 3.5%, determined on the contents of the Capsules
- **SPECIFIC GRAVITY** ⟨**841**⟩**:** 0.91–0.93, determined on the contents of the Capsules

PERFORMANCE TESTS

- **DISINTEGRATION AND DISSOLUTION OF DIETARY SUPPLEMENTS** ⟨**2040**⟩**:** Meet the requirements for *Rupture Test for Soft Gelatin Capsules*
- **WEIGHT VARIATION OF DIETARY SUPPLEMENTS** ⟨**2091**⟩**:** Meet the requirements

In-Process Revision

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in tight, light-resistant containers, and avoid exposure to excessive heat.
- **LABELING:** The label states the content of docosahexaenoic acid in mg/g. It also states the name and concentration of any added antioxidant.
- **USP REFERENCE STANDARDS** ⟨11⟩
  USP Docosahexaenoic Acid Ethyl Ester RS
  USP Eicosapentaenoic Acid Ethyl Ester RS
  USP Methyl Tricosanoate RS■2S (*USP33*)

BRIEFING

Omega-3 Acid Ethyl Esters. Because there is no existing *USP* monograph for this article, the following new monograph is being proposed. The *Assay* is conducted using the same chromatographic procedure in the USP general test chapter *Fats and Fixed Oils, Omega-3 Fatty Acids Determination and Profile* ⟨401⟩ that became official in the *First Supplement* to *USP 32*. Typical retention times obtained using a Macrogol 20000 brand of G16 phase column for eicosapentaenoic acid ethyl ester and docosohexaenoic acid ethyl ester are 20.5 and 25.7 min, respectively.

(DSN: C. Phinney.) RTS—C52079

Add the following:

■Omega-3 Acid Ethyl Esters

DEFINITION

Omega-3 Acid Ethyl Esters are obtained by transesterification of the body oil of fish of families such as *Engraulidae, Carangidae, Clupeidae, Osmeridae, Salmonidae* and *Scombridae* and subsequent purification processes including urea fractionation followed by molecular distillation. The content of eicosapentaenoic acid ethyl ester (EPAee) plus the content of docosohexaenoic acid ethyl ester (DHAee) is NLT 800 mg/g and NMT 880 mg/g, with NTL 430 mg/g and NMT 495 mg/g of EPAee and NLT 347 mg/g and NMT 403 mg/g of DHAee. It contains NLT 90% of the sum of alpha-linolenic acid ethyl ester (C18:3 n-3, EE), moroctic acid ethyl ester (C18:4 n-3, EE), eicosatetraenoic acid ethyl ester (C20:4 n-3, EE), eicosapentaenoic acid ethyl ester (EPAee) (C20:5 n-3, EE), heneicosapentaenoic acid ethyl ester (C21:5 n-3, EE), docosapentaenoic acid ethyl ester (C22:5 n-3, EE), and docosahexaenoic acid ethyl ester (DHAee) (C22:6 n-3, EE). Tocopherol may be added as an antioxidant.

IDENTIFICATION

- The retention times of the peaks for eicosapentaenoic acid ethyl ester and docosahexaenoic acid ethyl ester in the *Test Solution* correspond to those respective compounds in the *Standard Solution*, as obtained in the *Assay*.

ASSAY

- **CONTENT OF EPAEE, DHAEE, AND TOTAL OMEGA-3 ACIDS ETHYL ESTERS**
  (See *Fats and Fixed Oils, Omega-3 Fatty Acids Determination and Profile* ⟨401⟩.)

Analysis

Samples: *Standard Solution* and *Test Solution*

Calculate the content of EPAee and DHAee in the portion of Omega-3 Acid Ethyl Esters taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U)$$

R_U = peak area ratio of the EPAee or DHAee peak to the internal standard peak in the *Test Solution*

R_S = peak area ratio of the EPAee or DHAee peak to the internal standard peak in the *Standard Solution*

C_S = concentration of USP Eicosapentaenoic Acid Ethyl Ester RS or USP Docosapentaenoic Acid Ethyl Ester RS in the *Standard Solution* (mg/mL)

C_U = concentration of Omega-3 Ethyl Esters in the *Test Solution* (g/mL)

Calculate the content of total omega-3 acids ethyl esters in the portion of Omega-3 Acid Ethyl Esters taken:

$$\text{Result} = r_{FAn-3ee}\,[(\text{EPAee} + \text{DHAee})/(r_{EPAee} + r_{DHAee})] + \text{EPAee} + \text{DHAee}$$

$r_{FAn-3ee}$ = sum of the peak areas of alpha-linolenic acid ethyl ester (C18:3 n-3, EE), moroctic acid ethyl ester (C18:4 n-3, EE), eicosatetraenoic acid ethyl ester (C20:4 n-3, EE), heneicosapentaenoic acid ethyl ester (C21:5 n-3, EE), and docosapentaenoic acid ethyl ester (C22:5 n-3, EE) in the *Test Solution*

EPAee = content of EPAee (mg/g)

DHAee = content of DHAee (mg/g)

r_{EPAee} = peak area of the EPAee in the *Test Solution*

r_{DHAee} = peak area of the DHAee in the *Test Solution*

Acceptance criteria: It conforms to the acceptance criteria in *Impurity Table 1*.

Impurity Table 1

Name	Relative Retention Time	Acceptance Criteria, NLT (mg/g)	Acceptance Criteria, NMT (mg/g)
C18:3 n-3, EE[a]	0.585	—	—
C18:4 n-3, EE[b]	0.608	—	—
C20:4 n-3, EE[c]	0.777	—	—
C20:5 n-3, EE (EPAee)[d]	0.796	430	495
C21:5 n-3, EE[e]	0.889	—	—
C22:5 n-3, EE[f]	0.977	—	—
C22:6 n-3, EE (DHAee)[g]	1.000	347	403
EPAee + DHAee	—	800	880
Total omega-3 acid ethyl esters	—	900	—

[a] Alpha-linolenic acid ethyl ester.
[b] Moroctic acid ethyl ester.
[c] Eicosatetraenoic acid ethyl ester.
[d] Eicosapentaenoic acid ethyl ester.
[e] Heneicosapentaenoic acid ethyl ester.
[f] Docosapentaenoic acid ethyl ester (clupanodonic acid ethyl ester).
[g] Docosahexaenoic acid ethyl ester.

IMPURITIES

Inorganic Impurities

- **FATS AND FIXED OILS** ⟨401⟩**:** NMT 0.1 ppm each of Pb, Cd, As, and Hg

In-Process Revision

Organic Impurities

- **PROCEDURE 1: CHOLESTEROL**

Internal standard stock solution: 3 mg/mL of 5α-cholestane in *n*-heptane

Internal standard solution: 0.3 mg/mL of 5α-cholestane in *n*-heptane. [NOTE—Prepare fresh prior to use.]

Standard stock solution: 3.0 mg/mL of cholesterol in *n*-heptane. [NOTE—This solution is stable for 6 months stored in a freezer.]

Standard solution: Mix 1.0 mL of *Standard stock solution* and 1.0 mL of *Internal standard stock solution* in a 10.0-mL volumetric flask. Dilute with *n*-heptane to volume. [NOTE—Prepare this solution fresh daily.]

Alpha tocopherol stock solution: 1.5–2.0 mg/mL of USP Alpha Tocopherol RS in *n*-heptane. [NOTE—This solution is stable for 12 months stored in a freezer.]

System suitability solution: Mix 1.0 mL of the *Standard stock solution*, 1.0 mL of the *Internal standard stock solution*, and 2.0 mL of *Alpha tocopherol stock solution* in a 50-mL volumetric flask. Evaporate to dryness with the aid of heat, and dilute with ethyl acetate to volume. Dilute 1.0 mL of this solution with ethyl acetate to 10.0 mL. [NOTE—This solution is stable for 6 months stored in a freezer.]

Response factor solution: Mix 1.0 mg/mL of *Standard solution* and 1.0 mL of *Internal standard solution.* Proceed as directed in the *Sample solution* beginning with "Evaporate to dryness".

Sample solution: Transfer 100 mg of Omega-3 Acid Ethyl Esters to a 15-mL centrifuge tube. Add 1.0 mL of *Internal standard solution*. Evaporate to dryness at about 50° with a gentle stream of nitrogen. Add 0.5 mL of 50% potassium hydroxide and 3 mL of alcohol, fill the tube with nitrogen, and cap. Heat the sample at 100° for 60 min, using a heating block. Cool for about 10 min. Add 6 mL of water to the tube, and shake for 1 min. Extract the solution four times with 2.5-mL portions of ethyl ether, using a vortex mixer or suitable shaker for 1 min for each extraction. Transfer and combine the extracts into a large centrifuge tube, and wash with 5 mL of water, mixing completely with gentle inversion. Remove the water phase, and add 5 mL of 0.5 M potassium hydroxide to the ether phase, mixing carefully to avoid an emulsion. Remove the potassium hydroxide, and add another 5 mL of water mixing carefully. Transfer the ether phase into a small centrifuge tube. [NOTE—If an emulsion has occurred, a small amount of sodium chloride may be added to obtain a separation of the phases.] Evaporate the ether phase to dryness under a stream of nitrogen with careful heating. Dissolve the sample in 600 µL of ethyl acetate, and mix well. Transfer 200 µL of this solution to a sample vial, and dilute with ethyl acetate to about 2 mL.

Chromatographic system

(See *Chromatography* ⟨621⟩*, System Suitability*.)

Mode: GC

Detector: Flame ionization

Column: 0.25-mm × 30-m capillary column coated with a G27 phase of 0.25-µm thickness

Temperature

Injector: 320°

Detector: 300°

Column: See the temperature program table below.

Initial Temperature (°)	Temperature Ramp (°/min)	Final Temperature (°)	Hold Time at Final Temperature (min)
170	0	170	1
170	4	320	1.5

Carrier gas: Helium

Flow rate: 1.3 mL/min

Injection size: 1 µL

Injection type: Splitless injection system

System suitability

Sample: *System suitability solution*

Suitability requirements

Resolution: NLT 1.2 between alpha tocopherol and cholesterol

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the content of total cholesterol in the portion of Omega-3 Acid Ethyl Esters taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 1000$$

R_U = ratio of the cholesterol peak to the internal standard from the *Sample solution*

R_S = ratio of the cholesterol peak to the internal standard from the *Standard solution*

C_S = concentration of cholesterol in the *Standard solution* (mg/mL)

C_U = concentration of Omega-3 Acid Ethyl Esters in the *Sample solution* (mg/mL)

Acceptance criteria: NMT 3.0 mg/g

- **PROCEDURE 2: OLIGOMERS**

Mobile phase: Tetrahydrofuran

Sample solution 1: 1.00 mg/mL of Omega-3 Acid Ethyl Esters in tetrahydrofuran

Sample solution 2: [NOTE—Use *Sample solution 2* where the results of this test using *Sample solution 1* exceed the *Acceptance criteria* due to the presence of monoglycerides.] Weigh 50 mg into a quartz tube, add 1.5 mL of a 20-g/L solution of sodium hydroxide in methanol, cover with nitrogen, cap tightly with a polytef lined cap, mix, and heat on a water bath for 7 min. Allow to cool. Add 2.0 mL of boron trichloride–methanol solution, cover with nitrogen, cap tightly, mix and heat on a water bath for 30 min. Cool to 40°–50°, add 1 mL of isooctane, cap, and shakle vigorously for NLT 30 s. Immediately add 5 mL of saturated sodium chloride solution, cover with nitrogen, cap, and shake thorughly for NLT 15 s. Transfer the upper layer to a separate tube. Shake the methanol layer with 1 mL of isooctane. Carefully evaporate the solvent under a stream of nitrogen, then add 10.0 mL of tetrahydrofuran to the residue. Add a small amount of anhydrous sodium sulfate, and filter.

System suitability solution: Monodocosahexaenoin, didocosahexaenoin, and tridocosahexaenoin in *Mobile phase,* with concentrations of about 0.5, 0.3, and 0.2 mg/mL, respectively. [NOTE—Suitable grades of monodocosahexaenoin, didocosahexaenoin, and tridocosahexaenoin may be obtained from Nu-Chek Prep.]

Chromatographic system

(See *Chromatography* ⟨621⟩*, System Suitability*.)

Mode: LC

Detector: Differential refractometer

Columns: Three concatenated 7.8-mm × 30-cm columns; 7-µm packing L21. Two columns are 50-nm in pore size and the third is 10-nm, arranged so that the 50-nm pore size columns are closer to the injector.

Flow rate: 0.8 mL/min

Injection size: 40 µL

System suitability

Sample: *System suitability solution*

Suitability requirements

Elution order: Tridocosahexaenoin, didocosahexaenoin, and monodocosahexaenoin

Resolution: NLT 2.0 between monodocosahexaenoin and didocosahexaenoin, and NLT 1.0 between didocosahexaenoin and tridocosahexaenoin

In-Process Revision

Analysis

Sample: *Sample solution*

Measure the areas of the major peaks. Calculate the percentage of oligomers in the portion of Omega-3 Acid Ethyl Esters taken to prepare *Sample solution 1*:

$$\text{Result} = (r_I/r_T) \times 100$$

r_I = sum of the areas of the peaks with a retention time less than that of the ethyl esters peaks

r_T = sum of areas of all peaks

Calculate the percentage of oligomers in the portion of Omega-3 Acid Ethyl Esters taken to prepare *Sample solution 2*:

$$\text{Result} = (r_I/r_T) \times 100$$

r_I = sum of the areas of all peaks with retention times shorter than that of the methyl esters

r_T = sum of areas of all peaks

Acceptance criteria: NMT 1.0% of oligomers

- **PROCEDURE 3: LIMIT OF DIOXINS, FURANS, AND POLYCHLORINATED BIPHENYLS (PCBS):** Determine the content of polychlorinated dibenzo-para-dioxins (PCDDs) and polychlorinated dibenzofurans (PCDFs) by method No. 1613 revision B of the Environmental Protection Agency. Determine the content of polychlorinated biphenyls (PCBs) by method No. 1668 revision A of the Environmental Protection Agency.
  Acceptance criteria: The sum of PCDDs and PCDFs is NMT 1 pg/g of WHO toxic equivalents. The sum of PCBs (polychlorinated biphenyls, IUPAC congeners PCB-28, PCB-52, PCB-101, and PCB-118, PCB-138, PCB-153, PCB-180) is NMT 0.5 ppm.
- **PROCEDURE 4: LIMIT OF DDT, HEXACHLOROBENZENE (HCB), AND LINDANE:** Use a suitable method. The analytical procedure satisfies the following criteria: the method is not susceptible to interference from the components of Omega-3 Acid Ethyl Esters; the concentration of test and reference solutions and the setting of the apparatus are such that the responses used for quantification of the pesticide residues are within the dynamic range of the detector; test solutions containing pesticide residues at a level outside the dynamic range may be diluted within the calibration range provided that the concentration of the matrix in the solution is adjusted in the case where the calibration solutions must be matrix-matched; recovery for HCB, lindane, and DDT is NLT 70% and NMT 110%; the repeatability of the method RSD is NMT 20%; and the reproducibility of the method RSD is NMT 40%.
  Acceptance criteria: NMT 0.05 ppm of HCB, 0.05 ppm of lindane, and 0.05 ppm of DDT expressed as the sum of *p,p'*-DDE, *o,p'*-DDT, *p,p'*-DDT, *o,p'*-DDD, and *p,p'*-DDD
- **PROCEDURE 5: LIMIT OF TOTAL UNIDENTIFIED FATTY ACIDS ETHYL ESTERS:** From the chromatogram obtained with *Test Solution 4* in the *Assay* for *Content of EPAee, DHAee, and Total Omega-3 Acids Ethyl Esters*, determine the peak area of the largest single unidentified peak with a relative retention time different from those in the following table.

Identified Ethyl Ester	Relative Retention Time
Phytanic acid	0.416
C16:3 n-4	0.431
C16:4 n-1	0.468
C18:3 n-6	0.557
C18:3 n-4	0.574
C18:3 n-3	0.585
C18:4 n-3	0.608
C18:4 n-1	0.618
Furan acid 5	0.691
C19:5	0.710
C20:3 n-6	0.720
C20:4 n-6	0.736
Furan acid 7	0.744
C20:4 n-3	0.777
Furan acid 8	0.783
EPA	0.796
Furan acid 9	0.867
C21:5 n-3	0.889
C22:4	0.917
Furan acid 10	0.922
C22:5 n-6	0.939
Furan acid 11	0.963
C22:5 n-3	0.977
DHA	1.000

Calculate the content of unidentified fatty acids ethyl esters in area percentage:

$$\text{Result} = 100 - \Sigma \text{ Aiee}$$

Aiee = peak area of each identified ethyl ester in the table above

Acceptance criteria: The area of the largest single unidentified peak is NMT 0.5% of the total area. The total area of unidentified peaks as calculted above is NMT 2%.

SPECIFIC TESTS

- **FATS AND FIXED OILS ⟨401⟩,** *Acid Value*: NMT 2
- **FATS AND FIXED OILS ⟨401⟩,** *Anisidine Value*: NMT 15.0
- **FATS AND FIXED OILS ⟨401⟩,** *Peroxide Value*: NMT 10.0
- **ABSORBANCE**
  Sample solution: 0.24 mg/mL in isooctane
  Acceptance criteria: NMT 0.55, determined at 233 nm, with isooctane being used as the blank

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in tight, light-resistant containers under a nitrogen atmosphere. Store at controlled room temperature.
- **LABELING:** The label states the average content of DHA and EPA in mg/g, and the content of the total omega-3 acid ethyl esters. It also states the name of any added antioxidant.
- **USP REFERENCE STANDARDS ⟨11⟩**
  USP Alpha Tocopherol RS
  USP Docosahexaenoic Acid Ethyl Ester RS
  USP Eicosapentaenoic Acid Ethyl Ester RS
  USP Methyl Tricosanoate RS■2S (*USP33*)

BRIEFING

Schizochytrium Oil Capsules. Because there is no *USP* monograph for this dietary supplement ingredient, a new monograph is being proposed. The test for the *Content of DHA* references the gas chromatographic procedure described in the USP general test chapter *Fats and Fixed Oils, Omega-3 Fatty Acids Determination and Profile* ⟨401⟩ that was published on page 3941 of the *First Supplement* to *USP 32*.

(DSN: C. Phinney.) RTS—C55687

In-Process Revision

Add the following:

▪Schizochytrium Oil Capsules

DEFINITION

Schizochytrium Oil Capsules are prepared from Schizochytrium Oil and contain NLT 95.0% and NMT 105.0% of the labeled amount of docosahexaenoic acid (DHA, $C_{22}H_{32}O_2$) (C22: 6 n–3).

IDENTIFICATION

• **FATTY ACID PROFILE**

Fatty Acid	Shorthand Notation	Lower Limit (Area %)	Upper Limit (Area %)
Dihomo-gamma-linolenic acid	20:3 n–6	1.7	2.8
Arachidonic acid	20:4 n–6	0.6	1.3
Eicosapentaenoic acid (EPA)	20:5 n–3	1.3	3.9
Docosapentaenoic acid (DPA n–6)	22:5 n–6	10.5	16.5
Docosahexanoic acid (DHA)	22:6 n–3	30.0	40.0

Acceptance criteria: The retention time of the peaks of the docosahexaenoic acid methyl ester and the eicosapentanoic acid methyl ester of the *Test Solution* corresponds to that of *Standard Solution 2* as obtained in the test for *Content of EPA and DHA* in *Fats and Fixed Oils, Omega-3 Fatty Acids Determination and Profile* ⟨401⟩. The area percentage for the methyl esters of the fatty acids of the *Test Solution* meets the requirements for each fatty acid indicated in the table above.

OTHER COMPONENTS

• **CONTENT OF SCHIZOCHYTRIUM OIL:** Weigh NLT 10 Capsules in a tared weighing bottle. With a sharp blade or other appropriate means, carefully open the Capsules, without loss of the shell material, and transfer the combined Capsule contents to a 100-mL beaker. Remove any adhering substance from the emptied capsules by washing with several small portions of isooctane. Discard the washings, and allow the empty capsules to dry in a current of dry air until the isooctane is completely evaporated. Weigh the empty capsules in the original tared weighing bottle, and calculate the average net weight of schizochytrium oil/Capsule.

• **CONTENT OF DHA**

Analysis: Proceed as directed in *Fats and Fixed Oils* ⟨401⟩, *Omega-3 Fatty Acids Determination and Profile*.

Acceptance criteria: NLT 32.0% docosahexaenoic acid (DHA)

PERFORMANCE TESTS

• **DISINTEGRATION AND DISSOLUTION OF DIETARY SUPPLEMENTS ⟨2040⟩:** Meet the requirements for *Rupture Test for Soft Gelatin Capsules*

• **WEIGHT VARIATION ⟨2091⟩:** Meet the requirements

IMPURITIES

Inorganic Impurities

• **LIMIT OF ARSENIC**

[NOTE—For the preparation of all aqueous solutions and for the rinsing of glass, polytef, and plastic vessels before use, employ water that has been passed through a strong-acid, strong-base, mixed-bed ion-exchange resin before use. Select all reagents to have as low a content of arsenic as practicable, and store all reagent solutions in containers of borosilicate glass. Cleanse glass, polytef, and plastic vessels before use by soaking in warm 8 N nitric acid for 30 min and by rinsing with deionized water.]

Solution A: Transfer 1 g of ultrapure palladium metal into a Teflon beaker. Add 20 mL of water and 10 mL of nitric acid, and warm on a hot plate to dissolve. Allow the solution to cool to room temperature, transfer it into a 100-mL volumetric flask, and dilute with deionized water to volume.

Solution B: Transfer 1 g of ultrapure magnesium nitrate into a Teflon beaker. Add 40 mL of water and 1 mL of nitric acid, and warm on a hot plate to dissolve the solids. Allow the solution to cool to room temperature, transfer it into a 100-mL volumetric flask, and dilute with deionized water to volume.

Solution C: *Solution A*, *Solution B*, and 2% nitric acid (3:2:5). A volume of 5 µL provides 0.015 mg of palladium and 0.01 mg of magnesium nitrate.

Blank: Nitric acid and water (1:19)

Standard stock solution: Transfer 10.0 mL of *Standard Arsenic Solution*, prepared as directed in the test for *Arsenic* ⟨211⟩, to a 100-mL volumetric flask, add 40 mL of water and 5 mL of nitric acid, and dilute with water to volume. This solution contains 0.10 µg/mL of arsenic.

Standard solutions: Dilute the *Standard stock solution* with the *Blank* to obtain concentrations of 0.002, 0.005, 0.010, 0.025, and 0.050 µg/mL of arsenic.

Sample solution: For preparation of the *Sample solution*, use a microwave oven with a magnetron frequency of 2455 MHz and a selectable output power of 0–950 watts in 1% increments, equipped with advanced composite vessels with 100-mL polytef liners. Use rupture membranes to vent vessels should the pressure exceed 125 psi. The vessels fit into a turntable, and each vessel can be vented into an overflow container. Equip the microwave oven with an exhaust tube to ventilate fumes. [**CAUTION—**Wear proper eye protection and protective clothing and gloves.]

Transfer approximately 500 mg of schizochytrium oil from Capsules, weighed to the nearest 0.1 mg, into a Teflon digestion vessel liner. Prepare samples in duplicate. Add 15 mL of nitric acid, and swirl gently. Cover the vessels with lids, leaving the vent fitting off. Predigest overnight under a hood. Place the rupture membrane in the vent fitting, and tighten the lid. Place all vessels on the microwave oven turntable. Connect the vent tubes to the vent trap, and connect the pressure-sensing line to the appropriate vessel. Initiate a two-stage digestion procedure by heating the microwave at 15% power for 15 min, followed by 25% power for 45 min. Remove the turntable of vessels from the oven, and allow the vessels to cool to room temperature. [NOTE—A cool water bath may be used to speed the cooling process.] Vent the vessels when they reach room temperature. Remove the lids, and slowly add 2 mL of 30% hydrogen peroxide to each. Allow the reactions to subside, and seal the vessels. Return the vessels on the turntable to the microwave oven, and heat for an additional 15 min at 30% power. Remove the vessels from the oven, and allow them to cool to room temperature. Transfer the cooled digests into 25-mL volumetric flasks, and dilute with water to volume.

Analysis: Program the graphite furnace as follows. Dry at 115°, using a 1-s ramp, a 65-s hold, and an argon flow of 300 mL/min; char the sample at 1000°, using a 1-s ramp, a 20-s hold, and an airflow of 300 mL/min; cool down, and purge the air from the furnace for 10 s, using a 20° set temperature and an argon flow of 300 mL/min; atomize at 2400°, using a 0-s ramp and a 5-s hold with the argon flow stopped; and clean out at 2600° with a 1-s ramp and a 5-s hold. Separately inject equal volumes (20 µL) of the *Standard solutions*, the *Sample solution*, and the *Blank*, followed by an injection of 5 µL of the *Solution C* for each of the samples, into the graphite tube of a suitable graphite furnace atomic absorption spectrometer equipped with a hollow-cathode lamp for arsenic. Determine the peak area at the arsenic emission line at 193.7 nm, corrected for background absorption. Plot the corrected peak areas of the *Standard solutions* versus their contents of arsenic, in µg/mL, and calculate the regression line best fitting the points. Determine the concentration, C, in µg/mL, of arsenic in each mL of the *Sample solution* by interpolation from the regression line.

Calculate the content of arsenic in the portion of Capsules taken:

$$\text{Result} = 25 \times (C/W)$$

C = concentration as obtained above
W = weight of Capsules content taken to prepare the *Sample solution* (g)

Acceptance criteria: NMT 0.1 µg/g

- **LIMIT OF LEAD**

[NOTE—For the preparation of all aqueous solutions and for the rinsing of glass, polytef, and plastic vessels before use, employ water that has been passed through a strong-acid, strong-base, mixed-bed ion-exchange resin before use. Select all reagents to have as low a content of lead as practicable, and store all reagent solutions in containers of borosilicate glass. Cleanse glass, polytef, and plastic vessels before use by soaking in warm 8 N nitric acid for 30 min and by rinsing with deionized water.]

Solution A: 10 g of ultrapure monobasic ammonium phosphate in 1 mL of nitric acid and 40 mL of water to dissolve the phosphate. Dilute with deionized water to 100 mL.

Solution B: 1 g of ultrapure magnesium nitrate, to a Teflon beaker. Add 40 mL of water and 1 mL of nitric acid, and warm on a hot plate to dissolve the solids. Allow the solution to cool to room temperature, transfer it to a 100-mL volumetric flask, and dilute with deionized water to volume.

Solution C: *Solution A*, *Solution B*, and 2% nitric acid (2:1:2). A volume of 5 µL provides 0.2 mg of phosphate plus 0.01 mg of magnesium nitrate.

Blank: Nitric acid and water (1:19)

Standard stock solution: Transfer 10.0 mL of *Lead Nitrate Stock Solution*, prepared as directed in the test for *Heavy Metals* ⟨231⟩, to a 100-mL volumetric flask, add 40 mL of water and 5 mL of nitric acid, and dilute with water to volume. Transfer 1.0 mL of this solution to a second 100-mL volumetric flask, add 50 mL of water and 1 mL of nitric acid, and dilute with water to volume. This solution contains 0.10 µg/mL of lead.

Standard solutions: Dilute the *Standard stock solution* with the *Blank* to obtain concentrations of 0.002, 0.005, 0.010, 0.025, and 0.050 µg/mL of lead.

Sample solution: Prepare as directed for *Sample solution* in the test for *Limit of Arsenic.*

Analysis: Program the graphite furnace as follows. Dry at 120°, using a 1-s ramp, a 55-s hold, and an argon flow of 300 mL/min; char the sample at 850°, using a 1-s ramp, a 30-s hold, and an airflow of 300 mL/min; cool down, and purge the air from the furnace for 10 s, using a 20° set temperature and an argon flow of 300 mL/min; atomize at 2100°, using a 0-s ramp and a 5-s hold with the argon flow stopped; and clean out at 2600° with a 1-s ramp and a 5-s hold. Separately inject equal volumes (20 µL) of the *Standard solutions*, the *Sample solution*, and the *Blank*, followed by an injection of 5 µL of the *Solution C* for each of the samples, into the graphite tube of a suitable graphite furnace atomic absorption spectrometer equipped with a hollow-cathode lamp for lead. Determine the peak area at the lead emission line at 283.3 nm, corrected for background absorption. Plot the corrected peak areas of the *Standard solutions* versus their contents of lead, in µg/mL, and calculate the regression line best fitting the points. Determine the concentration, C, in µg/mL, of lead in each mL of the *Sample solution* by interpolation from the regression line.

Calculate the content of lead in the portion of Capsules taken:

$$\text{Result} = 25 \times (C/W)$$

C = concentration, as obtained above
W = weight of Capsules content taken to prepare the *Sample solution* (g)

Acceptance criteria: NMT 0.1 µg/g

- **LIMIT OF CADMIUM**

[NOTE—For the preparation of all aqueous solutions and for the rinsing of glass, polytef, and plastic vessels before use, employ water that has been passed through a strong-acid, strong-base, mixed-bed ion-exchange resin before use. Select all reagents to have as low a content of cadmium as practicable, and store all reagent solutions in containers of borosilicate glass. Cleanse glass, polytef, and plastic vessels before use by soaking in warm 8 N nitric acid for 30 min and by rinsing with deionized water.]

Solution A: 10 g of ultrapure monobasic ammonium phosphate in 40 mL of water and 1 mL of nitric acid to dissolve the phosphate. Dilute with deionized water to 100 mL.

Solution B: Transfer 1 g of ultrapure magnesium nitrate to a Teflon beaker. Add 40 mL of water and 1 mL of nitric acid, and warm on a hot plate to dissolve the solids. Allow the solution to cool to room temperature, transfer it to a 100-mL volumetric flask, and dilute with deionized water to volume.

Solution C: *Solution A*, *Solution B*, and 2% nitric acid to volume (2:1:2). A volume of 5 µL provides 0.2 mg of phosphate and 0.01 mg of magnesium nitrate.

Blank: Nitric acid and water (1:19)

Standard stock solution A: 0.1372 mg/mL of cadmium nitrate

Standard stock solution B: *Standard stock solution A*, nitric acid, and water (2:1:97). This solution contains 0.10 µg/mL of cadmium. [NOTE—Before make up to final volume dissolve in a portion of water and nitric acid.]

Standard solutions: Dilute the *Standard stock solution B* with the *Blank* to obtain concentrations of 0.002, 0.005, 0.010, 0.025, and 0.050 µg/mL of cadmium.

Sample solution: Prepare as directed for *Sample solution* in the test for *Limit of Arsenic.*

Analysis: Program the graphite furnace as follows. Dry at 120°, using a 1-s ramp, a 55-s hold, and an argon flow of 300 mL/min; char the sample at 850°, using a 1-s ramp, a 30-s hold, and an airflow of 300 mL/min; cool down, and purge the air from the furnace for 10 s, using a 20° set temperature and an argon flow of 300 mL/min; atomize at 2400°, using a 0-s ramp and a 5-s hold with the argon flow stopped; and clean out at 2600° with a 1-s ramp and a 5-s hold. Separately inject equal volumes (20 µL) of the *Standard solutions*, the *Sample solution*, and the *Blank*, followed by an injection of 5 µL of the *Solution C* for each of the samples, into the graphite tube of a suitable graphite furnace atomic absorption spectrometer equipped with a hollow-cathode lamp for cadmium. Determine the peak area at the cadmium emission line at 228.8 nm, corrected for background absorption. Plot the corrected peak areas of the *Standard solutions* versus their contents of cadmium, in µg/mL, and calculate the regression line best fitting the points. Determine the concentration, C, in µg/mL, of cadmium in each mL of the *Sample solution* by interpolation from the regression line. Calculate the content of cadmium in the Capsules taken:

$$\text{Result} = 25 \times (C/W)$$

C = concentration, as obtained above
W = weight of Capsules content taken to prepare the *Sample solution* (g)

Acceptance criteria: NMT 0.1 µg/g

- **LIMIT OF MERCURY:** Proceed as directed for *Mercury* ⟨261⟩, *Method IIa*, except to use a *Standard Mercury Solution* having the equivalent of 0.1 µg/mL of mercury.

Sample solution: Prepare as directed for the *Sample solution* in the test for *Limit of Arsenic* combining the 2 duplicate cooled digests into 1.0 mL of *Potassium Permanganate Solution.*

Acceptance criteria: NMT 0.1 µg/g

SPECIFIC TESTS

- **FATS AND FIXED OILS,** *Anisidine Value* ⟨**401**⟩**:** NMT 20.0
- **FATS AND FIXED OILS,** *Free Fatty Acids* ⟨**401**⟩**:** The free fatty acids in 10 g require for neutralization NMT 1.42 mL of 0.1 N sodium hydroxide.
- **FATS AND FIXED OILS,** *Peroxide Value* ⟨**401**⟩**:** NMT 5.0
- **FATS AND FIXED OILS,** *Total Oxidation Value (TOTOX)* ⟨**401**⟩**:** NMT 26, calculated:

In-Process Revision

Result = (2 × PV) + AV

PV = the peroxide value
AV = the anisidine value

- **FATS AND FIXED OILS,** *Unsaponifiable Matter* ⟨**401**⟩**:** NMT 4.5%

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in tight, light-resistant containers, and avoid exposure to excessive heat.
- **LABELING:** The label states the content of docosahexaenoic acid in mg/g. It also states the name and concentration of any added antioxidant.
- **USP REFERENCE STANDARDS** ⟨**11**⟩
  USP Docosahexaenoic Acid Ethyl Ester RS
  USP Eicosapentaenoic Acid Ethyl Ester RS
  USP Methyl Tricosanoate RS■2S *(USP33)*

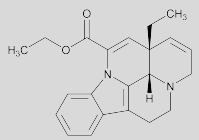
BRIEFING

Vinpocetine. Because there is no existing *USP* monograph for this dietary ingredient, a new monograph is being proposed that is based on the monograph in the *European Pharmacopoeia*. The liquid chromatographic procedure in the test for *Organic Impurities* is based on analysis performed with a Supelco Discovery C18 brand of L1 column. The typical retention time for vinpocetine is about 16 min. Interested parties are encouraged to submit comments.

(DSN: C. Phinney.) RTS—C65492

Add the following:

■Vinpocetine



$C_{22}H_{26}N_2O_2$ 350.45
Eburnamenine-14-carboxylic acid, ethyl ester, (3α,16α)-;
Ethyl apovincamin-22-oate. [42971-09-5].

DEFINITION

Vinpocetine contains NLT 98.5% and NMT 101.5% of $C_{22}H_{26}N_2O_2$, calculated on the dried basis.

IDENTIFICATION

- **A. INFRARED ABSORPTION** ⟨**197K**⟩
- **B.** The retention time of the main peak of the *Sample solution* in the test for *Organic Impurities* corresponds to the retention time of the principal peak for the *Stock standard solution*.

ASSAY

- **PROCEDURE**

Dissolve about 300 mg of Vinpocetine in 50 mL of a mixture of acetic anhydride and acetic acid (1:1), and titrate with 0.1 N perchloric acid VS determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction (see *Titrimetry* ⟨541⟩). Each mL of 0.1 N perchloric acid is equivalent to 35.05 mg of $C_{22}H_{26}N_2O_2$.

IMPURITIES

Inorganic Impurities

- **RESIDUE ON IGNITION** ⟨**281**⟩**:** NMT 0.1%
- **HEAVY METALS,** *Method II* ⟨**231**⟩**:** 0.001

Organic Impurities

- **PROCEDURE**

Ammonium acetate solution: Transfer 15.4 g of ammonium acetate to a 1-L volumetric flask, dilute with water to volume, and mix.

Mobile phase: Prepare a filtered and degassed mixture of *Ammonium acetate solution* and acetonitrile (45:55). Make adjustments if necessary (see *System Suitability* under *Chromatography* ⟨621⟩).

Sample solution: Transfer about 50.0 mg of Vinpocetine, accurately weighed, to a 50-mL volumetric flask, dissolve in and dilute with *Mobile phase* to volume, and mix.

Stock standard solution: Prepare a solution of USP Vinpocetine RS accurately weighed in *Mobile phase* having a known concentration of about 0.02 mg per mL.

Standard solution 1: Prepare a solution in *Mobile phase* containing 0.12 mg of USP Vinpocetine Related Compound A RS per mL and 0.10 mg each of USP Vinpocetine Related Compound B RS, USP Vinpocetine Related Compound C RS, and USP Vinpocetine Related Compound D RS per mL.

Standard solution 2: Dilute 1.0 mL of *Stock standard solution* and 1.0 mL of *Standard solution 1* with *Mobile phase* to 20.0 mL.

Chromatographic system
(See *Chromatography* ⟨621⟩*, System suitability.*)
Mode: LC
Detector: 280 nm
Column: 4.6-mm × 25-cm column; 5-µm packing L1
Flow rate: 1.0 mL
Chromatograph the *Stock standard solution* and *Standard solution 2*, and identify the vinpocetine peak and peaks due to the related compounds listed in *Impurity Table 1*. Record the peak responses as directed for *Analysis*: the resolution, *R*, between vinpocetine related compound B and vinpocetine related compound D is NLT 2.0.
Injection size: 15 µL (duplicate equal volumes)

System suitability
Sample: *Standard solution 2*
Suitability requirements
Resolution: NLT 2.0 between vinpocetine related compound B and vinpocetine related compound D

Analysis
Samples: *Sample solution* and *Standard solution 2*
Record the chromatograms for up to a minimum of 3 times the retention time of vinpocetine. Disregard any peak with an area less than 0.5 times the area of the peak due to vinpocetine in *Standard solution 2*. Calculate the percentage of vinpocetine related compounds A, B, C, and D in the portion of Vinpocetine taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from *Standard solution 2*
C_S = concentration of each of the known impurities in *Standard solution 2* (mg/mL)
C_U = concentraton of Vinpocetine in *Sample solution* (mg/mL)

Calculate the percentage of any unspecified individual impurity as for vinpocetine by the same formula indicated above, where C_S is the concentration of USP Vinpocetine RS in *Standard solution 2*.

Acceptance criteria: In addition to not exceeding the limits given in *Impurity Table 1*, NMT 1.0% of total impurities is found.

In-Process Revision

Impurity Table 1

Name	Relative Retention Time	Acceptance Criteria, NMT (%)
Vinpocetine	1.00	—
Vinpocetine related compound A[1]	0.40	0.6
Vinpocetine related compound B[2]	0.75	0.5
Vinpocetine related compound C[3]	0.83	0.3
Vinpocetine related compound D[4]	0.68	0.5
Unspecified individual impurity	—	0.1

[1]Ethyl (12*RS*,13a*SR*,13b*SR*)-13a-ethyl-12-hydroxy-2,3,5,6,12,13,13a,13b-octahydro-1*H*-indolo[3,2,1-de]pyrido[3,2,1-ij][1,5]naphthyridine-12-carboxylate (ethyl vincaminate).
[2]Methyl (13a*S*,13b*S*)-13a-ethyl-9-methoxy-2,3,5,6,13a,13b-hexahydro-1*H*-indolo[3,2,1-de]pyrido[3,2,1-ij][1,5]naphthyridine-12-carboxylate (apovincamine).
[3]Ethyl (13a*S*,13b*S*)-13a-ethyl-9-methoxy-2,3,5,6,13a,13b-hexahydro-1*H*-indolo[3,2,1-de]pyrido[3,2,1-ij][1,5]naphthyridine-12-carboxylate (methoxyvinpocetine).
[4]Ethyl (12*RS*,13a*RS*,13b*RS*)-13a-ethyl-2,3,5,6,12,13,13a,13b-octahydro-1*H*-indolo[3,2,1-de]pyrido[3,2,1-ij][1,5]naphthyridine-12-carboxylate (dihydrovinpocetine).

SPECIFIC TESTS

- **Loss on Drying ⟨731⟩:** Dry a sample in a vacuum at 100° for 3 h: it loses NMT 0.5% of its weight.
- **Specific Rotation ⟨781S⟩:** Between +127.0° and +134.0°, determined at 20°.
  Sample solution: 10 mg/mL in dimethylformamide

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in well-closed containers, and store at controlled room temperature.
- **USP Reference Standards ⟨11⟩**

NF MONOGRAPHS

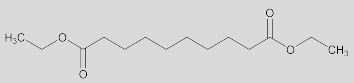
BRIEFING

Diethyl Sebacate. Because there is no existing *NF* monograph for this excipient, a new monograph is proposed based on comments and data received.

(EM2: H. Wang.) RTS—C69714

Add the following:

■Diethyl Sebacate



$CH_3CH_2OOC(CH_2)_8COOCH_2CH_3$

$C_{14}H_{26}O_4$ 258.35

Decanedioic acid, 1,10-diethyl ester;
Diethyl 1,10-decanedioate [110-40-7].

DEFINITION
Diethyl Sebacate consists of the diester of alcohol and sebacic acid. It contains NLT 98.0% and NMT 100.5% of $C_{14}H_{26}O_4$.

IDENTIFICATION
- **A. INFRARED ABSORPTION ⟨197F⟩**
- **B.** It meets the requirements of the test for *Refractive Index*.

ASSAY
- **PROCEDURE**

Analysis: Determine the Ester value, I_E, as directed in *Fats and Fixed Oils, Ester Value* ⟨401⟩.

Calculate the percentage of $C_{14}H_{26}O_4$ in the portion of Diethyl Sebacate taken:

$$\text{Result} = [(I_E \times M_{W1})/(M_{W2} \times N)] \times F \times 100$$

M_{W1} = molecular weight of $C_{14}H_{26}O_4$, 258.35 g/mol
M_{W2} = molecular weight of potassium hydroxide, 56.11 g/mol
N = ester group number per $C_{14}H_{26}O_4$, 2
F = conversion factor, 10^{-3} g/mg

Acceptance criteria: 98.0%–100.5%

IMPURITIES
Inorganic Impurities
- **RESIDUE ON IGNITION ⟨281⟩:** NMT 0.10%
- **HEAVY METALS,** *Method II* **⟨231⟩:** NMT 20 ppm

SPECIFIC TESTS
- **SPECIFIC GRAVITY ⟨841⟩:** 0.958–0.968 at 20°
- **REFRACTIVE INDEX ⟨831⟩:** 1.435–1.437 at 20°
- **FATS AND FIXED OILS,** *Acid Value* **⟨401⟩:** NMT 0.5
- **FATS AND FIXED OILS,** *Iodine Value* **⟨401⟩:** NMT 0.5

ADDITIONAL REQUIREMENTS
- **PACKAGING AND STORAGE:** Preserve in tight containers, and store in a cool, dry, and well-ventilated place.

- **USP REFERENCE STANDARDS ⟨11⟩**
USP Diethyl Sebacate RS■2S *(NF28)*

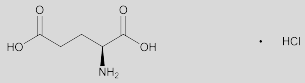
BRIEFING

L-Glutamic Acid, Hydrochloride. Because there is no existing *NF* monograph for this excipient, a new monograph is being proposed, based on the monograph appearing in *Food Chemicals Codex, 6th Edition*. Interested parties are encouraged to comment on the proposal.

(EM1: R. Lafaver. NOM: A. Wilk.) RTS—C64233

Add the following:

■L-Glutamic Acid, Hydrochloride



$C_5H_9NO_4 \cdot HCl$ 183.59

L-2-Aminoglutaric acid, hydrochloride;
2-Aminopentanedioic acid, hydrochloride [138-15-8].

DEFINITION
L-Glutamic Acid, Hydrochloride, contains NLT 98.5% and NMT 101.5% of $C_5H_9NO_4 \cdot HCl$, calculated on the dried basis.

IDENTIFICATION
- **INFRARED ABSORPTION ⟨197K⟩**

ASSAY
- **PROCEDURE**

Sample: 100 mg of L-Glutamic Acid, Hydrochloride, previously dried

Analysis: Dissolve the *Sample* in 0.5 mL of water, add 15.0 mL of 0.1 N perchloric acid VS, and heat on a water bath for 30 min. After cooling, add 45 mL of glacial acetic acid, and titrate the excess perchloric acid with 0.1 N sodium acetate, determining the endpoint potentiometrically. Perform a blank determination (see *Titrimetry* ⟨541⟩). Each mL of 0.1 N perchloric acid is equivalent to 18.36 mg of $C_5H_9NO_4 \cdot HCl$.

Acceptance criteria: 98.5%–101.5% on the dried basis

IMPURITIES
Inorganic Impurities
- **RESIDUE ON IGNITION ⟨281⟩:** NMT 0.25%
- **HEAVY METALS,** *Method I* **⟨231⟩:** NMT 5 ppm

SPECIFIC TESTS
- **OPTICAL ROTATION,** *Specific Rotation* **⟨781S⟩:** +25.2° to +25.8°, determined at 20°

Sample solution: 100 mg/mL, in 2 N hydrochloric acid
- **LOSS ON DRYING ⟨731⟩:** Dry a sample at 80° for 4 h: it loses NMT 0.5% of its weight.

ADDITIONAL REQUIREMENTS
- **PACKAGING AND STORAGE:** Store in well-closed, light-resistant containers.
- **USP REFERENCE STANDARDS ⟨11⟩**
USP L-Glutamic Acid, Hydrochloride RS■2S *(NF28)*

In-Process Revision

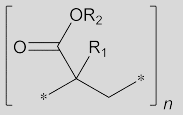
BRIEFING

Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer. Because there is no existing *NF* monograph for this excipient, a new monograph is being proposed, based on validated methods of analysis and to align with the *European Pharmacopoeia* monograph, Methacrylic Acid-Ethyl Acrylate Copolymer (1:1), Type B. The liquid chromatographic procedure in the test for *Limit of Methacrylic Acid and Ethyl Acrylate* employs a Thermo-Hypersil Aquasil C18 or Zorbax SB-AQ RP 18 brand of column that contains 5-µm packing L1. The typical retention times for methacrylic acid and ethyl acrylate are 2.8 min and 6.3 min, respectively.

(EM2: H. Wang.) RTS—C67224

Add the following:

▪Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer



$R_1 = CH_3$; R_2 = H or

$R_1 = CH_3$; R_2 = Na or

R_1 = H; $R_2 = C_2H_5$

Partially-Neutralized Poly(methacrylic acid, ethyl acrylate);
Partially-Neutralized Methacrylic acid-ethyl acrylate copolymer [25212-88-8].

DEFINITION

Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer consists of methacrylic acid and ethyl acrylate monomers arranged in a random distribution, some units of methacrylic acid in the copolymer are neutralized by sodium hydroxide. The non-neutralized methacrylic acid units in the partially-neutralized methacrylic acid and ethyl acrylate copolymer are NLT 43.2% and NMT 47.6%, calculated on the dried basis. It may contain suitable emulsifiers.

IDENTIFICATION

- **A. INFRARED ABSORPTION**

Sample: 100 mg of Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer

Analysis: Dissolve the *Sample* in 1 mL of dehydrated alcohol, and place 2 drops of the solution on a sodium chloride (or potassium bromide) plate. Dry to evaporate the solvent and allow to form a film and cover with another sodium chloride (or potassium bromide) plate.

Acceptance criteria: The IR absorption spectrum of Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer exhibits maxima corresponding to the same wavelengths as that of a similar preparation of USP Partially-Neutralized Methacrylic and Ethyl Acrylate Copolymer (1:1) RS, treated in the same manner.

- **B.** It meets the requirements of the *Assay*.

ASSAY

- **PROCEDURE**

Sample: 1 g, previously dried

Analysis: Dissolve the *Sample* in 40 mL of water and 60 mL of 2-propanol, and titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically (see *Titrimetry* ⟨541⟩). Each mL of 0.1 N sodium hydroxide is equivalent to 8.609 mg of methacrylic acid ($C_4H_6O_2$) units.

Acceptance criteria: 43.2%–47.6% for Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer

IMPURITIES

Inorganic Impurities

- **RESIDUE ON IGNITION ⟨281⟩:** 0.5%–3.0%
- **HEAVY METALS,** *Method II* **⟨231⟩:** NMT 20 ppm

Organic Impurities

- **PROCEDURE: LIMIT OF METHACRYLIC ACID AND ETHYL ACRYLATE**

Phosphoric acid solution: 0.1% phosphoric acid prepared from phosphoric acid

Mobile phase: Methanol and *Phosphoric acid solution* (3:7)

Standard solution: 1.0 µg/mL each of methacrylic acid and ethyl acrylate in methanol

Sample solution: Transfer 0.5 g of Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer to a 25-mL volumetric flask, and dissolve in 20 mL of methanol. Add *Phosphoric acid solution* dropwise to precipitate the polymer while continuously stirring until the volume of 25 mL is reached. [NOTE—Stir with a magnetic stirrer for 10 min. Any volume deviation caused by the precipitation is negligible for contents in the ppm range. Use a magnetic stirrer of appropriate size to avoid a large variance from the final volume of the *Sample solution*.] As soon as the solid matter has settled, filter the supernatant through a 0.45-µm filter. [NOTE—Solution that cannot be filtered is centrifuged at NLT 20,000 × *g* for NLT 30 min.] Use the clear supernatant.

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

Mode: LC

Detector: UV 205 nm

Column: 4.0-mm × 12.5-cm analytical column, 5-µm packing L1 or 4.6-mm × 15.0-cm analytical column, 5-µm packing L1

Flow rate: 1.2 mL/min

Injection size: 20 µL

[NOTE—Where appropriate, the volume must be adapted to the sensitivity of the detector.]

[NOTE—Column switching system may be used for extension of column lifetime.]

System suitability

Sample: *Standard solution*

[NOTE—The relative retention times for methacrylic acid and ethyl acrylate are 1.0 and 2.2, respectively.]

Suitability requirements

Resolution: NLT 5.0 between methacrylic acid and ethyl acrylate

Relative standard deviation: NMT 5.0%

In-Process Revision

Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of each monomer (methacrylic acid or ethyl acrylate) in the portion of Methacrylic Acid and Ethyl Acrylate Copolymer taken:

$$\text{Result} = (r_U/r_S) \times (C_S/W) \times V_F \times F \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of the *Standard solution* (µg/mL)
W = weight of Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer taken to prepare the *Sample solution* (g)
V_F = final volume of the *Sample solution*, 25 mL
F = conversion factor, 10^{-6} g/µg

Acceptance criteria: NMT 0.01% for the total amount of monomers

SPECIFIC TESTS

- **Loss on Drying ⟨731⟩:** Dry a sample at 110° for 6 h: it loses NMT 5.0% of its weight.
- **Viscosity ⟨911⟩:** Weigh 400 g of water and transfer to a short form, 600-mL beaker (about 80 mm in internal diameter and 120 mm high). After determining the *Loss on Drying*, weigh a quantity of undried Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer, equivalent to 100 g on the dried basis. Transfer the sample to the beaker very slowly under gentle stirring (avoid lumps). Ensure a homogeneous solution by gently stirring at room temperature for 3 h and taking care to avoid mixing in excess air. Afterwards allow the container to stand for 1 h, control the temperature to 23 ± 0.1°, and let the entrapped air dissipate. [NOTE—Ensure that the concentration of this solution is 20% (w/w).] Determine the viscosity of this solution at 23 ± 0.1° using a suitable rotational viscometer with a cylindrical spindle 1.9 cm in diameter and 6.5 cm high, attached to a shaft 0.3 cm in diameter.[1] The spindle rotates at 50 rpm at an immersion depth of 8.1 cm. Follow the instrument manufacturer's directions to measure the apparent viscosity.
  Acceptance criteria: 20–100 mPa · s

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in tight containers, and store at controlled room temperature.
- **Labeling:** Label it to indicate the range of non-neutralized methacrylic acid units. The labeling also indicates the name and quantity of any emulsifier if the content is 0.10% or greater.
- **USP Reference Standards ⟨11⟩**
  USP Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer (1:1) RS■2S *(NF28)*

BRIEFING

Methylpyrrolidone. Because there is no existing *NF* monograph for this excipient, a new monograph, based on the monograph appearing in *European Pharmacopoeia, 6.3 Edition*, is being proposed. Interested parties are encouraged to comment on the proposal.

(EM1: R. Lafaver. NOM: A. Wilk.) RTS—C65585

[1]A suitable spindle is available from Brookfield as an LV1 spindle, or the equivalent.

Add the following:

■Methylpyrrolidone

C_5H_9NO 99.1

1-Methyl-2-pyrrolidinone;
N-Methyl-2-pyrrolidone;
N-Methylpyrrolidone;
1-Methyl-2-Pyrrolidone;
Pyrrolidin, 1-methyl-2-one-;
1-Methylpyrrolidin-2-one;
N-Methyl-γ-butyrolactam;
N-Methyl tetrahydropyrrolone;
1-Methyl-2-oxopyrrolidine;
N-Methyl-1-oxotetramethyleneamine;
2-Methyl-2-azacyclopentanone [872-50-4].

IDENTIFICATION

- **Infrared Absorption ⟨197F⟩**

IMPURITIES

Inorganic Impurities

- **Heavy Metals ⟨231⟩:** NMT 10 ppm

Organic Impurities

- **Procedure**
  Standard solution: To 1 mL of USP Methylpyrrolidone RS, add 1 mL of pyrrolidone, and dilute with methylene chloride to 20 mL.
  Sample solution: Methylpyrrolidone (neat)
  Chromatographic system
  (See *Chromatography* ⟨621⟩, *System Suitability*.)
  Mode: GC
  Detector: Flame ionization
  Column: 0.32-mm × 30-m fused-silica capillary column, 5-µm of phase G2
  Temperature
  Injector: 280°
  Detector: 280°
  Column: See the temperature program table.

Initial Temperature (°)	Temperature Ramp (°/min)	Final Temperature (°)	Hold Time at Final Temperature (min)
100	—	100	0
100	3	170	30

  Carrier gas: Nitrogen
  Linear velocity: 20 cm/s
  Split ratio: 100:1
  Injection size: 1 µL
  System suitability
  Sample: *Standard solution*
  Suitability requirements
  Resolution: NLT 2.0 between pyrrolidone and methylpyrrolidone
  Analysis
  Samples: *Standard solution* and *Sample solution*
  Calculate the percentage of each impurity, excluding any solvent peaks and peaks NMT 0.02%, in the portion of Methylpyrrolidone taken:

$$\text{Result} = (r_U/r_T) \times 100$$

r_U = peak response of each individual impurity from the *Sample solution*
r_T = sum of the responses of all the peaks from the *Sample solution*

  Acceptance criteria: NMT 0.1% of any individual impurity; and NMT 0.3% of total impurities

In-Process Revision

SPECIFIC TESTS

- **ALKALINITY**

Bromothymol blue solution: Dissolve 50 mg of bromothymol blue in a mixture of 4 mL of 0.02 M sodium hydroxide and 20 mL of alcohol, and dilute with water to 100 mL.

Sample: Methylpyrrolidone (neat)

Analysis: Add 0.5 mL of *Bromothymol blue solution* as indicator to 50 mL of water and adjust with 0.02 M potassium hydroxide or 0.02 M hydrochloric acid until a yellow color is obtained. Add 50 mL of *Sample*. Titrate with 0.02 M hydrochloric acid to the initial coloration.

Acceptance criteria: NMT 8.0 mL of 0.02 M hydrochloric acid is required.

- **CLARITY OF SOLUTION**

[NOTE—The *Sample* is to be compared to the *Reference suspension* in diffused daylight 5 min after preparation of the *Reference suspension*.]

Hydrazine solution: 10 mg/mL of hydrazine sulfate. [NOTE—Allow to stand 4–6 h before use.]

Methenamine solution: Transfer 2.5 g of methenamine to a 100-mL glass-stoppered flask, add 25.0 mL of water, insert the glass stopper, and mix to dissolve.

Primary opalescent suspension

[NOTE—This suspension is stable for 2 months, provided it is stored in a glass container free from surface defects. The suspension must not adhere to the glass and must be well mixed before use.]

Transfer 25.0 mL of *Hydrazine solution* to the *Methenamine solution* in the 100-mL glass-stoppered flask.

[NOTE—Allow to stand for 24 h.]

Opalescence standard: Transfer 15.0 mL of the *Primary opalescent suspension* to a 1000-mL volumetric flask, and dilute with water to volume. [NOTE—This suspension should not be used beyond 24 h after preparation.]

Reference suspension: Transfer 5.0 mL of the *Opalescence standard* to a 100-mL volumetric flask, and dilute with water to volume.

Sample: Methylpyrollidone (neat)

Analysis: Transfer a sufficient portion of the *Sample* to a test tube of colorless, transparent, neutral glass with a flat base and an internal diameter of 15–25 mm to obtain a depth of 40 mm. Similarly transfer portions of *Reference suspension* and water to separate matching test tubes. Compare the *Sample, Reference suspension*, and water in diffused daylight, viewing vertically against a black background (see *Spectrophotometry and Light-Scattering* ⟨851⟩*, Visual Comparison*.)

[NOTE—The diffusion of light must be such that the *Reference suspension* can readily be distinguished from water.]

Acceptance criteria: The *Sample* shows the same clarity as that of water, or its opalescence is not more pronounced than that of the *Reference suspension.*

- **COLOR OF SOLUTION**

Sample Methylpyrollidone (neat)

Analysis: Transfer a sufficient portion of the *Sample* to a test tube of colorless, transparent, neutral glass with a flat base and an internal diameter of 15–25 mm, to obtain a depth of 40 mm. Similarly transfer a portion of water to a separate matching test tube. Compare the color of the *Sample* with that of water in diffused daylight, viewing vertically against a white background (see *Spectrophotometry and Light-Scattering* ⟨851⟩*, Visual Comparison*).

Acceptance criteria: The *Sample* has the color of water.

- **WATER,** *Method Ic* ⟨**921**⟩**:** NMT 0.1%, determined on 1.0 g

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in light-resistant containers.

USP Methylpyrrolidone RS■2S *(NF28)*

BRIEFING

Polydextrose, *NF 27* page 1306. On the basis of the comments and data received, it is proposed to make the following revisions.

1. Use an HPLC method to replace the current procedures for the *Assay*, a nonselective colorimetric assay in sulfuric acid medium for quantitation of polydextrose, and for the *Limit of Monomers*, a silyation in combination with GC determination of residual monomers. The submitted HPLC procedure in the *Assay* and in the test for *Limit of Monomers* is based on analyses performed using the Bio-Rad Aminex Ion Exclusion HPX-87H brand of L17 column; polydextrose elutes at approximately 5.8 min on this system.
2. USP Polydextrose RS is introduced into this monograph.
3. In the test for *Molecular Weight Limit*, the HPLC column designation is changed from L25 to L39. The subsections for *System suitability* and *Analysis* are revised.
4. In the test for *Limit of Lead*, the recovery spec is added in the monograph.

(EM2: H. Wang.) RTS—C72332

Polydextrose

[68424-04-4]

DEFINITION

Polydextrose is a randomly branched polymer prepared by melting and subsequent condensation of the ingredients, which consist of approximately 90 parts dextrose, 10 parts sorbitol, and up to 1 part citric acid or 0.1 part phosphoric acid. The 1,6-glycosidic linkage predominates in the polymer but other linkages are present. It contains NLT 90.0% of dextrose polymer units, calculated on the anhydrous and ash-free basis. It contains small quantities of free dextrose, sorbitol, and 1,6-anhydro-D-glucose (levoglucosan), with traces of citric acid or phosphoric acid.

IDENTIFICATION

- **A.** To 1 drop of a solution (1 in 10) add 4 drops of 5% phenol solution, then rapidly add 15 drops of sulfuric acid TS: a deep yellow to orange color is produced.
- **B.** With vigorous swirling, add 1 mL of acetone to 1 mL of a solution (1 in 10): the solution remains clear.
- **C.** With vigorous swirling, add 2 mL of acetone to the solution obtained in *Identification* test *B*: a heavy, milky turbidity develops immediately.
- **D.** To 1 mL of a solution (1 in 50) add 4 mL of alkaline cupric citrate TS. Boil vigorously for 2–4 min. Remove from heat, and allow the precipitate (if any) to settle: the supernatant is blue or blue-green.

ASSAY

- **PROCEDURE**

~~**Phenol solution:** Add 20 mL of water to 80 g of phenol.~~

~~**Dextrose stock standard solution:** 0.2 mg/mL of USP Dextrose RS~~

~~**Standard solution A:** 5 µg/mL of dextrose, from *Dextrose stock standard solution*~~

~~**Standard solution B:** 10 µg/mL of dextrose, from *Dextrose stock standard solution*~~

~~**Standard solution C:** 20 µg/mL of dextrose, from *Dextrose stock standard solution*~~

~~**Standard solution D:** 40 µg/mL of dextrose, from *Dextrose stock standard solution*~~

In-Process Revision

~~**Standard solution E:** 50 µg/mL of dextrose, from *Dextrose stock standard solution*~~
~~**Sample solution:** Transfer 10 mg of Polydextrose, weighed and calculated on the anhydrous and ash-free basis, to a 250-mL volumetric flask, and dilute with water to volume.~~
~~**Spectrometric conditions**~~
~~**Mode:** UV-Vis~~
~~**Analytical wavelength:** 490 nm~~
~~**Cell:** 1 cm~~
~~**Blank:** Prepare as directed under *Analysis* below.~~
~~**Analysis:** *Standard solution A, Standard solution B, Standard solution C, Standard solution D,* and *Standard solution E*~~
~~**Samples:** *Sample solution* and *Blank*~~
~~Freshly pipet 2.0 mL of each of the *Standard solutions* into a separate acetone-free, 15-mL vial equipped with a screw-cap. Transfer 2.0 mL of the *Sample solution* to a separate acetone-free, 15-mL vial equipped with a screw-cap, and transfer 2.0 mL of water to a separate acetone-free, 15-mL vial equipped with a screw-cap to provide the *Blank*. To each vial, add 0.12 mL of the *Phenol solution*, cap the vial, and mix gently. Uncap each vial, and rapidly add 5.0 mL of sulfuric acid. Immediately recap each vial, and shake vigorously.~~
~~[**CAUTION**—Wear rubber gloves and a safety shield while adding sulfuric acid.]~~
~~Allow the vials to stand at room temperature for 45 min. Determine the absorbances of the solutions using the *Spectrometric system*, using the *Blank* to set the instrument. Prepare a standard curve by plotting the absorbances of the solutions from the *Standard solutions* versus their contents of dextrose, in µg/mL. Draw the straight line best fitting the five points, and extrapolate the line until it intercepts the absorbance axis (y axis). From the curve, determine the concentration C_D, in µg/mL, of dextrose in the *Sample solution*.~~
~~Calculate the percentage of dextrose polymer units in the Polydextrose taken:~~

~~$$\text{Result} = F_T[25C_D/W_T - P_G - (F_2 \times P_L)]$$~~

~~F_T = experimentally derived correction factor to account for the polymer (which also contains a small amount of sorbitol) not giving the exact amount of color given by an equivalent amount of glucose monomers, 1.05~~
~~W_T = weight of the Polydextrose taken to prepare the *Sample solution* (mg)~~
~~P_G = percentage of dextrose determined in the test for *Limit of Monomers*~~
~~P_L = percentage of 1,6-anhydrous-D-glucose (levoglucosan) determined in the test for *Limit of Monomers*~~
~~F_2 = conversion factor from 1,6-anhydrous-D-glucose, which gives an equivalent amount of color to an equivalent weight of glucose, 1.11~~

■**Mobile phase:** 0.001 N sulfuric acid. Pass this solution through a filter having a 0.5-µm or finer porosity, and degas.
Standard solution: 4.0 mg/mL of USP Polydextrose RS, calculated on the anhydrous and ash-free basis, in *Mobile phase*
Sample solution: 4.0 mg/mL of Polydextrose, calculated on the anhydrous and ash-free basis, in *Mobile phase*

Acceptance criteria: NLT 90.0%

IMPURITIES

Inorganic Impurities

- **RESIDUE ON IGNITION ⟨281⟩:** NMT 0.3%
- **LIMIT OF LEAD**

[NOTE—Use reagent-grade chemicals with as low a lead content as is practicable, as well as high-purity water and gases. Before use in this analysis, rinse all glassware and plasticware twice with 10% nitric acid and twice with 10% hydrochloric acid, and then rinse them thoroughly with Purified Water.]
Matrix modifier solution: Prepare a solution in water containing 100.0 mg of dibasic ammonium phosphate per 10 mL of solution.
Lead nitrate stock solution: Dissolve 159.8 mg of lead nitrate in 100 mL of water to which has been added 1 mL of nitric acid, then dilute with water to 1000 mL. Prepare and store this solution in glass containers free from soluble lead salts.
Standard lead solution: On the day of use, dilute 10.0 mL of *Lead nitrate stock solution* with water to 100.0 mL. Each mL of *Standard lead solution* contains the equivalent of 10 µg of lead.
Standard solution A: 0.02 µg/mL of lead, from *Standard lead solution* in water
Standard solution B: 0.05 µg/mL of lead, from *Standard lead solution* in water
Standard solution C: 0.1 µg/mL of lead, from *Standard lead solution* in water
Standard solution D: 0.2 µg/mL of lead, from *Standard lead solution* in water
Standard solution E: 0.5 µg/mL of lead, from *Standard lead solution* in water
Sample solution: Transfer 1.0 g of Polydextrose, weighed and calculated on the anhydrous and ash-free basis, into a 10-mL volumetric flask, and dissolve in and dilute with water to volume.
Spiked sample solution: Transfer 1.0 g of Polydextrose, weighed and calculated on the anhydrous and ash-free basis, into a 10-mL volumetric flask, and dissolve in water. Add 100 µL of the *Standard lead solution*, and dilute with water to volume. This solution contains 0.1 µg/mL of added lead.
Spectrometric conditions
(See *Spectrophotometry and Light-Scattering* ⟨851⟩.)
Mode: Graphite furnace atomic absorption spectrophotometer, equipped with a pyrolytic tube with a platform and a lead hollow-cathode lamp, using a slit width of 0.7 mm (set low) and a deuterium arc lamp for background correction
Analytical wavelength: Lead emission line of 283.3 nm
Injection size: See *Samples* under *Analysis* below.
Temperature: The drying temperature of the furnace is maintained at 130° for 40 s after a 20-s ramp time using

In-Process Revision

an argon flow rate of 300 mL/min, the ashing temperature is maintained at 800° for 40 s after a 20-s ramp time using an argon flow rate of 300 mL/min, and the atomization temperature is maintained at 2400° for 6 s using an argon flow rate of 50 mL/min. Clean the graphite furnace at 2600° for 5 s after a 1-s ramp time using an argon flow rate of 300 mL/min, and recharge the graphite furnace at 20° for 20 s after a 2-s ramp time using an argon flow rate of 300 mL/min.

Analysis

Samples: 10-µL aliquots of the five *Standard solutions*, a mixture of 10 µL of the *Matrix modifier solution* and 10 µL of the *Sample solution*, and a mixture of 10 µL of the *Matrix modifier solution* and 10 µL of the *Spiked sample solution*.

Concomitantly determine the absorbances of the *Samples* using the *Spectrometric conditions* described above. Plot the absorbance of each *Standard solution*, compensated for background correction, versus its content of lead, in µg/mL, and draw the straight line best fitting the five points. From this plot, determine the concentrations, C_T and C_{ST}, in µg/mL, of lead in the *Sample solution* and the *Spiked sample solution*, respectively.

Calculate the percentage recovery taken:

$$\text{Result} = [(CST - CT)/A] \times 100$$

A = amount of lead added to the *Spiked sample solution*, 0.1 µg/mL

Calculate the content, in µg/g, of lead in the portion of Polydextrose taken:

$$\text{Result} = (CT/W) \times V$$

W = weight of Polydextrose taken to prepare the *Sample solution* (g)

V = volume of the *Sample solution*, 10 mL

Acceptance criteria: NMT 0.5 µg/g on the anhydrous and ash-free basis. The recovery is 80%-120%.

In-Process Revision

BRIEFING

Hydrogenated Polydextrose. Because there is no existing *NF* monograph for this excipient, a new monograph is being proposed, based on validated methods of analysis. The HPLC procedure in the *Assay* and *Limit of Monomers* is based on analyses performed using the Bio-Rad Aminex Ion Exclusion HPX-87H brand of L17 column. Hydrogenated Polydextrose elutes at approximately 5.8 min on this system.

(EM2: H. Wang.) RTS—C68840

Add the following:

▪Hydrogenated Polydextrose

DEFINITION

Hydrogenated Polydextrose is obtained by transition metal catalytic hydrogenation of Polydextrose in aqueous solution. It contains NLT 90.0% of dextrose polymer units, calculated on the anhydrous and ash-free basis. The polymer chain end groups are mainly sorbitol-terminated.

IDENTIFICATION

- **A.** To 1 drop of a solution (1 in 10), add 4 drops of 5% phenol solution, then rapidly add 15 drops of sulfuric acid TS: a deep yellow to orange color is produced.
- **B.** With vigorous swirling, add 1 mL of acetone to 1 mL of a solution (1 in 10): the solution remains clear.
- **C.** With vigorous swirling, add 2 mL of acetone to the solution obtained in *Identification* test *B*: a heavy, milky turbidity develops immediately.
- **D.** To 1 mL of a solution (1 in 50), add 4 mL of alkaline cupric citrate TS. Boil vigorously for 2–4 min. Remove from heat, and allow the precipitate (if any) to settle: the supernatant is blue or blue-green.
- **E.** Meets the requirements for dextrose under *Limit of Monomers*

ASSAY

- **PROCEDURE**

Mobile phase: 0.001 N sulfuric acid. Pass through a filter having a 0.5-µm or finer porosity, and degas.

Standard solution: 4.0 mg/mL of USP Polydextrose RS, calculated on the anhydrous and ash-free basis, in *Mobile phase*

Sample solution: 4.0 mg/mL of Hydrogenated Polydextrose, calculated on the anhydrous and ash-free basis, in *Mobile phase*

Chromatographic system

(See *Chromatography* ⟨621⟩*, System Suitability*.)

Mode: LC

Detector: Refractive index

Detector temperature: 35 ± 0.1°

Guard column: 4.6-mm × 3.0-cm guard column; packing L17

Analytical column: 7.8-mm × 30-cm analytical column; packing L17

Flow rate: 0.6 mL/min

Injection size: 20 µL

System suitability

Sample: *Standard solution*

Suitability requirements

Relative standard deviation: NMT 2.0%

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of dextrose polymer units in the Hydrogenated Polydextrose taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response for dextrose polymer units from the *Sample solution*

r_S = peak response for dextrose polymer units from the *Standard solution*

C_S = concentration of USP Polydextrose RS in the *Standard solution* (mg/mL)

C_U = concentration of Hydrogenated Polydextrose in the *Sample solution* (mg/mL)

Acceptance criteria: NLT 90.0% on the anhydrous and ash-free basis

IMPURITIES

Inorganic Impurities

- **RESIDUE ON IGNITION ⟨281⟩:** NMT 0.3%
- **LIMIT OF LEAD**

[NOTE—Use reagent-grade chemicals with a lead content of as low as possible, as well as high-purity water and gases. Before use in this analysis, rinse all glassware and plasticware twice with 10% nitric acid and twice with 10% hydrochloric acid, and then rinse them thoroughly with Purified Water.]

Matrix modifier solution: 10.0 mg/mL of dibasic ammonium phosphate

Lead nitrate stock solution: Dissolve 159.8 mg of lead nitrate in 100 mL of water to which has been added 1 mL of nitric acid, then dilute with water to 1000 mL. Prepare and store this solution in glass containers free from soluble lead salts.

Standard lead solution: On the day of use, dilute 10.0 mL of *Lead nitrate stock solution* with water to 100.0 mL. Each mL of *Standard lead solution* contains the equivalent of 10 µg of lead.

Standard solution A: 0.02 µg/mL of lead, from *Standard lead solution* in water

Standard solution B: 0.05 µg/mL of lead, from *Standard lead solution* in water

Standard solution C: 0.1 µg/mL of lead, from *Standard lead solution* in water

Standard solution D: 0.2 µg/mL of lead, from *Standard lead solution* in water

Standard solution E: 0.5 µg/mL of lead, from *Standard lead solution* in water

Sample solution: Transfer 1.0 g of Hydrogenated Polydextrose, weighed and calculated on the anhydrous and ash-free basis, into a 10-mL volumetric flask, dissolve in and dilute with water to volume.

Spiked sample solution: Transfer 1.0 g of Hydrogenated Polydextrose, weighed and calculated on the anhydrous and ash-free basis, into a 10-mL volumetric flask, and dissolve in water. Add 100 µL of the *Standard lead solution*, and dilute with water to volume. This solution contains 0.1 µg/mL of added lead.

Spectrometric conditions

(See *Spectrophotometry and Light-Scattering* ⟨851⟩.)

Mode: Graphite furnace atomic absorption spectrophotometer, equipped with a pyrolytic tube with a platform

Lamp: A lead hollow-cathode lamp, using a slit width of 0.7 mm (set low) and a deuterium arc lamp for background correction

Analytical wavelength: Lead emission line of 283.3 nm

Injection size: See *Samples* in the *Analysis* below.

Temperature: The drying temperature of the furnace is maintained at 130° for 40 s after a 20-s ramp time using an argon flow rate of 300 mL/min; the ashing temperature

In-Process Revision

is maintained at 800° for 40 s after a 20-s ramp time using an argon flow rate of 300 mL/min; and the atomization temperature is maintained at 2400° for 6 s using an argon flow rate of 50 mL/min. Clean the graphite furnace at 2600° for 5 s after a 1-s ramp time using an argon flow rate of 300 mL/min, and recharge the graphite furnace at 20° for 20 s after a 2-s ramp time using an argon flow rate of 300 mL/min.

Analysis

Samples: 10-µL aliquots of the five *Standard solutions*; a mixture of 10 µL of the *Matrix modifier solution* and 10 µL of the *Sample solution*; and a mixture of 10 µL of the *Matrix modifier solution* and 10 µL of the *Spiked sample solution*

Concomitantly determine the absorbances of the *Samples* using the *Spectrometric conditions* described above. Plot the absorbance of each *Standard solution*, compensated for background correction, versus its content of lead, in µg/mL, and draw the best straight line fitting the five points. From this plot, determine the concentrations, C_T and C_{ST}, in µg/mL, of lead in the *Sample solution* and the *Spiked sample solution*, respectively.

Calculate the percentage recovery taken:

$$\text{Result} = [(C_{ST} - C_T)/A] \times 100$$

A = quantity of lead added to the *Spiked sample solution*, 0.1 µg/mL

Calculate the content, in µg/g, of lead in Hydrogenated Polydextrose taken:

$$\text{Result} = (C_T/W) \times V$$

W = weight of Hydrogenated Polydextrose taken to prepare the *Sample solution* (g)

V = volume of the *Sample solution*, 10 mL

Acceptance criteria: NMT 0.5 µg/g; recovery is 80%-120%

- **LIMIT OF NICKEL**

[NOTE—All glassware used must be soaked in *1% Nitric acid* for at least 2 h and then rinsed with water.]

1% Nitric acid: Cautiously add 10 mL of nitric acid to a 1000-mL volumetric flask containing about 500 mL of water. Mix, and dilute with water to volume.

Blank solution: Use *1% Nitric acid*.

Nickel stock standard solution: Immediately before use, dilute an appropriate amount of nickel standard* with *1% Nitric acid* to prepare a solution containing the equivalent of 10 µg/mL of nickel.

Standard solutions: Into four identical 100-mL volumetric flasks, introduce respectively 1.0, 2.0, 5.0, and 10.0 mL of *Nickel stock standard solution*. Dilute with *1% Nitric acid* to volume, and mix. These standards contain 0.1, 0.2, 0.5, and 1.0 µg/mL of nickel.

Sample solution: Weigh 5 g of Hydrogenated Polydextrose into a 100-mL volumetric flask. Dissolve in and dilute with *1% Nitric acid* to volume, and mix.

Spectrometric conditions

(See *Spectrophotometry and Light-Scattering* ⟨851⟩.)

Mode: Atomic absorption spectrophotometer equipped with an air–acetylene flame

Lamp: Nickel hollow-cathode

Analytical wavelength: 352.0 nm

System suitability

Sample: *Standard solution* of 0.2 µg/mL of nickel

Suitability requirements

Relative standard deviation: NMT 20%

Analysis

Samples: *Standard solutions* and *Sample solution*

Use the *Blank solution* to zero the instrument. Concomitantly determine the absorbances of the *Samples* at least three times each. Record the average of the steady readings for each of the *Samples*. Clear the nebulizer using the *Blank solution*, and aspirate each of the *Samples* in turn. The standard chosen for reslope should be run every four to five samples. If there is a significant change in its response, reslope and repeat the previous samples.

Plot the absorbances of the *Standard solutions* versus concentration, in µg/mL, of nickel, and draw the straight line best fitting the four plotted points. From the graph so obtained, determine the concentration, C, in µg/mL, of nickel in the *Sample solution*. Calculate the quantity, in µg, of nickel in each g of Hydrogenated Polydextrose taken:

$$\text{Result} = (V \times C)/W$$

V = volume of the *Sample solution*, 100 mL

W = weight of Hydrogenated Polydextrose taken to prepare the *Sample solution* (g)

Acceptance criteria: NMT 2 µg/g

Organic Impurities

- **PROCEDURE 1: LIMIT OF 5-HYDROXYMETHYLFURFURAL AND RELATED COMPOUNDS**

Sample solution: 1.0 g of Hydrogenated Polydextrose, weighed and calculated on the anhydrous and ash-free basis, diluted with water to 100 mL

Analysis: Determine the absorbance of the *Sample solution* in a 1-cm quartz cell at 283 nm, with a suitable spectrophotometer, using water as the blank.

Calculate the percentage of 5-hydroxymethylfurfural and related compounds in the Hydrogenated Polydextrose taken:

$$\text{Result} = (V \times M_r \times A)/(\varepsilon_{283} \times L \times W) \times 100$$

V = volume of the *Sample solution*, 0.1 L

M_r = molecular weight of 5-hydroxymethylfurfural, 126 g/mol

A = absorbance of the *Sample solution*

ε_{283} = molar extinction coefficient of 5-hydroxymethylfurfural at a wavelength of 283 nm, 16830 $L \cdot mol^{-1} \cdot cm^{-1}$

L = path length of the spectrophotometer cell (cm)

W = weight of Hydrogenated Polydextrose taken to prepare the *Sample solution* (g)

Acceptance criteria: NMT 0.1%

- **PROCEDURE 2: LIMIT OF MONOMERS**

Mobile phase, Sample solution, and **Chromatographic system:** Prepare as directed in the *Assay*.

Standard solution: 0.08 mg/mL of each for USP 1,6-Anhydro-D-glucose RS and USP Sorbitol RS, and 0.04 mg/mL for USP Dextrose RS, in *Mobile phase*

System suitability

Sample: *Standard solution*

[NOTE—See the relative retention times table below.]

Name	Relative Retention Time
Dextrose (glucose)	0.7
Sorbitol	0.8
An isomer of 1,6-anhydro-D-glucose (D-anhydroglucose furanose form)	0.9
1,6-Anhydro-D-glucose (levoglucosan) (D-anhydroglucose pyranose form)	1.0

Suitability requirements

Resolution: NLT 1.0

Relative standard derivation: NMT 5.0%

Analysis

Samples: *Standard solution* and *Sample solution*

Use the peak response of USP 1,6-Anhydro-D-glucose RS in the *Standard solution* for calculation of the percentage of the isomer of 1,6-anhydro-D-glucose in the *Sample solution*. Calculate the percentage of each monomer in the portion of Hydrogenated Polydextrose taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

*Suitable nickel standards are available from e.g., Fisher Scientific, Fair Lawn, NJ (nickel, reference standard solution, 1000 ppm ±1%, certified, application for atomic absorption) or RICCA Chemical Company, Arlington, TX (nickel standard, 1000 ppm Ni, for atomic absorption).

r_U = peak response for the respective monomer from the *Sample solution*
r_S = peak response for the respective monomer from the *Standard solution*
C_S = concentration of the respective standard monomer in the *Standard solution* (mg/mL)
C_U = concentration of Hydrogenated Polydextrose in the *Sample solution* (mg/mL)

Acceptance criteria: NMT 4.0% of 1,6-anhydro-D-glucose, NMT 5.75% for sorbitol and NMT 0.25% for dextrose

[NOTE—In the case of 1,6-anhydro-D-glucose, the peak areas for the pyranose and furanose forms are combined.]

SPECIFIC TESTS

- **MOLECULAR WEIGHT LIMIT**

Mobile phase: Dissolve 35.0 g of sodium nitrate and 1.0 g of sodium azide in 100 mL of water. Dilute with water to 4 L. Pass through a filter having a 0.45-µm or finer porosity, and degas by applying an aspirator vacuum for 30 min. The resulting *Mobile phase* is 0.1 N sodium nitrate containing 0.025% sodium azide.

Standard solution: Transfer 20 mg each of USP Dextrose RS, stachyose, and 5800-, 23,700-, and 100,000-molecular weight (MW) pullulan standards into a 10-mL volumetric flask. Dissolve in and dilute with *Mobile phase* to volume. Pass through a syringe filter having a 0.45-µm or finer porosity into a suitable autosampler vial, and seal.

Sample solution: Transfer 50 mg of Hydrogenated Polydextrose into a 10-mL volumetric flask. Dissolve in and dilute with *Mobile phase* to volume. Pass through a syringe filter having a 0.45-µm or finer porosity into a suitable autosampler vial, and seal.

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

Mode: LC

Detector: Refractive index set at a sensitivity of 4×10^{-6} refractive index units full scale and maintained at a temperature of $35 \pm 0.1°$

Column: 7.8-mm × 30-cm; packing L39

Column temperature: 45°

Flow rate: 0.8 mL/min

[NOTE—After installation of a new column, pump *Mobile phase* through the column overnight at a rate of 0.3 mL/min. Before calibration or analysis, increase the flow slowly over a 1-min period to 0.8 mL/min. Continue to pump *Mobile phase* through the column at this flow rate for at least 1 h before the first injection. Check the flow gravimetrically, and adjust it if necessary. Reduce the flow rate to about 0.1 mL/min when the system is not in use.]

Injection size: 50 µL

System suitability

Sample: *Standard solution*

Chromatograph five replicate injections of the *Standard solution*, allowing 15 min between injections, and record the retention times of the components of the *Standard solution.* Insert the average retention time along with the molecular weight of each component in the *Standard solution* into the calibration table of the molecular weight distribution software. Check the regression results for a cubic fit of the calibration points, and obtain a correlation coefficient, R, for the line.

Suitability requirements

Retention time: The retention times for each component determined on replicate injections agree within ±2 s.

Resolution: Dextrose and stachyose are baseline resolved from one another and from the 5800-MW pullulan standard.

[NOTE—Prominent negative baseline valleys are usually observed between the peaks for the 5800-, 23,700-, and 100,000-MW pullulan standards.]

Correlation coefficient R: NLT 0.9999

Analysis

Samples: *Standard solution* and *Sample solution*

Use the molecular weight distribution software of the data reduction system to generate a molecular weight distribution plot of Hydrogenated Polydextrose.

Acceptance criteria: No measurable peak above a molecular weight of 22,000 is found.

- **pH** ⟨**791**⟩**:** 5.0–7.0, in a solution (1 in 10)
- **WATER DETERMINATION,** *Method I* ⟨**921**⟩**:** NMT 4.0%. Use anhydrous pyridine in the titration vessel.

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in tight, light-resistant containers. Store in a cool and dry place.
- **USP REFERENCE STANDARDS** ⟨**11**⟩

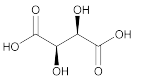
USP 1,6-Anhydro-D-glucose RS
USP Dextrose RS
USP Polydextrose RS
USP Sorbitol RS■2S *(NF28)*

BRIEFING

Tartaric Acid, *NF 27* page 1368. As part of USP modernization efforts, it is proposed to replace the existing nonspecific *Identification* test *B* with a more specific infrared absorption test employing a USP Reference Standard for comparison. Interested parties are encouraged to comment.

(EM1: R. Lafaver.) RTS—C74455

Tartaric Acid



$C_4H_6O_6$ 150.09

Butanedioic acid, 2,3-dihydroxy-;
Butanedioic acid, 2,3-dihydroxy-, [*R*-(*R**,*R**)]-;
Tartaric acid; L-(+)-Tartaric acid [526-83-0]; [87-69-4].

DEFINITION

Tartaric Acid, dried over phosphorus pentoxide for 3 h, contains NLT 99.7% and NMT 100.5% of $C_4H_6O_6$.

IDENTIFICATION

- **A. IDENTIFICATION TESTS—GENERAL,** *Tartrate* ⟨**191**⟩**:** It meets the requirements.

Change to read:

- **B. ■INFRARED ABSORPTION** ⟨**197K**⟩■2S *(NF28)*~~When ignited, it gradually decomposes, emitting an odor resembling that of burning sugar (distinction from citric acid).~~■2S *(NF28)*

ASSAY

- **PROCEDURE**

Sample: 2 g of Tartaric Acid, previously dried, in a conical flask

In-Process Revision

Analysis: Dissolve *Sample* in 40 mL of water, add phenolphthalein TS, and titrate with 1 N sodium hydroxide VS. Each mL of 1 N sodium hydroxide is equivalent to 75.04 mg of $C_4H_6O_6$.
Acceptance criteria: 99.7%–100.5%

IMPURITIES

Inorganic Impurities

- **RESIDUE ON IGNITION** ⟨**281**⟩**:** NMT 0.1%
- **CHLORIDE AND SULFATE,** *Sulfate* ⟨**221**⟩
  Sample solution: 10 mL of a 1-in-100 solution of Tartaric Acid
  Analysis: Add to *Sample solution* 3 drops of hydrochloric acid and 1 mL of barium chloride TS
  Acceptance criteria: No turbidity is produced.
- **HEAVY METALS,** *Method II* ⟨**231**⟩**:** NMT 10 ppm

SPECIFIC TESTS

- **OPTICAL ROTATION,** *Specific Rotation* ⟨**781S**⟩**:** +12.0° to +13.0°
  Sample solution: 200 mg/mL in water
- **LOSS ON DRYING** ⟨**731**⟩**:** Dry over phosphorus pentoxide for 3 h: it loses NMT 0.5% of its weight.
- **LIMIT OF OXALATE**
  Sample solution: 10 mL of a 1-in-10 solution of Tartaric Acid
  Analysis: Nearly neutralize the *Sample solution* with 6 N ammonium hydroxide, and add 10 mL of calcium sulfate TS.
  Acceptance criteria: No turbidity is produced.

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in well-closed containers.

Add the following:

■• **USP REFERENCE STANDARDS** ⟨**11**⟩

In-Process Revision

GENERAL CHAPTERS

General Tests and Assays

General Requirements for Tests and Assays

BRIEFING

⟨**1**⟩ **Injections,** *USP 32* page 31 and page 601 of *PF* 35(3) [May–June 2009]. As currently written, the *Volume in Container* section addresses the determination of volume in container only for liquid parenteral products. Therefore, the Parenteral Products—Industrial Expert Committee is proposing to add text that provides guidance for determining the volume in container for sterile solid formulations, currently absent from the compendia. In addition, it is proposed to change the section title *Volume in Container* to *Container Content*.

(PPI: D. Hunt) RTS—C74658

Change to read:

INGREDIENTS

Vehicles and Added Substances

Aqueous Vehicles—The vehicles for aqueous Injections meet the requirements of the *Pyrogen Test* ⟨151⟩ or the *Bacterial Endotoxins Test* ⟨85⟩, whichever is specified. *Water for Injection* generally is used as the vehicle, unless otherwise specified in the individual monograph. Sodium chloride may be added in amounts sufficient to render the resulting solution isotonic; and *Sodium Chloride Injection,* or *Ringer's Injection,* may be used in whole or in part instead of *Water for Injection,* unless otherwise specified in the individual monograph. For conditions applying to other adjuvants, see *Added Substances* in this chapter.

Other Vehicles—Fixed oils used as vehicles for nonaqueous Injections are of vegetable origin, are odorless or nearly so, and have no odor suggesting rancidity. They meet the requirements of the test for *Solid paraffin* under *Mineral Oil,* the cooling bath being maintained at 10°, have a *Saponification Value* between 185 and 200 (see *Fats and Fixed Oils* ⟨401⟩), have an *Iodine Value* between 79 and 141 (see *Fats and Fixed Oils* ⟨401⟩), and meet the requirements of the following tests.

~~*Unsaponifiable Matter*—Reflux on a steam bath 10 mL of the oil with 15 mL of sodium hydroxide solution (1 in 6) and 30 mL of alcohol, with occasional shaking until the mixture becomes clear. Transfer the solution to a shallow dish, evaporate the alcohol on a steam bath, and mix the residue with 100 mL of water: a clear solution results.~~

~~*Free Fatty Acids*—The free fatty acids in 10 g of oil require for neutralization not more than 2.0 mL of 0.020 N sodium hydroxide (see *Fats and Fixed Oils* ⟨401⟩).~~

■*Unsaponifiable Matter* (see *Fats and Fixed Oils* ⟨401⟩): not more than 1.5%.

Acid Value (see *Fats and Fixed Oils* ⟨401⟩): not more than 0.2.

Peroxide Value (see *Fats and Fixed Oils* ⟨401⟩): not more than 5.0.

Water, Method I ⟨921⟩: not more than 0.1%, using 50 mL of chloroform instead of 35 to 40 mL of methanol as the solvent.

Limit of Copper, Iron, Lead, and Nickel—Proceed as directed in the section *Trace Metals* under *Fats and Fixed Oils* ⟨401⟩. Not more than 1 ppm of copper is found; not more than 1 ppm of iron is found; not more than 1 ppm of lead is found; and not more than 1 ppm of nickel is found.■2S *(USP32)*

Synthetic mono- or diglycerides of fatty acids may be used as vehicles, provided they are liquid, remain clear when cooled to 10°, and have an *Iodine Value* of not more than 140 (see *Fats and Fixed Oils* ⟨401⟩).

These and other nonaqueous vehicles may be used, provided they are safe in the volume of Injection administered, and also provided they do not interfere with the therapeutic efficacy of the preparation or with its response to prescribed assays and tests.

Added Substances—Suitable substances may be added to preparations intended for injection to increase stability or usefulness, unless proscribed in the individual monograph, provided they are harmless in the amounts administered and do not interfere with the therapeutic efficacy or with the responses to the specified assays and tests. No coloring agent may be added, solely for the purpose of coloring the finished preparation, to a solution intended for parenteral administration (see also *Added Substances* under *General Notices* and *Antimicrobial Effectiveness Testing* ⟨51⟩).

Observe special care in the choice and use of added substances in preparations for injection that are administered in a volume exceeding 5 mL. The following maximum limits prevail unless otherwise directed: for agents containing mercury and the cationic, surface-active compounds, 0.01%; for chlorobutanol, cresol, phenol, and similar types of substances, 0.5%; and for sulfur dioxide, or an equivalent amount of the sulfite, bisulfite, or metabisulfite of potassium or sodium, 0.2%.

A suitable substance or mixture of substances to prevent the growth of microorganisms must be added to preparations intended for injection that are packaged in multiple-dose containers, regardless of the method of sterilization employed, unless one of the following conditions prevails: (1) there are different directions in the individual monograph; (2) the substance contains a radionuclide with a physical half-life of less than 24 hours; and (3) the active ingredients are themselves antimicrobial. Such substances are used in concentrations that will prevent the growth of or kill micro-organisms in the preparations for injection. Such substances also meet the requirements of *Antimicrobial Effectiveness Testing* ⟨51⟩ and *Antimicrobial Agents—Content* ⟨341⟩. Sterilization processes are employed even though such substances are used (see also *Sterilization and Sterility Assurance of Compendial Articles* ⟨1211⟩). The air

In-Process Revision

in the container may be evacuated or be displaced by a chemically inert gas. Where specified in a monograph, information regarding sensitivity of the article to oxygen is to be provided in the labeling.

Change to read:

PACKAGING

Containers for Injections

Containers, including the closures, for preparations for injections do not interact physically or chemically with the preparations in any manner to alter the strength, quality, or purity beyond the official requirements under the ordinary or customary conditions of handling, shipment, storage, sale, and use. The container is made of material that permits inspection of the contents. The type of glass preferable for each parenteral preparation is usually stated in the individual monograph. Unless otherwise specified in the individual monograph, plastic containers may be used for packaging injections (see *Containers—Plastics* ⟨661⟩).

For definitions of single-dose and multiple-dose containers, see *Containers* in the *General Notices and Requirements.* Containers meet the requirements under *Containers—Glass* ⟨660⟩ and *Containers—Plastics* ⟨661⟩.

Containers are closed or sealed in such a manner as to prevent contamination or loss of contents. Validation of container integrity must demonstrate no penetration of microbial contamination or chemical or physical impurities. In addition, the solutes and the vehicle must maintain their specified total and relative quantities or concentrations when exposed to anticipated extreme conditions of manufacturing and processing, and storage, shipment, and distribution. Closures for multiple-dose containers permit the withdrawal of the contents without removal or destruction of the closure. The closure permits penetration by a needle and, upon withdrawal of the needle, closes at once, protecting the container against contamination. Validation of the multiple-dose container integrity must include verification that such a package prevents microbial contamination or loss of product contents under anticipated conditions of multiple entry and use.

Piggyback containers are usually intravenous infusion containers used to administer a second infusion through a connector of some type or an injection port on the administration set of the first fluid, thereby avoiding the need for another injection site on the patient's body. Piggyback containers are also known as secondary infusion containers.

Potassium Chloride for Injection Concentrate

The use of a black closure system on a vial (e.g., a black flip-off button and a black ferrule to hold the elastomeric closure) or the use of a black band or series of bands above the constriction on an ampul is prohibited, except for *Potassium Chloride for Injection Concentrate.*

Neuromuscular Blocking and Paralyzing Agents

All injectable preparations of neuromuscular blocking agents and paralyzing agents must be packaged in vials with a cautionary statement printed on the ferrules or cap overseals. Both the container cap ferrule and the cap overseal must bear in black or white print (whichever provides the greatest color contrast with the ferrule or cap color) the words: "Warning: Paralyzing Agent" or "Paralyzing Agent" (depending on the size of the closure system). Alternatively, the overseal may be transparent and without words, allowing for visualization of the warning labeling on the closure ferrule.

Containers for Sterile Solids

Containers, including the closures, for dry solids intended for parenteral use do not interact physically or chemically with the preparation in any manner to alter the strength, quality, or purity beyond the official requirements under the ordinary or customary conditions of handling, shipment, storage, sale, and use.

A container for a sterile solid permits the addition of a suitable solvent and withdrawal of portions of the resulting solution or suspension in such manner that the sterility of the product is maintained.

Where the *Assay* in a monograph provides a procedure for the *Assay preparation,* in which the total withdrawable contents are to be withdrawn from a single-dose container with a hypodermic needle and syringe, the contents are to be withdrawn as completely as possible into a dry hypodermic syringe of a rated capacity not exceeding three times the volume to be withdrawn and fitted with a 21-gauge needle not less than 2.5 cm (1 inch) in length, with care being taken to expel any air bubbles, and discharged into a container for dilution and assay.

~~Volume in Container~~

▪Container Content▪2S (*USP33*)

~~Each container of an injection is filled with sufficient excess of the labeled "size" or that volume which is to be withdrawn. See *Injections* under *Pharmaceutical Dosage Forms* ⟨1151⟩.~~

▪Each container of an injection contains sufficient excess to allow withdrawal of the labeled quantity of drug. Such withdrawal shall be performed according to labeled directions, if provided.▪2S (*USP33*)

DETERMINATION OF VOLUME OF INJECTION IN CONTAINERS

▪This section is harmonized with the corresponding texts of the European Pharmacopoeia and/or the Japanese Pharmacopoeia. These pharmacopeias have undertaken not to make any unilateral change to this harmonized section. A portion of the present text (see below) is national USP text, and therefore not part of the harmonized text; it is marked with symbols (◆ ◆) to specify this fact.▪2S (*USP33*)

Suspensions and emulsions must be shaken before withdrawal of the contents and before the determination of the density. Oily and viscous preparations may be warmed according to the instructions on the label, if necessary, and thoroughly shaken immediately before removing the contents. The contents are then cooled to 20°–25°C before measuring the volume.

■◆Sterile solid formulations must be constituted according to labeled directions before removing the contents. Contents are then to be measured following the procedures for suspensions, emulsions, or solutions, as appropriate.◆■2S (*USP33*)

Single-Dose Containers—Select 1 container if the volume of the container is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. Take up individually the total contents of each container selected into a dry syringe of a capacity not exceeding three times the volume to be measured and fitted with a 21-gauge needle not less than 2.5 cm (1 inch) in length. Expel any air bubbles from the syringe and needle, and then discharge the contents of the syringe, without emptying the needle, into a standardized, dry cylinder (graduated to contain rather than to deliver the designated volumes) of such size that the volume to be measured occupies at least 40% of its graduated volume. Alternatively, the volume of the contents in mL may be calculated as the mass, in g, divided by the density. For containers with a nominal volume of 2 mL or less, the contents of a sufficient number of containers may be pooled to obtain the volume required for the measurement, provided that a separate, dry syringe assembly is used for each container. The contents of containers holding 10 mL or more may be determined by means of opening them and emptying the contents directly into the graduated cylinder or tared beaker.

The volume is not less than the nominal volume in the case of containers examined individually or, in the case of containers with a nominal volume of 2 mL or less, is not less than the sum of the nominal volumes of the containers taken collectively.

Multi-Dose Containers—For Injections in multiple-dose containers labeled to yield a specific number of doses of a stated volume, select 1 container, and proceed as directed for single-dose containers, using the same number of separate syringe assemblies as the number of doses specified. The volume is such that each syringe delivers not less than the stated dose.

Injections in Cartridges or Prefilled Syringes—Select 1 container if the volume is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. If necessary, fit the containers with the accessories required for their use (needle, piston, syringe) and transfer the entire contents of each container without emptying the needle into a dry tared beaker by slowly and constantly depressing the piston. Determine the volume in mL, calculated as the mass, in g, divided by the density.

The volume measured for each of the containers is not less than the nominal volume.

Large-Volume Intravenous Solutions—For intravenous solutions, select 1 container. Transfer the contents into a dry measuring cylinder of such a capacity that the volume to be determined occupies at least 40% of the nominal volume of the cylinder. Measure the volume transferred.

The volume is not less than the nominal volume.

Labeling on Ferrules and Cap Overseals

Only cautionary statements are to appear on the top (circle) surface of the ferrule or cap overseal of a vial containing an injectable product. A cautionary statement is one intended to prevent an imminent life-threatening situation if the injectable drug is used inappropriately. Examples of such statements include but are not limited to the following: ''Warning'', ''Dilute Before Using'', ''Paralyzing Agent'', ''I.M. Use Only'', and ''Chemotherapy''.

The text must be in contrasting color and conspicuous under ordinary conditions of use. The cautionary statement may appear solely on the ferrule, provided the cap overseal is constructed so as to allow the cautionary statement beneath the cap to be readily legible.

Identifying numbers or letters, such as code numbers, lot numbers, etc., may appear on the side (skirt) surface of the ferrule on vials containing injectable products. The appearance of such identifying data on the skirt surface of the ferrule, placed where it does not detract from, or interfere with, the cautionary statement on the top surface, should be considered to be a beneficial attribute of the in-process quality control of a product throughout the manufacturing process. Any anticounterfeiting scheme must not detract from or interfere with the cautionary statements.

Under no circumstances would advertising such as company names, logos, or product names be permitted to appear on the top (circle) surface of any ferrule or cap overseal.

(Official February 1, 2009)

Packaging and Storage

The volume of injection in single-dose containers provides the amount specified for parenteral administration at one time and in no case is more than sufficient to permit the withdrawal and administration of 1 L.

Preparations intended for intraspinal, intracisternal, or peridural administration are packaged only in single-dose containers.

Unless otherwise specified in the individual monograph, a multiple-dose container contains a volume of Injection sufficient to permit the withdrawal of not more than 30 mL.

The following injections are exempt from the 1-L restriction of the foregoing requirements relating to packaging:

1. Injections packaged for extravascular use as irrigation solutions or peritoneal dialysis solutions
2. Injections packaged for intravascular use as parenteral nutrition or as replacement or substitution fluid to be administered continuously during hemofiltration

Injections packaged for intravascular use that may be used for intermittent, continuous, or bolus replacement fluid administration during hemodialysis or other procedures, unless excepted above, must conform to the 1-L restriction.

Injections labeled for veterinary use are exempt from packaging and storage requirements concerning the limitation to single-dose containers and the limitation on the volume of multiple-dose containers.

Change to read:

FOREIGN AND PARTICULATE MATTER

All articles intended for parenteral administration shall be prepared in a manner designed to exclude particulate matter as defined in *Particulate Matter in Injections* ⟨788⟩ and other foreign matter. Each final container of all parenteral preparations shall be inspected to the extent possible for the presence of observable foreign and particulate matter (hereafter termed ''visible particulates'') in its contents. The inspection process shall be designed and qualified to ensure that every lot of all parenteral preparations is essentially free from visible particulates. Qualification of the inspection process shall be performed with reference to particulates in the visible range of a type that might emanate from the manufacturing or filling process. Every container whose contents shows evidence of visible particulates shall be rejected. The inspection for visible particulates may take place when inspecting for other critical defects, such as cracked or defective containers or seals, or when characterizing the appearance of a lyophilized product.

Where the nature of the contents or the container-closure system permits only limited capability for the inspection of the total contents, the 100% inspection of a lot shall be supple-

mented with the inspection of constituted (e.g., dried) or withdrawn (e.g., dark amber container) contents of a sample of containers from the lot.

All large-volume Injections for single-dose infusion and small-volume Injections are subject to the light obscuration or microscopic procedures and limits for subvisible particulate matter set forth in *Particulate Matter in Injections* ⟨788⟩, unless otherwise specified in the individual monograph. An article packaged as both a large-volume and a small-volume Injection meets the requirements set forth for small-volume Injections where the container is labeled as containing 100 mL or less, if the individual monograph states a test for *Particulate Matter in Injections* ⟨788⟩; it meets the requirements set forth for large-volume Injections for single-dose infusion where the container is labeled as containing more than 100 mL. ~~Injections administered exclusively by the intramuscular or subcutaneous route or packaged and labeled for use as irrigating solutions are exempt from requirements for *Particulate Matter in Injections* ⟨788⟩.~~

■Solutions for injection administered by the intramuscular or subcutaneous route must meet the requirements of *Particulate Matter in Injections* ⟨788⟩. Parenterals packaged and labeled exclusively for use as irrigating solutions are exempt from the requirements of *Particulate Matter in Injections* ⟨788⟩. Radiopharmaceutical preparations are exempt from the requirements of *Particulate Matter in Injections* ⟨788⟩. Parenteral products for which the labeling specifies the use of a final filter prior to administration are exempt from the requirements of *Particulate Matter in Injections* ⟨788⟩, provided that scientific data are available to justify this exemption.■1S (*USP33*)

Biological Tests and Assays

BRIEFING

⟨90⟩ Fetal Bovine Serum—Quality Attributes and Functionality Tests. Fetal Bovine Serum (FBS) and other types of bovine sera described in general information chapter *Bovine Serum* ⟨1024⟩ provide important guidelines for the biotechnology industry. This general information chapter provides analysts with (a) procedures to measure the FBS quality attributes and (b) functionality assays to assess performance of different types and lots of FBS.

(BB CGT: F. Atouf) RTS—C63092

Add the following:

▪⟨90⟩ FETAL BOVINE SERUM—QUALITY ATTRIBUTES AND FUNCTIONALITY TESTS

PROCESSING

Fetal bovine serum (FBS) is the light-brown liquid fraction of clotted fetal bovine blood. It is depleted of cells, fibrin, and clotting factors. Although the complete composition of FBS is undefined, FBS contains high levels of growth factors and low levels of immunoglobulins. In addition, it contains other key ingredients that are essential in supporting proliferation of cells in culture. This product is used both in life science basic research and industrial manufacturing. FBS is a by-product of the meat industry and is collected from bovine fetuses removed from cattle found to be pregnant at slaughter. FBS is harvested from abattoirs that are inspected by the competent authority in the country of origin. Dedicated trained personnel following written and approved procedures should perform collection and processing. The processing is performed aseptically to minimize risk of acquiring contaminating agents. The raw serum should be processed quickly to prevent hemolysis. The serum usual-

ly is allowed to clot and then is centrifuged in a refrigerated centrifuge; centrifugation should preferably be done at 4°. Serum typically is then removed from the clot, transferred to labeled containers, and frozen. All manufacturers employ sterile filtration before final packaging. Additionally, gamma irradiation provides the highest assurance of the absence of viral activity. Gamma irradiation doses of 25–40 kGy provide significant log reduction of viral and other adventitious agents while preserving cellular growth performance.

The screening of FBS for viral contamination is accomplished by using all applicable testing described in the Code of Federal Regulations 9 CFR 113.53 (known as full 9 CFR testing). Mycoplasma assays are performed by direct cultivation methods that employ aerobic and anaerobic incubations of solid medium in plates and semisolid broth in tubes. In addition, the absence of detectable mycoplasma is determined microscopically using the indirect method of bisbenzimide DNA staining. Large-volume sampling is important to detect low levels of mycoplasma.

FETAL BOVINE SERUM QUALITY ATTRIBUTES

Packaging and Storage—Store in sealed containers at a temperature of –10° or below.

Labeling—Label it to indicate that contents are Fetal Bovine Serum, and indicate lot number, expiration date, and storage conditions.

USP Reference Standards ⟨11⟩—*USP Endotoxin RS*. *USP Fetal Bovine Serum RS*.

pH ⟨791⟩—Between 7.00 and 8.00 in undiluted serum samples.

Osmolality ⟨758⟩—Between 280 and 360 mOsmol/kg.

Bacterial Endotoxins ⟨85⟩—It contains not more than 10 USP Endotoxin Units/mL of serum.

Total Protein Content ⟨1057⟩—Between 30 and 45 mg/mL.

Sterility ⟨71⟩—Meets requirements.

Identification—Radial Immunodiffusion

Reagents—

- FBS test samples
- Horse serum, negative control samples
- Bovine IgG calibrator (500 mg/L)
- Sheep Albumin Diluent (1% Sheep Albumin, 0.18% EDTA, 1.75% NaCl, and 1.21% Tris/HCl pH 7.4).

Materials/Apparatus—Ring measuring device is calibrated in 0.1-mm increments. Radial immunodiffusion (RID) plates are commercially available and contain anti-bovine IgG antiserum in a 1.5% agarose gel, 0.1 M phosphate buffer, pH 7.0, 0.1% sodium azide as bacteriostatic agent, and 1 μg/mL amphotericin B as an antifungal agent. Store at 2°–8°. Use RID plates that can measure bovine IgG in the range of 50–500 mg/L.

Standard Curve—Use the bovine IgG calibrators for system suitability and for generation of a calibration curve. Prepare two dilutions from a 500 mg/L bovine IgG stock solution. Dilute 120 μL of the 500 mg/L stock with 80 μL of diluent (medium dilution) and 25 μL of the 500 mg/L stock with 225 μL diluent (low dilution). Label each dilution respectively as 300 mg/L and 50 mg/L calibrators. Use the 500 mg/L, 300 mg/L, and 50 mg/L solutions to generate the standard curve, and load 5 μL of each sample into the 2.5-mm wells of the plate. At 72 h of incubation, measure ring diameters to the nearest 0.1 mm using the ring measuring device. Record the results and proceed to the generation of a standard curve.

The ring diameter should develop to completion at room temperature for 72 h. Using the result from each data point of the standard curve, generate a single linearity plot where y is the squared diameter (mm^2) of precipitin ring around the well and x is the Bovine IgG

concentration (mg/L). Calculate the linear least-squares-fit regression line of the form $y = m(x) + b$ with the help of suitable software and determine the values for slope (m), y-intercept (b), and coefficient of determination (R^2). The standard curve for the method is linear if R^2 is $\geq$0.98.

Procedure—Frozen undiluted samples of FBS are thawed and tested within 24 h if stored at 4°. Testing of FBS test and USP Fetal Bovine Serum RS samples is performed in triplicate. Prepare RID plates containing anti-bovine IgG to be tested for the various types of sera. Allow plates and reagents to equilibrate to room temperature before use by leaving the plates open for 10–15 min at room temperature to allow any condensation in the wells or on the gel surface to evaporate. Samples should not be applied to wells where moisture is visible. Prepare serial dilutions, if necessary, of FBS test and USP Fetal Bovine Serum RS samples in diluent. Dilute the negative control horse serum in diluent. Load 5 µL of each sample into the 2.5-mm wells of the plate, and incubate at room temperature for 72 h. [NOTE—The test samples and the negative control are loaded on the same plate.]

Calculation—After 72 h, measure the diameters of the rings using the ring measuring device, and record the results. Using the regression equation developed under standard curve deviation, calculate the concentration of bovine IgG in FBS samples. Concentration is expressed as mg/L.

Acceptance Criteria—Horse serum is negative (should not give a precipitation ring). FBS test and USP Fetal Bovine Serum RS samples are positive and should contain not more than 500 mg/L of IgG.

Hemoglobin Content—See *Spectrophotometry and Light Scattering* ⟨851⟩.

Sample Preparation—FBS samples are thawed, are stored at 4°, and are tested within the same day.

Procedure—Determine the absorbance of the serum sample using a spectrophotometric cell of 1-cm path length at the wavelengths of absorbance at 576, 623, and 700 nm and using water as a blank. Calculate the concentration of hemoglobin in mg/dL by the formula:

$$(Abs_{576} \times 115) - (Abs_{623} \times 102) - (Abs_{700} \times 39.1)$$

Acceptance Criteria—Contains not more than 30 mg/dL.

FBS FUNCTIONALITY TESTS

In the absence of a user-defined functionality assay, the following tests are suitable to determine the functionality of specific lots of FBS and to aid in the optimization of the growth conditions of mammalian cell cultures in the presence of FBS. For valid functionality confirmation independent of user-specific applications, tests are performed on the specified cell lines. For in-house validation of specialized cell culture applications, cell line(s) specific to those applications should be used and characterized. Use appropriate tissue culture vessels. Two tests described in this chapter are the *Growth-Promotion Curve* and the *Clonal Assay*. The decision about which type of test or the number of tests to be performed to assess suitability of a specific lot of FBS depends on the type of cell line used. For adherent cell lines, the number of colonies at the end of the culturing period represents a good assessment of the capacity of these cells, at low concentration, to grow in the presence of a specific lot of FBS. For cell lines growing in suspension cultures, the optimum growth kinetics is measured by counting viable cells after 7 days of culture.

Cell Lines—Five cell lines are recommended for use: (1) HFL1 (ATCC CCL-153) normal lung, fibroblast; (2) Mv1 Lu (ATCC CCL-64) mink lung, epithelial; (3) HL-60 (ATCC CCL-240) peripheral blood promyeloblast, suspension; (4) VERO (ATCC CCL-81) Monkey Kidney Fibroblast;

and (5) CHO (CCL-61) Chinese Hamster Ovary. The functionality tests described are to be performed on three cell lines, two of which are drawn from the five recommended cell lines and the third of which is the cell line relevant to the user's application. Cell lines are cultured with specific media as recommended by ATCC.

Materials—

- Suitable growth vessel/container
- Biological Safety Cabinet Class II, Type A
- Cell counter/hemocytometer
- Inverted microscope with digital camera accessory.
- Tissue culture vessels: T25 cm^2.

Preparation of Cells for Assays—Quick-thaw a vial in a 37° water bath, and determine cell count and viability. Prepare multiple cultures from each cell line in serum-supplemented growth medium. Incubate the cultures at 37° following instructions provided by ATCC for each of the cell lines used for the test. Examine the prepared cultures under a microscope to ensure uniform, near-confluent monolayers or suspensions. Expand cells until there are enough for assay (about 1×10^7 total cells; $>$90% viability).

Harvesting of Cultures—

1. Remove and discard the growth medium, and then rinse each culture with media lacking FBS.
2. For adherent cells, add 1 mL of Trypsin/EDTA for a few minutes for cells to disperse. Incubate at 37°, if necessary. Neutralize with 1 mL culture medium containing at least 10% FBS.
3. Spin down the cells in a centifuge. Aspirate off wash media, and resuspend cells in an appropriate volume for seeding.

Seeding of Cells—

1. On day 0: For the three cell lines to be tested prepare multiple cultures using seeding densities that ranges between 2×10^3 and 2×10^4 viable cells/mL. (Different inocula are chosen initially to determine optimum growth conditions. Once the appropriate inoculum is chosen, that condition is used to propagate the cells.) Following are the recommended seeding densities:

   Low seeding density: 2×10^3 viable cells/mL

   Mid seeding density: 6×10^3 viable cells/mL

   High seeding density: 2×10^4 viable cells/mL
2. Prepare cultures in triplicate for at least five time points (in days or hours according to the cell line), to determine the seeding density that will yield the optimal growth conditions for each cell line used.
3. Incubate the cultures at 37° in a humidified incubator saturated with 5% CO_2.
4. For each time point of measurement (days 0, 1, 2, 3, 4, and 7), take a photograph of each culture, in triplicate, for both the FBS test material and the USP Fetal Bovine Serum RS at each of the three concentrations for each cell line, and record the percentage of confluency for each of the conditions. [NOTE—Perform this step before trypsinization and cell counting.]
5. Harvest the cells from the three different seeding density cultures for each specific time point. For adherent cultures, harvest cells as described above.
6. Perform and record total cell count and viability for each of the nine cultures for the FBS test and the USP Fetal Bovine Serum RS for each cell line using an appropriate cell counter or hemacytometer. [NOTES—The schedule for counting may have to be changed for fast-growing cell lines or large cells that would become confluent before day 7 and/or for slow-growing lines that need to be in culture 8–10 days before reaching a plateau. Some adherent cell lines will never reach confluency.]

Growth-Promotion Curve

Measurements of cell proliferation rates often are used to determine the response of cells to exogenous stimuli. Quantitative assessment of cell growth conditions is an important factor in monitoring consistency of culture conditions. The optimal cell concentration range for subculturing, optimum inoculum, and doubling time are parameters that can be quantified and trended. Information about the growth kinetics of a culture is critical in the design of cell-based experiments. Cultures vary significantly in their growth properties from lag phase, log phase, and stationary phase. Document the growth characteristics of the culture during the three growth stages to determine population doubling time and cell cycle time. Cells that have entered the stationary phase may demonstrate reduced growth potential and change in morphology. Cells may become polarized and may secrete more extracellular matrix, making them difficult to remove from the substratum. Cells at the end of the log phase give the highest yield and greatest reproducibility.

Reagents—

- Growth media without FBS
- FBS test samples
- Growth medium + 10% FBS
- Trypsin/EDTA solution (0.25%/0.53 mM) in Hank's Balanced Salt Solution (HBSS)

Procedure—Once the cells have reached the end of the log phase, subculture the cells for the test. Follow the procedure described under *Seeding Cells* and prepare multiple cultures for the USP Fetal Bovine Serum RS, and test FBS for different cell lines at three seeding densities for which at least one growth curve displays a lag phase, log phase, and stationary phase and for which the log phase is linear at three or more time points.

Viable cell counts are determined on days 0, 1, 2, 3, 4, and 7.

Calculation and *Data Analysis*—Calculate the mean viable count [cells/cm^2 (adherent) or cells/mL (suspension)] and the mean percent viability for each data point. Plot the data on a semi-log scale graph with the viable count on the log scale on the *y*-axis and days (or hours) in culture on an arithmetic scale on the *x*-axis. Estimate the doubling time using a growth curve that is linear over three or more time points.

Acceptance Criteria—The R^2 value of the line should be equal to or greater than 0.98 in order to support calculation of a valid doubling time. The doubling time of the test sample should be no less than 90% of the doubling time of USP Fetal Bovine Serum RS.

Clonal Assay

This assay is designed to assess the optimal growth for adherent cell lines. Plating efficiency or colony formation at low cell density is a preferred method for analyzing the proliferative capacity and survival of single cells under optimal growth conditions. This is a very sensitive test and is often used for assessing the quality of serum lots. This technique reveals differences in the growth rate within the cell population and is capable of distinguishing between changes in growth rate (colony size) and cell survival (colony number). Because of the heterogeneous cell population of some cell cultures, remember that cells grow differently as isolated colonies at low densities. Consequently, few cells survive even under ideal conditions because all cell interaction is lost. Cloning is a survival assay that is also used for optimizing growth conditions (selection of medium and serum). If it can be confirmed that a single colony arose from a single cell, then cloning efficiency can be determined.

Reagents—

- Growth medium + 10% FBS (test serum)—Eagle minimum essential medium (EMEM) with 2 mM L-glutamine and Earle's BSS adjusted to contain 1.5 g/L sodium carbonate, 0.1 mM nonessential amino acids, and sodium pyruvate containing 100 U/mL penicillin and 100 g/mL streptomycin plus 10% FBS.
- Trypsin/EDTA solution (0.25%/0.53 mM) in HBSS.
- Dulbecco's Phosphate Buffer Saline without calcium or magnesium.
- Carbol Fuchsin–Methylene Blue Solution—Mix 20 g carbol fuchsin stock in 2 L methanol and stir for 10 min (1% carbol fuchsin). Mix 50 g methylene blue in 5 L methanol, and stir for 10 min (1% methylene blue). Prepare Carbol Fuschin–Methylene Blue working solution by mixing methylene blue, methanol, and carbol fuchsin in a ratio of 3 : 2 : 1. Mix for 20 min and filter through four folds of cheesecloth in a funnel. Aliquot and store in brown glass bottles at 15° to 25°.

Preparation of Test Sample—Multiple lots of FBS are used for this assay. For each lot of serum to be tested, add 20 mL of FBS to 180 mL of EMEM, and use the same test sample for the entire test. Sterilize using 0.22-m low protein binding filter units. Store growth medium at 4° until ready to use.

Preparation of Cells for Assay—This test is only for adherent cultures and is performed with the adherent cell lines described under *Cell Lines* (HFL1 and Mv 1 Lu). One week before testing serum, expand the cell lines as described under *Seeding of Cells*, change the medium every 2–3 days, and subculture the cells when they are about 90% confluent. Determine the cell count and viability (viability should be >90%) before performing the assay. Harvest cells as described under *Harvesting of Cultures*, wash twice, and resuspend cells in basal EMEM.

Procedure—The procedure involves plating single-cell suspension at low densities (2–50 cells/cm^2) from which discrete colonies will form. To count the colonies at the end of the assay, fix, stain, and count the number of colonies.

1. For each cell line label ten 60-mm × 15-mm tissue culture dishes for each serum lot that will be tested. Label the side of the lower half of each dish, including controls.
2. Transfer 5 mL of medium containing 10% of the appropriate test serum (10 replicates). Add 400 cells per culture dish (aim for a cell concentration of about 800 cells/mL).
3. Incubate for 10 to 14 days at 37° in a humidified incubator saturated with 5% CO^2.
4. Remove the supernatant and add enough Carbol Fuchsin–Methylene Blue Solution to cover each of the culture dishes for 10 min.
5. Remove the stain; rinse the culture dishes with several changes of distilled water; invert the dishes on paper towels; and allow to dry.
6. Count and record (1) the number of colonies and (2) the total surface of stained colonies (mm^2). Calculate means and standard deviations.

Acceptance Criteria—Percent plating efficiency is expressed by counting the number of colonies in a defined area divided by the number of cells seeded multiplied by 100. Compare results between lots of FBS, and select a serum lot that is good for various types of cells and optimal for a specific cell culture application.■2S (*USP33*)

OTHER TESTS AND ASSAYS

BRIEFING

〈**381**〉 **Elastomeric Closures for Injection,** *USP 32* page 145, the *Revision Bulletin* official May 1, 2009, and page 614 of *PF* 35(3) [May–June 2009]. On the basis of comments received and discussion by the Parenteral Products—Industrial Expert Committee, editorial changes to the *Introduction* are being proposed.

(PPI: D. Hunt.) RTS—C74657

Change to read:

INTRODUCTION

Elastomeric closures for containers used in the types of preparations defined in the general test chapter *Injections* 〈1〉 are made of materials obtained by vulcanization (cross-linking) polymerization, polyaddition, or polycondensation of macromolecular organic substances (elastomers). Closure formulations contain natural or synthetic elastomers and inorganic and organic additives to aid or control vulcanization, impart physical and chemical properties or color, or stabilize the closure formulation.

•This chapter applies to closures used for long-term storage of preparations defined in the general test chapter *Injections* 〈1〉. Such closures are typically used as part of a vial, bottle, or pre-fill syringe package system.• (RB 1-May-2009)

This chapter applies to closures formulated with natural or synthetic elastomeric substances. This chapter does not apply to closures made from silicone elastomer; however, it does apply to closures treated with silicone (e.g., Dimethicone, *NF*). When performing the tests in this chapter, it is not required that closures be treated with silicone, although there is no restriction prohibiting the use of siliconized closures.

•This chapter also applies to closures coated with other lubricious materials (e.g., materials chemically or mechanically bonded to the closure) that are not intended to, and in fact do not provide, a barrier to the base elastomer. When performing the tests, closures with lubricious nonbarrier coatings are to be tested in their coated state.

The following comments relate solely to closures laminated or coated with materials intended to provide, or in fact function as, a barrier to the base elastomer (e.g., PTFE or lacquer coatings). It is not permissible to use a barrier material in an attempt to change a closure that does not meet compendial requirements to one that does conform. Therefore, all *Physicochemical Tests* apply to the base formula of such closures, as well as to the coated or laminated closure. To obtain *Physicochemical Tests* results, the tests are to be performed on uncoated or nonlaminated closures of the same elastomeric compound, as well as to the laminated or coated closure. The *Functionality Tests* apply to and are to be performed using the laminated or coated elastomeric closure. *Biological Tests* apply to the lamination or coating material, as well as to the base formula. *Biological Tests* may be performed on the laminated or coated closure, or they may be performed on the laminate/coating material and the uncoated or nonlaminated closures of the same elastomeric compound. In the latter case, the results are to be reported separately. The base formula used for physicochemical or biological tests intended to support the compendial compliance of a barrier-coated closure should be similar to the corresponding coated closure in configuration and size.

For all *Elastomeric Closures for Injection* 〈381〉 tests performed on any closure type, it is important to document the closure being tested, including a full description of the elastomer, and any lubrication, coating, laminations, or treatments applied.• (RB 1-May-2009)

This chapter states test limits for Type I and Type II elastomeric closures. Type I closures are those used for aqueous preparations. Type II closures are typically intended for nonaqueous preparations and are those which, having properties optimized for special uses, may not meet all requirements listed for Type I closures because of physical configuration, material of construction, or both. If a closure fails to meet one or more of the Type I test requirements, but still meets the Type II requirements for the test(s), the closure is assigned a final classification of Type II.

■All elastomeric closures suitable for use with injectable preparations must comply with either Type I or Type II test limits. However, this specification is not intended to serve as the sole evaluation criterion for the selection of such closures.■1S *(USP33)*

~~This chapter is intended as an initial screen to identify elastomeric closures that might be appropriate for use with injectable preparations on the basis of their biological compatibility,~~

■It is appropriate to use this chapter when identifying elastomeric closures that might be acceptable for use with injectable preparations on the basis of their biological reactivity,■1S *(USP33)* their aqueous extract physicochemical properties, and their functionality. ~~All elastomeric closures suitable for use with injectable preparations comply with either Type I or Type II test limits. However, this specification is not intended to serve as the sole evaluation criteria for the selection of such closures.~~

■■1S *(USP33)*
The following closure evaluation requirements are beyond the scope of this chapter:

— The establishment of closure identification tests and specifications
— The verification of closure–product physicochemical compatibility
— The identification and safety determination of closure leachables found in the packaged product
— The verification of packaged product closure functionality under actual storage and use conditions

The manufacturer of the injectable product (the end user) must obtain from the closure supplier an assurance that the composition of the closure does not vary and that it is the same as that of the closure used during compatibility testing. When the supplier informs the end user of changes in the composition, compatibility testing must be repeated, totally or partly, depending on the nature of the changes. Closures must be properly stored, cleaned for removal of environmental contaminants and endotoxins, and,

■for aseptic processes,■2S *(USP33)* sterilized prior to use in packaging injectable products.

In-Process Revision

Physical Tests and Determinations

BRIEFING

⟨**645**⟩ **Water Conductivity,** *USP 32* page 240. While the majority of water used for production is *Purified Water* and *Water for Injection* that is produced on site (referred to as ''bulk water''), the Pharmaceutical Water Expert Committee recognizes the need for and the use of commercially-available ''packaged'' *Purified Water* and *Water for Injection* in some production environments. Also, there are sterile waters such as *Sterile Purified Water* and *Sterile Water for Injection* (and *Inhalation* and *Irrigation*). As the tests/limits for these various types of waters have been updated in recent years, some of the terminology regarding ''bulk'', ''sterile'', and ''packaged'' needs to be updated and/or clarified. The conductivity test method and limits for *Purified Water* and *Water for Injection*, whether in a packaged or bulk form, are directed to the ''*Bulk Water*'' section of this general test chapter. This does not represent a change because these monographs direct the analyst to this section already. The section ''*Packaged Water*'' is renamed ''*Sterile Water*,'' because the tests in the section are intended for *Sterile Purified Water*, *Sterile Water for Injection*, etc., and not the packaged form of the bulk article. There is no change to the test limits or methods. This is a change to the names of sections and to be consistent with monographs and related general chapters. There are associated changes in *Water for Pharmaceutical Purposes* ⟨1231⟩ and the monographs for *Sterile Purified Water*, *Sterile Water for Injection*, *Sterile Water for Inhalation***,** and *Sterile Water for Irrigation***.** All changes align the use of these terms.

(PW: A. Hernandez-Cardoso.) RTS—C76228

Change to read:

Electrical conductivity in water is a measure of the ion-facilitated electron flow through it. Water molecules dissociate into ions as a function of pH and temperature and result in a very predictable conductivity. Some gases, most notably carbon dioxide, readily dissolve in water and interact to form ions, which predictably affect conductivity as well as pH. For the purpose of this discussion, these ions and their resulting conductivity can be considered intrinsic to the water.

Water conductivity is also affected by the presence of extraneous ions. The extraneous ions used in modeling the conductivity specifications described below are the chloride and sodium ions. The conductivity of the ubiquitous chloride ion (at the theoretical endpoint concentration of 0.47 ppm when it was a required attribute test in *USP XXII* and earlier revisions) and the ammonium ion (at the limit of 0.3 ppm) represent a major portion of the allowed water impurity level. A balancing quantity of cations, such as sodium ions, is included in this allowed impurity level to maintain electroneutrality. Extraneous ions such as these may have significant impact on the water's chemical purity and suitability for use in pharmaceutical applications. The procedure ~~described~~

■■2S (*USP33*)
Online conductivity testing provides real-time measurements and opportunities for real-time process control, decision, and intervention. Precaution should be taken while collecting water samples for off-line conductivity measurements. The sample may be affected by the sampling method, the sampling container, and environmental factors such as ambient carbon dioxide concentration and organic vapors.

Change to read:

INSTRUMENT SPECIFICATIONS AND OPERATING PARAMETERS

Water conductivity must be measured accurately using calibrated instrumentation. The conductivity cell constant, a factor that represents the geometrical properties of the conductivity sensor, must be known within ±2%. The cell constant can be verified directly by using a solution of known or traceable conductivity, or indirectly by comparing the instrument reading taken with the conductivity sensor in question to readings from a conductivity sensor of known or traceable cell constant.

Meter calibration is accomplished by replacing the conductivity sensor with NIST (or equivalent local national authority) -traceable precision resistors (accurate to ±0.1% of the stated value) or an equivalently accurate adjustable resistance device, such as a Wheatstone Bridge, to give a predicted instrument response. Each scale on the meter may require separate calibration prior to use. The frequency of recalibration is a function of instrument design, degree of use, etc. However, because some multiple-scale instruments have a single calibration adjustment, recalibration may be required between each use of a different scale. Excluding the conductivity sensor cell constant accuracy, the instrument accuracy must be ±0.1 μS/cm.

In order to increase the measurement accuracy on the conductivity ranges used, which can be large, and to ensure a complete equipment calibration, it is suggested that periodic verification of the entire equipment be performed. This could be done by comparing the conductivity/resistivity values displayed by the measuring equipment with those of an external calibrated conductivity-measuring device. The two nontemperature-compensated conductivity or resistivity values must be equivalent to within ±20% of each other, or at a difference that is acceptable on the basis of product water criticality and/or the water conductivity ranges in which the measurements are taken. The two conductivity sensors should be positioned close enough together to measure the same water sample in the same environmental conditions.

In addition to the verification method performed in non-temperature-compensated mode, a similar verification performed in temperature-compensated mode could be performed to ensure an appropriate accuracy of the equipment when such a mode is used for trending or other purposes.

Because temperature has a substantial impact on conductivity readings of specimens at high and low temperatures, many instruments automatically correct the actual reading to display the value that theoretically would be observed at the nominal temperature of 25°. This is typically done using a temperature sensor embedded in the conductivity sensor and an algorithm in the instrument's circuitry. This temperature compensation al-

In-Process Revision

gorithm may not be accurate. Conductivity values used in this method are nontemperature-compensated measurements. Temperature measurement is required for the performance of the *Stage 1* test. It may be made using the temperature sensor embedded in the conductivity cell sensor. An external temperature sensor positioned near the conductivity sensor is also acceptable. Accuracy of the temperature measurement must be $\pm 2^{\circ}$.

■The procedures below shall be performed using instrumentation that has been calibrated, has conductivity sensor cell constants that have been accurately determined, and has temperature compensation function that has been disabled. For both online and offline measurements, the suitability of instrumentation for quality control testing is also dependent on the sampling location(s) in the water system. The selected sampling instrument location(s) must reflect the quality of the water used.■2S (*USP33*)

BULK WATER

~~The procedure below shall be performed using instrumentation that has been calibrated, has conductivity sensor cell constants that have been accurately determined, and has temperature compensation function that has been disabled. For both online and offline measurements, the suitability of instrumentation for quality control testing is also dependent on the sampling location(s) in the water system. The selected sampling instrument location(s) must reflect the quality of the water used.~~

■The procedure and test limits in this section are intended for Purified Water, Water for Injection, Water for Hemodialysis, the condensate of Pure Steam, and any other monographs which specify this section.■2S (*USP33*)

The combined conductivities of the intrinsic and extraneous ions vary as a function of pH and are the basis for the conductivity specifications described in the *Stage 3—pH and Conductivity Requirements* table and used when performing *Stage 3* of the test method. Two preliminary stages are included in the test method. If the test conditions and conductivity limits are met at either of these preliminary stages, the water meets the requirements of this test. Proceeding to the third stage of the test in these circumstances is unnecessary. Only in the event of failure at the final test stage is the sample judged noncompliant with the requirements of the test.

Procedure

STAGE 1

Stage 1 is intended for online measurement or may be performed offline in a suitable container.

1. Determine the temperature of the water and the conductivity of the water using a nontemperature-compensated conductivity reading.

2. Using the *Stage 1—Temperature and Conductivity Requirements* table, find the temperature value that is not greater than the measured temperature, i.e., the next lower temperature. The corresponding conductivity value on this table is the limit. [NOTE—Do not interpolate.]

3. If the measured conductivity is not greater than the table value, the water meets the requirements of the test for conductivity. If the conductivity is higher than the table value, proceed with *Stage 2.*

Stage 1—Temperature and Conductivity Requirements
(for nontemperature-compensated conductivity measurements only)

Temperature	Conductivity Requirement (μS/cm)
0	0.6
5	0.8
10	0.9
15	1.0
20	1.1
25	1.3
30	1.4
35	1.5
40	1.7
45	1.8
50	1.9
55	2.1
60	2.2
65	2.4
70	2.5
75	2.7
80	2.7
85	2.7
90	2.7
95	2.9
100	3.1

STAGE 2

4. Transfer a sufficient amount of water (100 mL or more) to a suitable container, and stir the test specimen. Adjust the temperature, if necessary, and, while maintaining it at $25 \pm 1^{\circ}$, begin vigorously agitating the test specimen while periodically observing the conductivity. When the change in conductivity (due to uptake of atmospheric carbon dioxide) is less than a net of 0.1 μS/cm per 5 minutes, note the conductivity.

5. If the conductivity is not greater than 2.1 μS/cm, the water meets the requirements of the test for conductivity. If the conductivity is greater than 2.1 μS/cm, proceed with *Stage 3.*

STAGE 3

6. Perform this test within approximately 5 minutes of the conductivity determination in Step 5, while maintaining the sample temperature at $25 \pm 1^{\circ}$. Add a saturated potassium chloride solution to the same water sample (0.3 mL per 100 mL of the test specimen), and determine the pH to the nearest 0.1 pH unit, as directed under *pH* ⟨791⟩.

7. Referring to the *Stage 3—pH and Conductivity Requirements* table, determine the conductivity limit at the measured pH value. If the measured conductivity in Step 4 is not greater than the conductivity requirements for the pH determined in Step 6, the water meets the requirements of the test for conductivity. If either the measured conductivity is greater than this value or the pH is outside the range of 5.0 to 7.0, the water does not meet the requirements of the test for conductivity.

Stage 3—pH and Conductivity Requirements
(for atmosphere- and temperature-equilibrated samples only)

pH	Conductivity Requirement (μS/cm)

WATER

The procedure and test limits are intended for ~~water packaged in bulk but manufactured elsewhere or for~~

▪▪2S (*USP33*)
Sterile Purified Water, Sterile Water for Injection, Sterile Water for Inhalation, and Sterile Water for Irrigation,

▪and any other monographs which specify this section.▪2S (*USP33*)
~~All these~~

▪The sterile▪2S (*USP33*)
waters are derived from Purified Water or Water for Injection, and therefore have been determined to be compliant with the *Bulk Water* requirements before being stored in the container. The specification provided represents the maximum allowable conductivity value, taking into consideration the limitation of the measurement method and reasonable container leaching. Such specification and the sampling volume choices should be defined and validated on the basis of the intended purpose of the water.

Procedure

Transfer a sufficient amount of water to a suitable container, and stir the test specimen. Adjust the temperature, if necessary, and, while maintaining it at 25 ± 1°, begin vigorously agitating the test specimen while periodically observing the conductivity. When the change in conductivity (due to uptake of ambient carbon dioxide) is less than a net of 0.1 μS/cm per 5 minutes, note the conductivity.

For containers with a nominal volume of 10 mL or less, if the conductivity is not greater than 25 μS/cm, the water meets the requirements. For containers with a nominal volume greater than 10 mL, if the conductivity is not greater than 5 μS/cm, the water meets the requirements.

GENERAL CHAPTERS

General Information

BRIEFING

⟨**1059**⟩ **Excipient Performance.** The following general information chapter has been prepared by the Excipient Performance Joint Advisory Panel of the Excipient General Chapters, Excipient Monographs 1 and Excipient Monographs 2 Expert Committees. A pharmaceutical dosage form typically consists of both active ingredient(s) and excipients. The latter play a critical role in manufacturing, stability, and performance. The properties of excipients that ensure satisfactory and consistent performance depend on the dosage form, the product, the manufacturing process, and the performance requirements. Excipient monographs in the *National Formulary (NF)* provide methods and specifications that ensure excipient identity, quality, and purity. General tests, procedures, and acceptance criteria provided in the *NF* are used to evaluate material attributes of excipients.

Excipient properties that are important to dosage form performance may not be identified or specified in compendial monographs. The proposed chapter resolves this deficiency by commenting on a number of functional categories identified in the *USP–NF*. This information includes a summary of the functional capabilities of an excipient, as well as information about the physical and chemical properties of excipients that may be useful in ensuring consistent and desirable excipient performance. Additional sections will be added as needed.

The tests, procedures, and acceptance criteria delineated in the proposed chapter will not be compendial requirements, but may provide useful information to support private agreements between buyers and suppliers and also, if needed, regulatory requirements for specified excipients and drug products. The expert committee seeks input from readers of *Pharmacopeial Forum* and *USP–NF* regarding the format and content of the chapter.

(EGC: K. Moore) RTS—C76303

Add the following:

▪⟨1059⟩ EXCIPIENT PERFORMANCE

INTRODUCTION

Excipients are used in virtually all drug products and are essential to product performance. Thus, the successful manufacture of a robust product requires the use of well-defined excipients and processes that together yield

In-Process Revision

a consistent product. Typically, excipients are manufactured and supplied to comply with compendial standards. The development, manufacture, and performance of pharmaceutical dosage forms often depend upon the physical and chemical properties of excipients that may not be provided in *National Formulary (NF)* monographs. Also, functionality tests are usually not provided in *NF* monographs.

An excipient may have different functional purposes and may possess various required characteristics (e.g., particle size, particle size distribution, or surface area), depending on its use in a formulation or manufacturing process. A listing of excipients grouped by functional category summarizes the most typically identified purpose these excipients serve in drug products. The list of excipients included in each category is not comprehensive and is not intended to limit in any way the choice or use of the excipient. For the complete list, refer to the *USP* and *NF* Excipients, Listed by Category in the *National Formulary*, under *Contents*.

Excipient functionality is a broad, qualitative, and descriptive term for the purpose or role an excipient serves in a formulation. Of greater importance, however, are the quantitative performance requirements (e.g., critical material attributes) of excipients that must be evaluated and controlled to ensure consistent performance throughout the product life cycle. Not all critical material attributes of an excipient may be identified or evaluated by tests, procedures, and acceptance criteria in *NF* monographs. Excipient suppliers and users therefore at times wish to identify and control critical excipient attributes that go beyond monograph specifications. This requires a thorough understanding of the formulation, the manufacturing processes, and the physical and chemical properties of each ingredient. Manufacturers should anticipate lot-to-lot and supplier-to-supplier variability in excipient properties and should have in place appropriate controls if needed to ensure consistent excipient performance.

This general chapter provides an overview of the key functional categories of excipients, tests that may assess excipient functionality, and test procedures that may not be presented in compendial monographs. The functional categories have been organized by their most typical use in common pharmaceutical dosage forms (Tablets and Capsules; Oral Liquids; Semisolids, Topicals and Suppositories; Parenterals; and Aerosols) to provide a greater level of specificity for each functional category. Several functional categories (e.g., antioxidant) can apply to multiple dosage form types. The association of a functional category with a particular dosage form in this chapter is not absolute and does not limit use of an excipient to a single type of dosage form. Because of the complex nature and interplay of formulation ingredients, processing, and dosage form performance requirements, the information provided in this chapter should not be viewed as either restrictive or completely comprehensive. Each functional category includes a general description; the mechanisms by which the excipients achieve their activity; physical properties common to these excipients; chemical properties; and a list of pharmacopeial general chapters that may be useful in the development of specific tests, procedures, and acceptance criteria that help ensure that the critical material attributes are adequately monitored and controlled.

TABLETS AND CAPSULES

Functional Category: Diluent

Description: Diluents are components that are incorporated into tablet or capsule dosage forms to increase dosage form volume or weight. Sometimes referred to as fillers, diluents often comprise a significant proportion

of the dosage form, and the quantity and type of diluent selected often depend on its physical and chemical properties. Because the diluent may comprise a large portion of the dosage form, successful and robust manufacturing and dosage form performance depend on the measurement and control of the critical material attributes.

Functional Mechanism: Among the most important functional roles diluents play is to impart desirable manufacturing properties (e.g., powder flow, tablet compaction strength, wet or dry granule formation, homogeneity) and performance (e.g., content uniformity, disintegration, dissolution, tablet integrity, friability, physical and chemical stability). Some diluents (e.g., microcrystalline cellulose) are occasionally referred to as dry binders because of the high degree of tablet strength they impart to the final compressed tablet.

Physical Properties: The primary physical properties relevant to tablet/capsule diluents are those that can have a direct effect on diluent and formulation performance. These include: (1) particle size and size distribution, (2) particle shape, (3) bulk/tapped/true density, (4) specific surface area, (5) crystallinity, (6) moisture content, (7) powder flow, (8) solubility, and (9) compaction properties for tablet dosage forms.

Chemical Properties: Tablet diluents comprise a large and diverse group of materials that include inorganics (e.g., dibasic calcium phosphate, calcium carbonate), single-component organic materials (e.g., lactose monohydrate, mannitol), and multicomponent or complex organics (e.g., microcrystalline cellulose, starch). They may be soluble or insoluble in water, and they may be neutral, acidic, or alkaline in nature. These chemical properties of diluents may affect drug substance physical or chemical stability and performance positively or negatively. Appropriate selection of excipients with desirable physical and chemical properties can enhance the physical and chemical stability as well as the performance of the drug substance and dosage form. The detailed composition of an excipient may be important because excipient function could be influenced by the presence of minor concomitant components that are essential for proper performance. Pharmaceutical scientists may need to control the presence of undesirable components (e.g., heavy metals or peroxides) to ensure adequate dosage form stability and performance.

General Chapters: The following general chapters may be useful to ensure consistency in diluent functions: *Bulk Density and Tapped Density* ⟨616⟩, *Density of Solids* ⟨699⟩, *Crystallinity* ⟨695⟩, *Crystallinity Determination by Solution Calorimetry* ⟨696⟩, *Loss on Drying* ⟨731⟩, *Water Determination* ⟨921⟩, *Optical Microscopy* ⟨776⟩, *Particle Size Distribution Estimation by Analytical Sieving* ⟨786⟩, *Light Diffraction Measurement of Particle Size* ⟨429⟩, *Powder Fineness* ⟨811⟩, *Specific Surface Area* ⟨846⟩, and *Powder Flow* ⟨1174⟩.

Functional Category: Binder

Description: Tablet/capsule binders are incorporated into formulations to facilitate the agglomeration of powder into granules during mixing with a granulating fluid such as water, hydroalcoholic mixtures, or other solvents. The binder may be either dissolved or dispersed in the granulation liquid or blended in a dry state; other components and the granulation liquid may be added separately during agitation. Following evaporation of the granulation liquid, binders typically produce dry granules that achieve the desired properties such as granule size, size distribution, shape, content, mass, and active content. Wet granulation facilitates the further processing of the granules by improving one or more

granule properties such as: flow, handling, strength, resistance to segregation, dustiness, appearance, solubility, compaction, or drug release.

Functional Mechanism: Binders are soluble or partially soluble in the granulating solvent or, as in the case of native starches, can be made soluble. Concentrated binder solutions also have adhesive properties. Upon addition of liquid, binders typically facilitate the production of moist granules (agglomerates) by altering interparticle adhesion. They may also modify interfacial properties, viscosity, and/or other properties. During drying they may produce solid bridges that yield significant residual dry granule strength.

Physical Properties: Dispersion or dissolution of binder in the granulation liquid depends on its physical properties: surface tension, particle size, size distribution, solubility, and viscosity are among the important properties depending on the application. Homogeneous incorporation of binder into a dry blend also depends on its physical properties such as particle size, shape, and size distribution. Viscosity often is an important property to consider for binders and, for polymers, is influenced by the nature of the polymer structure, molecular weight, and molecular weight distribution. Polymeric binders may form gels.

Chemical Properties: Tablet/capsule binders may be categorized as: (1) natural polymers, (2) synthetic polymers, or (3) sugars. The chemical nature of polymers, including polymeric structure, monomer properties and sequence, functional groups, degree of substitution, and cross-linking influence the complex interactions that can occur during granulation. Natural polymers in particular may exhibit greater variation in their properties because of variations in their sources and therefore composition.

General Chapters: The following general chapters may be useful to ensure consistency in binder functions: *Bulk Density and Tapped Density* ⟨616⟩, *Crystallinity* ⟨695⟩, *Density of Solids* ⟨699⟩, *Loss on Drying* ⟨731⟩, *Particle Size Distribution Estimation by Analytical Sieving* ⟨786 ⟩, *Specific Surface Area* ⟨846⟩, *Viscosity* ⟨911⟩, *Powder Flow* ⟨1174⟩, and *Chromatography* ⟨621⟩.

Functional Category: Disintegrant

Description: Disintegrants are functional components that are added to formulations to promote rapid disintegration into smaller units and to allow a drug substance to dissolve more rapidly. Disintegrants are natural, synthetic, or chemically modified natural polymeric substances. When disintegrants come in contact with water or stomach or intestinal fluid they function by absorbing liquid and start to swell, dissolve, or form gels. This causes the tablet structure to rupture and disintegrate, producing increased surfaces for enhanced dissolution of the drug substance.

Functional Mechanism(s): The ability to interact strongly with water is essential to disintegrant function. Four major mechanisms describe the function of the various disintegrants: volume increase by swelling, deformation, capillary action (wicking), and repulsion. In tablet formulations, the function of disintegrants is best described as a combination of two or more of these effects. The onset and degree of the locally achieved actions depend on various parameters of a disintegrant, such as its chemical nature and its particle size distribution and particle shape, as well as some important tablet parameters such as hardness and porosity.

Physical Properties: The primary physical properties relevant to a disintegrant are those that describe the product's particle structure as a dry powder or its structure

when in contact with water. These properties include (1) particle size distribution, (2) water absorption rate, (3) swelling ratio or swelling index, and (4) the characterization of the resulting product whether it is still particulate or a gel is formed.

Chemical Properties: Polymers used as disintegrants are either non-ionic or anionic with counterions such as sodium, calcium, or potassium. Non-ionic polymers are natural or physically modified polysaccharides such as starches, celluloses, pullulan, or cross-linked polyvinylpyrrolidone. The anionic polymers mainly are chemically modified cellulose products or low-crosslinked polyacrylates. These chemical properties should be considered in the case of ionic polymers. Disintegration performance will be affected by pH changes in the gastrointestinal tract or by complex formation with ionic active pharmaceutical ingredients (APIs).

General Chapters: The following general chapters may be useful to ensure consistency in disintegrant functions: *Light Diffraction Measurement of Particle Size* ⟨429⟩, *Particle Size Distribution Estimation by Analytical Sieving* ⟨786⟩, *Optical Microscopy* ⟨776⟩, and *Powder Flow* ⟨1174⟩.

Functional Category: Lubricant

Description: Lubricants typically are used to reduce the frictional forces between particles, and between particles and metal contact surfaces of manufacturing equipment such as tablet punches and dies used in the manufacture of solid dosage forms. Liquid lubricants may be absorbed into the granule matrix before compaction. Liquid lubricants also may be used to reduce metal–metal friction on manufacturing equipment.

Functional Mechanism: Boundary lubricants function by adhering to solid surfaces (granules and machine parts) and reducing the particle–particle friction or the particle–metal friction. The orientation of the adherent lubricant particles is influenced by the properties of the substrate surface. For optimal performance, the boundary lubricant particles should be composed of small, plate-like crystals or stacks of plate-like crystals. Fluid-film lubricants melt under pressure and thereby create a thin fluid film around particles and on the surface of punches and dies in tablet presses, which helps to reduce friction. Fluid-film lubricants re-solidify after the pressure is removed. Liquid lubricants are released from the granules under pressure and create a fluid film. They do not re-solidify when the pressure is removed but are reabsorbed or redistributed through the tablet matrix over the course of time.

Physical Properties: The primary physical properties that may be important for the function of boundary lubricants include particle size, surface area, hydration state, and polymorphic form. Purity (e.g., stearate:palmitate ratio) and moisture content also may be important. The primary physical properties of possible importance for fluid-film lubricants are particle size and solid state/thermal behavior. Purity may also be important.

Chemical Properties: Lubricants can be classified as boundary lubricants, fluid-film lubricants, or liquid lubricants. Boundary lubricants are salts of long-chain fatty acids (e.g., magnesium stearate) or fatty acid esters (e.g., sodium stearyl fumarate) with a polar head and fatty acid tail. Fluid-film lubricants are solid fats (e.g., hydrogenated vegetable oil, type 1), glycerides (glyceryl behenate and distearate), or fatty acids (e.g., stearic acid) that melt when subjected to pressure. Liquid lubricants are liquid materials that are released from granules under pressure.

General Chapters: The following general chapters may be useful to ensure consistency in lubricant functions: *Light Diffraction Measurement of Particle Size* ⟨429⟩, *Parti-*

cle Size Distribution Estimation by Analytical Sieving ⟨786⟩, *Specific Surface Area* ⟨846⟩, *X-ray Diffraction* ⟨941⟩, *Loss on Drying* ⟨731⟩, *Water Determination* ⟨921⟩, *Crystallinity* ⟨695⟩, *Crystallinity Determination by Solution Calorimetry* ⟨696⟩, *Optical Microscopy* ⟨776⟩, and *Thermal Analysis* ⟨891⟩.

Other Information: Certain lubricants, particularly those used in effervescent dosage forms, do not fall into the chemical categories defined above. These materials are used in special situations, and they are not suitable for universal application. Talc is an inorganic material that may have some lubricant properties. It is generally used in combination with fluid-film lubricants to reduce sticking to punches and dies.

Functional Category: Glidant and/or Anticaking Agent

Description: Glidants and anticaking agents are used to promote powder flow and to reduce the caking or clumping that can occur when powders are stored in bulk. In addition, glidants and anticaking agents reduce the incidence of bridging during the emptying of powder hoppers and during powder processing.

Functional Mechanism: Glidants are thought to work by a combination of adsorption onto the surface of larger particles and reduction of particle–particle adhesive and cohesive forces, thus allowing particles to move more easily relative to one another. In addition, glidants may be dispersed between larger particles and thus may reduce friction between larger particles. Anticaking agents may absorb free moisture that otherwise would allow the development of particle–particle bridges that are implicated in caking phenomena.

Physical Properties: Primary physical properties of potential importance for glidants and anticaking agents are particle size, particle size distribution, and surface area. They may be slightly hygroscopic.

Chemical Properties: Glidants and anticaking agents typically are finely divided inorganic materials. They are insoluble in water but are not hydrophobic. Some of these materials are complex hydrates.

General Chapters: The following general chapters may be useful to ensure consistency in glidant or anticaking agent functions: *Light Diffraction Measurement of Particle Size* ⟨429⟩, *Particle Size Distribution Estimation by Analytical Sieving* ⟨786⟩, *Specific Surface Area* ⟨846⟩, *Loss on Drying* ⟨731⟩, and *Water Determination* ⟨921⟩.

Functional Category: Coloring Agent

Description: Coloring agents are incorporated into dosage forms in order to produce a distinctive appearance that may serve to differentiate a particular formulation from others that have a similar physical appearance. These substances are subdivided into dyes (water-soluble substances), lakes (insoluble forms of a dye that result from its irreversible adsorption onto a hydrous metal oxide), inorganic pigments (substances such as titanium dioxide or iron oxides), and natural colorants (colored compounds not considered dyes per se, such as riboflavin). Coloring agents are subject to federal regulations, and consequently the current regulatory status of a given substance must be determined before its use.

The Federal Food, Drug, and Cosmetic Act defines three categories of coloring agents:

- FD&C colors: those certifiable for use in coloring foods, drugs, and cosmetics

- D&C colors: dyes and pigments considered safe in drugs and cosmetics when in contact with mucous membranes or when ingested
- Ext. D&C colors: colorants that, because of their oral toxicity, are not certifiable for use in ingestible products but are considered safe for use in externally applied products.

Functional Mechanism: Water-soluble dyes usually are dissolved in a granulating fluid for use, although they may also be adsorbed onto carriers such as starch, lactose, or sugar from aqueous or alcoholic solutions. These latter products are often dried and used as formulation ingredients. Because of their insoluble character, lakes are almost always blended with other dry excipients during formulation. For this reason, direct-compression tablets are often colored with lakes.

Physical Properties: Particle size and size distribution of dyes and lakes can influence product processing times (blending and dissolution), color intensity, and uniformity of appearance.

Chemical Properties: The most important properties of a coloring agent are its depth of color and resistance to fading over time. Substances can be graded on their efficiency in reflecting desired colors of visible light, as well as on their molar absorptivities at characteristic wavelengths. A coloring agent should be physically and chemically nonreactive with other excipients and the drug substances. The quality of a coloring agent ordinarily is measured by a determination of its strength, performance, or assay. The impurity profile is established by measurements of insoluble matter, inorganic salt content, metal content, and organic impurities.

General Chapters: Two general chapters are useful to ensure consistency in selected coloring agent functions: *Color—Instrumental Measurement* ⟨1061⟩ and *Light Diffraction Measurement of Particle Size* ⟨429⟩. Instrumental methods should be used to determine the absolute color of a coloring agent.

Other Information: Coloring agents are subject to federal regulations, and consequently the current regulatory status of a given substance must be determined before it is used. Following is a list of coloring agents and currently applicable sections of the Code of Federal Regulations (CFR).

Color	CFR
Ferric Oxides	21 CFR 73.1200
Titanium Dioxide	21 CFR 73.575 & 21 CFR 73.1575
FD&C Blue #1/Brilliant Blue FCF Aluminum Lake	21 CFR 82.51 & 21 CFR 82.101
FD&C Blue #2/Indigo Carmine Aluminum Lake	21 CFR 82.51 & 21 CFR 82.102
FD&C Red #40/Allura Red AC Aluminum Lake	21 CFR 74.340 & 21 CFR 74.1340
FD&C Yellow #5/Tartrazine Aluminum Lake	21 CFR 82.51 & 21 CFR 82.705
FD&C Yellow #6/Sunset Yellow FCF Aluminum Lake	21 CFR 82.51 & 21 CFR 82.706
D&C Yellow #10 Aluminum Lake	21 CFR 82.1051 & 21 CFR 82.1710
D&C Red #30/Helendon Pink Aluminum Lake	21 CFR 82.1051 & 21 CFR 82.1330
D&C Red #7/Lithol Rubin B Calcium Lake	21 CFR 82.1051 & 21 CFR 82.1307
D&C Red #27/Phloxine Aluminum Lake	21 CFR 82.1051 & 21 CFR 82.1327

Functional Category: Capsule Shell

Description: The word capsule is derived from the Latin capsula, which means a small container. Among other benefits, capsules enable pharmaceutical powders and liquids to be formulated for dosing accuracy as well as ease of transportation. The capsule material should be compatible with all other ingredients in the drug product. Hard capsules typically consist of two parts: both are cylindrical, and one part is slightly longer than other and is called the body. The cap fits closely on the body to enclose the capsule. In contrast, the soft capsule is a one-piece unit that may be seamed along an axis or may be seamless. The capsule material may be derived from hydrolysis of collagen that originates from porcine, bovine, or fish sources, or it can be of non-animal origin, e.g., cellulosic or polysaccharide chemical entities. The capsule shell also contains other additives such as plasticizers, colorants, and preservatives. In some cases, capsule shells are sterilized to prevent microbial growth. The capsule shell is an integral part of the formulation, and therefore robust manufacturing and formulation performance depends on the measurement and control of critical attributes.

Functional Mechanism: Capsules can enclose solid as well as semisolid and liquid formulations. Capsules have a variety of benefits including: masking unpleasant taste, facilitating blinding in clinical studies, promoting ease of swallowing, and presenting a unique appearance. Conventional capsule shells should dissolve rapidly at 37° in biological fluids such as gastric and intestinal media. However, the solubility properties of the shell can be modified, e.g., with enteric and controlled-release polymers, to control the release of capsule contents.

Physical Properties: The primary physical properties relevant to the capsule shell are those that can have a direct effect on product performance: 1) moisture content, 2) gas permeability, 3) stability on storage, 4) disintegration, 5) compactness, and 6) brittleness. The moisture content varies with the type of capsule. Hard gelatin capsules typically contain 13%–16% water compared to hypromellose (hydroxypropyl methylcellulose/HPMC) capsules that typically contain 4%—7% water content. Soft gelatin capsules contain 6%–8% water. Moisture content has a significant impact on capsule brittleness. Equilibrium water content also may be crucial to dosage form stability because water migration will take place between the shell and capsule contents. Gas permeability may be important and generally is greater for HPMC capsules than gelatin capsules because of the presence of open structures. Gelatin capsules may undergo cross-linking upon storage at elevated temperature and humidity (e.g. 40°/75% RH), but under these conditions HPMC capsules do not cross-link. The aldehyde content in the powder fill should be considered because it can promote cross-linking of gelatin shell material. Gelatin capsules should disintegrate within 15 min when exposed to 0.5% HCl at 36°–38° but not below 30°. HPMC capsules also can disintegrate below 30°.

Chemical Properties: Gelatin is a commercial protein derived from native protein collagen. The product is obtained by partial hydrolysis of collagen derived from skin, white connective tissue, and bones of animals. Type A gelatin is derived by acid treatment, and Type B gelatin is derived from base treatment. The common sources of commercial gelatin are pigskin, cattle hide, cattle bone, cod skin, and tilapia skin. The gelatin capsule shell also typically contains coloring agents, plasticizers such as polyhydric alcohols, natural gums and sugars, and preservatives such as sodium metabisulfite and esters of para-hydroxy benzoic acid. The more commonly used nongelatin capsules today are made from HPMC. Different capsule types contain different moisture levels and may thus influence drug product stability. The detailed composition of an excipient may be important because

the shell function can be influenced by small amounts of impurities in the excipients (e.g., peroxides in oils or aldehydes in lactose and starches) that can cause capsule cross-linking. The presence in capsule shells of undesirable materials such as metals, odorants, water-insoluble substances, and sulfur dioxide should be evaluated to ensure stability and performance.

General Chapters: The following general chapters may be useful to ensure consistency in selected capsule shell functions: *Microbial Enumeration Tests* ⟨61⟩, *Tests for Specified Organisms* ⟨62⟩, *Residue on Ignition* ⟨281⟩, *Arsenic* ⟨211⟩, *Heavy Metals* ⟨231⟩, *Water Determination* ⟨921⟩, *Color Instrumental Method* ⟨1061⟩, *Disintegration* ⟨701⟩, *Dissolution* ⟨711⟩, and *Gel Strength of Gelatin* ⟨1081⟩.

Functional Category: Coating Agent

Description: Reasons for coating pharmaceutical dosage forms include masking unpleasant tastes or odors, improving ingestion and appearance, protecting active ingredients from the environment, and modifying the release of the active ingredient (e.g., controlled-release rates or gastrointestinal targeting). The materials used as coating agents include natural, semisynthetic, and synthetic materials. These may be powders or colloidal dispersions (latexes or pseudolatexes) that usually are applied as solutions or dispersions in aqueous or nonaqueous systems. Waxes and lipids may be applied as coatings in the molten state without the use of solvents.

Functional Mechanism: Coating agents are composed of film-forming materials that impart desirable pharmaceutical properties such as appearance, patient acceptance, and ease of swallowing. Coating agents also may serve other functional purposes such as providing a barrier against undesirable chemical reactions or untimely release of a drug from its components. After intake, the coating may dissolve by processes such as hydration, solubilization, or disintegration, depending on the nature of the material used. Enteric coatings are insoluble in acidic (low pH) media but dissolve readily in neutral pH conditions. However, most common coatings do not have pH-specific solubility. The coating thickness may vary by application and the nature of the coating agents. In the coating process, the polymer chains spread out on the core surface and coalesce into a continuous film as the solvent evaporates. Plastic polymers, waxes, and lipid-based coatings may be applied without solvents by melting and atomization. Molten fluid droplets, upon impact on the surface of the fluidized drug particles, spread and re-solidify to form film layers. Therefore, coating materials generally have the ability to form a complete and stable film around the substrate. The coating preparation typically is applied uniformly and is carefully dried to ensure that a consistent product is produced. Suitable plasticizers may be required to lower the minimum film-forming temperature of the polymer, and their potential effect on drug release should be considered.

Physical Properties: Film coating is a complex process, and the characteristics of a film-forming polymer play an important role: the particle size of colloidal dispersions varies with their origin (latex, pseudolatex, or re-dispersed powder) and may have an effect on the film-forming mechanism. Polymer solutions or dispersions with a low viscosity and high pigment-binding capacity reduce the coating time and facilitate relatively simple and cost-effective manufacturing. The concentration–viscosity relationship for the film-forming agent should be evaluated for process optimization. The surface tension of coating preparations can influence the spray pattern in the manufacturing process. The applied coating must withstand mechanical stress during coating or packaging operations. Therefore, the film should possess high elasticity and sufficient mechanical strength. It can be useful to analyze tensile properties of isolated films. For coatings

that are applied in a molten state without solvents (plastic polymers, waxes, and lipid-based coatings), melting range and melt viscosity are the properties of prime consideration.

Chemical Properties: Film-forming agents are of natural, semisynthetic, or synthetic origin and are available in different chemical grades. *NF* monographs often describe classes of polymeric materials that allow a considerable range of composition, structure, or molecular weight. These factors should be considered when pharmaceutical scientists identify and quantitate critical material attributes to ensure consistent performance.

General Chapters: The following general chapters may be useful in ensuring consistency in selected excipient functions: *Viscosity* ⟨911⟩, *Tensile Strength* ⟨881⟩, *Light Diffraction Measurement of Particle Size* ⟨429⟩, *Fats and Fixed Oils* ⟨401⟩, *Thermal Analysis* ⟨891⟩, and *Dissolution* ⟨711⟩.

Additional Information: Additives often are included in a coating formulation. Fillers (e.g., sugar alcohols, microcrystalline cellulose) may be added to increase the solids content of the coating agent without increasing viscosity. Stearic acid can be used to improve the protective function/moisture barrier of a coating. Water-soluble or -insoluble ingredients may be added to create pores in the film to adjust the release pattern of sustained-release formulations. Coloring agents (e.g., titanium dioxide, kaolin) may be added to modify appearance.

Functional Category: Plasticizer

Description: A plasticizer is a low molecular weight substance that, when added to another material—usually a polymer—makes the latter flexible, resilient, and easier to handle. Modern plasticizers are synthetic organic chemicals, the majority of which are esters such as citrates and phthalates. They are key components that determine the physical properties of polymeric pharmaceutical systems such as tablet film coatings and capsule shells.

Functional Mechanism: Plasticizers function by increasing the intermolecular and intramolecular mobility of the macromolecules that comprise polymeric materials. They achieve this by interfering with the normal intermolecular and intramolecular bonding mechanisms in such systems. The most effective plasticizers exert their effect at low concentrations, typically less than 5% w/w. Plasticizers commonly are added to film coatings (aqueous and nonaqueous systems) and capsule shells (hard and soft varieties) to improve their workability and mechanical ruggedness. Without the addition of plasticizers, such materials can split or fracture prematurely. Plasticizers also are added to semisolid pharmaceutical preparations such as creams and ointments to enhance their rheological properties.

Physical Properties: The most common plasticizers are low molecular weight (< 500 Da) solids or liquids. They typically have low melting points ($< 100^\circ$) and can be volatile (i.e., exert an appreciable vapor pressure) at ambient temperature. Plasticizers can significantly reduce the glass transition temperature of the system to which they are added.

Chemical Properties: As noted, many modern plasticizers are synthetic esters such as citrates and phthalates. Traditional pharmaceutical plasticizers include oils, sugars, and their derivatives.

General Chapters: The following general chapters may be useful in ensuring consistency in selected excipient functions: *Melting Range or Temperature* ⟨741⟩, *Water Determination* ⟨921⟩, *Organic Volatile Impurities* ⟨467⟩, *Specific Gravity* ⟨841⟩, *Refractive Index* ⟨831⟩, and *Thermal Analysis* ⟨891⟩.

Other Information: The choice of an appropriate plasticizer often is guided by reference to its "solubility parameter," which is related to its cohesive energy density. Solubility parameter values for many common materials are tabulated in standard reference texts. To ensure maximum effectiveness, the solubility parameter of the plasticizer and the polymeric system being plasticized should be matched as closely as possible.

ORAL LIQUIDS

Functional Category: pH Modifier (Acidifying/Alkalizing/Buffering Agent)

Description: The hydrogen ion concentration, $[H^+]$, in an aqueous solution is expressed as $pH = -\log(H^+)$. The pH of pure water is 7 at 25°. An aqueous solution is acidic at $pH < 7$ and alkaline at $pH > 7$. An acid may be added to acidify a solution. Similarly, a base may be used to alkalize a solution. A buffer is a weak acid (or base) and its salt. When a buffer is present in a solution, the addition of small quantities of strong acid or base leads to only a small change in solution pH. Buffer capacity is influenced by salt/acid (or base/salt) ratio and total concentration of acid (or base) and salt. The pH of pharmaceutical solutions typically is controlled using acidifying/alkalizing and buffering agents to: 1) maintain a pH close to that of relevant body fluid to avoid irritation; 2) improve drug stability that is pH dependent; 3) control equilibrium solubility of weak acids or bases; and 4) maintain consistent ionization state of molecules during chemical analysis, e.g., high-performance liquid chromatography (HPLC).

Functional Mechanism: The ionization equilibria of weak bases, weak acids, and water are the key to the functions of acidifying, alkalizing, and buffering agents. The autoprotolytic reaction of water can be expressed as

$$H_2O + H_2O \leftrightarrow H_3O^+ + OH^-$$

The autoprotolysis constant (or ion product) of water is $K_w = 1 \times 10^{-14}$ at 25° and varies significantly with temperature. Because the concentrations of hydrogen and hydroxyl ions in pure water are equal, each has the value of approximately 1×10^{-7} mole/L, leading to the neutral pH of 7 at 25°. When an acid, base, or salt of weak acid (or base) is added, the ionization equilibrium of water is shifted so that $[H^+][OH^-]$ remains constant, thus resulting a solution pH that is different from 7.

Physical Properties: The ionization equilibrium of a weak acid, HA, can be written as

$$HA + H_2O \leftrightarrow H_3O^+ + A^-$$

The ionization constant of a weak acid (or conjugate acid of a base) is commonly expressed as $pK_a = -\log(K_a)$, where $K_a = [H_3O^+][A^-]/[HA]$. A lower pK_a corresponds to a stronger acid. Similarly, the ionization constant of a weak base (or conjugate base of an acid) is expressed as $pK_b = -\log(K_b)$. The ionization equilibrium of water ($pK_a + pK_b = pK_w$) equals 14 at 25°. Buffers and pH modifiers influence solution osmolality, osmolarity, and water conductivity.

Chemical Properties: When used in chemical analysis, buffers must be chemically compatible with the reagents and test substance. Buffers, when used in physiological systems, should not interfere with pharmacological activity of the medicament or normal function of the organism.

In-Process Revision

General Chapters: The following general chapters may be useful to ensure consistency in selected pH modifier or buffering agent functions: *Water Conductivity* ⟨645⟩, *pH* ⟨791⟩, and *Osmolality and Osmolarity* ⟨785⟩.

Functional Category: Wetting and/or Solubilizing Agent

Description: Solubilizers can be used to dissolve insoluble molecules. They function by facilitating spontaneous phase transfer to yield a thermodynamically stable solution. A number of solubilizers are available commercially. Acceptable solubilizers for pharmaceutical applications have been fully evaluated in animals for safety and toxicology.

Functional Mechanism: Solubilizers comprise a variety of different chemical structures/classes. Some solubilizers may have unique chemical structures. For example, a hydrophilic moiety may be tethered with a hydrophobic moiety to yield distinct micelle shapes and morphologies in water, thus facilitating solubilization. The mechanism of solubilization often is associated with a favorable interaction of the insoluble agent and the interior core of the solubilizer assembly (e.g. micelles). In other cases, unique hydrophobic sites that are capable of forming inclusion complexes are present. Other types of solubilizers utilize a range of polymeric chains that interact with hydrophobic molecules to increase solubility by dissolving the insoluble agent into the polymeric chains.

Physical Properties: Solubilizers are solid, liquid, or waxy materials. Their physical properties depend on their chemical structures. The physical properties and performance of the solubilizers, however, depend on the surface-active properties of the solubilizers and on the hydrophilic–lipophilic balance (HLB). Solubilizers with lower HLB values behave as emulsifiers, and those with higher HLB values behave as solubilizers. For example, sodium lauryl sulfate (HLB 40) is hydrophilic and highly water soluble and, upon dispersion in water, spontaneously forms micelles.

The unique hydrophilicity and hydrophobicity properties of solubilizers are characterized by their aggregate numbers or critical micelle concentrations (CMC). The CMC value is unique to an individual solubilizer bearing hydrophilic, lipophilic, and/or hydrophobic chains. CMC is a measure of the concentration at which the surface-active molecule aggregates and solubilizes the solute by incorporating part into the hydrophobic interior and accommodating the rest in the hydrophilic exterior aqueous layer. Such interactions with the insoluble molecule further stabilize the molecules in the entire assemblies without precipitation to yield a continuous solution.

Chemical Properties: The chemical and surface-active properties depend on the structures of the solubilizers. Because of the complex nature of solute–solvent–solubilizer interactions, pharmaceutical scientists must carefully consider, identify, and control the critical material attributes of solubilizers.

General Chapters: The following general chapters may be useful to ensure consistency in selected solubilizing agent function: *Fats and Fixed Oils* ⟨401⟩, *Specific Gravity* ⟨841⟩, *pH* ⟨791⟩, *Specific Surface Area* ⟨846⟩, *Thermal Analysis* ⟨891⟩, *Spectrophotometry and Light-Scattering* ⟨851⟩, *Scanning Electron Microscopy* ⟨1181⟩, *Viscosity* ⟨911⟩, and *Light Diffraction Measurement of Particle Size* ⟨429⟩.

Functional Category: Antimicrobial Preservative

Description: Antimicrobial preservatives are used to kill or prevent growth of bacteria, yeast, and mold in the dosage form.

Functional Mechanism: Preservatives work by a variety of mechanisms to control microbes. Most of them work at the cell membrane, causing membrane damage and cell leakage. Other modes of action include transport inhibition, protein precipitation, and proton-conducting uncoupling. Some preservatives are -cidal (kill bacteria or yeast and mold); some are -static (inhibit growth of microorganisms); and others are sporicidal (kill spores). Several of the preservatives can act synergistically (e.g., combinations of parabens).

Physical Properties: Antimicrobials generally are soluble in water at concentration ranges at which they are effective. The vapor pressure of these agents is important, especially if the dosage form is intended to be lyophilized or spray dried. Several of these agents are flammable. Understanding of an excipient's partition coefficient is important because partitioning of a preservative into an oil phase will diminish the preservative's concentration in the aqueous phase, which in turn can reduce its value as a preservative.

Chemical Properties: Phenolic preservatives can undergo oxidation and color formation. Incompatibilites of preservatives (cationic and anionic mixtures, adsorption to tubes or filters, binding to surfactants and proteins) should be taken into account during product development.

General Chapters: The following general chapters may be useful to ensure consistency in selected excipient functions: *Injections* ⟨1⟩, *Antimicrobial Effectiveness Testing* ⟨51⟩, *Microbial Limit Tests* ⟨61⟩, and *Antimicrobial Agents—Content* ⟨341⟩.

Other Information: Be aware of safety and labeling requirements, specifically for benzalkonium chloride (eye and skin irritation), benzoic acid and benzoate salts (risk of jaundice in newborn babies), benzyl alcohol (should not given to premature babies or neonates and may cause allergic reactions in children aged 3 years or less), bronopol (may cause skin reaction), chlorocresol (allergic reactions), organic mercury compounds (allergic reaction), parabens (allergic reactions), and sorbic acid and salts (skin reactions). Because of the risk of organic mercury toxicity, thimerosal should not be used. Use of preservative is contraindicated in parenteral products in which the fill volume is greater than 30 mL or comes in contact with cerebrospinal fluid. Antioxidants and chelating agents tend to potentiate antimicrobial efficacy.

Functional Category: Chelating and/or Complexing Agents

Description: Chelating/complexing agents form soluble complex molecules with certain metal ions (e.g., copper, iron, manganese, lead, and calcium) and essentially remove the ions from solution to minimize or eliminate their ability to react with other elements and/or to precipitate. The agents are used in pharmaceuticals (oral, parenteral, and topical formulations), cosmetics, and foods to sequester ions from solution and to form stable complexes. Chelating agents are also referred to as chelants, chelators, or sequestering agents.

Functional Mechanism: Chelating/complexing agents are used to sequester undesirable metal ions from solution. Their chemical structure acts as a ''claw'' to associate with the metal atom by forming a heterocyclic ring structure. Complexing agents function similarly but mechanistically do not (by definition) require a two-point claw structure because they can associate via one or more binding sites. All chelating agents are complexing agents, but not all complexing agents are chelating agents. As excipients, chelating agents are used as antioxidant synergists, antimicrobial synergists, and water softeners. By ''removing '' metal ions from solution, chelating agents reduce the propensity for oxidative reactions. Chelating agents also have the ability to enhance antimicrobial effectiveness by forming a metal ion deficient environment that otherwise could feed microbial growth.

Physical Properties: Chelating and complexing agents are freely soluble in water. Various salt (disodium and calcium disodium) and hydrated forms (anhydrous, dihydrate, and trihydrate) of edetic acid exist. Edetic acid and its derivatives appear as white to off-white crystalline solids. Oxyquinoline sulfate appears as a pale yellow crystalline powder. *USP–NF* recognizes that chelating/complexing agents are stable below 100°, but dehydration and/or decomposition can occur at higher temperatures. Chelating agents exhibit different degrees of hygroscopicity. Because low proportions of chelating agents are used in formulations (typically not more than 0.2%), they are not expected to significantly affect the bulk solid mechanical and flow properties of solid formulations. Because these agents are used in very low levels, their particle size distribution is important to enable acceptable dosage form content uniformity.

Chemical Properties: Chelating/complexing agents complex with metal ions via any combination of ionic and covalent bonds. Dilute aqueous solutions may be neutral, acidic, or alkaline. Edetic acid and its salts are incompatible with strong oxidizers, strong bases, and polyvalent metal ions (e.g., copper and nickel). Specific agents are selected for a formulation based on their solubility, affinity for the target metal ion, and stability. Edetate salts are more soluble than the free acid. Unlike other edetate salts and the free acid, edetate calcium disodium does not sequester calcium and therefore is preferred to prevent hypocalcemia. It is also preferred to chelate heavy metals with the release of calcium ions. Alternatively, disodium edetate can be used to treat hypercalcemia. Edetic acid will decarboxylate if heated above 150°.

General Chapters: The following general chapters may be useful to ensure consistency in selected excipient functions: *Antimicrobial Effectiveness Testing* ⟨51⟩; *Microbial Enumeration Tests* ⟨61⟩; *Heavy Metals* ⟨231⟩; *Iron* ⟨241⟩; *Lead* ⟨251⟩; *Antimicrobial Agents—Content* ⟨341⟩; *Light Diffraction Measurement of Particle Size* ⟨429⟩; *Loss on Drying* ⟨731⟩; *pH* ⟨791⟩; *Water Determination* ⟨921⟩; *Biotechnology-derived Articles* ⟨1045⟩; and *Cell and Gene Therapy Products* ⟨1046⟩, *Manufacturing of Cell Therapy Products*.

Functional Category: Antioxidant

Description: This category applies to antioxidants used as in vitro stabilizers of pharmaceutical preparations to mitigate oxidative processes. Antioxidants used for their biological activity in vivo may be regarded as active ingredients with therapeutic effects and are not discussed. Antioxidants delay the onset and/or significantly reduce the rate of complex oxidative reactions that could otherwise have a detrimental impact on the drug substance. Antioxidants also can be considered for protecting nonactive components like unsaturated oils, pegylated lipids, flavors, and essential oils. Thus antioxidants preserve the overall integrity of the dosage form

against oxidative stress. Antioxidants are most effective when incorporated in the formula to prevent or delay the onset of chain reactions and to inhibit free radicals and hydroperoxides from engaging in the cascading processes described above. Effective application of antioxidants and evaluation of their efficacy necessitate an understanding of oxidative mechanisms and the nature of the by-products they generate. Autoxidation is initiated when oxygen reacts with a substrate to form highly reactive species known as free radicals ($RH \rightarrow R \cdot$). After ''initiation'' the free radicals in the presence of oxygen can trigger chain reactions ($R \cdot + O_2 \rightarrow ROO \cdot$ and $ROO \cdot + RH \rightarrow R \cdot + ROOH$) to form peroxy radicals, hydroperoxides, and new alkyl radicals that can initiate and then propagate their own chain reactions. The cascading reactions during the propagation phase can be accelerated by heat, light, and metal catalysts. In the presence of trace amounts of metal catalysts (Cu^{+}, $Cu2^{+}$, $Fe2^{+}$, and $Fe3^{+}$), hydroperoxides (ROOH) readily decompose to $RO \cdot$ and $ROO \cdot$ and can subsequently trigger reactions with the API and/or the excipients (e.g., hydrocarbons) to form hydroxyl acids, keto acids, and aldehydes that can have further undesirable effects. Note that hydroperoxides are not solely the reaction products of oxidative mechanisms within a formulation. Residual amounts of hydroperoxides can also be found in commonly used excipients like polyethylene glycols (PEG), polyvinlypyrrolidone (PVP), and polysorbates. The initiation phase generally is slow and has limited impact on the quality of the finished product. The propagation phase, in contrast, involves rapid, irreversible degradation of chemical species.

Functional Mechanism: Antioxidants can be grouped by their mode of action. Phenolic antioxidants that block free radical chain reactions are also known as true or primary antioxidants. This group consists of monohydroxy or polyhydroxy phenol compounds with ring substitutions. They have very low activation energy to donate hydrogen atom(s) in exchange for the radical electrons that are rapidly delocalized by free radicals. By accepting the radical electrons they stabilize free radicals. The reaction yields antioxidant free radicals that can also react with lipid free radicals to form other stable compounds. Thus they can block oxidative chain reactions both in the initiation and propagation stages. Because of their solubility behavior, phenolic antioxidants are most effective in protecting oils and oil-soluble actives against oxidative stress. Reducing agents generally are water-soluble antioxidants (e.g., L-ascorbic acid) with lower redox potential than the drug or the excipient they are protecting. They delay the onset and the rate of oxidative reactions by sacrificially reacting with oxygen and other reactive species. The oxygen-scavenging potential of the reducing agents may be sensitive to pH and can also be negatively affected in the presence of trace metals. Chelating agents bind with free metals (Cu+, Cu2+, Fe2+, and Fe3+) that may be present in trace amounts in the formulation. The newly formed complex ions are nonreactive. Chelating agents therefore remove the capacity of the metal catalysts to participate in oxidative reactions that occur during the propagation stage.

The utility of antioxidants can be maximized by synergistic use of one or two primary antioxidants along with reducing and chelating agents. The combined effect is often greater than the sum of the individual effects of each antioxidant (synergistic effect).

Physical Properties: Solubility of the antioxidant should be greatest in the formulation phase (oily, aqueous, or emulsion interface) where the drug substance is most soluble. The temperature at which the antioxidant decomposes is critical for autoclaved preparations where loss of antioxidant activity may occur. Stability of the antioxidant also must be considered and may be a function of pH and processing conditions. Metal ions may react with

propyl gallate to form colored complexes. At alkaline pH, certain proteins and sodium salts may bring about discoloration of *tert*-butylhydroquinone (TBHQ).

Chemical Properties: Activation energy, oxidation-reduction potential, stability at different formulation (e.g., pH), and processing (e.g., heat) conditions are important chemical properties. If the dosage form's expected shelf life depends on the antioxidant's function, the concentration must be factored in and periodically assessed to ensure a sufficient amount of antioxidant remains but does not exceed safety limits.

General Chapters: The following general chapters may be useful for assessing selected excipient antioxidant functions: *Specific Surface Area* ⟨846⟩, *Crystallinity* ⟨695⟩, *Chromatography* ⟨621⟩, *Water Determination* ⟨921⟩, *Melting Range or Temperature* ⟨741⟩, and *Iron* ⟨241⟩.

Functional Category: Sweetening Agent

Description: Sweetening agents are used to sweeten oral dosage forms and to mask unpleasant flavors.

Functional Mechanism: Sweetening agents bind to receptors on the tongue that are responsible for the sensation of sweetness. The longer the sweetener molecule remains attached to the receptor, the sweeter the substance is perceived to be. The standard for sweetness is sucrose.

Physical Properties: The primary physical properties relevant to sweeteners relate to their compatibility with the other ingredients in the formulation (e.g., acidic ingredients), processing conditions (e.g., heating), particle size and distribution, moisture content, isomerism, sweetness, and taste-masking capability. These properties may be formulation dependent.

Chemical Properties: Sweeteners can be divided into three main groups: sugars (which have a ring structure), sugar alcohols (sugars that do not have a ring structure), and artificial sweeteners. All sweeteners are water soluble. The stability of many sweeteners is affected by pH and other ingredients in the formulation. Some sweeteners may catalyze the degradation of some active ingredients, especially in liquids and in cases when the manufacturing processes involve heating.

General Chapters: The following general chapters may be useful to ensure consistency in selected excipient functions: *Optical Rotation* ⟨781⟩, *Specific Rotation*; *Water Determination* ⟨921⟩; *Loss on Drying* ⟨731⟩; and *Melting Range or Temperature* ⟨741⟩.

Other Information: Products that contain aspartame must include a warning on the label stating that the product contains phenylalanine. Sugar alcohols have a glycemic index well below that of glucose. However, sorbitol is slowly metabolized to fructose and glucose, which raises blood sugar levels. Sugar alcohols in quantities generally greater than 20 g/day act as an osmotic laxative, especially when they are contained in a liquid formulation. Preservative systems should be carefully chosen to avoid incompatibility with the sweetener; some sweeteners are incompatible with certain preservatives.

SEMISOLIDS, TOPICALS, AND SUPPOSITORIES

Functional Category: Suppository Base

Description: Suppository bases are used in the manufacture of suppositories (for rectal administration) and pessaries (for vaginal administration). They can be hydrophobic or hydrophilic.

Functional Mechanism: Suppositories should melt at just below body temperature (37°), thereby allowing the drug to be released either by erosion and partition if the drug is dissolved in the base or by erosion and dissolution if the drug is suspended in the base. Hard fat suppository bases melt at approximately body temperature. Hydrophilic suppository bases also melt at body temperature and typically also dissolve or disperse in aqueous media. Thus release takes place via a combination of erosion and dissolution.

Physical Properties: The important physical characteristic of suppository bases is melting range. In general suppository bases melt between 27° and 45°. However, individual bases usually have a much narrower melting range within these temperature boundaries, typically 2°–3°. The choice of a particular melting range is dictated by the influence of the other formulation components on the melting range of the final product.

Chemical Properties: Hard fat suppository bases are mixtures of semisynthetic triglyceride esters of longer-chain fatty acids. They may contain varying proportions of mono- and di-glycerides and may also contain ethoxylated fatty acids. They are available in many different grades that are differentiated by melting range, hydroxyl number, acid value, iodine value, solidification range, and saponification number.

Hydrophilic suppository bases are mixtures of hydrophilic semisolid materials that in combination are solid at room temperature and yet release the drug by melting, erosion, and dissolution when administered to the patient. Hydrophilic suppository bases have much higher levels of hydroxyl groups or other hydrophilic groups than do hard fat suppository bases. Polyethylene glycols that show appropriate melting behavior are examples of hydrophilic suppository bases.

General Chapters: The following general chapters may be useful to ensure consistency in selected excipient functions: *Fats and Fixed Oils* ⟨401⟩, *Congealing Temperature* ⟨651⟩, *Melting Range or Temperature* ⟨741⟩, and *Pharmaceutical Dosage Forms* ⟨1151⟩.

Other Information: Some materials included in suppositories based on hard fats have much higher melting ranges. These materials typically are microcrystalline waxes that help stabilize molten suspension formulations. Suppositories may also be manufactured from glycerinated gelatin.

Functional Category: Suspending and/or Viscosity-increasing Agent

Description: Suspending and/or viscosity-increasing agents are used in pharmaceutical formulations to stabilize disperse systems (e.g., suspensions or emulsions), to reduce the rate of solute or particulate transport, or to decrease the fluidity of liquid formulations.

Functional Mechanism(s): A number of mechanisms contribute to the dispersion stabilization or viscosity-increasing effect of these agents. The most common is the increase in viscosity–due to the entrapment of solvent by macromolecular chains or clay platelets—and the disruption of laminar flow. Other mechanisms include gel formation via a three-dimensional network of excipient molecules or particles throughout the solvent continuum and steric stabilization wherein the macromolecular or mineral component in the dispersion medium adsorbs to the surfaces of particles or droplets of the dispersed phase. The latter two mechanisms increase formulation stability by immobilizing the dispersed phase.

Physical Properties: Each of the mechanisms—increased viscosity, gel formation, or steric stabilization—is a manifestation of the rheological character of the excipient.

Because of the molecular weights and sizes of these excipients, the rheological profiles of their dispersions are non-Newtonian. Dispersions of these excipients display viscoelastic properties. The molecular weight distribution and polydispersity of the macromolecular excipients in this category are important criteria for their characterization.

Chemical Properties: The majority of the suspending and/or viscosity-increasing agents are (a) hydrophilic carbohydrate macromolecules (acacia, agar, alginic acid, carboxymethylcellulose, carrageenans, dextrin, gellan gum, guar gum, hydroxyethyl cellulose, hydroxypropyl cellulose, hypromellose, maltodextrin, methylcellulose, pectin, propylene glycol alginate, sodium alginate, starch, tragacanth, and xanthan gum) and (b) noncarbohydrate hydrophilic macromolecules, including gelatin, povidone carbomers, polyethylene oxide, and polyvinyl alcohol. Minerals (e.g., attapulgite, bentonite, magnesium aluminum silicate, and silicon dioxide) comprise the second-largest group of suspending and/or viscosity-increasing agents. Aluminum monostearate is the one nonmacromolecular, non-mineral excipient in this functional category. It consists chiefly of variable proportions of aluminum monostearate and aluminum monopalmitate.

General Chapter: The following general chapter may be useful to ensure consistency in selected excipient functions: *Viscosity* ⟨911⟩.

Functional Category: Ointment Base

Description: An ointment is a viscous semisolid preparation used topically on a variety of body surfaces. An ointment base is the major component of an ointment and controls its physical properties.

Functional Mechanism: Ointment bases serve as vehicles for topical application of medicinal substances and also as emollients and protective agents for skin.

Physical Properties: Ointment bases are liquids with a relatively high viscosity so that solids can be suspended as a stable mixture.

Ointment bases are classified as: (a) oleaginous ointment bases that are anhydrous, do not absorb water readily, are insoluble in water, and are not removable by water (e.g., petrolatum); (b) absorption ointment bases that are anhydrous and absorb some water but are insoluble in water and are not water removable (e.g., lanolin); (c) emulsion ointment bases that are water-in-oil or oil-in-water emulsions and are hydrous, absorb water, and are insoluble in water (e.g., creams of water, oils, waxes, and/or paraffins); and (d) water-soluble ointment bases that are anhydrous and absorb water and are soluble in water and are water removable (e.g., polyethylene glycol).

Chemical Properties: Ointment bases are selected to be inert and chemically stable.

General Chapters: The following general chapters may be useful to ensure consistency in selected excipient functions: *Viscosity* ⟨911⟩ and *Congealing Temperature* ⟨651⟩.

Functional Category: Stiffening Agent

Description: A stiffening agent is an agent or a mixture of agents that increases the viscosity or hardness of a preparation, especially in ointments and creams.

Functional Mechanism: In general, stiffening agents are high melting point solids that increase the melting point of ointments or increase the consistency or body of

creams. Stiffening agents can be either hydrophobic (e.g., hard fat or paraffin) or hydrophilic (e.g., polyethylene glycol, high molecular weight).

Physical Properties: The primary physical property relevant to stiffening agents is their high melting point or melting range. Typical melting ranges for stiffening agents range from 43° to 47° (cetyl esters wax), 53° to 57° (glyceryl distearate), 69° to 74° (glyceryl behenate), and 85° to 88° (castor oil, hydrogenated).

Chemical Properties: Stiffening agents comprise a diverse group of materials that include glycerides of saturated fatty acids, solid aliphatic alcohols, esters of saturated fatty alcohols and saturated fatty acids, saturated hydrocarbons, blends of fatty alcohols and a polyoxyethylene derivative of a fatty acid ester of sorbitan, and higher ethylene glycol polymers.

General Chapters: The following general chapters may be useful to ensure consistency in selected excipient functions: *Melting Range or Temperature* ⟨741⟩, *Congealing Temperature* ⟨651⟩, and *Viscosity* ⟨911⟩.

Other Information: Some of the materials included as stiffening agents increase the water-holding capacity of ointments (e.g., petrolatum) or function as co-emulsifiers in creams. Examples include stearyl alcohol and cetyl alcohol.

Functional Category: Emollient

Description: Emollients are excipients used in topical preparations to impart lubrication, spreading ease, texture, and softening of the skin and to counter the potentially drying/irritating impact of surfactants on the skin.

Functional Mechanism: Emollients help form a protective film and maintain the barrier function of the epidermis. Their efficacy may be described by three mechanisms of action: protection against the delipidizing and drying effects of surfactants, humectancy due to occlusion (by providing a layer of oil on the surface of the skin, emollients slow water loss and thus increase the moisture-retention capacity of the stratum corneum), and lubricity, adding slip or glide to the preparation.

Physical Properties: Emollients impart one or more of the following attributes to a pharmaceutical preparation: spreading capacity, pleasant feel to the touch, softness of the skin, and indirect moisturization of the skin by preventing trans-epidermal water loss.

Chemical Properties: Emollients are either oils or are derived from components of oils as esters of fatty acids. Depending on the nature of its fatty acid ester, an emollient may be liquid, semisolid, or solid at room temperature. Generally, the higher the molecular weight of the fatty acid moiety (carbon chain length) the richer the feel and softness of the touch. Fluidity generally is imparted by shorter chain length and higher degree of unsaturation in the fatty acid moiety. The degree of branching of ester bonds also influences the emollient properties.

General Chapter: The following general chapter may be useful to ensure consistency in selected excipient functions: *Fats and Fixed Oils* ⟨401⟩.

PARENTERALS

Functional Category: Pharmaceutical Water

Description: Water is used as a solvent, vehicle, diluent, or filler for many drug products, especially those supplied in liquid form. These can include injectible drugs, ophthalmic drugs, oral solutions, inhalation solutions, and others. Water is also a vehicle for buffers and antimicrobial agents and is a volume expander for infusion solu-

In-Process Revision

tions. Its use in dosage form preparation also can include granulation preparation for solid oral dosage forms and applications in the preparation of ointments and gels.

USP includes monographs for eight grades of pharmaceutical waters. One of these types of USP water is always the water of choice when pharmaceutical scientists prepare a pharmaceutical dosage form for human or animal use. However, USP also contains references to other types of water, such as distilled water, deionized water, and others according to specific use as summarized in general information chapter *Water for Pharmaceutical Purposes* ⟨1231⟩.

Functional Mechanism: A solvent is able to dissolve materials because it is able to disrupt the intermolecular attractive forces and to allow the individual molecules to become dispersed throughout the bulk solvent. Water is a favored solvent and vehicle in the majority of applications because it is easy to handle, safe, and inexpensive.

Physical Properties: Water is liquid at normal temperature and pressure. It forms ice at the freezing temperatures of 0°; or lower, and it vaporizes at a normal boiling temperature of 100°, depending upon atmospheric pressure. Vaporized water in the form of steam is used for sterilization purposes because the latent heat of steam is significantly higher than that of boiling water.

Chemical Properties: Water in its pure form is neutral in pH and has very low conductivity and total organic carbon (TOC). However, pH, conductivity, and TOC are affected by storage conditions and exposure of water to gases in the air. Exposure of water to atmospheric CO_2 lowers the pH of water. Storage of water in plastic containers may increase the TOC content of water over time. Water stored in glass containers may result in an increase in pH and conductivity of water over time.

General Chapters: The following general chapters may be useful to ensure consistency in selected excipient functions: *Injections* ⟨1⟩, *Water for Pharmaceutical Purposes* ⟨1231⟩, *Water for Health Applications* ⟨1230⟩, *Bacterial Endotoxins Test* ⟨85⟩, *Total Organic Carbon* ⟨643⟩, and *Water Conductivity* ⟨645⟩.

Functional Category: Diluent

Description: Diluents or bulking agents used in lyophilized pharmaceuticals include various saccharides, sugar alcohols, amino acids, and polymers. The primary functions of bulking agents are to provide a pharmaceutically elegant lyophized cake with non-collapsed structural integrity and to prevent drug loss due to blow-out. In addition, bulking agents are selected to facilitate efficient drying and to provide a physically and chemically stable formulation matrix. Frequently, complementary combinations of bulking agents are used to improve functionality.

So-called ''good cake forming'' excipients, such as mannitol, are frequently used because they tend to crystallize during freezing, thereby allowing efficient drying and the formation of a structurally robust cake. For some active ingredients, crystallization during lyophilization helps improve stability. Therefore the use of bulking agents that promote crystallization during lyophilization is important. Amino acids and cosolvents have been used to achieve this effect. Most biopolymer active ingredients remain amorphous upon freeze-drying, and bulking agents such as disaccharides may function as lyoprotectants by helping to maintain a stable amorphous phase during freezing and drying to prevent denaturation. Solubility enhancement of an insoluble crystalline active ingredient is sometimes achieved with the use of a biopolymer that enhances solubility or prevents crystallization of the active ingredient during lyophilization or

subsequent reconstitution. Bulking agents are also selected on the bases of biocompatiability, buffering capability, and tonicity-modifying properties.

Functional Mechanisms: A bulking agent that readily crystallizes during lyophilization helps maintain the structural integrity of the cake formed during primary drying, thereby preventing macroscopic collapse and pharmaceutical inelegance. Microscopic collapse of amorphous components in the formulation may still occur (with some potentially undesirable results) but will not result in macroscopic collapse if the bulking agent properties and concentration are adequate. The bulking agent also should possess a high eutectic melting temperature with ice to permit relatively high primary drying temperatures with commensurate rapid and efficient drying.

Lyoprotectant properties of lyophilization diluents (i.e., those that protect the drug substance during lyophilization) typically are achieved by the formation of a highly viscous glassy phase that includes the biopolymer drug substance in combination with low molecular weight amorphous saccharides such as sucrose, trehalose, or certain amino acids. A typical approach for protein pharmaceutical formulation is to combine a sugar alcohol that readily crystallizes and an amorphous diluent; this mixture acts as a lyoprotectant.

Physical Properties: Bulk agents are dissolved in aqueous solution before lyophilization. Therefore chemical purity and the absence of bioburden and pyrogenic materials are essential properties of the bulk excipient. However, the physical form and particle properties of the bulk excipient are generally not relevant to the final properties of the lyophilized formulation.

The physical properties that are essential to product performance during and after lyophilization include the glass transition temperature of the amorphous frozen concentrate before drying, the glass transition temperature of the final dried formulation cake, and the eutectic melting temperature of the crystalline bulking agent with ice. The glass transition temperature of the formulation depends on the glass transition temperatures of the individual components, concentrations, and interactions. Although approximations can be made based on reported transition temperatures for individual components, current practice includes the measurement of formulation glass transition temperatures by thermal analysis or freeze-drying microscopy.

The physical states of the bulking agent during and after lyophilization are important physical properties. Both formulation composition and processing parameters play roles in determining whether the bulking agent is amorphous or takes a specific crystalline form. For example, although mannitol is easily crystallized during lyophilization, it can also be amorphous based on formulation composition or can crystallize as a hydrate or metastable polymorph. Rate of freezing, drying temperatures, and annealing are among the important process parameters used to control the physical state of the formulation and its components. Moisture retention and adsorption after lyophilization also may contribute to formulation stability and performance.

Chemical Properties: Reactivity of the bulking agent with respect to other formulation components, especially the active ingredient, may be critical. Reducing sugars are well known to react with aromatic and aliphatic amines. Glycols may contain trace peroxide levels that can initiate oxidative degradation. The ability of saccharides and polyhydric alcohols to form hydrogen bonds to biopolymers may play a role in their lyoprotection effects.

General Chapters: The following general chapters may be useful to ensure consistency in selecting bulking agent functions: *Injections* ⟨1⟩; *Biotechnology-Derived Articles* ⟨1045⟩, *Product Formulation*; *Crystallinity* ⟨695⟩; *Crystallin-*

ity Determination by Solution Calorimetry ⟨696⟩; *Pharmaceutical Dosage Forms* ⟨1151⟩; and *Water—Solid Interactions in Pharmaceutical Systems* ⟨1241⟩.

Functional Category: Tonicity Agent

Description: To avoid crenation or hemolysis of red blood cells and to mitigate pain and discomfort if solutions are injected or introduced into the eyes and nose, solutions should be made isotonic. This requires that the effective osmotic pressure of solutions for injection is approximately the same as that in the blood. When drug products are prepared for administration to membranes such as eyes or nasal or vaginal tissues, solutions should be made isotonic with respect to these tissues.

Functional Mechanism: Tonicity is equal to the sum of the concentrations of the solutes that have the capacity to exert an osmotic force across a membrane and thus reflects overall osmolality. Tonicity applies to the impermeant solutes within a solvent–in contrast to osmolarity, which takes into account both permeant and impermeant solutes. For example, urea is a permeant solute, meaning that it can pass through the cell membrane freely and is not factored when determining the tonicity of a solution. In contrast, NaCl is impermeant and cannot pass through a membrane without the help of a concentration gradient and will therefore contribute to a solution's tonicity.

Physical Properties: Solutions of sodium chloride, dextrose, and Lactated Ringer's are common examples of pharmaceutical preparations that contain tonicity agents. Not all solutes contribute to the tonicity, which in general depends only on the number of solute particles present in a solution, not the kinds of solute particles. For example, mole for mole, sodium chloride solutions display a higher osmotic pressure than do glucose solutions of the same molar concentration. This is because when glucose dissolves it remains one particle, but when NaCl dissolves, it becomes two particles: Na^+ and Cl^- .

Chemical Properties: Tonicity agents may be present as ionic and/or nonionic types. Examples of ionic tonicity agents are alkali metal or earth metal halides such as $CaCl_2$, KBr, KCl, LiCl, NaI, NaBr or NaCl, Na_2SO_4, or boric acid. Non-ionic tonicity agents include glycerol, sorbitol, mannitol, propylene glycol, or dextrose.

General Chapters: The following general chapters may be useful to ensure ensure consistency in selected excipient functions: *Injections* ⟨1⟩; *Biotechnology-Derived Articles* ⟨1045⟩, *Product Formulation*; *Pharmaceutical Dosage Forms* ⟨1151⟩, *Ophthalmic Preparations*; and *Pharmaceutical Calculations in Prescription Compounding* ⟨1160⟩.

AEROSOLS

Functional Category: Propellant

Description: Propellants are compounds that are gaseous under ambient conditions. They are used in pharmaceuticals (nasal sprays and respiratory and topical formulations), cosmetics, and foods to provide force to expel contents from a container.

Functional Mechanism: Propellant substances are low boiling point liquids that are relatively inert toward active ingredients and excipients. They can be characterized by three properties: whether they form a liquid phase at ambient temperatures and useful pressures, their solubility and/or miscibility in the rest of the formulation, and their flammability. Their performance is judged by their ability to provide adequate and predictable pressure throughout the usage life of the product.

Propellants that have both a liquid and gas phase in the product provide consistent pressures as long as there is liquid phase present—the pressure in the headspace is maintained by the equilibrium between the two phases. In contrast, the pressure provided by propellants that have no liquid phase may change relatively rapidly as the contents of the container are expelled. As the headspace becomes larger, the pressure within the container falls proportionately. Propellants that have no liquid phase but have significant pressure-dependent solubility in the rest of the formulation have performance characteristics between the other two systems. In such cases, as the headspace increases, the propellant comes out of solution to help to maintain the pressure of the system.

In metered-dose inhalers the propellant has a liquid phase that is an integral part of the dispensed pharmaceutical product. Actuating the metering valve dispenses a defined volume of the liquid contents. The propellant spontaneously boils and provides atomizing and propulsive force. A predictable change in active concentration occurs from the beginning to the end of the container life cycle as the liquid phase of the propellant vaporizes to reestablish the equilibrium pressure of the system as the headspace increases.

Physical Properties: Propellants have boiling points well below ambient temperatures. Density and solubility properties are significant considerations when one selects a propellant. Apaflurane and norflurane have liquid-phase densities that are greater than that of water. Hydrocarbon propellants (butane, isobutene, and propane) and dimethyl ether have liquid-phase densities that are less than that of water.

Chemical Properties: Propellants typically are stable materials that contribute to long shelf lives of formulations. However, the hydrocarbon propellants (butane, isobutene, and propane) and dimethyl ether are all flammable materials. Apaflurane, carbon dioxide, nitrogen, and norflurane are nonflammable. Nitrous oxide is not flammable but supports combustion. Chlorofluorocarbon propellants are considered to be ozone-depleting substances. Their use in foods, drugs, devices, or cosmetics is regulated by 21 CFR 2.125. Albuterol metered-dose inhalers formulated with chlorofluorocarbon propellants have not been available in the United States since January 1, 2009.

General Chapters: The following general chapters may be useful to ensure consistency in selected excipient functions: *Aerosols, Nasal Sprays, Metered-dose Inhalers, and Dry Powder Inhalers* ⟨601⟩, *Chromatography* ⟨621⟩, and *Water Determination* ⟨921⟩.■2S (*USP33*)

BRIEFING

⟨**1072**⟩ **Disinfectants and Antiseptics,** *USP 32* page 517. On the basis of internal deliberations of the Expert Committee, changes are proposed to enhance clarity.

CLASSIFICATION OF DISINFECTANTS

Chemical disinfectants are classified by their chemical type. This includes aldehydes, alcohols, halogens, peroxides, quaternary ammonium compounds, and phenolic compounds (see *Table 2*).

Table 2. General Classification of Antiseptics, Disinfectants, and Sporicidal Agents

Chemical Entity	Classification	Example
Aldehydes	Sporicidal agent	2% Glutaraldehyde
Alcohols	General purpose disinfectant, antiseptic, antiviral agent	70% Isopropyl alcohol, 70% alcohol
Chlorine and sodium hypochlorite	Sporicidal agent	0.5% Sodium hypochlorite
Phenolics	General purpose disinfectant	500 μg per g Chlorocresol, 500 μg per g chloroxylenol
Ozone	Sporicidal agent	8% Gas by weight

In-Process Revision

Table 2. General Classification of Antiseptics, Disinfectants, and Sporicidal Agents *(Continued)*

Chemical Entity	Classification	Example
Hydrogen peroxide	Vapor phase sterilant, liquid sporicidal agent, antiseptic	4 μg per g H_2O_2 vapor, 10%–25% solution, 3% solution
Substituted diguanides	Antiseptic agent	0.5% Chlorhexidine gluconate
Peracetic acid	Liquid sterilant, vapor phase sterilant	0.2% Peracetic acid, 1 μg per g peracetic acid
Ethylene oxide	Vapor-phase sterilant	600 μg per g Ethylene oxide
Quaternary ammonium compounds	General purpose disinfectant, antiseptic	~~200 μg per g~~ ■Concentration dependent on application, ■2S *(USP33)* Benzalkonium chloride
β-Propiolactone	Sporicidal agent	100 μg per g β-Propiolactone

The effectiveness of a disinfectant depends on its intrinsic biocidal activity, the concentration of the disinfectant, the contact time, the nature of the surface disinfected, the hardness of water used to dilute the disinfectant, the amount of organic materials present on the surface, and the type and the number of microorganisms present. Under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA), the Environmental Protection Agency (EPA) registers chemical disinfectants marketed in the United States and requires manufacturers to supply product information on the use dilution, type of microorganisms killed, and the necessary contact time. Certain liquid chemical sterilizers intended for use on critical or semicritical medical devices are defined and regulated by the U.S. Food and Drug Administration (FDA).

Change to read:

SELECTION OF A DISINFECTANT FOR USE IN A PHARMACEUTICAL MANUFACTURING ENVIRONMENT

When selecting a disinfectant for use in a pharmaceutical manufacturing area, the following points should be considered: the number and types of microorganisms to be controlled; the spectrum of activity of commercially available disinfectants; ~~the reputation of the disinfectant supplier;~~

■■2S *(USP33)*
the claims as a sterilant; the disinfectant or sanitizer supported by the EPA registrations; the concentration, application method, and contact time of the disinfectant; the nature of the surface material being disinfected and its compatibility with the disinfectant; the amount of organic compounds on the surface that may inactivate a disinfectant; the possible need to maintain a residual bactericidal activity of the disinfectant on the surface; the corrosiveness of the disinfectant to equipment with repeated application; the safety considerations for operators applying the disinfectant; the compatibility of the disinfectant with cleaning agents and other disinfectants; the planned disinfectant rotation; and the steps that need to be taken to avoid the contamination of pharmaceutical products by a disinfectant.[2]

Change to read:

THEORETICAL DISCUSSION OF DISINFECTANT ACTIVITY

Plots of the log of the number of microorganisms per mL surviving in a disinfectant solution indicate that first-order kinetics can be applied as a gross approximation to the reduction in microbial count with respect to time. In practice, the plots show a more sigmoid curve with a slower initial reduction in numbers followed by an increasing rate with respect to time.

The rate constant, *K,* for the disinfection process can be calculated by the formula:

$$(1 / t)(\log N_O / N)$$

in which t is the time, in minutes, for the microbial count to be reduced from N_O to N; N_O is the initial number of organisms, in cfu per mL; and N is the final number, in cfu per mL, of organisms.

As with a first-order chemical reaction, the same concentration of disinfectant reduces the number of organisms more rapidly at elevated temperatures. This can be expressed as a temperature, *T,* coefficient per 10° rise in temperature, Q_{10}, calculated by the formula:

$$\text{Time to decontamination at } T^\circ / \text{Time to decontamination at } T$$

in which T is $T^\circ - 10$.

Further evidence that a first-order reaction is an inadequate description of disinfection is that the Q_{10} values for chemical and enzyme reactions are 2 to 3, while the common disinfectants phenol and alcohol have a Q_{10} of 4 and 45, respectively.

Critical to the successful employment of disinfectants is an understanding of the effect of disinfectant concentration on microbial reduction. A plot of the log of the time to reduce the microbial population in a standard inoculum to zero against the log of the disinfectant concentration is a straight line with the slope of the line termed the concentration exponent, *n*. The relationship can be expressed as follows:

$$n = (\text{log of the kill time at concentration } C_2) - (\text{log of the kill time at concentration } C_1) / (\log C_1 - \log C_2)$$

in which C_1 and C_2 are the higher and lower disinfectant concentrations, respectively.

The wide differences in concentration exponents, *n,* have practical consequences in picking the use dilution of different disinfectants and in using dilution to neutralize a disinfectant in disinfectant-effectiveness testing and routine microbial monitoring of the manufacturing environment. For example, mercuric chloride has a concentration exponent of 1, so a 3-fold dilution will reduce the disinfectant activity by 3^1 (or by one-third), while phenol with a concentration exponent of 6 will have a 3^6 (or a 729-fold) reduction in disinfectant activity. Disinfectants with a larger concentration exponent or dilution coefficient rapidly lose activity when diluted. The concentration exponents for some disinfectants are listed in *Table 3*.

[2] Denny, V.F.; Marsik, F.J. Current Practices in the Use of Disinfectants within the Pharmaceutical Industry. PDA J. of Pharmaceutical Sci. and Tech., 1997, 51, (6), 227–228.

Table 3. Concentration Exponents of Common Antiseptics, Disinfectants, and Sterilants

Disinfectant	Concentration Exponents
Hydrogen peroxide	0.5
Sodium hypochlorite	0.5
Mercuric chloride	1
Chlorhexidine	2
Formaldehyde	1
Alcohol	9
Phenol	6
Quaternary ammonium compounds	0.8 to 2.5
Aliphatic alcohols	6.0 to 12.7
Phenolic compounds	4 to 9.9

Another important consideration may be the pH of the disinfectant. Many disinfectants are more active in the ionized form, while others are more active in the nonionized form. The degree of ionization will depend on the pK_a of the agent and the pH of the disinfection environment. For example, phenol, with a pK_a of 10, will be more effective at a pH below 7 where it is nonionized.~~, while acetic acid will be more effective at a pH below 4 where it is ionized~~

MICROBIAL RESISTANCE TO DISINFECTANTS

The development of microbial resistance to antibiotics is a well-described phenomenon. The development of microbial resistance to disinfectants is less likely

■to occur at significant levels,■2S (*USP33*) as disinfectants are more powerful biocidal agents than antibiotics. ~~and are~~

■In addition, they are normally■2S (*USP33*) applied in high concentrations against low populations of microorganisms usually not growing actively, so the selective pressure for the development of resistance is less profound. However, the most frequently isolated microorganisms from an environmental monitoring program may be periodically subjected to use-dilution testing with the agents used in the disinfection program to confirm their susceptibility,

■as there are real differences among different species in resistance to the lethal effects of different sanitizers.■2S (*USP33*)

Change to read:

DISINFECTANT CHALLENGE TESTING

Under FIFRA, the EPA requires companies that register public health antimicrobial pesticide products including disinfectants, sanitization agents, sporicidal agents, and sterilants to ensure the safety and effectiveness of their products before they are sold or distributed. Companies registering these products must address the chemical composition of their product, include toxicology data to document that their product is safe if used as directed on the label, include efficacy data to document their claims of effectiveness against specific organisms and to support the directions for use provided in the labeling, and provide labeling that reflects the required elements for safe and effective use. While these directions provide valuable information, they may not be helpful in terms of the products' use as disinfectants in a manufacturing environment.

In the United States, the official disinfectant testing methods are published by AOAC International[3] and include the Phenol-Coefficient Test, Use-Dilution Method Test, Hard Surface Carrier Method, and Sporicidal Carrier Test. A scientific study submit-

[3] AOAC International Official Methods of Analysis, 15th, 16th, and 17th editions. Arlington, VA.

In-Process Revision

ted for EPA review in support of disinfectant registration must be conducted at a laboratory facility that follows the Good Laboratory Practices (GLP) regulations (21 CFR 58). To demonstrate the efficacy of a disinfectant within a pharmaceutical manufacturing environment, it may be deemed necessary to conduct the following tests: (1) use-dilution tests (screening disinfectants for their efficacy at various concentrations and contact times against a wide range of standard test organisms and environmental isolates); (2) surface challenge tests (using standard test microorganisms and microorganisms that are typical environmental isolates, applying disinfectants to surfaces at the selected use concentration with a specified contact time, and determining the log reduction of the challenge microorganisms); and (3) a statistical comparison of the frequency of isolation and numbers of microorganisms isolated prior to and after the implementation of a new disinfectant. This is considered necessary because critical process steps like disinfection of aseptic processing areas, as required by GMP regulations, need to be validated, and the EPA registration requirements do not address how disinfectants are used in the pharmaceutical, biotechnology, and medical device industries. For the surface challenge tests, the test organisms are enumerated using swabs, surface rinse, or contact plate methods. Neutralizers that inactivate the disinfectants should be included in either the diluent or microbiological media used for microbial enumeration or both. ~~(see *Table 5*). Additional information~~

■Information ■2S *(USP33)*
on disinfectant neutralization may be found in *Validation of Microbial Recovery from Pharmacopeial Articles* ⟨1227⟩.

~~Table 5. Neutralizing Agents for Common Disinfectants~~

~~Disinfectant~~	~~Neutralizing Agent~~
~~Alcohols~~	~~Dilution or polysorbate 80~~
~~Glutaraldehyde~~	~~Glycine and sodium bisulfite~~
~~Sodium hypochlorite~~	~~Sodium thiosulfate~~
~~Chlorhexidine~~	~~Polysorbate 80 and lecithin~~
~~Mercuric chloride and other mercurials~~	~~Thioglycolic acid~~
~~Quaternary ammonium compounds~~	~~Polysorbate 80 and lecithin~~
~~Phenolic compounds~~	~~Dilution or polysorbate 80 and lecithin~~

~~Universal neutralizer broths may be formulated to contain a range of neutralizing agents. For example, Dey/Engley (D/E) broth contains 0.5% polysorbate 80, 0.7% lecithin, 0.1% sodium thioglycolate, 0.6% sodium thiosulfate, 0.25% sodium bisulfite, 0.5% tryptone, 0.25% yeast extract, and 1.0% dextrose; letheen broth contains 0.5% polysorbate 80, 0.07% lecithin, 1.0% peptamin, 0.5% beef extract, and 0.5% sodium chloride; and Tryptone–Azolectin–Tween (TAT) broth-base + tween 20 contains 4.0% (v/v) polysorbate 20, 0.5% lecithin, and 2.0% tryptone.~~

■The disinfectant efficacy test must have realistic acceptance criteria. ■2S *(USP33)*
In practice, sufficient organisms need to be inoculated on a 2-inch × 2-inch square of the surface being decontaminated, i.e., a coupon, to demonstrate at least a 2 (for bacterial spores) to 3 (for vegetative bacteria) log reduction during a predetermined contact time (i.e., 10 minutes over and above the recovery observed with a control disinfectant application). The efficacy of the neutralizers and their ability to recover inoculated microorganisms from the material should be demonstrated during the use-dilution or surface-challenge studies. Points to remember are that disinfectants are less effective against the higher numbers of microorganisms used in laboratory challenge tests than they are against the numbers that are found in clean rooms (see *Microbiological Evaluation of Clean Rooms and Other Controlled Environments* ⟨1116⟩); that inocula from the log growth phase that are typically employed in laboratory tests are more resistant, with the exception of spores formed during the static phase, than those from a static or dying culture or stressed organisms in the environment; and that microorganisms may be physically removed during actual disinfectant application in the manufacturing area.

Although not all inclusive, typical challenge organisms that may be employed are listed in ~~*Table 6*~~ ■*Table 5*. ■2S *(USP33)*

~~Table 6~~

■Table 5. ■2S *(USP33)*
Typical Challenge Organisms

AOAC Challenge Organisms	Typical Environmental Isolates
Bactericide: *E.coli,* ATCC 11229; *S. aureus,* ATCC 6538; *P. aeruginosa,* ATCC 15442	Bactericide: *M.luteus*, *S.epidermidis*, *Coynebacterium jeikeium*, *P.vesicularis*
Fungicide: *C. albicans,* ATCC 10231or 2091*Penicillium chrysogenum*, ATCC 11709;*A.brasiliensis*, ATCC 16404	Fungicide: *P. chrysogenum, A. brasiliensis*
Sporicide: *B. subtilis,* ATCC 19659	Sporicide: *B. sphaericus*, *B. thuringiensis*

Because a wide range of different materials of construction are used in clean rooms and other controlled areas, each material needs to be evaluated separately to validate the efficacy of a given disinfectant. ~~*Table 7*~~

■*Table 6* ■2S *(USP33)*
contains a list of common materials used in clean room construction.

~~Table 7~~

■Table 6. ■2S *(USP33)*
Typical Surfaces to be Decontaminated by Disinfectants in a Pharmaceutical Manufacturing Area

Material	Application
Stainless steel 304L and 316L grades	Work surfaces, filling equipment, and tanks
Glass	Windows and vessels
Plastic, vinyl	Curtains
Plastic, polycarbonate	Insulation coating
Lexan® (plexiglass)	Shields
Epoxyl-coated gypsum	Walls and ceilings
Fiberglass-reinforced plastic	Wall paneling
Tyvek®	Equipment wraps
Terrazzo tiles	Floors

DISINFECTANTS IN A CLEANING AND SANITIZATION PROGRAM

The selection of suitable disinfectants and the verification of their effectiveness in surface challenge testing is critical in the development of a cleaning and sanitization program.

Issues associated with the successful implementation of such a program are the development of written procedures, staff training, decisions on disinfectant rotation, institution of application methods and contact times, environmental monitoring to demonstrate efficacy, and personnel safety.

The cGMP 21 CFR 211.67, *Equipment Cleaning and Maintenance,* details the requirements for written procedures for cleaning, maintenance, and sanitization of pharmaceutical manufacturing equipment. These procedures should address the assignment of responsibility, establishment of schedules, details of cleaning operations, protection of clean equipment prior to use, inspection for cleanliness immediately prior to use, and maintenance of cleaning and sanitization records.

Staff involved in disinfection require training in microbiology, industry practices for cleaning and sanitization, safe handling of concentrated disinfectants, the preparation and disposal of disinfectants, and appropriate application methods. It should be emphasized that the preparation of the correct dilutions is critical because many disinfectant failures can be attributed to use of disinfectant solutions that are too dilute. Typically disinfectants used in aseptic processing and filling areas are diluted with Sterile Purified Water, and are prepared aseptically. Alternately, the disinfectant may be diluted with Purified Water, and then sterile filtered to eliminate microorganisms that may potentially persist in a disinfectant. Diluted disinfectants must have an assigned expiration dating justified by effectiveness studies.

~~Because it is theoretically possible that the selective pressure of the continuous use of a single disinfectant could result in the presence of disinfectant-resistant microorganisms in a manufacturing area, in some quarters the rotation of disinfectants has been advocated. However, the literature supports the belief that the exposure of low numbers of microorganisms on facility and equipment surfaces within a clean room where they are not actively proliferating will not result in the selective pressure that may be seen with the antibiotics.~~

■The rotation of an effective disinfectant with a sporicide is encouraged.■2S (*USP33*)
It is prudent to augment the daily use of a bactericidal disinfectant with weekly (or monthly) use of a sporicidal agent. The daily application of sporicidal agents is not generally favored because of their tendency to corrode equipment and because of the potential safety issues with chronic operator exposure. Other disinfection rotation schemes may be supported on the basis of a review of the historical environmental monitoring data. Disinfectants applied on potential product contact surfaces are typically removed with 70% alcohol wipes. The removal of residual disinfectants should be monitored for effectiveness as a precaution against the possibility of product contamination.

The greatest safety concerns are in the handling of concentrated disinfectants and the mixing of incompatible disinfectants. For example, concentrated sodium hypochlorite solutions (at a concentration of more than 5%) are strong oxidants and will decompose on heating, on contact with acids, and under the influence of light, producing toxic and corrosive gases including chlorine. In contrast, dilute solutions (at a concentration of less than 0.5%) are not considered as hazardous. Under no circumstances should disinfectants of different concentrations be mixed. Material Safety Data Sheets for all the disinfectants used in a manufacturing area should be available to personnel handling these agents. Appropriate safety equipment such as face shields, safety glasses, gloves, and uniforms must be issued to personnel handling the disinfectant preparation, and personnel must be trained in the proper use of this equipment. Safety showers and eye wash stations must be situated in the work area where disinfectant solutions are prepared.

BRIEFING

⟨**1086**⟩ **Impurities in Official Articles,** *USP 32* page 546. As a result of comments received and discussions by the Monograph Redesign Committee and the General Chapters Expert Committee, it is proposed to incorporate terminology changes to align with the monograph redesign process. Discussions from the international harmonization process have been considered. Other minor changes are also introduced.

⟨1086⟩ IMPURITIES IN ~~OFFICIAL ARTICLES~~

■DRUG SUBSTANCES AND DRUG PRODUCTS■2S (*USP33*)

Change to read:

INTRODUCTION

This general information chapter ~~covers impurities or degradation products in drug substances and degradation products in drug products~~

■is intended to provide common terminology for impurities and degradation products that may be present in compendial drug substances and drug products.■2S (*USP33*)
Impurities or degradation products in drug substances can arise during the manufacturing process or during storage of the drug substance. The degradation products in drug products can arise from drug substances or reaction products of the drug substance with

■the environment, with■2S (*USP33*)
an excipient or ~~an immediate container–closure system~~

■as a result of the interaction with the container–closure system materials that are in intimate contact with the product.■2S (*USP33*)
Biological and biotechnological

■products, fermentation products and semisynthetic products derived therefrom,■2S (*USP33*)
and radiopharmaceutical products are not covered in this chapter.

~~Concepts about purity change with time and are inseparable from developments in analytical chemistry. If a material previously considered to be pure can be resolved into more than one component, that material can be redefined into new terms of purity and impurity. Inorganic, organic, biochemical, isomeric,~~

In-Process Revision

~~or polymeric components can all be considered impurities. Microbiological species or strains are sometimes described in similar terms of resolving into more than one component.~~

■■2S (*USP33*)

Communications about impurities ~~or~~

■and■2S (*USP33*)
degradation products in compendial articles may be improved by including in this Pharmacopeia the definitions of terms and the contexts in which these terms are used. (See *Definitions* below.) There has been much activity and discussion in recent years about the definition of terms. Certain industry-wide concerns about terminology and context deserve widespread publication and ready retrievability and are included here. See ~~Foreign Substances and Impurities~~

■section *5.60, Impurities and Foreign Substances*■2S (*USP33*) in section ~~*Tests and Assays*~~

■*5, Monograph Components*■2S (*USP33*)
under *General Notices and Requirements,* as well as the general chapter *Ordinary Impurities* ⟨466⟩. Some other general chapters added over the years have also addressed topics of purity or impurity as these have come into focus or as analytical methodology has become available. Analytical aspects are enlarged upon in the chapter *Validation of Compendial Procedures* ⟨1225⟩.

~~Monographs for drug substances usually cite one of three types of purity tests: (1) a chromatographic purity test coupled with a nonspecific assay; (2) a chromatographic purity indicating method that serves as the assay; or (3) a specific test and limit for a known impurity, an approach that usually requires a Reference Standard for that impurity. Modern separation methods clearly play a dominant role in scientific research today because these methods simultaneously separate and measure components and fulfill the analytical ideal of making measurements only on purified specimens. Nevertheless, the more classical methods based on titrimetry, colorimetry, spectrophotometry, single or multiple partitions, or changes in physical constants (or any other tests or assays) lose none of their previous validities. The *purity profile* of a specimen that is constructed from the results of experiments using a number of analytical methods is the ultimate goal.~~

■■2S (*USP33*)

Purity or impurity measurements for drug products present a challenge to Pharmacopeial standards-setting. Where degradation of a drug product over time is at issue, the same analytical methods that are stability-indicating are also purity-indicating. Resolution of the active ingredient(s) from the excipients necessary to the preparation presents the same qualitative problem. Thus, many monographs for Pharmacopeial preparations feature chromatographic assays. Where more significant impurities are known, some monographs set forth specific limit tests. In general, however, this Pharmacopeia does not repeat impurity tests in subsequent preparations where these appear in the monographs of drug substances and where these impurities are not expected to increase. It is presumed that adequate retention specimens are in storage for the exact batch of drug substances used in any specific lot of a drug product. Whenever analysis of an official article raises a question of the official attributes of any of the drug substances used, subsequent analysis of retention specimens is in order.

~~Pharmaceutical manufacturers interact with regulatory agencies in developing new drug substances and new drug products, and cooperate with the compendia in writing official monographs for the compendial articles the manufacturers produce. Establishment of impurity limits in drug substances and drug products should proceed on a rational basis so that everyone involved in the development and approval phases can carry on their work in a predictable manner. Although drug development in the United States is the primary focus of this section of the chapter, the subject also has broad applicability across national boundaries.~~

~~Manufacturers share with regulatory agencies and with the compendia the goal of making available to the public high-quality products that are both safe and efficacious. This goal continues to be achieved through rational approaches to the complex process of drug development. Tests used at all stages of drug development and marketing should not be interpreted individually but as a whole. Controls on raw materials and on manufacturing as well as those on drug substances, along with toxicological and clinical studies performed, ensure the safety and efficacy of drug products. It is more rational to identify impurities or degradation products and to set limits based on the factors detailed here, relying on the scientific judgments of manufacturers, the compendia, and regulators to arrive at sets of acceptable limits for identified and unidentified impurities or degradation products.~~

~~Limits are set for impurity levels or degradation products as one of the steps in ensuring the identity, strength, quality, and chemical purity of drug substances or drug products. The ultimate goal is to produce a final drug product of high quality that is safe and efficacious and remains so throughout its shelf life. The setting of limits for impurities or degradation products in drug substances is a complex process that considers a number of factors:~~

~~(1) the toxicology of a drug substance containing typical levels of impurities and/or the toxicology of impurities relative to a drug substance;~~

~~(2) the route of administration, e.g., oral, topical, parenteral, or intrathecal;~~

~~(3) the daily dose, i.e., frequency and amount (micrograms or grams) administered of a drug substance;~~

~~(4) the target population (age and disease state), e.g., neonates, children, or senior citizens;~~

~~(5) the pharmacology of an impurity, when appropriate;~~

~~(6) the source of a drug substance, e.g., synthetic, natural product, or biotechnology;~~

~~(7) the duration of therapy, i.e., administration over a long period (treatment of chronic conditions) versus administration intended for a short duration (treatment of acute conditions); and~~

~~(8) the capability of a manufacturer to produce consistently high-quality material.~~

~~Concepts for setting impurity or degradation product limits in drug substances are based on chemistry and safety concerns. As such, limits for organic and inorganic impurities and residual solvents should be established for drug substances. The basic tenet for setting limits is that levels of impurities or degradation products in a drug substance must be controlled to ensure its safety and quality throughout its development to use in a drug product.~~

~~For drug products the concept for setting degradation product limits is based on sound scientific judgment as applied to available data on the safety and stability of the drug product, which may include the degradation pathways of the drug substance, the manufacturing process, known excipient interactions, any safety assessment studies, stability studies conducted under the recommended storage conditions, and ancillary studies that may provide additional information on the stability profile of the drug product. A rationale should be provided for exclusion of those impurities that are not degradation products (e.g., process impurities from drug substance and impurities arising from excipients).~~

~~For drug substances and drug products, limits are appropriately set no higher than the level that can be justified (e.g., safety data, literature references, etc.) and no lower than the level achievable by the manufacturing process and analytical capability. Where there is no safety concern, limits should be based on (a) data generated on actual batches of the drug substance or drug product, allowing sufficient latitude to deal with normal process and analytical variation, and (b) stability characteristics.~~

~~Documented evidence that the analytical procedure used to evaluate impurities or degradation products is validated and suitable for the detection and quantification of impurities or degradation products should be established.~~

~~The setting of limits on impurities or degradation products is an evolutionary process, beginning in the United States before an investigational new drug (IND) is filed and continuing until well after the approval of a new drug application (NDA). Therefore, it is appropriate to address different stages in drug development as separate issues. There are three points in the drug development process where the setting of limits may be significantly different: (1) at the initial IND application, (2) at the filing of the NDA, and (3) after NDA approval. The filing of an abbreviated new drug application (ANDA) is another activity in which limits are set on impurities or degradation products. Since the approach may vary from that of filing an NDA, it is addressed as a separate issue. The underlying assumption is that the analytical methods used to evaluate impurities or degradation products are suitable for their intended purpose at each stage in the development.~~

▪▪2S (*USP33*)

Delete the following:

~~▪INITIAL IND FILING~~

~~**Drug Substances**—At the initial IND filing, the chemical nature of a drug substance has generally been defined. The manufacturing process normally is in an early stage of development, and materials may be produced on a laboratory scale. Usually few batches have been made and, therefore, little historical data is available. The reference materials of a drug substance may be relatively impure. Limits for the purity of a drug substance are set to indicate drug quality. The setting of limits on related substances and process contaminants can be characterized as follows.~~

~~(1) Limits are set on total impurities, and an upper limit may be set on any single impurity. The limit for total impurities should maintain, if possible, a nominal composition material balance.~~

~~(2) Impurity profiles are documented. These are profiles of the lots of drug substances used in clinical studies and in toxicological studies that establish the safety of drug substances. The lots used in these studies should be typical products of the manufacturing process in use at that time.~~

~~(3) Limits for residual solvents are based on the known toxicology of the solvents and on the manufacturing capabilities and dosing regimens.~~

~~(4) General inorganic impurities are monitored by appropriate tests such as a heavy metals limit test and/or a test for residue on ignition. Traditional compendial limits are applied unless otherwise indicated. Specific residual metals that appear during manufacturing should be monitored by appropriate analytical techniques, and limits should be set based on the toxicological properties of these metals.~~

~~(5) Appropriate limits are set for impurities known to be toxic.~~

~~(6) If appropriate, enantiomeric purity is controlled.~~

~~Although water is not classified as an impurity, limits for water content may be needed to ensure the stability or ease of processing a drug substance.~~

~~**Drug Product**—At the initial IND filing, the dosage form of a drug product has been identified, which is appropriate for early clinical studies (and may or may not be representative of the drug product that will eventually be marketed). Usually, few batches have been made and, therefore, little historical data is available.~~

~~(1) Qualitative and quantitative limits on degradation products may not be established at this point due to the limited data available. Typically, degradation products will be monitored as part of the stability evaluation of the drug product.~~

~~(2) Dating for use of a drug product in clinical studies will be based on data from ongoing stability studies. If the data indicate the presence of degradation products, dating and storage conditions are controlled to ensure any degradation products are controlled within industry accepted limits or within limits established through safety assessment studies.~~

~~(3) Limits for residual solvents, if appropriate, are based on the known toxicology of the solvents and on the manufacturing capabilities and dosing regimens. When amendments to the IND are filed, limits for impurities in drug substance and degradation products in drug substance or drug product may be updated based on additional data as they become available.~~ ▪▪2S (*USP33*)

Add the following:

▪DRUG SUBSTANCE

Classification of Impurities—Impurities can be classified into the following categories:

1. Organic impurities (process- and drug-related)
2. Inorganic impurities
3. Residual solvents

Organic impurities can arise during the manufacturing process and/or storage of the drug substance. They can be identified or unidentified, volatile or nonvolatile, and include the following:

1. Starting materials
2. Byproducts
3. Intermediates
4. Degradation products
5. Reagents, ligands, and catalysts
6. Geometric and stereoisomers

Inorganic impurities can result from the manufacturing process. They are normally known and identified and include the following:

1. Reagents, ligands, and catalysts
2. Heavy metals or other residual metals
3. Inorganic salts
4. Other materials (e.g. filter aids, charcoal)

Residual solvents are organic liquids used as vehicles for the preparation of solutions or suspensions in the synthesis of a drug substance. Because these are generally of known toxicity, the selection of appropriate controls is easily accomplished (see *Residual Solvents* ⟨467⟩).

Concepts for setting impurity or degradation product limits in drug substances are based on chemistry and safety concerns. As such, limits for organic and inorganic impurities and residual solvents should be established for drug substances. The basic tenet for setting limits is that levels of impurities or degradation products in a drug substance must be controlled throughout its development to ensure its safety and quality for use in a drug product.

Documented evidence that the analytical procedure used to evaluate impurities or degradation products is validated and suitable for the detection and quantification of impurities or degradation products should be established.■2S (*USP33*)

Delete the following:

~~▪NDA FILING~~

~~**Drug Substances**—During the IND phases of drug development, the manufacturing process for a drug substance may undergo a number of revisions. Generally, the scale will have changed from laboratory size and will approach or reach full production batch size. A number of batches will normally have been produced, and a historical data base of the results of testing for impurities will exist. When significant changes in a manufacturing process are made, the impurity profile should be reviewed to determine if the toxicological studies are still supportive.~~

~~At the NDA stage a reference standard of defined purity is available, analytical methods have been validated, impurity and degradation profiles are known, and enantiomeric purity has been evaluated. The setting of limits on related substances and process contaminants can be characterized as follows:~~

~~(1) Consistency of the impurity profile of a drug substance has been established.~~
~~(2) IND limits for total and individual impurities (identified and unidentified) are reviewed and adjusted based on manufacturing experience and toxicological data.~~
~~(3) Impurities present in significant amounts are identified and individual limits are set. However, it is not always possible to identify or prepare authentic substances for impurities. The labile nature of some impurities precludes this possibility. Limits may be set on these substances based on comparison of lots produced and used in toxicological and clinical studies.~~
~~(4) The impurity profiles of the lots designated for marketing should not be significantly higher than those of the lot(s) used for toxicological and clinical studies.~~
~~(5) The composition material balance should be used, if possible, to evaluate the adequacy of the controls.~~
~~(6) Limits for residual solvents are based on the known toxicology of the solvents and on the manufacturing capabilities and dosing regimens.~~
~~(7) Limits are set for inorganic impurities by appropriate tests such as a heavy metals limit test and/or by a test for residue on ignition. Traditional compendial limits are applied unless otherwise indicated. Based on toxicological properties, limits may be set for specific residual metals that appear during manufacturing.~~
~~(8) Additional guidance for setting limits can be found in various ICH and FDA guidance documents.~~

~~**Drug Product**—Similarly, for the drug product, the dosage form may change, the number or scale of batches may increase, and more stability data will have become available. Methods will have been validated. The setting of limits can be characterized as follows:~~

~~(1) IND limits for total and individual degradation products (identified and unidentified) are reviewed and adjusted based on manufacturing experience, stability data, and toxicological data.~~
~~(2) Degradation products present in significant amounts are identified and individual limits are set. However, it is not always possible to identify or prepare authentic substances for degradation products.~~
~~(3) The degradation product profiles of the lots designated for marketing should not be significantly higher than those of the lot(s) used for toxicological and clinical studies.~~
~~(4) The mass balance should be used, if possible, to evaluate the adequacy of the controls.~~
~~(5) Limits for residual solvents, if appropriate, are based on the known toxicology of the solvents and on the manufacturing capabilities and dosing regimens.~~
~~(6) Additional guidance for setting limits can be found in various ICH and FDA guidance documents.~~■2S (*USP33*)

Add the following:

▪DRUG PRODUCT

The specification for a drug product should include a list of degradation products expected to occur during manufacture of the commercial product and under recommended storage conditions. Stability studies, knowledge of degradation pathways, product development studies, and laboratory studies should be used to characterize the degradation profile. The selection of degradation products in the drug product specification should be based on the degradation products found in batches manufactured by the proposed commercial process.

This rationale should include a discussion of the degradation profiles observed in the safety and clinical development batches and in stability studies, together with a consideration of the degradation profile of batches manufactured by the proposed commercial process. For de-

gradation products known to be unusually potent or to produce toxic or unexpected pharmacological effects, the quantitation/detection limit of the analytical procedures should be commensurate with the level at which the degradation products should be controlled.

For drug products the concept for setting degradation product limits is based on sound scientific judgment as applied to available data on the safety and stability of the drug product, data that may include the degradation pathways of the drug substance, the manufacturing process, known excipient interactions, any safety assessment studies, stability studies conducted under the recommended storage conditions, and ancillary studies that may provide additional information on the stability profile of the drug product. Impurities that are not degradation products (e.g. process impurities from the drug substance) are often not controlled in the drug product, as they are typically controlled in the drug substance and these impurities are not expected to increase over time. Additional guidance for setting limits can be found in various ICH and FDA guidance documents, as well as in the USP monograph submission guidelines.

Documented evidence that the analytical procedure used to evaluate impurities or degradation products is validated and suitable for the detection and quantification of impurities or degradation products should be established.

Drug products should contain levels of residual solvents no higher than can be supported by safety data (see *Residual Solvents* ⟨467⟩).■2S (*USP33*)

Delete the following:

▪~~POST NDA APPROVAL~~

~~After approval and marketing of a pharmaceutical product, significant changes may be made in manufacturing the drug substance. There may be technological, ecological, economic, or safety reasons for these changes. If they occur, the Pharmacopeial and NDA impurity and degradation product limits and rationale should be reviewed; the limits should be revised when indicated to ensure similar or improved quality of the drug substance or drug product.~~■2S (*USP33*)

Delete the following:

▪~~ANDA FILING~~

~~The drug substance for a pharmaceutical product eligible for ANDA status is frequently an official article and should be well characterized analytically. Drug substances are typically available from multiple sources, and each source may have a different manufacturing process. Therefore, it is essential that the dosage form manufacturer evaluate each supplier's drug substance impurity or degradation profiles. Limits can then be set based on the more detailed concepts described for NDA filing, including review of compendial monographs for appropriateness.~~■2S (*USP33*)

Change to read:

DEFINITIONS

Concomitant Components—Concomitant components are characteristic of many drug substances and are not considered to be impurities in the Pharmacopeial sense. Limits on contents, or specified ranges, or defined mixtures are set forth for concomitant components in this Pharmacopeia. Examples of concomitant components are geometric and optical isomers (or racemates) and antibiotics that are mixtures. Any component that can be considered a toxic impurity because of significant undesirable biological effect is not considered to be a concomitant component.

▪**Degradation Product**—An impurity resulting from a chemical change in the drug substance brought about during manufacture and/or storage of the drug product by the effect of, for example, light, temperature, pH, water, or by reaction with an excipient and/or the immediate container–closure system.■2S (*USP33*)

Foreign Substances (Extraneous Contaminants)~~— Foreign substances (extraneous contaminants), which are introduced by contamination or adulteration, are not consequences of the synthesis or preparation of compendial articles and thus~~

▪An impurity that arises from any source extraneous to the manufacturing process and that is introduced by contamination or adulteration. These impurities■2S (*USP33*) cannot be anticipated when monograph tests and assays are selected. The presence of objectionable foreign substances not revealed by monograph tests and assays constitutes a variance from the official standard. Examples of foreign substances include ephedrine in Ipecac or a pesticide in an oral liquid analgesic. Allowance is made in this Pharmacopeia for the detection of foreign substances by unofficial methods. (See ~~Foreign Substances and Impurities~~

▪section *5.60, Impurities and Foreign Substances*■2S (*USP33*) in section ~~*Tests and Assays*~~

▪*5, Monograph Components*■2S (*USP33*) under *General Notices and Requirements*.)

In-Process Revision

Identified Impurities and Identified Degradation Products—Impurities or degradation products for which structural characterizations have been achieved.

▪**Impurity—**Any component of a drug substance that is not the chemical entity defined as the drug substance and in addition, for a drug product, any component that is not a formulation ingredient.▪2S *(USP33)*

Inorganic Impurities—Inorganic impurities can result from the manufacturing process (e.g., residual metals, inorganic salts, filter aids, etc.). Inorganic impurities are typically controlled by tests such as *Heavy Metals* ⟨231⟩ and *Residue on Ignition* ⟨281⟩. Information found in *Plasma Spectrochemistry* ⟨730⟩ and *Ion Chromatography* ⟨1065⟩ may also be of value.

▪**Intermediate—**A material that is produced during steps of the synthesis of a drug substance and that undergoes further chemical transformation before it becomes a drug substance. The intermediate is often isolated during the process.▪2S *(USP33)*

Ordinary Impurities—Some monographs make reference to ordinary impurities. For more details see *Ordinary Impurities* ⟨466⟩.

▪**Other impurities—**See section *5. Monograph Components* under *General Notices and Requirements.*

Polymorphs—Different crystalline forms of the same drug substance. These can include solvation or hydration products (also knows as pseudopolymorphs) and amorphous forms. Although polymorphs are not impurities by definition, an understanding of the crystalline forms, hydration or solvation states, or amorphous nature is critical to the overall characterization of the drug substance.▪2S *(USP33)*

Process Contaminants—Process contaminants are identified or unidentified substances (excluding related substances and water), including reagents, catalysts, other inorganic impurities (e.g., heavy metals, chloride, or sulfate); and may also include foreign substances (extraneous contaminants). These contaminants may be introduced during manufacturing or handling procedures.

▪**Reagent—**A substance other than a starting material, intermediate, or solvent that is used in the manufacture of a drug substance.▪2S *(USP33)*

Related Substances—Related substances are structurally related to a drug substance. These substances may be (a) identified or unidentified impurities arising from synthesis manufacturing process such as

▪starting materials,▪2S *(USP33)*
intermediates or by-products and do not increase on storage or (b) identified or unidentified degradation products that result from drug substance or drug product manufacturing processes or arise during storage of a material.

Residual Solvents—

▪An organic liquid used as a vehicle for the preparation of solutions or suspensions in the synthesis of a drug substance▪2S *(USP33)*
(see *Residual Solvents* ⟨467⟩).

Specified Impurities and Specified Degradation Products—Previously referred to as Signal Impurities, specified impurities or specified degradation products are impurities or degradation products that are individually listed and limited with specific acceptance criteria in individual monographs as applicable. Specified impurities or specified degradation products can be identified or unidentified.

▪**Starting Material—**A material that is used in the synthesis of a drug substance and is incorporated as an element into the structure of an intermediate and/or of the drug substance. Starting materials are often commercially available and have well-defined chemical and physical properties and structure.

Stereomeric Impurity—A compound with the same 2–dimensional chemical structure as the drug substance but differs in the 3–dimensional orientation of substituents at chiral centers within that structure. In those cases where all chiral centers are in the opposite orientation, the impurity is an enantiomer (enantiomeric impurity). Determinations of impurities in this category often require special chiral chromatographic approaches. Diastereomeric or epimeric impurities occur when only some of the chiral centers are present in the opposite orientation. ▪2S *(USP33)*

Toxic Impurities—Toxic impurities have significant undesirable biological activity, even as minor components, and require individual identification and quantification by specific tests. These impurities may arise out of the synthesis, preparation, or degradation of compendial articles. Based on validation data, individualized tests and specifications are selected. These feature comparison to a Reference Standard of the impurity, if available. It is incumbent on the manufacturer to provide data that would support the classification of such impurities as toxic impurities.

Unidentified Impurities and Unidentified Degradation Products—Impurities or degradation products for which structural characterizations have not been achieved and that are identified solely by qualitative analytical properties (e.g., chromatographic retention times).

Unspecified Impurities and Unspecified Degradation Products—Impurities or degradation products that are limited by general acceptance criteria but not individually listed with their own specific acceptance criteria in individual monographs.

BRIEFING

⟨**1151**⟩ **Pharmaceutical Dosage Forms,** *USP 32* page 663. This general information chapter is being revised in its entirety to represent current compendial thinking with respect to official preparations. The proposed revision incorporates concepts outlined in a Stimuli to the Revision Process article, *Development of a Compendial Taxonomy and Glossary for Pharmaceutical Dosage Forms*, authored by an Ad Hoc Committee composed of the chairs of the Pharmaceutical Dosage Forms Expert Committee, Biopharmaceutics Expert Committee, Nomenclature and Labeling Expert Committee, and the Council of Experts for the revision cycle, 2000—2005, and published in *PF* 29(5). The Stimuli article proposed a tiered categorization for pharmaceutical dosage forms proceeding from route of administration to physical form and ultimately release pattern. This proposed general information chapter emphasizes the second tier of the compendial taxonomy, the physical dosage form, rather than the route of administration, with the intention of avoiding redundancy for dosage forms given by multiple routes.

The proposed revision is organized into four sections providing discussion of general considerations, product quality tests, dosage form monographs, and a glossary. General considerations include dose uniformity, stability, bioavailability, manufacture, and route of administration. The discussion of product quality tests reflects the universally applied as well as dosage form specific testing that help assure safety and efficacy from manufacture through shelf life. The dosage form monographs provide general descriptions, discussion of general principles of their manufacturing or compounding, and recommendations for proper use and storage. The glossary is intended to provide guidance in selection of official names for official articles but also as a resource to provide definitions beyond those used in official names for dosage forms. The glossary clearly distinguishes preferred from not preferred terminology.

The revised general information chapter presents current concepts relating to the naming of dosage forms. Outdated forms such as elixirs, spirits, tinctures, and syrups are herein recognized as solutions. Lotions are defined as emulsions typically for topical use. While inserts are defined as solid dosage forms for placement within body cavities, suppositories are differentiated as only for placement within the rectum.

This general information chapter is intended to be supplemented by more detailed discussion of characteristics, quality tests, and other considerations based on route of administration. Early drafts of such concepts relating to topical and transdermal dosage forms are presented in *PF* 35(3) [May–June 2009]. Proposed general test chapter ⟨3⟩ *Topical and Transdermal Drug Products—Product Quality Tests*, providing quality testing procedures, complements the performance testing proposed in ⟨725⟩ *Topical and Transdermal Drug Products—Product Performance Tests*. Additional revision proposals of similar standards for the oral (gastro-intestinal), mucosal, by inhalation, and by injection routes are planned.

⟨1151⟩ PHARMACEUTICAL DOSAGE FORMS

~~Dosage forms are provided for most of the Pharmacopeial drug substances, but the processes for the preparation of many of them are, in general, beyond the scope of the Pharmacopeia. In addition to defining the dosage forms, this section presents the general principles involved in the manufacture of some of them, particularly on a small scale. Other information that is given bears on the use of the Pharmacopeial substances in extemporaneous compounding of dosage forms.~~

~~BIOAVAILABILITY~~

~~Bioavailability, or the extent to which the therapeutic constituent of a pharmaceutical dosage form intended for oral or topical use is available for absorption, is influenced by a variety of factors. Among the inherent factors known to affect absorption are the method of manufacture or method of compounding; the particle size and crystal form or polymorph of the drug substance; and the diluents and excipients used in formulating the dosage form, including fillers, binders, disintegrating agents, lubricants, coatings, solvents, suspending agents, and dyes. Lubricants and coatings are foremost among these. The maintenance of a demonstrably high degree of bioavailability requires particular attention to all aspects of production and quality control that may affect the nature of the finished dosage form.~~

~~TERMINOLOGY~~

~~Occasionally it is necessary to add solvent to the contents of a container just prior to use, usually because of instability of some drugs in the diluted form. Thus, a solid diluted to yield a suspension is called [DRUG] *for Suspension;* a solid dissolved and diluted to yield a solution is called [DRUG] *for Solution;* and a solution or suspension diluted to yield a more dilute form of the drug is called [DRUG] *Oral Concentrate*. After dilution, it is important that the drug be homogeneously dispersed before administration.~~

~~AEROSOLS~~

~~Pharmaceutical aerosols are products that are packaged under pressure and contain therapeutically active ingredients that are released upon activation of an appropriate valve system. They are intended for topical application to the skin as well as local application into the nose (nasal aerosols), mouth (lingual aerosols), or lungs (inhalation aerosols). These products may be fitted with valves enabling either continuous or metered dose delivery; hence, the terms "[DRUG] Metered Topical Aerosols," "[DRUG] Metered Nasal Aerosols," etc.~~

~~The term "aerosol" refers to the fine mist of spray that results from most pressurized systems. However, the term has been broadly misapplied to all self-contained pressurized products, some of which deliver foams or semisolid fluids. In the case of *Inhalation Aerosols*, the particle size of the delivered medication must be carefully controlled, and the average size of the particles should be under 5 µm. These products are also known as metered-dose inhalers (MDIs). Other aerosol sprays may contain particles up to several hundred micrometers in diameter.~~

~~The basic components of an aerosol system are the container, the propellant, the concentrate containing the active ingredient(s), the valve, and the actuator. The nature of these components determines such characteristics as particle size distribution, uniformity of dose for metered valves, delivery rate, wetness and temperature of the spray, spray pattern and velocity or plume geometry, foam density, and fluid viscosity.~~

~~Types of Aerosols~~

~~Aerosols consist of two-phase (gas and liquid) or three-phase (gas, liquid, and solid or liquid) systems. The two-phase aerosol consists of a solution of active ingredients in liquefied propellant and the vaporized propellant. The solvent is composed of the propellant or a mixture of the propellant and cosolvents such as alcohol, propylene glycol, and polyethylene glycols, which are often used to enhance the solubility of the active ingredients.~~

In-Process Revision

Three-phase systems consist of a suspension or emulsion of the active ingredient(s) in addition to the vaporized propellants. A suspension consists of the active ingredient(s) that may be dispersed in the propellant system with the aid of suitable excipients such as wetting agents and/or solid carriers such as talc or colloidal silicas.

A foam aerosol is an emulsion containing one or more active ingredients, surfactants, aqueous or nonaqueous liquids, and the propellants. If the propellant is in the internal (discontinuous) phase (i.e., of the oil in water type), a stable foam is discharged; and if the propellant is in the external (continuous) phase (i.e., of the water in oil type), a spray or a quick breaking foam is discharged.

Propellants

The propellant supplies the necessary pressure within an aerosol system to expel material from the container and, in combination with other components, to convert the material into the desired physical form. Propellants may be broadly classified as liquefied or compressed gases having vapor pressures generally exceeding atmospheric pressure. Propellants within this definition include various hydrocarbons, especially halogenated derivatives of methane, ethane, and propane, low molecular weight hydrocarbons such as the butanes and pentanes, and compressed gases such as carbon dioxide, nitrogen, and nitrous oxide. Mixtures of propellants are frequently used to obtain desirable pressure, delivery, and spray characteristics. A good propellant system should have the proper vapor pressure characteristics consistent with the other aerosol components.

Valves

The primary function of the valve is to regulate the flow of the therapeutic agent and propellant from the container. The spray characteristics of the aerosol are influenced by orifice dimension, number, and location. Most aerosol valves provide for continuous spray operation and are used on most topical products. However, pharmaceutical products for oral or nasal inhalation often utilize metered dose valves that must deliver a uniform quantity of spray upon each valve activation. The accuracy and reproducibility of the doses delivered from metering valves are generally good, comparing favorably to the uniformity of solid dosage forms such as tablets and capsules. However, when aerosol packages are stored improperly, or when they have not been used for long periods of time, valves must be primed before use. Materials used for the manufacture of valves should be inert to the formulations used. Plastic, rubber, aluminum, and stainless steel valve components are commonly used. Metered dose valves must deliver an accurate dose within specified tolerances.

Actuators

An actuator is the fitting attached to an aerosol valve stem, which when depressed or moved, opens the valve, and directs the spray containing the drug preparation to the desired area. The actuator usually indicates the direction in which the preparation is dispensed and protects the hand or finger from the refrigerant effects of the propellant. Actuators incorporate an orifice that may vary widely in size and shape. The size of this orifice, the expansion chamber design, and the nature of the propellant and formulation influence the delivered dose as well as the physical characteristics of the spray, foam, or stream of solid particles dispensed. For inhalation aerosols, an actuator capable of delivering the medication in the proper particle size range and with the appropriate spray pattern and plume geometry is utilized.

Containers

Aerosol containers usually are made of glass, plastic, or metal, or a combination of these materials. Glass containers must be precisely engineered to provide the maximum in pressure safety and impact resistance. Plastics may be employed to coat glass containers for improved safety characteristics, or to coat metal containers to improve corrosion resistance and enhance stability of the formulation. Suitable metals include stainless steel, aluminum, and tin plated steel. Extractables or leachables (e.g., drawing oils, cleaning agents, etc.) and particulates on the internal surfaces of containers should be controlled.

Manufacture

Aerosols are usually prepared by one of two general processes. In the "cold fill" process, the concentrate (generally cooled to a temperature below 0°) and the refrigerated propellant are measured into open containers (usually chilled). The valve actuator assembly is then crimped onto the container to form a pressure tight seal. During the interval between propellant addition and crimping, sufficient volatilization of propellant occurs to displace air from the container. In the "pressure fill" method, the concentrate is placed in the container, and either the propellant is forced under pressure through the valve orifice after the valve is sealed, or the propellant is allowed to flow under the valve cap and then the valve assembly is sealed ("under the cap" filling). In both cases of the "pressure fill" method, provision must be made for evacuation of air by means of vacuum or displacement with a small amount of propellant vapor. Manufacturing process controls usually include monitoring of proper formulation and propellant fill weight and pressure testing, leak testing, and valve function testing of the finished aerosol. Microbiological attributes should also be controlled.

Extractable Substances

Since pressurized inhalers and aerosols are normally formulated with organic solvents as the propellant or the vehicle, leaching of extractables from the elastomeric and plastic components into the formulation is a potentially serious problem. Thus, the composition and the quality of materials used in the manufacture of the valve components (e.g., stem, gaskets, housing, etc.) must be carefully selected and controlled. Their compatibility with formulation components should be well established so as to prevent distortion of the valve components and to minimize changes in the medication delivery, leak rate, and impurity profile of the drug product over time. The extractable profiles of a representative sample of each of the elastomeric and plastic components of the valve should be established under specified conditions and should be correlated to the extractable profile of the aged drug product or placebo, to ensure reproducible quality and purity of the drug product. Extractables, which may include polynuclear aromatics, nitrosamines, vulcanization accelerators, antioxidants, plasticizers, monomers, etc., should be identified and minimized wherever possible.

Specifications and limits for individual and total extractables from different valve components may require the use of different analytical methods. In addition, the standard USP biological testing (see the general test chapters *Biological Reactivity Tests, In Vitro* ⟨87⟩ and *Biological Reactivity Tests, In Vivo* ⟨88⟩) as well as other safety data may be needed.

Labeling

Medicinal aerosols should contain at least the following warning information on the label as in accordance with appropriate regulations.

Warning—Avoid inhaling. Avoid spraying into eyes or onto other mucous membranes.

In-Process Revision

NOTE—The statement "Avoid inhaling" is not necessary for preparations specifically designed for use by inhalation. The phrase "or other mucous membranes" is not necessary for preparations specifically designed for use on mucous membranes.

Warning—Contents under pressure. Do not puncture or incinerate container. Do not expose to heat or store at temperatures above 120° F (49° C). Keep out of reach of children.

In addition to the aforementioned warnings, the label of a drug packaged in an aerosol container in which the propellant consists in whole or in part of a halocarbon or hydrocarbon shall, where required under regulations of the FDA, bear either of the following warnings:

Warning—Do not inhale directly; deliberate inhalation of contents can cause death.

Warning—Use only as directed; intentional misuse by deliberately concentrating and inhaling the contents can be harmful or fatal.

BOLUSES

Boluses are large elongated tablets intended for administration to animals (see *Tablets*).

CAPSULES

Capsules are solid dosage forms in which the drug is enclosed within either a hard or soft soluble container or "shell." The shells are usually formed from gelatin; however, they also may be made from starch or other suitable substances. Hard shell capsule sizes range from No. 5, the smallest, to No. 000, which is the largest, except for veterinary sizes. However, size No. 00 generally is the largest size acceptable to patients. Size 0 hard gelatin capsules having an elongated body (known as size OE) also are available, which provide greater fill capacity without an increase in diameter. Hard gelatin capsules consist of two, telescoping cap and body pieces. Generally, there are unique grooves or indentations molded into the cap and body portions to provide a positive closure when fully engaged, which helps prevent the accidental separation of the filled capsules during shipping and handling. Positive closure also may be affected by spot fusion ("welding") of the cap and body pieces together through direct thermal means or by application of ultrasonic energy. Factory filled hard gelatin capsules may be completely sealed by banding, a process in which one or more layers of gelatin are applied over the seam of the cap and body, or by a liquid fusion process wherein the filled capsules are wetted with a hydroalcoholic solution that penetrates into the space where the cap overlaps the body, and then dried. Hard shell capsules made from starch consist of two, fitted cap and body pieces. Since the two pieces do not telescope or interlock positively, they are sealed together at the time of filling to prevent their separation. Starch capsules are sealed by the application of a hydroalcoholic solution to the recessed section of the cap immediately prior to its being placed onto the body.

The banding of hard shell gelatin capsules or the liquid sealing of hard shell starch capsules enhances consumer safety by making the capsules difficult to open without causing visible, obvious damage, and may improve the stability of contents by limiting O_2 penetration. Industrially filled hard shell capsules also are often of distinctive color and shape or are otherwise marked to identify them with the manufacturer. Additionally, such capsules may be printed axially or radially with strengths, product codes, etc. Pharmaceutical grade printing inks are usually based on shellac and employ FDA approved pigments and lake dyes.

In extemporaneous prescription practice, hard shell capsules may be hand filled; this permits the prescriber a latitude of choice in selecting either a single drug or a combination of drugs at the exact dosage level considered best for the individual patient. This flexibility gives hard shell capsules an advantage over compressed tablets and soft shell capsules as a dosage form. Hard shell capsules are usually formed from gelatins having relatively high gel strength. Either type may be used, but blends of pork skin and bone gelatin are often used to optimize shell clarity and toughness. Hard shell capsules also may be formed from starch or other suitable substances. Hard shell capsules may also contain colorants, such as D&C and FD&C dyes or the various iron oxides, opaquing agents such as titanium dioxide, dispersing agents, hardening agents such as sucrose, and preservatives. They normally contain between 10% and 15% water.

Hard gelatin capsules are made by a process that involves dipping shaped pins into gelatin solutions, after which the gelatin films are dried, trimmed, and removed from the pins, and the body and cap pieces are joined. Starch capsules are made by injection molding a mixture of starch and water, after which the capsules are dried. A separate mold is used for caps and bodies, and the two parts are supplied separately. The empty capsules should be stored in tight containers until they are filled. Since gelatin is of animal origin and starch is of vegetable origin, capsules made with these materials should be protected from potential sources of microbial contamination.

Hard shell capsules typically are filled with powder, beads, or granules. Inert sugar beads (nonpareils) may be coated with active ingredients and coating compositions that provide extended release profiles or enteric properties. Alternatively, larger-dose active ingredients themselves may be suitably formed into pellets and then coated. Semisolids or liquids also may be filled into hard shell capsules; however, when the latter are encapsulated, one of the sealing techniques must be employed to prevent leakage.

In hard gelatin capsule filling operations, the body and cap of the shell are separated prior to dosing. In hard starch shell filling operations, the bodies and caps are supplied separately and are fed into separate hoppers of the filling machine. Machines employing various dosing principles may be employed to fill powders into hard shell capsules; however, most fully automatic machines form powder plugs by compression and eject them into empty capsule bodies. Accessories to these machines generally are available for the other types of fills. Powder formulations often require adding fillers, lubricants, and glidants to the active ingredients to facilitate encapsulation. The formulation, as well as the method of filling, particularly the degree of compaction, may influence the rate of drug release. The addition of wetting agents to the powder mass is common where the active ingredient is hydrophobic. Disintegrants also may be included in powder formulations to facilitate deaggregation and dispersal of capsule plugs in the gut. Powder formulations often may be produced by dry blending; however, bulky formulations may require densification by roll compaction or other suitable granulation techniques.

Powder mixtures that tend to liquefy may be dispensed in hard shell capsules if an absorbent such as magnesium carbonate, colloidal silicon dioxide, or other suitable substance is used. Potent drugs are often mixed with an inert diluent before being filled into capsules. Where two mutually incompatible drugs are prescribed together, it is sometimes possible to place one in a small capsule and then enclose it with the second drug in a larger capsule. Incompatible drugs also can be separated by placing coated pellets or tablets, or soft shell capsules of one drug into the capsule shell before adding the second drug.

Thixotropic semisolids may be formed by gelling liquid drugs or vehicles with colloidal silicas or powdered high molecular weight polyethylene glycols. Various waxy or fatty compounds may be used to prepare semisolid matrices by fusion.

Soft shell capsules made from gelatin (sometimes called softgels) or other suitable material require large scale production methods. The soft gelatin shell is somewhat thicker than that of hard shell capsules and may be plasticized by the addition of a polyol such as sorbitol or glycerin. The ratio of dry plasticizer to dry gelatin determines the "hardness" of the shell and may be varied to accommodate environmental conditions as well as the nature of the contents. Like hard shells, the shell composition may include approved dyes and pigments, opaquing agents such as titanium dioxide, and preservatives. Flavors may be added and up to 5% sucrose may be included for its sweetness and to produce a chewable shell. Soft gelatin shells normally contain 6% to 13% water. Soft shell capsules

also may be printed with a product code, strength, etc. In most cases, soft-shell capsules are filled with liquid contents. Typically, active ingredients are dissolved or suspended in a liquid vehicle. Classically, an oleaginous vehicle such as a vegetable oil was used; however, nonaqueous, water miscible liquid vehicles such as the lower molecular weight polyethylene glycols are more common today due to fewer bioavailability problems.

Available in a wide variety of sizes and shapes, soft-shell capsules are both formed, filled, and sealed in the same machine; typically, this is a rotary die process, although a plate process or reciprocating die process also may be employed. Soft-shell capsules also may be manufactured in a bubble process that forms seamless spherical capsules. With suitable equipment, powders and other dry solids also may be filled into soft-shell capsules.

Liquid-filled capsules of either type involve similar formulation technology and offer similar advantages and limitations. For instance, both may offer advantages over dry-filled capsules and tablets in content uniformity and drug dissolution. Greater homogeneity is possible in liquid systems, and liquids can be metered more accurately. Drug dissolution may benefit because the drug may already be in solution or at least suspended in a hydrophilic vehicle. However, the contact between the hard- or soft-shell and its liquid content is more intimate than exists with dry-filled capsules, and this may enhance the chances for undesired interactions. The liquid nature of capsule contents presents different technological problems than dry-filled capsules in regard to disintegration and dissolution testing. From formulation, technological, and biopharmaceutical points of view, liquid-filled capsules of either type have more in common than liquid-filled and dry-filled capsules having the same shell composition. Thus, for compendial purposes, standards and methods should be established based on capsule contents rather than on whether the contents are filled into hard- or soft-shell capsules.

DELAYED-RELEASE CAPSULES

Capsules may be coated, or, more commonly, encapsulated granules may be coated to resist releasing the drug in the gastric fluid of the stomach where a delay is important to alleviate potential problems of drug inactivation or gastric mucosal irritation. The term "delayed-release" is used for Pharmacopeial monographs on enteric-coated capsules that are intended to delay the release of medicament until the capsule has passed through the stomach, and the individual monographs include tests and specifications for *Drug release* (see *Drug Release* ⟨724⟩) or *Disintegration* (see *Disintegration* ⟨701⟩).

EXTENDED-RELEASE CAPSULES

Extended-release capsules are formulated in such manner as to make the contained medicament available over an extended period of time following ingestion. Expressions such as "prolonged-action," "repeat-action," and "sustained-release" have also been used to describe such dosage forms. However, the term "extended-release" is used for Pharmacopeial purposes and requirements for *Drug release* (see *Drug Release* ⟨724⟩) typically are specified in the individual monographs.

CONCENTRATE FOR DIP

Concentrate for Dip is a preparation containing one or more active ingredients usually in the form of a paste or solution. It is used to prepare a diluted suspension, emulsion, or solution of the active ingredient(s) for the prevention and treatment of ectoparasitic infestations of animals. The diluted preparation (Dip) is applied by complete immersion of the animal or, where appropriate, by spraying. Concentrate for Dip may contain suitable antimicrobial preservatives.

CREAMS

Creams are semisolid dosage forms containing one or more drug substances dissolved or dispersed in a suitable base. This term has traditionally been applied to semisolids that possess a relatively fluid consistency formulated as either water-in-oil (e.g., *Cold Cream*) or oil-in-water (e.g., *Fluocinolone Acetonide Cream*) emulsions. However, more recently the term has been restricted to products consisting of oil-in-water emulsions or aqueous microcrystalline dispersions of long-chain fatty acids or alcohols that are water-washable and more cosmetically and aesthetically acceptable. Creams can be used for administering drugs via the vaginal route (e.g., *Triple Sulfa Vaginal Cream*).

ELIXIRS

See *Solutions*.

EMULSIONS

Emulsions are two-phase systems in which one liquid is dispersed throughout another liquid in the form of small droplets. Where oil is the dispersed phase and an aqueous solution is the continuous phase, the system is designated as an oil-in-water emulsion. Conversely, where water or an aqueous solution is the dispersed phase and oil or oleaginous material is the continuous phase, the system is designated as a water-in-oil emulsion. Emulsions are stabilized by emulsifying agents that prevent coalescence, the merging of small droplets into larger droplets and, ultimately, into a single separated phase. Emulsifying agents (surfactants) do this by concentrating in the interface between the droplet and external phase and by providing a physical barrier around the particle to coalescence. Surfactants also reduce the interfacial tension between the phases, thus increasing the ease of emulsification upon mixing.

Natural, semisynthetic, and synthetic hydrophilic polymers may be used in conjunction with surfactants in oil-in-water emulsions as they accumulate at interfaces and also increase the viscosity of the aqueous phase, thereby decreasing the rate of formation of aggregates of droplets. Aggregation is generally accompanied by a relatively rapid separation of an emulsion into a droplet-rich and droplet-poor phase. Normally the density of an oil is lower than that of water, in which case the oil droplets and droplet aggregates rise, a process referred to as creaming. The greater the rate of aggregation, the greater the droplet size and the greater the rate of creaming. The water droplets in a water-in-oil emulsion generally sediment because of their greater density.

The consistency of emulsions varies widely, ranging from easily pourable liquids to semisolid creams. Generally oil-in-water creams are prepared at high temperature, where they are fluid, and cooled to room temperature, whereupon they solidify as a result of solidification of the internal phase. When this is the case, a high internal-phase volume to external-phase volume ratio is not necessary for semisolid character, and, for example, stearic acid creams or vanishing creams are semisolid with as little as 15% internal phase. Any semisolid character with water-in-oil emulsions generally is attributable to a semisolid external phase.

All emulsions require an antimicrobial agent because the aqueous phase is favorable to the growth of microorganisms. The presence of a preservative is particularly critical in oil-in-water emulsions where contamination of the external phase occurs readily. Since fungi and yeasts are found with greater frequency than bacteria, fungistatic as well as bacteriostatic properties are desirable. Bacteria have been shown to degrade nonionic and anionic emulsifying agents, glycerin, and many natural stabilizers such as tragacanth and guar gum.

Complications arise in preserving emulsion systems, as a result of partitioning of the antimicrobial agent out of the aqueous phase where it is most needed, or of complexation with emulsion ingredients that reduce effectiveness. Therefore, the effectiveness of the preservative system should always be tested

in the final product. Preservatives commonly used in emulsions include methyl-, ethyl-, propyl-, and butyl parabens, benzoic acid, and quaternary ammonium compounds.

See also *Creams* and *Ointments*.

EXTRACTS AND FLUIDEXTRACTS

Extracts are concentrated preparations of vegetable or animal drugs obtained by removal of the active constituents of the respective drugs with suitable menstrua, by evaporation of all or nearly all of the solvent, and by adjustment of the residual masses or powders to the prescribed standards.

In the manufacture of most extracts, the drugs are extracted by percolation. The entire percolates are concentrated, generally by distillation under reduced pressure in order to subject the drug principles to as little heat as possible.

Fluidextracts are liquid preparations of vegetable drugs, containing alcohol as a solvent or as a preservative, or both, and so made that, unless otherwise specified in an individual monograph, each mL contains the therapeutic constituents of 1 g of the standard drug that it represents.

A fluidextract that tends to deposit sediment may be aged and filtered or the clear portion decanted, provided the resulting clear liquid conforms to the Pharmacopeial standards.

Fluidextracts may be prepared from suitable extracts.

GELS

Gels (sometimes called Jellies) are semisolid systems consisting of either suspensions made up of small inorganic particles or large organic molecules interpenetrated by a liquid. Where the gel mass consists of a network of small discrete particles, the gel is classified as a two-phase system (e.g., *Aluminum Hydroxide Gel*). In a two-phase system, if the particle size of the dispersed phase is relatively large, the gel mass is sometimes referred to as a magma (e.g., *Bentonite Magma*). Both gels and magmas may be thixotropic, forming semisolids on standing and becoming liquid on agitation. They should be shaken before use to ensure homogeneity and should be labeled to that effect. (See *Suspensions*.)

Single-phase gels consist of organic macromolecules uniformly distributed throughout a liquid in such a manner that no apparent boundaries exist between the dispersed macromolecules and the liquid. Single-phase gels may be made from synthetic macromolecules (e.g., *Carbomer*) or from natural gums (e.g., *Tragacanth*). The latter preparations are also called mucilages. Although these gels are commonly aqueous, alcohols and oils may be used as the continuous phase. For example, mineral oil can be combined with a polyethylene resin to form an oleaginous ointment base.

Gels can be used to administer drugs topically or into body cavities (e.g., *Phenylephrine Hydrochloride Nasal Jelly*).

IMPLANTS (PELLETS)

Implants or pellets are small sterile solid masses consisting of a highly purified drug (with or without excipients) made by compression or molding. They are intended for implantation in the body (usually subcutaneously) for the purpose of providing continuous release of the drug over long periods of time. Implants are administered by means of a suitable special injector or surgical incision. This dosage form has been used to administer hormones such as testosterone or estradiol. They are packaged individually in sterile vials or foil strips.

INFUSIONS, INTRAMAMMARY

Intramammary infusions are suspensions of drugs in suitable oil vehicles. These preparations are intended for veterinary use only, and are administered by instillation via the teat canals into the udders of milk-producing animals.

INHALATIONS

Inhalations are drugs or solutions or suspensions of one or more drug substances administered by the nasal or oral respiratory route for local or systemic effect.

Solutions of drug substances in sterile water for inhalation or in sodium chloride inhalation solution may be nebulized by use of inert gases. Nebulizers are suitable for the administration of inhalation solutions only if they give droplets sufficiently fine and uniform in size so that the mist reaches the bronchioles. Nebulized solutions may be breathed directly from the nebulizer or the nebulizer may be attached to a plastic face mask, tent, or intermittent positive pressure breathing (IPPB) machine.

Another group of products, also known as metered dose inhalers (MDIs) are propellant driven drug suspensions or solutions in liquified gas propellant with or without a cosolvent and are intended for delivering metered doses of the drug to the respiratory tract. An MDI contains multiple doses, often exceeding several hundred. The most common single dose volumes delivered are from 25 to 100 µL (also expressed as mg) per actuation.

Examples of MDIs containing drug solutions and suspensions in this pharmacopeia are *Epinephrine Inhalation Aerosol* and *Isoproterenol Hydrochloride and Phenylephrine Bitartrate Inhalation Aerosol*, respectively.

Powders may also be administered by mechanical devices that require manually produced pressure or a deep inhalation by the patient (e.g., *Cromolyn Sodium for Inhalation*).

A special class of inhalations termed inhalants consists of drugs or combination of drugs, that by virtue of their high vapor pressure, can be carried by an air current into the nasal passage where they exert their effect. The container from which the inhalant generally is administered is known as an inhaler.

INJECTIONS

An Injection is a preparation intended for parenteral administration or for constituting or diluting a parenteral article prior to administration (see *Injections* ⟨1⟩).

Each container of an Injection is filled with a volume in slight excess of the labeled "size" or that volume that is to be withdrawn. The excess volumes recommended in the accompanying table are usually sufficient to permit withdrawal and administration of the labeled volumes.

	Recommended Excess Volume	
Labeled Size	For Mobile Liquids	For Viscous Liquids
0.5 mL	0.10 mL	0.12 mL
1.0 mL	0.10 mL	0.15 mL
2.0 mL	0.15 mL	0.25 mL
5.0 mL	0.30 mL	0.50 mL
10.0 mL	0.50 mL	0.70 mL
20.0 mL	0.60 mL	0.90 mL
30.0 mL	0.80 mL	1.20 mL
50.0 mL or more	2%	3%

IRRIGATIONS

Irrigations are sterile solutions intended to bathe or flush open wounds or body cavities. They are used topically, never parenterally. They are labeled to indicate that they are not intended for injection.

LOTIONS

See *Solutions* or *Suspensions*.

In-Process Revision

~~LOZENGES~~

~~Lozenges are solid preparations, that are intended to dissolve or disintegrate slowly in the mouth. They contain one or more medicaments, usually in a flavored, sweetened base. They can be prepared by molding (gelatin and/or fused sucrose or sorbitol base) or by compression of sugar-based tablets. Molded lozenges are sometimes referred to as pastilles while compressed lozenges are often referred to as troches. They are usually intended for treatment of local irritation or infections of the mouth or throat but may contain active ingredients intended for systemic absorption after swallowing.~~

~~OINTMENTS~~

~~Ointments are semisolid preparations intended for external application to the skin or mucous membranes.~~

~~Ointment bases recognized for use as vehicles fall into four general classes: the hydrocarbon bases, the absorption bases, the water-removable bases, and the water-soluble bases. Each therapeutic ointment possesses as its base a representative of one of these four general classes.~~

~~Hydrocarbon Bases~~

~~These bases, which are known also as ''oleaginous ointment bases,'' are represented by *White Petrolatum* and *White Ointment*. Only small amounts of an aqueous component can be incorporated into them. They serve to keep medicaments in prolonged contact with the skin and act as occlusive dressings. Hydrocarbon bases are used chiefly for their emollient effects, and are difficult to wash off. They do not ''dry out'' or change noticeably on aging.~~

~~Absorption Bases~~

~~This class of bases may be divided into two groups: the first group consisting of bases that permit the incorporation of aqueous solutions with the formation of a water-in-oil emulsion *(Hydrophilic Petrolatum* and *Lanolin)*, and the second group consisting of water-in-oil emulsions that permit the incorporation of additional quantities of aqueous solutions *(Lanolin)*. Absorption bases are useful also as emollients.~~

~~Water-Removable Bases~~

~~Such bases are oil-in-water emulsions, e.g., *Hydrophilic Ointment*, and are more correctly called ''creams.'' (See *Creams*.) They are also described as ''water washable,'' since they may be readily washed from the skin or clothing with water, an attribute that makes them more acceptable for cosmetic reasons. Some medicaments may be more effective in these bases than in hydrocarbon bases. Other advantages of the water-removable bases are that they may be diluted with water and that they favor the absorption of serous discharges in dermatological conditions.~~

~~Water-Soluble Bases~~

~~This group of so-called ''greaseless ointment bases'' comprises water-soluble constituents. *Polyethylene Glycol Ointment* is the only Pharmacopeial preparation in this group. Bases of this type offer many of the advantages of the water-removable bases and, in addition, contain no water-insoluble substances such as petrolatum, anhydrous lanolin, or waxes. They are more correctly called ''Gels.'' (See *Gels*.)~~

~~**Choice of Base**—The choice of an ointment base depends upon many factors, such as the action desired, the nature of the medicament to be incorporated and its bioavailability and stability, and the requisite shelf life of the finished product. In some cases, it is necessary to use a base that is less than ideal in order to achieve the stability required. Drugs that hydrolyze rapidly, for example, are more stable in hydrocarbon bases than in bases containing water, even though they may be more effective in the latter.~~

~~OPHTHALMIC PREPARATIONS~~

~~Drugs are administered to the eyes in a wide variety of dosage forms, some of which require special consideration. They are discussed in the following paragraphs.~~

~~Ointments~~

~~Ophthalmic ointments are ointments for application to the eye. Special precautions must be taken in the preparation of ophthalmic ointments. They are manufactured from sterilized ingredients under rigidly aseptic conditions and meet the requirements under *Sterility Tests* ⟨71⟩. If the specific ingredients used in the formulation do not lend themselves to routine sterilization techniques, ingredients that meet the sterility requirements described under *Sterility Tests* ⟨71⟩, along with aseptic manufacture, may be employed. Ophthalmic ointments must contain a suitable substance or mixture of substances to prevent growth of, or to destroy, microorganisms accidentally introduced when the container is opened during use, unless otherwise directed in the individual monograph, or unless the formula itself is bacteriostatic (see *Added Substances* under *Ophthalmic Ointments* ⟨771⟩). The medicinal agent is added to the ointment base either as a solution or as a micronized powder. The finished ointment must be free from large particles and must meet the requirements for *Leakage* and for *Metal Particles* under *Ophthalmic Ointments* ⟨771⟩. The immediate containers for ophthalmic ointments shall be sterile at the time of filling and closing. It is mandatory that the immediate containers for ophthalmic ointments be sealed and tamper-proof so that sterility is assured at time of first use.~~

~~The ointment base that is selected must be nonirritating to the eye, permit diffusion of the drug throughout the secretions bathing the eye, and retain the activity of the medicament for a reasonable period under proper storage conditions.~~

~~Petrolatum is mainly used as a base for ophthalmic drugs. Some absorption bases, water-removable bases, and water-soluble bases may be desirable for water-soluble drugs. Such bases allow for better dispersion of water-soluble medicaments, but they must be nonirritating to the eye.~~

~~Solutions~~

~~Ophthalmic solutions are sterile solutions, essentially free from foreign particles, suitably compounded and packaged for instillation into the eye. Preparation of an ophthalmic solution requires careful consideration of such factors as the inherent toxicity of the drug itself, isotonicity value, the need for buffering agents, the need for a preservative (and, if needed, its selection), sterilization, and proper packaging. Similar considerations are also made for nasal and otic products.~~

~~ISOTONICITY VALUE~~

~~Lacrimal fluid is isotonic with blood, having an isotonicity value corresponding to that of a 0.9% sodium chloride solution. Ideally, an ophthalmic solution should have this isotonicity value; but the eye can tolerate isotonicity values as low as that of a 0.6% sodium chloride solution and as high as that of a 2.0% sodium chloride solution without marked discomfort.~~

~~Some ophthalmic solutions are necessarily hypertonic in order to enhance absorption and provide a concentration of the active ingredient(s) strong enough to exert a prompt and effective action. Where the amount of such solutions used is small, dilution with lacrimal fluid takes place rapidly so that discomfort from the hypertonicity is only temporary. However, any adjust-~~

ment toward isotonicity by dilution with tears is negligible where large volumes of hypertonic solutions are used as collyria to wash the eyes; it is, therefore, important that solutions used for this purpose be approximately isotonic.

BUFFERING

Many drugs, notably alkaloidal salts, are most effective at pH levels that favor the undissociated free bases. At such pH levels, however, the drug may be unstable so that compromise levels must be found and held by means of buffers. One purpose of buffering some ophthalmic solutions is to prevent an increase in pH caused by the slow release of hydroxyl ions by glass. Such a rise in pH can affect both the solubility and the stability of the drug. The decision whether or not buffering agents should be added in preparing an ophthalmic solution must be based on several considerations. Normal tears have a pH of about 7.4 and possess some buffer capacity. The application of a solution to the eye stimulates the flow of tears and the rapid neutralization of any excess hydrogen or hydroxyl ions within the buffer capacity of the tears. Many ophthalmic drugs, such as alkaloidal salts, are weakly acidic and have only weak buffer capacity. Where only 1 or 2 drops of a solution containing them are added to the eye, the buffering action of the tears is usually adequate to raise the pH and prevent marked discomfort. In some cases pH may vary between 3.5 and 8.5. Some drugs, notably pilocarpine hydrochloride and epinephrine bitartrate, are more acid and overtax the buffer capacity of the lacrimal fluid. Ideally, an ophthalmic solution should have the same pH, as well as the same isotonicity value, as lacrimal fluid. This is not usually possible since, at pH 7.4, many drugs are not appreciably soluble in water. Most alkaloidal salts precipitate as the free alkaloid at this pH. Additionally, many drugs are chemically unstable at pH levels approaching 7.4. This instability is more marked at the high temperatures employed in heat sterilization. For this reason, the buffer system should be selected that is nearest to the physiological pH of 7.4 and does not cause precipitation of the drug or its rapid deterioration.

An ophthalmic preparation with a buffer system approaching the physiological pH can be obtained by mixing a sterile solution of the drug with a sterile buffer solution using aseptic technique. Even so, the possibility of a shorter shelf life at the higher pH must be taken into consideration, and attention must be directed toward the attainment and maintenance of sterility throughout the manipulations.

Many drugs, when buffered to a therapeutically acceptable pH, would not be stable in solution for long periods of time. These products are lyophilized and are intended for reconstitution immediately before use (e.g., *Acetylcholine Chloride for Ophthalmic Solution*).

STERILIZATION

The sterility of solutions applied to an injured eye is of the greatest importance. Sterile preparations in special containers for individual use on one patient should be available in every hospital, office, or other installation where accidentally or surgically traumatized eyes are treated. The method of attaining sterility is determined primarily by the character of the particular product (see *Sterilization and Sterility Assurance of Compendial Articles* ⟨1211⟩).

Whenever possible, sterile membrane filtration under aseptic conditions is the preferred method. If it can be shown that product stability is not adversely affected, sterilization by autoclaving in the final container is also a preferred method.

Buffering certain drugs near the physiological pH range makes them quite unstable at high temperature.

Avoiding the use of heat by employing a bacteria retaining filter is a valuable technique, provided caution is exercised in the selection, assembly, and use of the equipment. Single filtration, presterilized disposable units are available and should be utilized wherever possible.

PRESERVATION

Ophthalmic solutions may be packaged in multiple dose containers when intended for the individual use of one patient and where the ocular surfaces are intact. It is mandatory that the immediate containers for ophthalmic solutions be sealed and tamper proof so that sterility is assured at time of first use. Each solution must contain a suitable substance or mixture of substances to prevent the growth of, or to destroy, microorganisms accidentally introduced when the container is opened during use.

Where intended for use in surgical procedures, ophthalmic solutions, although they must be sterile, should not contain antibacterial agents, since they may be irritating to the ocular tissues.

THICKENING AGENT

A pharmaceutical grade of methylcellulose (e.g., 1% if the viscosity is 25 centipoises, or 0.25% if 4000 centipoises) or other suitable thickening agents such as hydroxypropyl methylcellulose or polyvinyl alcohol occasionally are added to ophthalmic solutions to increase the viscosity and prolong contact of the drug with the tissue. The thickened ophthalmic solution must be free from visible particles.

Suspensions

Ophthalmic suspensions are sterile liquid preparations containing solid particles dispersed in a liquid vehicle intended for application to the eye (see *Suspensions*). It is imperative that such suspensions contain the drug in a micronized form to prevent irritation and/or scratching of the cornea. Ophthalmic suspensions should never be dispensed if there is evidence of caking or aggregation.

Strips

Fluorescein sodium solution should be dispensed in a sterile, single use container or in the form of a sterile, impregnated paper strip. The strip releases a sufficient amount of the drug for diagnostic purposes when touched to the eye being examined for a foreign body or a corneal abrasion. Contact of the paper with the eye may be avoided by leaching the drug from the strip onto the eye with the aid of sterile water or sterile sodium chloride solution.

PASTES

Pastes are semisolid dosage forms that contain one or more drug substances intended for topical application. One class is made from a single phase aqueous gel (e.g., *Carboxymethylcellulose Sodium Paste*). The other class, the fatty pastes (e.g., *Zinc Oxide Paste*), consists of thick, stiff ointments that do not ordinarily flow at body temperature, and therefore serve as protective coatings over the areas to which they are applied.

The fatty pastes appear less greasy and more absorptive than ointments by reason of a high proportion of drug substance(s) having an affinity for water. These pastes tend to absorb serous secretions, and are less penetrating and less macerating than ointments, so that they are preferred for acute lesions that have a tendency towards crusting, vesiculation, or oozing.

A dental paste is intended for adhesion to the mucous membrane for local effect (e.g., *Triamcinolone Acetonide Dental Paste*). Some paste preparations intended for administration to animals are applied orally. The paste is squeezed into the mouth of the animal, generally at the back of the tongue, or is spread inside the mouth.

In-Process Revision

PELLETS

See *Implants*.

POWDERS

Powders are intimate mixtures of dry, finely divided drugs and/or chemicals that may be intended for internal (Oral Powders) or external (Topical Powders) use. Because of their greater specific surface area, powders disperse and dissolve more readily than compacted dosage forms. Children and those adults who experience difficulty in swallowing tablets or capsules may find powders more acceptable. Drugs that are too bulky to be formed into tablets or capsules of convenient size may be administered as powders. Immediately prior to use, oral powders are mixed in a beverage or apple sauce.

Often, stability problems encountered in liquid dosage forms are avoided in powdered dosage forms. Drugs that are unstable in aqueous suspensions or solutions may be prepared in the form of granules or powders. These are intended to be constituted by the pharmacist by the addition of a specified quantity of water just prior to dispensing. Because these constituted products have limited stability, they are required to have a specified expiration date after constitution and may require storage in a refrigerator.

Oral powders may be dispensed in doses premeasured by the pharmacist, i.e., divided powders, or in bulk. Traditionally, divided powders have been wrapped in materials such as bond paper and parchment. However, the pharmacist may provide greater protection from the environment by sealing individual doses in small cellophane or polyethylene envelopes.

Granules for veterinary use may be administered by sprinkling the dry powder on animal feed or by mixing it with animal food.

Bulk oral powders are limited to relatively nonpotent drugs such as laxatives, antacids, dietary supplements, and certain analgesics that the patient may safely measure by the teaspoonful or capful. Other bulky powders include douche powders, tooth powders, and dusting powders. Bulk powders are best dispensed in tight, wide mouth glass containers to afford maximum protection from the atmosphere and to prevent the loss of volatile constituents.

Dusting powders are impalpable powders intended for topical application. They may be dispensed in sifter-top containers to facilitate dusting onto the skin. In general, dusting powders should be passed through at least a 100-mesh sieve to assure freedom from grit that could irritate traumatized areas (see *Powder Fineness* ⟨811⟩).

PREMIXES

Premixes are mixtures of one or more drug substances with suitable vehicles. Premixes are intended for admixture to animal feedstuffs before administration. They are used to facilitate dilution of the active drug components with animal feed. Premixes should be as homogeneous as possible. It is essential that materials of suitable fineness be used and that thorough mixing be achieved at all stages of premix preparation. Premixes may be prepared as powder, pellets, or in granulated form. The granulated form is free flowing and free from aggregates.

SOLUTIONS

Solutions are liquid preparations that contain one or more chemical substances dissolved, i.e., molecularly dispersed, in a suitable solvent or mixture of mutually miscible solvents. Since molecules in solutions are uniformly dispersed, the use of solutions as dosage forms generally provides for the assurance of uniform dosage upon administration, and good accuracy when diluting or otherwise mixing solutions.

Substances in solutions, however, are more susceptible to chemical instability than the solid state and dose for dose, generally require more bulk and weight in packaging relative to solid dosage forms. For all solutions, but particularly those containing volatile solvents, tight containers, stored away from excessive heat, should be used. Consideration should also be given to the use of light resistant containers when photolytic chemical degradation is a potential stability problem. Dosage forms categorized as "Solutions" are classified according to route of administration, such as "Oral Solutions" and "Topical Solutions," or by their solute and solvent systems, such as "Spirits," "Tinctures," and "Waters." Solutions intended for parenteral administration are officially entitled "Injections" (see *Injections* ⟨1⟩).

Oral Solutions

Oral Solutions are liquid preparations, intended for oral administration, that contain one or more substances with or without flavoring, sweetening, or coloring agents dissolved in water or cosolvent water mixtures. Oral Solutions may be formulated for direct oral administration to the patient or they may be dispensed in a more concentrated form that must be diluted prior to administration. It is important to recognize that dilution with water of Oral Solutions containing cosolvents, such as alcohol, could lead to precipitation of some ingredients. Hence, great care must be taken in diluting concentrated solutions when cosolvents are present. Preparations dispensed as soluble solids or soluble mixtures of solids, with the intent of dissolving them in a solvent and administering them orally, are designated "for Oral Solution" (e.g., *Potassium Chloride for Oral Solution*).

Oral Solutions containing high concentrations of sucrose or other sugars traditionally have been designated as Syrups. A near saturated solution of sucrose in purified water, for example, is known as Syrup or "Simple Syrup." Through common usage the term, syrup, also has been used to include any other liquid dosage form prepared in a sweet and viscid vehicle, including oral suspensions.

In addition to sucrose and other sugars, certain polyols such as sorbitol or glycerin may be present in Oral Solutions to inhibit crystallization and to modify solubility, taste, mouth feel, and other vehicle properties. Antimicrobial agents to prevent the growth of bacteria, yeasts, and molds are generally also present. Some sugarless Oral Solutions contain sweetening agents such as sorbitol or aspartame, as well as thickening agents such as the cellulose gums. Such viscid sweetened solutions, containing no sugars, are occasionally prepared as vehicles for administration of drugs to diabetic patients.

Many oral solutions, that contain alcohol as a cosolvent, have been traditionally designated as Elixirs. However, many others designated as Oral Solutions also contain significant amounts of alcohol. Since high concentrations of alcohol can produce a pharmacologic effect when administered orally, other cosolvents, such as glycerin and propylene glycol, should be used to minimize the amount of alcohol required. To be designated as an Elixir, however, the solution must contain alcohol.

Topical Solutions

Topical Solutions are solutions, usually aqueous but often containing other solvents, such as alcohol and polyols, intended for topical application to the skin, or as in the case of *Lidocaine Oral Topical Solution,* to the oral mucosal surface. The term "lotion" is applied to solutions or suspensions applied topically.

Otic Solutions

Otic Solutions, intended for instillation in the outer ear, are aqueous, or they are solutions prepared with glycerin or other solvents and dispersing agents (e.g., *Antipyrine and Benzocaine Otic Solution* and *Neomycin and Polymyxin B Sulfates and Hydrocortisone Otic Solution*).

Ophthalmic Solutions

See *Ophthalmic Preparations*.

Spirits

Spirits are alcoholic or hydroalcoholic solutions of volatile substances prepared usually by simple solution or by admixture of the ingredients. Some spirits serve as flavoring agents while others have medicinal value. Reduction of the high alcoholic content of spirits by admixture with aqueous preparations often causes turbidity.

Spirits require storage in tight, light resistant containers to prevent loss by evaporation and to limit oxidative changes.

Tinctures

Tinctures are alcoholic or hydroalcoholic solutions prepared from vegetable materials or from chemical substances.

The proportion of drug represented in the different chemical tinctures is not uniform but varies according to the established standards for each. Traditionally, tinctures of potent vegetable drugs essentially represent the activity of 10 g of the drug in each 100 mL of tincture, the potency being adjusted following assay. Most other vegetable tinctures represent 20 g of the respective vegetable material in each 100 mL of tincture.

PROCESS P

Carefully mix the ground drug or mixture of drugs with a sufficient quantity of the prescribed solvent or solvent mixture to render it evenly and distinctly damp, allow it to stand for 15 minutes, transfer it to a suitable percolator, and pack the drug firmly. Pour on enough of the prescribed solvent or solvent mixture to saturate the drug, cover the top of the percolator, and, when the liquid is about to drip from the percolator, close the lower orifice and allow the drug to macerate for 24 hours or for the time specified in the monograph. If no assay is directed, allow the percolation to proceed slowly, or at the specified rate, gradually adding sufficient solvent or solvent mixture to produce 1000 mL of tincture, and mix (for definitions of flow rates, see under *Extracts and Fluidextracts*). If an assay is directed, collect only 950 mL of percolate, mix this, and assay a portion of it as directed. Dilute the remainder with such quantity of the prescribed solvent or solvent mixture as calculation from the assay indicates is necessary to produce a tincture that conforms to the prescribed standard, and mix.

PROCESS M

Macerate the drug with 750 mL of the prescribed solvent or solvent mixture in a container that can be closed, and put in a warm place. Agitate it frequently during 3 days or until the soluble matter is dissolved. Transfer the mixture to a filter, and when most of the liquid has drained away, wash the residue on the filter with a sufficient quantity of the prescribed solvent or solvent mixture, combining the filtrates, to produce 1000 mL of tincture, and mix.

Tinctures require storage in tight, light resistant containers, away from direct sunlight and excessive heat.

Waters, Aromatic

Aromatic waters are clear, saturated aqueous solutions (unless otherwise specified) of volatile oils or other aromatic or volatile substances. Their odors and tastes are similar, respectively, to those of the drugs or volatile substances from which they are prepared, and they are free from empyreumatic and other foreign odors. Aromatic waters may be prepared by distillation or solution of the aromatic substance, with or without the use of a dispersing agent.

Aromatic waters require protection from intense light and excessive heat.

SUPPOSITORIES

Suppositories are solid bodies of various weights and shapes, adapted for introduction into the rectal, vaginal, or urethral orifice of the human body. They usually melt, soften, or dissolve at body temperature. A suppository may act as a protectant or palliative to the local tissues at the point of introduction or as a carrier of therapeutic agents for systemic or local action. Suppository bases usually employed are cocoa butter, glycerinated gelatin, hydrogenated vegetable oils, mixtures of polyethylene glycols of various molecular weights, and fatty acid esters of polyethylene glycol.

The suppository base employed has a marked influence on the release of the active ingredient incorporated in it. While cocoa butter melts quickly at body temperature, it is immiscible with body fluids and this inhibits the diffusion of fat soluble drugs to the affected sites. Polyethylene glycol is a suitable base for some antiseptics. In cases where systemic action is expected, it is preferable to incorporate the ionized rather than the nonionized form of the drug, in order to maximize bioavailability. Although nonionized drugs partition more readily out of water-miscible bases such as glycerinated gelatin and polyethylene glycol, the bases themselves tend to dissolve very slowly and thus retard release in this manner. Oleaginous vehicles such as cocoa butter are seldom used in vaginal preparations because of the nonabsorbable residue formed, while glycerinated gelatin is seldom used rectally because of its slow dissolution. Cocoa butter and its substitutes (Hard Fat) are superior for allaying irritation, as in preparations intended for treating internal hemorrhoids.

Cocoa Butter Suppositories

Suppositories having cocoa butter as the base may be made by means of incorporating the finely divided medicinal substance into the solid oil at room temperature and suitably shaping the resulting mass, or by working with the oil in the melted state and allowing the resulting suspension to cool in molds. A suitable quantity of hardening agents may be added to counteract the tendency of some medicaments such as chloral hydrate and phenol to soften the base. It is important that the finished suppository melt at body temperature.

The approximate weights of suppositories prepared with cocoa butter are given below. Suppositories prepared from other bases vary in weight and generally are heavier than the weights indicated here.

Rectal Suppositories for adults are tapered at one or both ends and usually weigh about 2 g each.

Vaginal Suppositories are usually globular or oviform and weigh about 5 g each. They are made from water soluble or water miscible vehicles such as polyethylene glycol or glycerinated gelatin.

Suppositories with cocoa butter base require storage in well-closed containers, preferably at a temperature below 30° (controlled room temperature).

Cocoa Butter Substitutes

Fat-type suppository bases can be produced from a variety of vegetable oils, such as coconut or palm kernel, which are modified by esterification, hydrogenation, and fractionation to obtain products of varying composition and melting temperatures (e.g., *Hydrogenated Vegetable Oil* and *Hard Fat*). These products can be so designed as to reduce rancidity. At the same time, desired characteristics such as narrow intervals between melt-

In-Process Revision

ing and solidification temperatures, and melting ranges to accommodate various formulation and climatic conditions, can be built in.

Glycerinated Gelatin Suppositories

Medicinal substances may be incorporated into glycerinated gelatin bases by addition of the prescribed quantities to a vehicle consisting of about 70 parts of glycerin, 20 parts of gelatin, and 10 parts of water.

Glycerinated gelatin suppositories require storage in tight containers, preferably at a temperature below 35°.

Polyethylene Glycol Base Suppositories

Several combinations of polyethylene glycols having melting temperatures that are above body temperature have been used as suppository bases. Inasmuch as release from these bases depends on dissolution rather than on melting, there are significantly fewer problems in preparation and storage than exist with melting type vehicles. However, high concentrations of higher molecular weight polyethylene glycols may lengthen dissolution time, resulting in problems with retention. Labels on polyethylene glycol suppositories should contain directions that they be moistened with water before inserting. Although they can be stored without refrigeration, they should be packaged in tightly closed containers.

Surfactant Suppository Bases

Several nonionic surface active agents closely related chemically to the polyethylene glycols can be used as suppository vehicles. Examples of such surfactants are polyoxyethylene sorbitan fatty acid esters and the polyoxyethylene stearates. These surfactants are used alone or in combination with other suppository vehicles to yield a wide range of melting temperatures and consistencies. One of the major advantages of such vehicles is their water dispersibility. However, care must be taken with the use of surfactants, because they may either increase the rate of drug absorption or interact with drug molecules, causing a decrease in therapeutic activity.

Tableted Suppositories or Inserts

Vaginal suppositories occasionally are prepared by the compression of powdered materials into a suitable shape. They are prepared also by encapsulation in soft gelatin.

SUSPENSIONS

Suspensions are liquid preparations that consist of solid particles dispersed throughout a liquid phase in which the particles are not soluble. Dosage forms officially categorized as "Suspensions" are designated as such if they are not included in other more specific categories of suspensions, such as Oral Suspensions, Topical Suspensions, etc. (see these other categories). Some suspensions are prepared and ready for use, while others are prepared as solid mixtures intended for constitution just before use with an appropriate vehicle. Such products are designated "for Oral Suspension", etc. The term "Milk" is sometimes used for suspensions in aqueous vehicles intended for oral administration (e.g., *Milk of Magnesia*). The term "Magma" is often used to describe suspensions of inorganic solids such as clays in water, where there is a tendency for strong hydration and aggregation of the solid, giving rise to gel-like consistency and thixotropic rheological behavior (e.g., *Bentonite Magma*). The term "Lotion" has been used to categorize many topical suspensions and emulsions intended for application to the skin (e.g., *Calamine Lotion*). Some suspensions are prepared in sterile form and are used as Injectables, as well as for ophthalmic and otic administration. These may be of two types, ready to use or intended for constitution with a prescribed amount of Water for Injection or other suitable diluent before use by the designated route. Suspensions should not be injected intravenously or intrathecally.

Suspensions intended for any route of administration should contain suitable antimicrobial agents to protect against bacteria, yeast, and mold contamination (see *Emulsions* for some consideration of antimicrobial preservative properties that apply also to Suspensions). By its very nature, the particular matter in a suspension may settle or sediment to the bottom of the container upon standing. Such sedimentation may also lead to caking and solidification of the sediment with a resulting difficulty in redispersing the suspension upon agitation. To prevent such problems, suitable ingredients that increase viscosity and the gel state of the suspension, such as clays, surfactants, polyols, polymers, or sugars, should be added. It is important that suspensions always be shaken well before use to ensure uniform distribution of the solid in the vehicle, thereby ensuring uniform and proper dosage. Suspensions require storage in tight containers.

Oral Suspensions

Oral Suspensions are liquid preparations containing solid particles dispersed in a liquid vehicle, with suitable flavoring agents, intended for oral administration. Some suspensions labeled as "Milks" or "Magmas" fall into this category.

Topical Suspensions

Topical Suspensions are liquid preparations containing solid particles dispersed in a liquid vehicle, intended for application to the skin. Some suspensions labeled as "Lotions" fall into this category.

Otic Suspensions

Otic Suspensions are liquid preparations containing micronized particles intended for instillation in the outer ear.

Ophthalmic Suspensions

See *Ophthalmic Preparations*.

SYRUPS

See *Oral Solutions*.

SYSTEMS

In recent years, a number of dosage forms have been developed using modern technology that allows for the uniform release or targeting of drugs to the body. These products are commonly called delivery systems. The most widely used of these are Transdermal Systems.

Transdermal Systems

Transdermal drug delivery systems are self contained, discrete dosage forms that, when applied to intact skin, are designed to deliver the drug(s) through the skin to the systemic circulation. Systems typically comprise an outer covering (barrier), a drug reservoir, which may have a rate controlling membrane, a contact adhesive applied to some or all parts of the system and the system/skin interface, and a protective liner that is removed before applying the system. The activity of

these systems is defined in terms of the release rate of the drug(s) from the system. The total duration of drug release from the system and the system surface area may also be stated.

Transdermal drug delivery systems work by diffusion: the drug diffuses from the drug reservoir, directly or through the rate-controlling membrane and/or contact adhesive if present, and then through the skin into the general circulation. Typically, modified-release systems are designed to provide drug delivery at a constant rate, such that a true steady-state blood concentration is achieved and maintained until the system is removed. At that time, blood concentration declines at a rate consistent with the pharmacokinetics of the drug.

Transdermal drug delivery systems are applied to body areas consistent with the labeling for the product(s). As long as drug concentration at the system/skin interface remains constant, the amount of drug in the dosage form does not influence plasma concentrations. The functional lifetime of the system is defined by the initial amount of drug in the reservoir and the release rate from the reservoir.

NOTE—Drugs for local rather than systemic effect are commonly applied to the skin embedded in glue on a cloth or plastic backing. These products are defined traditionally as plasters or tapes.

Ocular System

Another type of system is the ocular system, which is intended for placement in the lower conjunctival fornix from which the drug diffuses through a membrane at a constant rate (e.g., *Pilocarpine Ocular System*).

Intrauterine System

An intrauterine system, based on a similar principle but intended for release of drug over a much longer period of time, e.g., one year, is also available (e.g., *Progesterone Intrauterine Contraceptive System*).

TABLETS

Tablets are solid dosage forms containing medicinal substances with or without suitable diluents. They may be classed, according to the method of manufacture, as compressed tablets or molded tablets.

The vast majority of all tablets manufactured are made by compression, and compressed tablets are the most widely used dosage form in this country. Compressed tablets are prepared by the application of high pressures, utilizing steel punches and dies, to powders or granulations. Tablets can be produced in a wide variety of sizes, shapes, and surface markings, depending upon the design of the punches and dies. Capsule-shaped tablets are commonly referred to as caplets. Boluses are large tablets intended for veterinary use, usually for large animals.

Molded tablets are prepared by forcing dampened powders under low pressure into die cavities. Solidification depends upon crystal bridges built up during the subsequent drying process, and not upon the compaction force.

Tablet triturates are small, usually cylindrical, molded or compressed tablets. Tablet triturates were traditionally used as dispensing tablets in order to provide a convenient, measured quantity of a potent drug for compounding purposes. Such tablets are rarely used today. Hypodermic tablets are molded tablets made from completely and readily water-soluble ingredients and formerly were intended for use in making preparations for hypodermic injection. They are employed orally, or where rapid drug availability is required such as in the case of *Nitroglycerin Tablets*, sublingually.

Buccal tablets are intended to be inserted in the buccal pouch, and sublingual tablets are intended to be inserted beneath the tongue, where the active ingredient is absorbed directly through the oral mucosa. Few drugs are readily absorbed in this way, but for those that are (such as nitroglycerin and certain steroid hormones), a number of advantages may result.

Soluble, effervescent tablets are prepared by compression and contain, in addition to active ingredients, mixtures of acids (citric acid, tartaric acid) and sodium bicarbonate, which release carbon dioxide when dissolved in water. They are intended to be dissolved or dispersed in water before administration. Effervescent tablets should be stored in tightly closed containers or moisture-proof packs and labeled to indicate that they are not to be swallowed directly.

Chewable Tablets

Chewable tablets are formulated and manufactured so that they may be chewed, producing a pleasant-tasting residue in the oral cavity that is easily swallowed and does not leave a bitter or unpleasant aftertaste. These tablets have been used in tablet formulations for children, especially multivitamin formulations, and for the administration of antacids and selected antibiotics. Chewable tablets are prepared by compression, usually utilizing mannitol, sorbitol, or sucrose as binders and fillers, and containing colors and flavors to enhance their appearance and taste.

Preparation of Molded Tablets

Molded tablets are prepared from mixtures of medicinal substances and a diluent usually consisting of lactose and powdered sucrose in varying proportions. The powders are dampened with solutions containing high percentages of alcohol. The concentration of alcohol depends upon the solubility of the active ingredients and fillers in the solvent system and the desired degree of hardness of the finished tablets. The dampened powders are pressed into molds, removed, and allowed to dry. Molded tablets are quite friable and care must be taken in packaging and dispensing.

Formulation of Compressed Tablets

Most compressed tablets consist of the active ingredient and a diluent (filler), binder, disintegrating agent, and lubricant. Approved FD&C and D&C dyes or lakes (dyes adsorbed onto insoluble aluminum hydroxide), flavors, and sweetening agents may also be present. Diluents are added where the quantity of active ingredient is small or difficult to compress. Common tablet fillers include lactose, starch, dibasic calcium phosphate, and microcrystalline cellulose. Chewable tablets often contain sucrose, mannitol, or sorbitol as a filler. Where the amount of active ingredient is small, the overall tableting properties are in large measure determined by the filler. Because of problems encountered with bioavailability of hydrophobic drugs of low water solubility, water-soluble diluents are used as fillers for these tablets.

Binders give adhesiveness to the powder during the preliminary granulation and to the compressed tablet. They add to the cohesive strength already available in the diluent. While binders may be added dry, they are more effective when added out of solution. Common binders include acacia, gelatin, sucrose, povidone, methylcellulose, carboxymethylcellulose, and hydrolyzed starch pastes. The most effective dry binder is microcrystalline cellulose, which is commonly used for this purpose in tablets prepared by direct compression.

A disintegrating agent serves to assist in the fragmentation of the tablet after administration. The most widely used tablet disintegrating agent is starch. Chemically modified starches and cellulose, alginic acid, microcrystalline cellulose, and cross-linked povidone, are also used for this purpose. Effervescent mixtures are used in soluble tablet systems as disintegrating agents. The concentration of the disintegrating agent, method of addition, and degree of compaction play a role in effectiveness.

Lubricants reduce friction during the compression and ejection cycle. In addition, they aid in preventing adherence of tablet material to the dies and punches. Metallic stearates, stearic acid, hydrogenated vegetable oils, and talc are used as lubricants. Because of the nature of this function, most lubricants are hydrophobic, and as such tend to reduce the rates of tablet disintegration and dissolution. Consequently, excessive concentrations of lubricant should be avoided. Polyethylene glycols and some lauryl sulfate salts have been used as soluble lubricants, but such agents generally do not possess optimal lubricating properties, and comparatively high concentrations are usually required.

Glidants are agents that improve powder fluidity, and they are commonly employed in direct compression where no granulation step is involved. The most effective glidants are the colloidal pyrogenic silicas.

Colorants are often added to tablet formulations for esthetic value or for product identification. Both D&C and FD&C dyes and lakes are used. Most dyes are photosensitive and they fade when exposed to light. The federal Food and Drug Administration regulates the colorants employed in drugs.

Manufacturing Methods

Tablets are prepared by three general methods: wet granulation, dry granulation (roll compaction or slugging), and direct compression. The purpose of both wet and dry granulation is to improve flow of the mixture and/or to enhance its compressibility.

Dry granulation (slugging) involves the compaction of powders at high pressures into large, often poorly formed tablet compacts. These compacts are then milled and screened to form a granulation of the desired particle size. The advantage of dry granulation is the elimination of both heat and moisture in the processing. Dry granulations can be produced also by extruding powders between hydraulically operated rollers to produce thin cakes which are subsequently screened or milled to give the desired granule size.

Excipients are available that allow production of tablets at high speeds without prior granulation steps. These directly compressible excipients consist of special physical forms of substances such as lactose, sucrose, dextrose, or cellulose, which possess the desirable properties of fluidity and compressibility. The most widely used direct compaction fillers are microcrystalline cellulose, anhydrous lactose, spray-dried lactose, compressible sucrose, and some forms of modified starches. Direct compression avoids many of the problems associated with wet and dry granulations. However, the inherent physical properties of the individual filler materials are highly critical, and minor variations can alter flow and compression characteristics so as to make them unsuitable for direct compression.

Physical evidence of poor tablet quality is discussed under *Stability Considerations in Dispensing Practice* ⟨1191⟩.

WEIGHT VARIATION AND CONTENT UNIFORMITY

Tablets are required to meet a weight variation test (see *Uniformity of Dosage Units* ⟨905⟩) where the active ingredient comprises a major portion of the tablet and where control of weight may be presumed to be an adequate control of drug content uniformity. Weight variation is not an adequate indication of content uniformity where the drug substance comprises a relatively minor portion of the tablet, or where the tablet is sugar-coated. Thus, the Pharmacopeia generally requires that coated tablets and tablets containing 50 mg or less of active ingredient, comprising less than 50% by weight of the dosage form unit, pass a content uniformity test (see *Uniformity of Dosage Units* ⟨905⟩), wherein individual tablets are assayed for actual drug content.

DISINTEGRATION AND DISSOLUTION

Disintegration is an essential attribute of tablets intended for administration by mouth, except for those intended to be chewed before being swallowed and for some types of extended release tablets. A disintegration test is provided (see *Disintegration* ⟨701⟩), and limits on the times in which disintegration is to take place, appropriate for the types of tablets concerned, are given in the individual monographs.

For drugs of limited water solubility, dissolution may be a more meaningful quality attribute than disintegration. A dissolution test (see *Dissolution* ⟨711⟩) is required in a number of monographs on tablets. In many cases, it is possible to correlate dissolution rates with biological availability of the active ingredient. However, such tests are useful mainly as a means of screening preliminary formulations and as a routine quality control procedure.

Coatings

Tablets may be coated for a variety of reasons, including protection of the ingredients from air, moisture, or light, masking of unpleasant tastes and odors, improvement of appearance, and control of the site of drug release in the gastrointestinal tract.

PLAIN COATED TABLETS

Classically, tablets have been coated with sugar applied from aqueous suspensions containing insoluble powders such as starch, calcium carbonate, talc, or titanium dioxide, suspended by means of acacia or gelatin. For purposes of identification and esthetic value, the outside coatings may be colored. The finished coated tablets are polished by application of dilute solutions of wax in solvents such as chloroform or powdered mix. Water-protective coatings consisting of substances such as shellac or cellulose acetate phthalate are often applied out of nonaqueous solvents prior to application of sugar coats. Excessive quantities should be avoided. Drawbacks of sugar coating include the lengthy time necessary for application, the need for waterproofing, which also adversely affects dissolution, and the increased bulk of the finished tablet. These factors have resulted in increased acceptance of film coatings. Film coatings consist of water soluble or dispersible materials such as hydroxypropyl methylcellulose, methylcellulose, hydroxypropylcellulose, carboxymethylcellulose sodium, and mixtures of cellulose acetate phthalate and polyethylene glycols applied out of nonaqueous or aqueous solvents. Evaporation of the solvents leaves a thin film that adheres directly to the tablet and allows it to retain the original shape, including grooves or identification codes.

~~DELAYED-RELEASE TABLETS~~

~~Where the drug may be destroyed or inactivated by the gastric juice or where it may irritate the gastric mucosa, the use of "enteric" coatings is indicated. Such coatings are intended to delay the release of the medication until the tablet has passed through the stomach. The term "delayed release" is used for Pharmacopeial purposes, and the individual monographs include tests and specifications for *Drug release* (see *Drug Release* ⟨724⟩) or *Disintegration* (see *Disintegration* ⟨701⟩).~~

~~EXTENDED-RELEASE TABLETS~~

~~Extended-release tablets are formulated in such manner as to make the contained medicament available over an extended period of time following ingestion. Expressions such as "prolonged action," "repeat action," and "sustained release" have also been used to describe such dosage forms. However, the term "extended release" is used for Pharmacopeial purposes, and requirements for *Drug release* typically are specified in the individual monographs.~~

▪GENERAL CONSIDERATIONS

This chapter provides general descriptions of and definitions for drug products, or dosage forms, commonly used to administer the drug substance [active pharmaceutical ingredient (API)]. It discusses general principles involved in the manufacture or compounding of these dosage forms, and recommendations for proper use and storage. A glossary is provided as a resource on nomenclature.

A dosage form is a combination of drug substances and excipients to facilitate dosing, administration, and delivery of the medicine to the patient. The design and testing of all dosage forms target drug product quality.[1] A testing protocol must consider not only the physical, chemical, and biological properties of the dosage form as appropriate but also the administration route and desired dosing regimen. The interrelationships of dosage forms and routes of administration have been summarized in the compendial taxonomy for pharmaceutical dosage forms (*Figure 1*).[2] The organization of this general information chapter is by the physical attributes of each particular dosage form (*Tier Two*), generally without specific reference to route of administration. Information specific to route of administration is given when needed.

Tests to ensure compliance with pharmacopeial standards for dosage form performance fall into one of the following areas.

[1] In the United States, a drug with a name recognized in *USP–NF* must comply with compendial identity standards or be deemed adulterated, misbranded, or both. To avoid being deemed adulterated, such drugs also must comply with compendial standards for strength, quality, or purity, unless labeled to show all respects in which the drug differs. See the Federal Food, Drug, and Cosmetic Act (FDCA), Sections 501(b) and 502(e)(3)(b), and Food and Drug Administration (FDA) regulations at 21 CFR 299.5. In addition, to avoid being deemed misbranded, drugs recognized in *USP–NF* also must comply with compendial standards for packing and labeling, FDCA Section 502(g). "Quality" is used herein as suitable shorthand for all such compendial requirements. This approach also is consistent with U.S. and FDA participation in the International Conference on Harmonization (ICH). The ICH guideline on specifications, Q6A, notes that "specifications are chosen to confirm the quality of the drug substance and drug product. . ." and defines "quality" as "The suitability of either a drug substance or drug product for its intended use. This term includes such attributes as identity, strength, and purity."

Immediate Extended Delayed

Tier Four: Comprehensive Testing Strategy

Dose Uniformity (see also *Uniformity of Dosage Units* ⟨905⟩)—Consistency in dosing for a patient or consumer requires that the variation in the drug substance content of each dosage unit be accurately controlled throughout the manufactured batch or compounded lot of drug product. Uniformity of dosage units typically is demonstrated by one of two procedures: content uniformity or weight variation. The procedure for content uniformity requires the assay of drug substance content of individual units, and that for weight variation uses the weight of the individual units to estimate their content. Weight variation may be used where the underlying distribution of drug substance in the blend is presumed to be uniform and well-controlled, as in solutions. In such cases the content of drug substance may be adequately estimated by the net weight. Content uniformity does not rely on the assumption of blend uniformity and can be applied in all cases. Tablets and capsules are assigned a limit below which the weight variation procedure is not applicable. Successful development and manufacture of dosage forms requires careful evaluation of drug substance particle or droplet size, incorporation techniques, and excipient properties.

Stability (see also *Pharmaceutical Stability* ⟨1150⟩)—Drug product stability involves the evaluation of chemical stability, physical stability, and performance over time. The chemical stability of the drug substance in the dose form matrix must support the expiration dating for the commercially prepared dosage forms and a beyond-use date for a compounded dosage form. Test procedures for potency must be stability indicating (see *Validation of Compendial Procedures* ⟨1225⟩). Degradation products should be quantified. In the case of dispersed or emulsified systems, consideration must be given to the potential for settling or separation of the formulation components. Any physical changes to the dosage form must be easily reversed (e.g., by shaking) prior to dosing or administration. In vitro release test procedures such as dissolution and disintegration provide a measure of continuing consistency in performance over time (see *Dissolution* ⟨711⟩, *Disintegration* ⟨701⟩, and *Drug Release* ⟨724⟩).

Bioavailability (see also *In Vitro and In Vivo Evaluation of Dosage Forms* ⟨1088⟩, and *Assessment of Drug Product Performance—Bioavailability, Bioequivalence, and Dissolution* ⟨1090⟩)—Bioavailability is influenced by factors such as the method of manufacture or compounding, particle size, crystal form (polymorph) of the drug substance, the properties of the excipients used to formulate the dosage form, and physical changes as the drug product ages. Assurance of consistency in bioavailability over time (bioequivalence) requires close attention to all aspects of the production (or compounding) and testing of the dosage form. In vitro release (disintegration and dissolution) testing is commonly used as a surrogate to demonstrate consistent availability of the API from the formulated dosage.

Manufacture—Although detailed instructions about the manufacture of any of these dosage forms are beyond the scope of this general information chapter, general manufacturing principles have been included, as well as suggested testing for proper use and storage. Further information relative to extemporaneous compounding of dosage forms can be found in *Pharmaceutical Compounding—Nonsterile Preparations* ⟨795⟩ and *Pharmaceutical Compounding—Sterile Preparations* ⟨797⟩.

Route of Administration—The primary routes of administration for pharmaceutical dosage forms can be defined as mucosal, oral, parenteral (by injection), inhalation, and topical/dermal, and each has subcategories as needed. Many tests employed to ensure quality generally are applied across all of the administration routes, but some tests are specific for individual routes. For example, products intended for injection must be evaluated for *Sterility* ⟨71⟩ and *Pyrogen Test* ⟨151⟩, and the manufacturing process (and sterilization technique) employed for parenterals (by injection) should ensure compliance with these tests. Tests for particulate matter may be required for solution dosage forms depending on the route of administration (e.g., by injection—*Particulate Matter in Injections* ⟨788⟩, or mucosal—*Particulate Matter in Ophthalmic Solutions* ⟨789⟩). Additionally, dosage forms intended for the inhalation route of administration must be monitored for particle size and spray pattern (for a metered-dose inhaler or dry-powder inhaler) and droplet size (for nasal sprays). Further information regarding administration routes and suggested testing can be found in the *Guide to General Chapters*, *Charts 4–8* and *10–13*.

An appropriate manufacturing process and testing regimen help ensure that a dosage form can meet the appropriate quality attributes for the intended route of administration.

PRODUCT QUALITY TESTS, GENERAL

ICH Guidance Q6A (available at www.ich.org) recommends specifications (list of tests, references to analytical procedures, and acceptance criteria) to ensure that commercialized drug products are safe and effective at the time of release and over their shelf life. Tests that are universally applied to ensure safety and efficacy (and strength, quality, and purity) include description, identification, assay, and impurities.

Description—According to the ICH guidance a qualitative description (size, shape, color, etc.) of the dosage form should be provided. The acceptance criteria should include the final acceptable appearance. If any of these characteristics change during manufacturing or storage, a quantitative procedure may be appropriate. It specifies the content or the label claim of the article. This parameter is not part of the USP dosage form monograph because it is product specific. USP monographs define the product by specifying the range of acceptable assayed content of the active substance(s) present in the dosage form, together with any additional information about the presence or absence of other components, excipients, or adjuvants.

Identification—Identification tests are discussed in the *General Notices and Requirements*. Identification tests should establish the identity of the drug or drugs present in the drug product and should discriminate between compounds of closely related structure that are likely to be present. Identification tests should be specific for the drug substances. The most conclusive test for identity is the infrared absorption spectrum (see *Spectrophotometry and Light-Scattering* ⟨851⟩ and *Spectrophotometric Identification Tests* ⟨197⟩). If no suitable infrared spectrum can be obtained, other analytical methods can be used. Near-infrared (NIR) or Raman spectrophotometric methods also could be acceptable as the sole identification method of the drug product formulation (see *Near-infrared Spectrophotometry* ⟨1119⟩ and *Raman Spectroscopy* ⟨1120⟩). Identification by a chromatographic retention time from a single procedure is not regarded as specific. The use of retention times from two chromatographic procedures for which the separation is based on different principles or a combination of tests in a single procedure can be acceptable (see *Chromatography* ⟨621⟩ and *Thin-Layer Chromatographic Identification Test* ⟨201⟩).

Assay—A specific and stability-indicating test should be used to determine the strength (API content) of the drug product. Some examples of these procedures are *Antibiotics—Microbial Assays* ⟨81⟩, *Chromatography* ⟨621⟩, or *Assay for Steroids* ⟨351⟩. In cases when the use of a nonspecific assay is justified, e.g., *Titrimetry* ⟨541⟩, other supporting analytical procedures should be used to achieve specificity. When evidence of excipient interference with a nonspecific assay exists, a procedure with demonstrated specificity should be used.

Impurities—Process impurities, synthetic by-products, and other inorganic and organic impurities may be present in the API and excipients used in the manufacture of the drug product. These impurities are evaluated by tests in API and excipients monographs. Impurities arising from degradation of the drug substance or from the drug-product manufacturing process should be monitored. *Residual Solvents* ⟨467⟩ is applied to all products where relevant.

In addition to the universal tests listed above, the following tests may be considered on a case-by-case basis.

Physicochemical Properties—Examples include *pH* ⟨791⟩, *Viscosity* ⟨911⟩, and *Specific Gravity* ⟨841⟩.

Particle Size—For some dosage forms, particle size can have a significant effect on dissolution rates, bioavailability, therapeutic outcome, and stability. Procedures such as *Aerosols, Nasal Sprays, Metered-Dose Inhalers, and Dry Powder Inhalers* ⟨601⟩, and *Particle Size Distribution Estimation by Analytical Sieving* ⟨786⟩ could be used.

Uniformity of Dosage Units—See discussion of dose uniformity above.

Water Content—A test for water content is included when appropriate (see *Water Determination* ⟨921⟩).

Microbial Limits—The type of microbial test(s) and acceptance criteria are based on the nature of the drug substance, method of manufacture, and the route of administration (see *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* ⟨61⟩ and *Microbiological Examination of Nonsterile Products: Tests for Specified Microorganisms* ⟨62⟩).

Antimicrobial Preservative Content—Acceptance criteria for preservative content in multidose products should be established. They are based on the levels of antimicrobial preservative necessary to maintain the product's microbiological quality at all stages throughout its proposed usage and shelf life (see *Antimicrobial Effectiveness Testing* ⟨51⟩).

Antioxidant Preservative Content—If antioxidant preservatives are present in the drug product, tests of their content should be performed.

Sterility—Depending on the route of administration—e.g., ophthalmic preparations, implants, and solutions for injection—sterility of the product is demonstrated as appropriate (see *Sterility Tests* ⟨71⟩).

Dissolution—A test to measure release of the drug substance(s) from the drug product normally is included for dosage forms such as tablets, capsules, suspensions, granules for suspensions, implants, transdermal delivery systems, and medicated chewing gums. Single-point measurements typically are used for immediate-release dosage forms. For modified-release dosage forms, appropriate test conditions and sampling procedures are established as needed (see *Dissolution* ⟨711⟩ and *Drug Release* ⟨724⟩). In some cases, dissolution testing may be replaced by disintegration testing (see *Disintegration* ⟨701⟩).

Hardness and Friability—These parameters are evaluated as in-process controls. Acceptance criteria depend on packaging, supply chain, and intended use (see *Tablet Friability* ⟨1216⟩ and *Tablet Breaking Force* ⟨1217⟩).

Extractables—When evidence exists that extractables from the container-closure systems (e.g., rubber stopper, cap liner, or plastic bottle) have an impact on the safety or efficacy of the drug product, a test is included to evaluate the presence of extractables and leachables.

Depending on the type and composition of the dosage form, other tests such as alcohol content, redispersibility, particle size distribution, rheological properties, reconstitution time, endotoxins/pyrogens, particulate matter, functionality testing of delivery systems, and osmolarity may be necessary.

DOSAGE FORMS

Aerosols

Aerosols are preparations packaged under pressure and contain therapeutic agent(s) and a propellant that are released upon activation of an appropriate valve system. Upon activation of the valve system, the drug substance is released as a plume of fine particles or droplets. Only one dose is released from the preparation upon activation of a metered valve. In the case of topical products, activation of the valve results in a continuous release of the formulation.

In this chapter, the aerosol dosage form refers only to those products packaged under pressure that release a fine mist of particles or droplets when activated (see *Glossary*). Other products that produce dispersions of fine droplets or particles will be covered in subsequent sections (e.g., *Dry Powder Inhalers* and *Sprays*).

TYPICAL COMPONENTS

Typical components of aerosols are the formulation containing one or more drug substances and propellant, the container, the valve, and the actuator. Each component plays a role in determining various characteristics of the emitted plume, such as droplet or particle size distribution, uniformity of delivery of the therapeutic agent, delivery rate, and plume velocity and geometry. The metering valve and actuator act in tandem to generate the plume of droplets or particles. The metering valve allows measure of an accurate volume of the liquid formulation under pressure within the container. The activator directs the metered volume to a small orifice that is open to the atmosphere. Upon activation, the formulation is forced through the opening, forming the fine mist of particles that are directed to the site of administration.

Aerosol preparations may consist of either a two-phase (gas and liquid) or a three-phase (gas, liquid, and solid or liquid) formulation. The two-phase formulation consists of drug(s) dissolved in liquefied propellant. Liquid cosolvents, such as alcohol, propylene glycol, and polyethylene glycols often are added to enhance the solubility of the drug substance(s). Three phase inhalation and nasal aerosol systems consist of a suspension or emulsion of the drug substance(s) [i.e., API(s)] in addition to the vaporizable propellants. The suspension or emulsion of the finely divided drug substance typically is dispersed in the liquid propellant with the aid of suitable biocompatible surfactants or other excipients.

Propellants for aerosol formulations are typically low molecular weight hydrofluorocarbons or hydrocarbons that are liquid when constrained in the container, exhibit a suitable vapor pressure at room temperature, and are biocompatible and nonirritating. Compressed gases do not supply a constant pressure over use and typically are not employed as propellants.

Metal containers can withstand the vapor pressure produced by the propellant and reduce the opportunity that leachable components will enter the formulation. Excess formulation may be added to the container to ensure that the full number of labeled doses can be accurately administered. The container and closure must be able to withstand the pressures anticipated under normal use conditions as well as when the system is exposed to elevated temperatures.

TYPES OF AEROSOL DOSAGE FORMS

Aerosol dosage forms can be delivered via various routes. The design of the container and metering valve, as well as the formulation, are designed to target the site of administration.

Inhalation aerosols are intended to produce fine particles or droplets for inhalation through the mouth and deposition in the pulmonary tree. The design of the delivery system releases one dose with each actuation. These products are commonly known as metered-dose inhalers.

Nasal aerosols produce fine particles or droplets for inhalation through the nasal vestibule and deposition in the nasal cavity. One dose is released with each activation of the valve.

Lingual aerosols are intended to produce fine particles or droplets for deposition in the mouth. The design of the delivery system releases one dose with each actuation.

Topical aerosols produce fine particles or droplets for application to the skin. Formulations that are intended for inhalation, nasal, or lingual administration are typically aqueous based, but topical aerosols may utilize nonaqueous solvents to achieve rapid drying or disinfectant action for abraded skin surfaces.

PACKAGING

The accuracy of a system's delivered dose is demonstrated at the range of pressures likely to be encountered as a result of ambient temperature variations or storage in a refrigerator. As an alternative, the system should include clear instructions for use to ensure the container and contents have been equilibrated to room temperature prior to use.

LABELING FOR PROPER USE

Typical warning statements include:

- Contents under pressure. Do not puncture or incinerate container.
- Do not expose to heat or store at temperatures above 49°.

- Keep out of the reach of children unless otherwise prescribed.
- Use only as directed; intentional misuse by deliberate concentration and inhaling of the contents can be harmful or fatal.

Many experts recommend the addition of a statement indicating that patients and/or consumers should seek advice and instruction from a health care professional about the proper use of the device.

Capsules

Capsules are solid dosage forms in which the API and excipients are enclosed within a soluble container or shell. The shells may be composed of two pieces, a body and a cap, or they may be composed of a single piece. Two-piece capsules are commonly referred to as hard-shell capsules, and one-piece capsules are often referred to as soft-shell capsules. This distinction, although it is imprecise, reflects differing levels of plasticizers in the two compositions and the fact that one-piece capsules typically are more pliable than two-piece capsules.

The shells of capsules usually are made from gelatin. However, they also may be made from cellulose polymers or other suitable material. Most capsules are designed for oral administration.

Two-Piece or Hard-Shell Capsules—Two-piece capsules consist of two telescoping cap and body pieces in a range of standard sizes.

One-Piece or Soft-Shell Capsules—One-piece capsules typically are used to deliver an API as a solution or suspension. Liquid formulations placed into one-piece capsules may offer advantages by comparison with dry-filled capsules and tablets in achieving content uniformity of potent APIs or acceptable dissolution of APIs with poor aqueous solubility. Because the contact between the shell wall and its liquid contents is more intimate than in dry-filled capsules, undesired interactions may be more likely to occur (including gelatin crosslinking and pellicle formation).

Modified-Release Capsules—The release of APIs from capsules can be modified in several ways, including coating the filled capsule shells or the contents in the case of dry-filled capsules.

Delayed-Release Capsules—Capsules sometimes are formulated to include enteric-coated granules to protect acid-labile APIs from the gastric environment or to prevent adverse events such as irritation. Enteric-coated multiparticulate capsule dosage forms may reduce variability in bioavailability associated with gastric emptying times for larger particles (i.e., tablets) and to minimize the likelihood of a therapeutic failure when coating defects occur during manufacturing.

PREPARATION

Two-Piece Capsules—Two-piece gelatin capsules usually are formed from blends of gelatins that have relatively high gel strength in order to optimize shell clarity and toughness or from hypromellose. They also may contain colorants such as D&C and FD&C dyes[3] or various iron oxides, opaquing agents such as titanium dioxide, dispersing agents, and preservatives. Gelatin capsule shells normally contain between 12% and 16% water.

[3] In 1960 Congress enacted the Color Additive Amendments, requiring FDA to regulate dyes, pigments, or other coloring agents in foods, drugs, and cosmetics separately from food additives. Under the law, color additives are deemed unsafe unless they are used in compliance with FDA regulations. The law provides a framework for the listing and certification of color additives. See FDCA section 721; see FDA regulations at 21 CFR Part 70. Colors must also be listed in pertinent FDA regulations for specific uses; the list of color additives for drugs that are exempt from certification is published at 21 CFR Part 73, Subpart B. FDA also conducts a certification program for batches of color additives that are required to be certified before sale; see 21 CFR Part 74 (Subpart B re: drugs). Regulations regarding certification procedures, general specifications, and the listing of certified provisionally listed colors, are at 21 CFR Part 80. FDA maintains a color additives website, with links to various legal and regulatory resources, at: http://www.cfsan.fda.gov/~dms/coltoc.html

The shells are manufactured in one set of operations and later filled in a separate manufacturing process. Two-piece shell capsules are made by a process that involves dipping shaped pins into gelatin or hypromellose solutions, followed by drying, cutting, and joining steps.

Powder formulations for two-piece gelatin capsules generally consist of the API and at least one excipient. Both the formulation and the method of filling can affect release of the API. In the filling operation, the body and cap of the shell are separated before filling. Following the filling operation, the machinery rejoins the body and cap and ensures satisfactory closure of the capsule by exerting appropriate force on the two pieces. The joined capsules can be sealed after filling by a band at the joint of the body and cap or by other suitable means. In compounding prescription practice, two-piece capsules may be hand-filled. This permits the prescriber the choice of selecting either a single API or a combination of APIs at the exact dose level considered best for an individual patient.

One-Piece Capsules—One-piece shell capsules are formed, filled, and sealed in a single process on the same machine and are available in a wide variety of sizes, shapes, and colors. The most common type of one-piece capsule is that produced by a rotary die process that results in a capsule with a seam. The soft gelatin shell is somewhat thicker than that of two-piece capsules and is plasticized by the addition of polyols such as glycerin, sorbitol, or other suitable material. The ratio of the plasticizer to the gelatin can be varied to change the flexibility of the shell depending on the nature of the fill material, its intended usage, or environmental conditions.

In most cases, one-piece capsules are filled with liquids. Typically, APIs are dissolved or suspended in a liquid vehicle. Classically, an oleaginous vehicle such as a vegetable oil was used. However, nonaqueous, water-miscible liquid vehicles such as the lower molecular weight polyethylene glycols now are more common. The physicochemical properties of the vehicle can be chosen to ensure stability of the API as well as to influence the release profile from the capsule shell.

Dry Powder Inhalers

The dry powder inhaler (DPI) consists of a mixture of drug(s) and carrier, and all components exist in a finely divided solid state packaged as a unit dose. The dose is released from the packaging by an appropriate mechanism and is mobilized into a fine mist only upon oral inhalation by the patient.

TYPICAL COMPONENTS

The basic components of the DPI are the formulation consisting of the drug(s) and carrier, both in the dry state; packaging that contains an amount equivalent to a unit dose; and a mechanism designed to open the unit-dose container and permit mobilization of the powders by the patient inhaling through the built-in mouthpiece. Typically, the unit-dose container is either a capsule made of gelatin or other suitable non-animal-derived material (e.g., hypromellose or starch), or the container may consist of a series of unit doses in foil-lined blisters arranged in a strip. When the drug is contained in a capsule, release of the medication takes place when the capsule is pierced. As a consequence of this release mechanism, the device is designed to minimize the generation of capsule fragments that might subsequently be inhaled. When the drug is contained in a blister pack, the mechanism is designed to advance an unused blister to a platform where the foil lining can be peeled back to expose the powder mixture to an air stream created when the patient inhales. To facilitate dosing compliance, some delivery devices incorporate dosing administration information such as number of doses remaining.

PACKAGING

For drug contained in blister-pack strips, the packs must be designed to allow individual blister cavities to be opened without compromising the seal of adjacent cavities. Package components must provide acceptable protection from humidity, light, and/or oxygen as appropriate. Containers for DPIs typically are made of plastic, but metal may be suitable. Packaging for the encapsulated drug must provide protection from humidity extremes to ensure that capsule breakage will occur in the desired fashion.

LABELING AND USE

Typical warning statements include:

- Keep out of the reach of children unless otherwise prescribed.
- Do not attempt to dissemble mechanism. Discard the device after all doses have been administered.
- Keep the device level while in use.
- Do not breathe into the device.

Many experts recommend the addition of a statement indicating that patients and/or consumers should seek advice and instruction from a health care professional about the proper use of the device.

Emulsions (Creams and Lotions)

Creams—Creams are semisolid emulsion dosage forms. They often contain more than 20% water and volatiles and typically contain less than 50% hydrocarbons, waxes, or polyols as the vehicle for the API. Creams generally are intended for external application to the skin or to the mucous membranes. Creams have a relatively soft, spreadable consistency and can be formulated as either a water-in-oil emulsion (e.g., *Cold Cream* or *Fatty Cream* as in the *European Pharmacopoeia*) or as an oil-in-water emulsion (e.g., *Betamethasone Valerate Cream*). Creams generally are described as either nonwashable or washable, reflecting the fact that an emulsion with an aqueous external continuous phase is more easily removed than one with a nonaqueous external phase (water-in-oil emulsion). Where the term ''cream'' is used without qualification, a water-washable product is generally inferred.

Lotions—Lotions are an emulsified liquid dosage form generally intended for external application to the skin. Historically, some topical suspensions such as calamine lotion have been called lotions but that nomenclature is not currently preferred. Lotions share many characteristics with creams. The distinguishing factor is that they are more fluid than semisolid and thus pourable. Due to their fluid character, lotions are more easily applied to large skin surfaces than semisolid preparations. Lotions may contain antimicrobial agents as preservatives.

PREPARATION

Pharmaceutical Compounding—Nonsterile Preparations ⟨795⟩ provides general information regarding the preparation of emulsions.

Creams—Creams may be formulated from a variety of oils, both mineral and vegetable, and from fatty alcohols, fatty acids, and fatty esters. The solid excipients are melted at the time of preparation. Emulsifying agents include nonionic surfactants, detergents, and soaps. Soaps are usually formed from a fatty acid in the oil phase hydrolyzed by a base dissolved in the aqueous phase in situ during the preparation of creams.

Preparation usually involves separating the formula components into two portions: lipid and aqueous. The lipid portion contains all water-insoluble components and the aqueous portion the water-soluble components. Both phases are heated to a temperature above the melting point of the highest melting component. The phases then are mixed and the mixture is stirred until reaching

ambient temperature or the mixture has congealed. Mixing generally is continued during the cooling process to promote uniformity. Traditionally, the aqueous phase is added to the lipid phase, but comparable results have been obtained with the reverse procedure. High-shear homogenation may be employed to reduce particle or droplet size and improve the physical stability of the resultant dosage form.

The API(s) can be added to the phase in which it is soluble at the beginning of the manufacturing process, or it can be added after the cream is prepared by a suitable dispersion process such as levigation or milling with a roller mill. Creams usually require the addition of a preservative(s) unless they are compounded immediately prior to use and intended to be consumed in a relatively short period of time.

Lotions—Lotions usually are prepared by dissolving or dispersing the API into the more appropriate phase (oil or water), adding the appropriate emulsifying or suspending agents, and mixing the oil and water phases to form a uniform fluid emulsion.

LABELING AND PACKAGING

Some products may require labeling directions indicating to shake well prior to application and to avoid freezing. Storage limits must be specifically indicated to prevent melting of semisolid components. Instructions to ensure proper dosing and administration must accompany the product. Tight containers are used for preparation and storage to prevent loss by evaporation.

Feed Additives

Feed additives are preparations used in veterinary medicine to deliver the API(s) via the water or food given to animals. The feed additive may be either a solid or liquid and sometimes is called a premix. Feed additives are further subdivided into three types.

TYPE A MEDICATED ARTICLES

Type A medicated articles are products containing one or more animal APIs, and that are sold to licensed feed mills or producers and are intended to be further diluted by mixing into food or water prior to consumption by the animals. Because these preparations are not actually dosed to animals, they are not considered dosage forms.

TYPE B MEDICATED FEEDS

Type B medicated feeds are products that contain a type A medicated article, or another type B medicated feed, plus a substantial quantity of nutrients (not less than 25% of the total weight). Like type A medicated articles, type B medicated feeds are intended for mixture with food or water and additional nutrients, are not to be fed directly to the animals, and are not considered dosage forms.

TYPE C MEDICATED FEEDS

Type C medicated feeds are made from type A medicated articles or type B medicated feeds and are prepared at concentrations of the API appropriate for administration to animals by mixing in food or water. Administration of type C medicated feeds can be accomplished by blending directly into the feed; top-dressing the preparation onto the animal's normal daily rations; or heating, steaming, and extruding into pellets that are mixed or top-dressed onto the animal's food. Another form of type C medicated feeds is compressed or molded blocks from which animals receive the API or nutrients via licking the block.

PREPARATION

Type A medicated articles that are liquids are produced by mixing the API(s) with a suitable solvent (e.g., water or propylene glycol). The API(s) is usually dissolved to produce a solution, but suspension products also could be produced.

Type A medicated articles that are solids are produced by blending the API with excipients to provide a uniform dosage form when mixed with the animal's feed. Often the API is first mixed with an excipient (e.g., starch or sodium aluminosilicate) that has a similar particle size and can help distribute the API uniformly throughout the final drug product. This pre-blend is then mixed with bulking excipients (e.g., calcium carbonate or soybean hulls). Mineral oil may be added to aid uniform distribution, to prevent particle segregation during shipping, and to minimize formation of airborne API particles during production of type B or C medicated feeds.

Type B or C medicated feeds are produced at licensed feed mills or by farm producers. Type A medicated articles are added to the feeds (e.g., ground corn or oats) during the milling process of making feeds. Liquid type A medicated articles often are sprayed in at set rates, and solid type A medicated articles are added slowly to aid in creating uniform distribution in the feeds. Liquid type A medicated articles can also be mixed in with bulk water sources at prescribed amounts.

LABELING AND PACKAGING

Type A medicated articles or type B medicated feeds include special labeling to indicate that they should be used in the manufacture of animal feeds or added to the drinking water. The labels indicate that they are not to be fed directly to animals. Also included is a statement indicating ''Not for Human Use''. Type A medicated articles or type B medicated feeds are packaged either in paper bags, often with polyethylene liners, for solids and in plastic containers for liquids. Typical sizes are 50-lb bags or several-gallon containers.

Foams

Medicated foams are emulsions containing a dispersed phase of gas bubbles in a liquid continuous phase containing the API. Medicated foams are packaged in pressurized containers or special dispensing devices and are intended for application to the skin or mucous membranes. The medicated foam is formed at the time of application. Surfactants are used to ensure the dispersion of the gas and the two phases. Medicated foams have a fluffy, semisolid consistency and can be formulated to break to a liquid quickly or to remain as foam to ensure prolonged contact.

Medicated foams intended to treat severely injured skin or open wounds must be sterile.

PREPARATION

A foam may contain one or more APIs, surfactants, aqueous or nonaqueous liquids, and the propellants. If the propellant is in the internal (discontinuous) phase (i.e., is of the oil-in-water type), a stable foam is discharged. If the propellant is in the external (continuous) phase (i.e., is of the water-in-oil type), a spray or a quick-breaking foam is discharged. Quick-breaking foams formulated with alcohol create a cooling sensation when applied to the skin and may have disinfectant properties.

LABELING AND USE

Foams formulated with flammable components should be appropriately labeled. Labeling indicates that prior to dispensing, a foam drug product is shaken well to ensure uniformity. The instructions for use must clearly note spe-

cial precautions that are necessary to preserve sterility. In the absence of a metering valve, delivered volume may be variable.

Medical Gases (Inhalation Materials)

Medical gases are products that are administered directly as a gas. A medical gas has a direct pharmacological action or acts as a diluent for another medical gas. Gases employed as excipients for administration of aerosol products, as an adjuvant in packaging, or produced by other dosage forms, are not included in this definition.

Components—Medical gases may be single components or defined mixtures of components. Mixtures also can be extemporaneously prepared at the point of use.

Administration—Medical gases may be administered to the patient via the pulmonary route or via extracorporeal methods. The dose of medical gas typically is metered by a volume rate of flow under ambient temperature and pressure conditions. Administration of a highly compressed gas generally requires a regulator to decrease the pressure, a variable-volume flow controller, and suitable tubing to conduct the gas to the patient. For pulmonary administration, the gas flow will be directed to the nose or mouth by a suitable device or into the trachea through a mechanical ventilator. When medical gases are administered chronically, provision for humidification is common. Care should be exercised to avoid microbial contamination.

STORAGE

Medical gases are stored in a compressed state in cylinders or other suitable containers. The containers must be constructed of materials that can safely withstand the expected pressure and must be impact resistant. In some cases each container holds a single defined dose (e.g., general anesthetics), but in other cases the container holds sufficient gas for extended administration.

SPECIAL CONSIDERATIONS

The container and system fittings should be appropriate for the medical gas. Adaptors should not be used to connect containers to patient-use supply system piping or equipment. Large quantities of gases such as oxygen or nitrogen can be stored in the liquid state in a cryogenic container and converted into a gas, as needed, by evaporation. Additional rules concerning the construction and use of cryogenic containers are promulgated by governmental agencies (e.g., U.S. Department of Commerce).

Containers, tubing, and administration masks employed for gases containing oxygen are free of any compound that would be sensitive to oxidation or that would be irritating to the respiratory tract.

A significant fraction of the dose of a medical gas may be released into the general vicinity of the patient due to incomplete absorption. Adequate ventilation may be necessary to protect health care workers and others from exposure to the gas (e.g., nitrous oxide).

LABELING

Warning statements to be placed on pressurized containers include:

- Contents under pressure.
- Do not puncture or incinerate container.
- Do not expose to heat or store at temperatures above 49°.
- Keep out of the reach of children unless otherwise prescribed.
- Use only as directed; intentional misuse may be harmful or fatal.

If required under the individual monograph, label to indicate method of manufacture (such as oxygen via air liquefaction). When piped directly from the storage container to the point of use, the gas must be labeled for content at each outlet.

When oxygen is in use, a posted warning should indicate the necessity of extinguishing smoking materials and avoiding the use of open flames or other potential ignition sources.

Gels

Gels (sometimes called jellies) are semisolid systems consisting either of suspensions of small inorganic particles or of organic molecules interpenetrated by a liquid. Gels can be classed either as single-phase or two-phase systems.

A two-phase gel consists of a network of small discrete particles (e.g., *Aluminum Hydroxide Gel* or *Psyllium Hemicellulose*). In a two-phase system the gel mass sometimes is referred to as a magma (e.g., *Bentonite Magma*) if the particle size of the suspended material is large. Both gels and magmas may be thixotropic, forming semisolids on standing and becoming liquid on agitation. They should be shaken before use to ensure homogeneity and should be so labeled (see *Suspensions*).

Single-phase gels consist of organic macromolecules uniformly distributed throughout a liquid in such a manner that no apparent boundaries exist between the dispersed macromolecules and the liquid. Single-phase gels may be made from natural or synthetic macromolecules (e.g., *Carbomer*, *Hydroxypropyl Methylcellulose*, or *Starch*) or natural gums (e.g., *Tragacanth*). The latter preparations are also called mucilages. Although these gels commonly are aqueous, alcohols and oils may be used as the continuous phase. For example, mineral oil can be combined with a polyethylene resin to form an oleaginous ointment base.

Gels can be administered by the topical or mucosal routes. Gels containing antibiotics administered by teat infusion are often the dosage form used in veterinary medicine to treat mastitis.

PREPARATION

See *Pharmaceutical Compounding—Nonsterile Preparations* ⟨795⟩ for general procedures. Also see the information contained under *Dosage Forms, Suspensions* for the formulation and manufacture of gels containing inorganic components or APIs in the solid phase. See *Pharmaceutical Compounding—Sterile Preparations* ⟨797⟩ for general procedures for the preparation of sterile gels such as *Lidocaine Hydrochloride Jelly*.

Gels formed with large organic molecules may be formed by dispersing the molecule in the continuous phase (e.g., by heating starch), by cross-linking the dispersed molecules by changing the pH (as for *Carbomer Copolymer*), or by reducing the continuous phase (as for jellies formed with sucrose).

Care should be taken to ensure uniformity of the APIs by dispersing them by vigorous mixing or milling or by shaking if the preparation is less viscous.

PACKAGING AND STORAGE

Store in tight containers to prevent water loss. Avoid freezing.

Granules

Granules are solid dosage forms that are composed of agglomerations of smaller particles. These multicomponent compositions are prepared for oral administration and are used to facilitate flexible dosing regimens, address stability challenges, allow taste masking, or facilitate flexibility in administration (for instance, to pediatric patients, geriatric patients, or animals). Granular dosage forms may be formulated for direct oral administration and may facilitate compounding of multiple APIs by allowing compounding pharmacists to blend various granular compositions in the retail or hospital pharmacy. More commonly, granules are reconsti-

tuted to a suspension by the addition of water or a supplied liquid diluent immediately prior to delivery to the patient. Effervescent granules are formulated to liberate gas (carbon dioxide) upon addition of water. Common examples of effervescent granules include antacid and potassium supplementation preparations. Common therapeutic classes formulated as granule dosage forms include antibiotics, certain laxatives (such as senna extract products), electrolytes, and various cough and cold remedies that contain multiple APIs.

Granular dosages also are employed in veterinary medicine when they are often placed on top of or mixed with an animal's food. They are frequently provided with a measuring device to allow addition to feeds. The resultant mix facilitates dosing.

PREPARATION

Granules often are the precursors used in tablet compression or capsule filling. Although this application represents a pharmaceutical intermediate and not a final dosage form, numerous commercial products are based on granules. In the typical manufacture of granules, the API is blended with excipients (processing aids) and wetted with an appropriate pharmaceutical solvent or blend of solvents to promote agglomeration. This composition is dried and sized to yield the desired material properties.

Frequently, granules are used because the API is unstable in aqueous environments and cannot be exposed to water for periods sufficient to accommodate manufacture, storage, and distribution in a suspension. Preparation of the liquid dosage form from the granules immediately prior to dispensing allows acceptable stability for the duration of use. Granules manufactured for this purpose are packaged in quantities sufficient for a limited time period—usually one course of therapy that typically does not exceed 2 weeks. In addition to the API, other ingredients may be added to ensure acceptable stability (e.g., buffers, antioxidants, or chelating agents) or to provide color, sweetness, flavor, and for suspensions, acceptable viscosity to ensure adequate suspension of the particulate to enable uniform dosing.

Effervescent granules typically are formulated from sodium or potassium bicarbonate and an acid such as citric or tartaric acid. To prevent untimely generation of carbon dioxide, manufacturers should take special precautions to limit residual water in the product due to manufacture and to select packaging that protects the product from moisture. The manufacture of effervescent granules can require specialized facilities designed to maintain very low humidity (approximately 10% relative humidity). Effervescent powder mixtures are purposely formed into relatively course granules to reduce the rate of dissolution and provide a more controlled effervescence.

PACKAGING AND STORAGE

Granules for reconstitution may be packaged in unit-of-use containers or in containers with sufficient quantities to accommodate a typical course of therapy (frequently 10 days to 2 weeks with antibiotic products). Packaging should provide suitable protection from moisture. This is particularly true for effervescent granules. Granules may be stored under controlled room temperature conditions unless other conditions are specifically noted.

Many granule products specify refrigerated storage following reconstitution and direct the patient to discard unused contents after a specified date that is based on the stability of the API in the reconstituted preparation.

LABELING AND USE

Effervescent granules (and tablets) are labeled to indicate that they are not to be swallowed directly.

Reconstitution of granules must ensure complete wetting of all ingredients and sufficient time and agitation to allow the soluble components to dissolve. Specific instructions for reconstitution provided by the manufacturer should be carefully followed.

Reconstituted suspensions should be shaken before use to re-suspend the dispersed particulates. This is especially true of suspension preparations dosed from multiple-dose containers. For particularly viscous suspensions prone to air entrapment, instructions may advise the user how to shake the preparation to re-suspend settled particulates while minimizing air entrapment.

SPECIAL CONSIDERATIONS

For granules reconstituted to form suspensions for oral administration, acceptable suspension of the particulate phase depends on the particle size of the dispersed phase as well as the viscosity of the vehicle. Temperature can influence the viscosity, which influences suspension properties and the ease of removal of the dose from the bottle. In addition, temperature cycling can lead to changes in the particle size of the dispersed phase via Ostwald ripening. Thus, clear instructions should be provided regarding the appropriate storage temperature for the product.

Medicated Gums

Medicated gum is a semisolid confection that is designed to be chewed rather than swallowed. Medicated gums release the API(s) into the saliva. Medicated gums can deliver therapeutic agents for local action in the mouth (such as antibiotics to control gum disease) or for systemic absorption via the buccal or gastrointestinal routes (e.g., nicotine or aspirin). Most medicated gums are manufactured using the conventional melting process derived from the confectionary industry or alternatively may be directly compressed from gum powder. Medicated gums are formulated from insoluble synthetic gum bases such as polyisoprene, polyisobutylene, isobutyleneisoprene copolymer, styrene butadiene rubber, polyvinyl acetate, polyethylene, ester gums, or polyterpenes. Plasticizers and softeners such as propylene glycol, glycerin, oleic acid, or processed vegetable oils are added to keep the gum base pliable and to aid incorporation of the API(s), sweeteners, and flavoring agents. Sugars as well as artificial sweeteners and flavorings are incorporated to improve taste, and dyes may be used to enhance appearance. Some medicated gums are coated with magnesium stearate to reduce tackiness and improve handling during packaging. A preservative may be added.

PREPARATION

Melted Gum—The gum base is melted at a temperature of about 115° until it has the viscosity of thick syrup and at that point is filtered through a fine-mesh screen. This molten gum base is transferred to mixing tanks where the sweeteners, plasticizers, and typically the API are added and mixed. Colorings, flavorings, and preservatives are added and mixed while the melted gum is cooling. The cooled mixture is shaped by extrusion or rolling and cutting. Dosage units of the desired shape and potency are packaged individually. Additional coatings such as powder coatings to reduce tackiness or film or sugar coatings may be added to improve taste or facilitate bulk packaging.

Directly Compressed Gum—The gum base is supplied in a free-flowing granular powder form. The powder gum base is then dry blended with sweeteners, flavors, the API, and lubricant. The blend is then processed through a conventional tablet press and tableted into desired shapes. The resulting medicated gum tablets

can be further coated with sugar or sugar-free excipients. These tablets can be packaged in blisters or bottles as needed.

SPECIAL CONSIDERATIONS

Medicated gums are typically dispensed in unit-dose packaging. The patient instructions also may include a caution to avoid excessive heat.

Implants

Implants are long-acting dosage forms that provide continuous release of the API for periods of months to years. They are administered by the parenteral route. For systemic delivery they may be placed subcutaneously, or for local delivery they can be placed in a specific region in the body.

Several types of implants are available. Pellet implants are small, sterile, solid masses composed of an API with or without excipients. They are usually administered by means of a suitable special injector (e.g., trocar) or by surgical incision. Release of the API from pellets typically is controlled by diffusion and dissolution kinetics. The size of the pellets and rate of erosion will influence the release rate, which typically follows first-order kinetics. Drug release from pellets for periods of 6 months or more is possible. Pellet implants have been used to provide extended delivery of hormones such as testosterone or estradiol.

Resorbable microparticles are a type of implants that provide extended release of drug over periods varying from a few weeks to months. They can be administered subcutaneously or intramuscularly for systemic delivery, or they may be deposited in a desired location in the body for site-specific delivery. Injectable resorbable microparticles (or microspheres) generally range from 20 to 100 μm in diameter. They are composed of a drug dispersed within a biocompatible, bioresorbable polymeric excipient (matrix). Poly(lactide-co-glycolide) polymers have been used frequently. These excipients typically resorb by hydrolysis of ester linkages. The microparticles are administered by suspension in an aqueous vehicle followed by injection with a conventional syringe and needle. Release of the drug from the microparticles begins after physiological fluid enters the polymer matrix, dissolving some of the drug that then is released by a diffusion-controlled process. Drug release also can occur as the matrix erodes.

Polymer implants can be formed as a single shaped mass such as a cylinder. The polymer matrix must be biocompatible, but it can be either biodegradable or non-biodegradable. Shaped polymer implants are administered by means of a suitable special injector. Release kinetics typically are not zero-order, but zero-order kinetics are possible. Drug release can be controlled by the diffusion of the API from the bulk polymer matrix or by the properties of a rate-limiting polymeric membrane coating. Polymer implants are used to deliver potent small molecules like steroids (e.g., estradiol for cattle) and large molecules like peptides [e.g., luteinizing hormone-releasing hormone (LHRH)]. Example durations of drug release are 2 and 3 months for biodegradable implants and 1 year for non-biodegradable implants. An advantage of biodegradable implants is that they do not require removal after release of all drug content. Non-biodegradable polymer implants can be removed before or after drug release is complete or may be left in situ. An implant can have a tab with a hole in it to facilitate suturing it in place, e.g., for an intravitreal implant for local ocular delivery. Such implants may provide therapeutic release for periods as long as 2.5 years.

Some implants are designed to form as a mass in situ. These implants are initially prepared as liquid formulations comprising polymer, API, and solvent for the polymer. The polymer solvent can be water or an organic solvent. After administration of the liquid formulation

to a patient by subcutaneous or intramuscular administration, it forms a gel or a solid polymeric matrix that traps the API and extends the API release for days or months. In situ-forming implants also are used for local delivery of the API to treat periodontal disease. The implant is formed within the periodontal pocket.

Another type of implant can be fabricated from a metal such as titanium and plastic components. These implants are administered by means of a suitable injector or by surgical installation. A solution of API inside the implant, like an LHRH solution, is released via an osmotically driven pump inside the implant. Duration of release may be as long as 1 year or more. Release kinetics are zero order. After the drug is delivered, metal-based implants are removed.

Drug-eluting stents combine the mechanical effect of the stent to maintain arterial patency with the prolonged pharmacologic effect of the incorporated API (to reduce restenosis, inhibit clot formation, or combat infection). As an example, a metal stent can be coated with a non-biodegradable or biodegradable polymer-containing API. The resultant coating is a polymeric matrix that controls the extended release of the API.

PREPARATION

Pellet implants are made by API compression or molding. Cylindrical polymeric implants typically are made by melt extrusion of a blend of API and polymer, resulting in a rod that is cut into shorter lengths. Polymer implants also can be made by injection molding. Still other implants are assembled from metal tubes and injection-molded plastic components.

Sterility can be achieved by terminal sterilization or by employing aseptic manufacturing procedures.

PACKAGING AND STORAGE

All implants are individually packaged (typically in their injector or for veterinary use in cartridges that are placed in the injector guns), are sterile (except for some animal health products), and conform to the appropriate standards for injection. Biodegradable implants are protected from moisture so the polymer does not hydrolyze and alter drug release kinetics before use.

Inserts

Inserts are solid dosage forms that are inserted into a body cavity other than the rectum (see *Suppositories*). The API is delivered in inserts for local or systemic action. Inserts applied to the eye, such as *Pilocarpine Ocular System*, typically are sterile. Vaginal inserts for humans are usually globular or oviform and weigh about 5 g each. Vaginal inserts for cattle are T-shaped, are formed of polymer, are removable, and can be used for up to 8 days. One veterinary application is for estrus synchronization. Inserts intended to dissolve in vaginal secretions usually are made from water-soluble or water-miscible vehicles such as polyethylene glycol or glycerinated gelatin. Vaginal inserts such as dinoprostone vaginal insert (e.g., see USP monograph *Dinoprostone Vaginal Suppositories*) are formulated to deliver medication to the cervix and to be removed or recovered once the API has been released. Intrauterine inserts such as *Progesterone Intrauterine Contraceptive System* are used to deliver APIs locally to achieve efficacy while reducing side effects. Some intrauterine inserts are formulated to remain in the uterus for extended periods of time. An intra-urethral insert of alprostadil is available for the treatment of erectile dysfunction.

PREPARATION

For general considerations see *Pharmaceutical Compounding—Nonsterile Preparations* ⟨795⟩. Inserts vary considerably in their preparation. Inserts may be molded (using technology similar to that employed to prepare lozenges, suppositories, or plastics), compressed from powders (as in tableting), or formulated as special applications of capsules (soft gelatin capsules and hard gelatin capsules have been employed for extemporaneously compounded preparations). Inserts may be formulated to melt at body temperature or disintegrate upon insertion. Design of the dosage form should take into consideration the fluid volume available at the insertion site and minimize the potential to cause local irritation. Most inserts are formulated to ensure retention at the site of administration.

STORAGE AND LABELING

Appropriate storage conditions must be clearly indicated in the labeling for all inserts, especially for those that are designed to melt at body temperature. Instructions to ensure proper dosing and administration must accompany the product.

Liquids

As a dosage form a liquid consists of a pure chemical in its liquid state. Examples include mineral oil, isoflurane, and ether. This dosage form term is not applied to solutions. In veterinary medicine liquids may be administered topically or diluted via mixing with drinking water or food.

STORAGE AND LABELING

Storage, packaging, and labeling consider the physical properties of the material and are designed to maintain potency and purity.

Lotions (see *Emulsions*)

Lozenges

Lozenges are solid oral dosage forms that are designed to dissolve or disintegrate slowly in the mouth. They contain one or more APIs that are slowly liberated from the flavored and sweetened base. They are frequently intended to provide local action in the oral cavity or the throat but also include those intended for systemic absorption after dissolution. The typical therapeutic categories of APIs delivered in lozenges are antiseptics, analgesics, decongestants, antitussives, and antibiotics. Molded lozenges are called cough drops or pastilles. Molded lozenges mounted on a stick are known as lollipops. Lozenges prepared by compression or by stamping or cutting from a uniform bed of paste sometimes are known as troches. Troches are often produced in a circular shape.

Lozenges can be made using sugars such as sucrose and dextrose or can provide the benefits of a sugar-free formulation that is usually based on sorbitol or mannitol. Polyethylene glycols and hypromellose sometimes are included to slow the rate of dissolution.

MANUFACTURE

Excipients used in molded lozenge manufacture include gelatin, fused sucrose, sorbitol, or another carbohydrate base.

Molded lozenges using a sucrose or sorbitol base containing APIs such as phenol, dextromethorphan, fentanyl, and dyclonine hydrochloride and menthol are

prepared by cooking the sugar (sucrose, corn syrup, and sorbitol) and water at about 150° to reduce the water content to less than 2%. The molten sugar solution is transferred to a cooling belt or cooling table, and medicaments, flavorings, and colorings are added and thoroughly mixed while cooling. Individual dosage units of the desired shape are formed by filling the molten mass into molds. These lozenges are quickly cooled in the molds to trap the base in the glassy state. Once formed, the lozenges are removed from the molds and packaged. Care is taken to avoid excessive moisture during storage to prevent crystallization of the sugar base.

Compressed lozenges are made using excipients that may include a filler, binder, sweetening agent, flavoring agent, and lubricant. Sugars such as sucrose, sorbitol, and mannitol often are included because they can act as filler and binder as well as serve as sweetening agents. Approved FD&C and D&C dyes or lakes (dyes adsorbed onto insoluble aluminum hydroxide) also may be present.

The manufacturing of compressed lozenges is essentially the same as that for conventional tableting, with the exception that a tablet press capable of making larger tablets and exerting greater force to produce harder tablets may be required (see *Tablets*).

The paste used to produce lozenges manufactured by stamping or cutting contains a moistening agent, sucrose, and flavoring and sweetening agents. The homogenous paste is spread as a bed of uniform thickness, and the lozenges are cut or stamped from the bed and are allowed to dry. Some lozenges are prepared by forcing dampened powders under low pressure into mold cavities and then ejecting them onto suitable trays for drying at moderate temperatures.

PACKAGING AND STORAGE

Many lozenges are sensitive to moisture, and typically a monograph indicates that the package or container type is well closed and/or moisture resistant. Storage instructions may include protection from high humidity.

Ointments

Ointments are semisolid preparations intended for external application to the skin or mucous membranes. APIs delivered in ointments are intended for local action or for systemic absorption. Ointments usually contain less than 20% water and volatiles and more than 50% hydrocarbons, waxes, or polyols as the vehicle. Ointment bases recognized for use as vehicles fall into four general classes: hydrocarbon bases, absorption bases, water-removable bases, and water-soluble bases.

Hydrocarbon Bases—Also known as oleaginous ointment bases, they allow the incorporation of only small amounts of an aqueous component. Ointments prepared from hydrocarbon bases act as occlusive dressings and provide prolonged contact of the API with the skin. They are difficult to remove and do not change physical characteristics upon aging.

Absorption Bases—Allow the incorporation of aqueous solutions. Such bases include only anhydrous components (e.g., *Hydrophilic Petrolatum*) or water-in-oil emulsions (e.g., *Lanolin*). Absorption bases are also useful as emollients.

Water-Removable Bases—Oil-in-water emulsions (e.g., *Hydrophilic Ointment*) and are sometimes referred to as creams (see *Emulsions*). They may be readily washed from the skin or clothing with water, making them acceptable for cosmetic reasons. Other advantages of the water-removable bases are that they can be diluted with water and that they favor the absorption of serous discharges in dermatological conditions.

Water-Soluble Bases—Also known as greaseless ointment bases, they are formulated entirely from water-soluble constituents. *Polyethylene Glycol Ointment* is the only official preparation in this group. They offer many of the advantages of the water-removable bases and, in addition, contain no water-insoluble substances such as petrolatum, anhydrous lanolin, or waxes. They are more correctly categorized as gels (see *Gels*).

The choice of an ointment base depends on the action desired, the characteristics of the incorporated API, and the latter's bioavailability if systemic action is desired. The product's stability may require the use of a base that is less than ideal in meeting other quality attributes. APIs that hydrolyze rapidly, for example, are more stable in hydrocarbon bases than in bases that contain water.

Ophthalmic ointments are intended for application directly to the eye or eye-associated structures such as the subconjunctival sac. They are manufactured from sterilized ingredients under aseptic conditions and meet the requirements under *Sterility Tests* ⟨71⟩. Ingredients meeting the requirements described under *Sterility Tests* ⟨71⟩ are used if they are not suitable for sterilization procedures. Ophthalmic ointments in multiple-dose containers contain suitable antimicrobial agents to control microorganisms that might be introduced during use unless otherwise directed in the individual monograph or unless the formula itself is bacteriostatic (see *Ophthalmic Ointments* ⟨771⟩*, Added Substances*). The finished ointment is free from large particles and must meet the requirements for *Leakage* and for *Metal Particles* under *Ophthalmic Ointments* ⟨771⟩. The immediate container for ophthalmic ointments is sterile at the time of filling and closing. The immediate containers for ophthalmic ointments are sealed and made tamper-proof so that sterility is ensured at time of first use.

A suitable ophthalmic ointment base is nonirritating to the eye and permits diffusion of the API throughout the secretions bathing the eye. Petrolatum is most commonly used as a base for ophthalmic drugs. Some absorption bases, water-removable bases, and water-soluble bases may be desirable for water-soluble APIs if the bases are nonirritating.

MANUFACTURE

Ointments typically are prepared by either direct incorporation into a previously prepared ointment base or by fusion (heating during the preparation of the ointment). A levigating agent is often added to facilitate the incorporation of the medicament into the ointment base by the direct incorporation procedure. In the fusion method, the ingredients are heated, often in the range of 60° to 80°. Homogenization is often necessary. The rate of cooling is an important manufacturing detail because rapid cooling can impart increased structure to the product of the fusion method.

PACKAGING AND STORAGE

Protect from moisture. For emulsified systems, temperature extremes can lead to physical instability of the preparation. When this is the case products should be clearly labeled to specify appropriate storage conditions. Ointments typically are packaged either in ointment jars or ointment tubes. Ointment jars are often used for more viscous ointments that do not require sterility. Ointment tubes typically are used for less viscous ointments and those such as ophthalmic ointments that require the maintenance of sterility. The package sizes for ophthalmic preparations are controlled to minimize the likelihood of contamination and loss of sterility.

Pastes

Pastes are semisolid preparations of stiff consistency and contain a high percentage of finely dispersed solids. Pastes are intended for application to the skin, oral cavity, or mucous membranes. In veterinary practice, pastes are used for systemic delivery of APIs.

Pastes ordinarily do not flow at body temperature and thus can serve as occlusive, protective coatings. As a consequence, pastes are more often used for protective action than are ointments.

Fatty pastes that have a high proportion of hydrophilic solids appear less greasy and more absorptive than ointments. They are used to absorb serous secretions and are often preferred for acute lesions that have a tendency toward crusting, vesiculation, or oozing.

Dental pastes may be applied to the teeth, or alternatively they may be indicated for adhesion to the mucous membrane for a local effect (e.g., *Triamcinolone Acetonide Dental Paste*). Some paste preparations intended for animals are administered orally. The paste is squeezed into the mouth of the animal, generally at the back of the tongue, or is spread inside the mouth.

PREPARATION

Pastes can be prepared by direct incorporation or by fusion (the use of heat to soften the base). The solid ingredients often are incorporated following comminution and sieving. If a levigating agent is needed, a portion of the ointment base is often employed rather than a liquid.

LABELING AND STORAGE

Veterinary products should be labeled to ensure they are not administered to humans. Labeling should indicate the need for protection from heat.

Transdermal Systems (Patches)

Transdermal drug delivery systems (TDSs) are discrete dosage forms that are designed to deliver the API(s) through intact skin to the systemic circulation. Typically, a TDS is composed of an outer covering (barrier), a drug reservoir (possibly covered with a rate-controlling membrane), a contact adhesive applied to some or all parts of the system (to attach the TDS to the skin surface), and a protective layer that is removed before the patch is applied. The activity of a TDS is defined in terms of the release rate of the API(s) from the system. The total duration of drug release from the system and the system surface area also may be stated.

Most TDSs can be considered either matrix-type or reservoir-type systems. Matrix-type patches are often further divided into monolithic adhesive matrix or polymer matrix types. Reservoir-type systems include liquid reservoir systems and solid-state reservoir systems. Solid-state reservoir patches also include multilaminate adhesive and multilaminate polymer matrix systems.

Drug delivery from some TDSs is controlled by diffusion kinetics. The API diffuses from the drug reservoir directly or through the rate-controlling membrane and/or contact adhesive and then through the skin into the general circulation. Modified-release systems are generally designed to provide drug delivery at a constant rate so that a true steady-state blood concentration is achieved and maintained until the system is removed. Other TDSs work by active transport of the API. For example, iontophoretic transdermal delivery uses the current between two electrodes to enhance the movement of ionized APIs through the skin.

TDSs are applied to the body areas recommended by the labeling. The API content of the system provides a reservoir that, by design, maintains a constant API concentration at the system-skin interface. The dosing interval of the system is a function of the amount of API in the reservoir and the release rate. Some API concentration

may remain in the reservoir at the end of the dosing interval, in particular for diffusion-controlled delivery mechanisms. [NOTE—Where the API is intended for local action, it may be embedded in adhesive on a cloth or plastic backing. This type of product is more correctly called a plaster or tape (see *Plasters* and *Tapes*).]

PREPARATION

TDSs require a backing, a means of storing the API for delivery to the skin, an adhesive to attach the system to the skin, and a removable release liner to protect the adhesive, API, and excipients before application. The backing has low moisture- and vapor-transmission rates to support product stability. The adhesive layer may contain the API and permeation enhancers in the case of matrix-type systems or multi-laminate reservoir systems for which a priming dose is desired. Adhesive may be applied to the entire patch release surface or merely to the periphery. Liquid reservoir systems are often formed–filled–sealed between the backing and release-controlling materials. For monolithic adhesive matrix systems, the API and excipients are applied as a solution or suspension either to the backing or the release liner, and the solvent is allowed to evaporate.

PACKAGING AND STORAGE

Storage conditions are clearly specified because extreme temperature excursions can influence the performance of some systems.

LABELING

The labeling should clearly indicate any performance limitations of the system (e.g., influence of application site, hydration state, hair, or other variables).

Pellets

Pellets are dosage forms composed of small, solid particles of uniform shape sometimes called beads. Typically, pellets are nearly spherical but this is not required. Pellets may be administered by the oral (gastrointestinal) or by the injection route (see also *Implants*). Pellet formulations may provide several advantages including physical separation for chemically or physically incompatible materials, extended release of the API, or delayed release to protect an acid-labile API from degradation in the stomach or to protect stomach tissues from irritation. Extended-release pellet formulations may be designed with the API dispersed in a matrix, or the pellet may be coated with an appropriate polymer coating that modifies the drug-release characteristics. Alternatively, the pellet design may combine these two approaches. In the case of delayed-release formulations, the coating polymer is chosen to resist dissolution at the lower pH of the gastric environment but to dissolve in the higher pH intestinal environment. Injected or surgically administered pellet preparations (see *Implants*) are often used to provide continuous therapy for periods of months or years.

Pellet dosage forms may be designed as single or multiple entities. Often implanted pellets will contain the desired API content in one or several units. In veterinary practice, 4 to 8 pellets may be implanted in the ears for cattle, depending on animal size. Oral pellets typically are contained within hard gelatin capsules for administration. Although there are no absolute requirements for size, the useful size range of pellets is governed by the practical constraints of the volume of commonly used capsules and the need to include sufficient numbers of pellets in each dose to ensure uniform dosing of the API. As a result, many pellets used for oral administration fall within a size range of 8 to 24 mesh. Pellet formulations sometimes are used to minimize variability associated with larger dosage forms caused by gastric retention upon stomach emptying.

Enteric-coated (delayed-release) pellet formulations and some extended-release formulations are prepared by applying a coating to the formulated particles. The coating must be applied as a continuous film over the entire surface of each particle. Because a small population of imperfectly coated particles may be unavoidable, oral pellets are designed to require the administration of a large number in a single dose to minimize any adverse influence of imperfectly coated pellets on drug delivery.

PREPARATION

The desired performance characteristics determine the manufacturing method chosen. In general, pellet dosage forms are manufactured by wet extrusion processes followed by spheronization, by wet or dry coating processes, or by compression. Manufacture of pellets by wet coating usually involves the application of successive coatings upon nonpareil seeds. This manufacturing process frequently is conducted in fluid-bed processing equipment. Dry powder coating or layering processes often are performed in specialized rotor granulation equipment. The extent of particle growth achievable in wet coating processes is generally more limited than the growth that can be obtained with dry powder layering techniques, but either method allows the formulator to develop and apply multiple layers of coatings to achieve the desired release profile. The manufacture of pellets by compression is largely restricted to the production of material for subcutaneous implantation. This method of manufacture provides the necessary control to ensure dose uniformity and generally is better suited to aseptic processing requirements.

Alternatively, microencapsulation techniques can be used to manufacture pellets. Coacervation coating techniques typically produce coated particles that are much smaller than those made by other techniques.

PACKAGING AND STORAGE

Pellets for oral administration generally are filled into hard gelatin capsules and are placed in bottles or blister packages. The packaging provides suitable protection from moisture to ensure the stability of the pellet formulation as well as to preserve desirable moisture content of the capsule shells. Pellets for implantation are sterile and should be packaged in tight containers suitable for maintaining sterile contents. Pellets may be stored under controlled room temperature conditions unless other conditions are specifically noted.

LABELING AND USE

Pellets for oral administration that are formulated to provide delayed or controlled release must be swallowed intact to ensure preservation of the desired release characteristics. These products should be labeled accordingly to ensure that the material is not crushed or chewed during administration.

Pills

Pills are API-containing small round solid bodies intended for oral administration. At one time pills were the most extensively used oral dosage form, but they have been replaced by compressed tablets and capsules. Pills are distinguished from tablets because pills are manufactured by a wet massing and molding technique, while tablets are formed by compression.

PREPARATION

Excipients are selected on the basis of their ability to produce a mass that is firm and plastic. The API is triturated with powdered excipients in serial dilutions to attain a uniform mixture. Liquid excipients that act to bind and provide plasticity to the mass are subsequently added

to the dry materials. The mass is formed by kneading. The properties of firmness and plasticity are necessary to permit the mass to be worked and retain the shape produced. Cylindrical pill pipes are produced from portions of the mass. The pill pipe is cut into individual lengths corresponding to the intended pill size, and the pills are rolled to form the final shape. Pill-making machines can automate the preparation of the mass, production of pill piping, and the cutting and rolling of pills.

PACKAGING AND LABELING

Labeling and use instructions for pills are similar to those for tablets. Although many pills are resistant to breakage, some pills are friable. Appropriate handling guidelines should be provided in such cases in order to avoid breakage.

Plasters

A plaster is a semisolid substance for external application and usually is supplied on a support material. Plasters are applied for prolonged periods to provide protection, support, or occlusion (maceration).

Plasters consist of an adhesive layer that may contain active substances. This layer is spread uniformly on an appropriate support that is usually made of a rubber base or synthetic resin. Unmedicated plasters are designed to provide protection or mechanical support to the site of application. These plasters are neither irritating nor sensitizing to the skin.

Plasters are available in a range of sizes or cut to size to effectively provide prolonged contact to the site of application. They adhere firmly to the skin but can be peeled off the skin without causing injury.

One example of a plaster currently in use is salicylic acid plasters used for the removal of corns by the keratolytic action of salicylic acid.

PACKAGING AND STORAGE

Plasters are preserved in well-closed containers, preferably at controlled room temperature.

Powders

Powders are defined as a solid or a mixture of solids in a finely divided state intended for internal or external use. Powders used as pharmaceutical dosage forms may contain one or more APIs and can be mixed with water for oral administration or injection. Often pediatric antibiotics utilize a powder dosage form for improved stability. In some areas medicated powders are used for extemporaneous compounding of preparations for simultaneous administration of multiple APIs. Medicated powders also can be inhaled for pulmonary administration (see *Dry Powder Inhalers*). Aerosolized powders for the lungs typically contain processing aids to improve flow and ensure uniformity (see *Aerosols, Nasal Sprays, Metered-Dose Inhalers, and Dry Powder Inhalers* ⟨601⟩). Powders can also be used topically as a dusting powder.

Externally applied powders should have a particle size of 150 μm or less (typically in the 50- to 100-μm range) in order to prevent a gritty feel on the skin that could further irritate traumatized skin. Powders are grouped according to the following terms: very coarse, coarse, moderately coarse, fine, and very fine (see *Powder Fineness* ⟨811⟩). The performance of powder dosage forms can be affected by the physical characteristics of the powder. Particle size can influence the dissolution rate of the particles and affect bioavailability. For dispersed delivery systems, particle size can influence the mixing and segregation behavior of the particle, which in turn affects the uniformity of the dosage form.

PREPARATION

Powder dosage forms can be produced by the combination of multiple components into a uniform blend. This can also involve particle size reduction, a process referred to as comminution. Mills and pulverizers are used to reduce the particle size of powders when necessary. As the particle size is decreased, the number of particles and the surface area increase, which can increase the dissolution rate and bioavailability of the API.

Blending techniques for powders include those used in compounding pharmacy such as spatulation and trituration (see *Pharmaceutical Compounding Nonsterile Preparations* ⟨795⟩). Industrial processes may employ sifting or tumbling the powders in a rotating container. One of the most common tumble blenders is a V-blender, which is available in a variety of scales suitable for small-scale and large-scale compounding and industrial production.

Powder flow can be influenced by both particle size and shape. Larger particles generally flow more freely than do fine particles. Powder flow is an important attribute that can affect the packaging or dispensing of a medicated powder.

PACKAGING AND STORAGE

Powders for pharmaceutical use can be packaged in multiple- or single-unit containers. Bulk containers have been used for antacid powders and for laxative powders. In these instances the patient dissolves the directed amount in water prior to administration. This type of multiple-unit packaging is acceptable for many APIs but should not be utilized for powders that require exact dosing. Multiple-unit powders for topical application often are packaged in a container with a sifter top.

Potent APIs in a powder dosage form are dispensed in unit-of-use allocations in folded papers, cellophane envelopes, or packets. Powder boxes are often used by the dispensing pharmacist to hold multiple doses of individual folded papers. Hygroscopic powders pose special challenges and typically are dispensed in moisture-resistant packaging.

LABELING

Typical warning statements include:

- External powders must indicate: ''External Use Only''.
- Oral powders should indicate: ''For Oral Use Only''.
- Powders intended for veterinary use must indicate: ''For Veterinary Use Only''.

Individual monographs specify the labeling requirements for powder dosage forms that are listed in *USP–NF*. Oral powders for reconstitution prior to dispensing typically have a limited shelf life (for example, 2 weeks), and the dispensed product should indicate a beyond-use date based on the date of the water addition. Pharmaceutical powders that are compounded indicate a beyond-use date. Compounded preparations typically are intended for immediate use and have short-term storage durations.

Medicated Soaps And Shampoos

Medicated soaps and shampoos are solid or liquid preparations intended for topical application to the skin or scalp followed by subsequent rinsing with water. Soaps and shampoos are emulsions or surface-active compositions that readily form emulsions or foams upon the addition of water followed by rubbing. Incorporation of APIs in soaps and shampoos combines the cleansing/degreasing abilities of the vehicle and facilitates the topical application of the API to affected areas, even large areas, of the body. The surface-active properties of the vehicle facilitate contact of the API with the skin or scalp. Medicated soap and shampoo formulations frequently contain suitable antimicrobial agents to protect against bacteria, yeast, and mold contamination.

PREPARATION

The preparation of medicated soaps and shampoos follows techniques frequently used for the preparation of emulsified systems. To ensure uniformity, the API(s) must be added to the vehicle prior to congealing (in the case of soaps) followed by thorough mixing. If the medication is present as a suspension, the particle size must be controlled to promote uniform distribution of the API and possibly optimize performance. Because soap manufacture frequently involves processing the ingredients at elevated temperature, care must be exercised to avoid excessive degradation of the API during processing.

PACKAGING AND STORAGE

Individual monographs specify the packaging and storage requirements for medicated soaps and shampoos in *USP–NF*.

LABELING AND USE

Medicated soaps and shampoos are clearly labeled to indicate ''For External Use Only''. The preparations also clearly advise the patient to discontinue use and consult a physician/veterinarian if skin irritation or inflammation occurs or persists following application.

Solutions

A solution is a liquid preparation that contains one or more dissolved chemical substances in a suitable solvent or mixture of mutually miscible solvents. Because molecules of a drug substance in solution are uniformly dispersed, the use of solutions as dosage forms generally provides assurance of uniform dosage upon administration and good accuracy when the solution is diluted or otherwise mixed.

Substances in solutions are more susceptible to chemical instability than they are in the solid state and dose-for-dose generally are heavier and more bulky than solid dosage forms. These factors increase the cost of packaging and shipping relative to that of solid dosage forms. Solution dosage forms can be administered by injection; inhalation; and the mucosal, topical/dermal, and gastrointestinal routes. Terminology for solutions in veterinary practice includes spot-ons or pour-ons that refer to solutions that are applied to an animal's skin for systemic absorption, dips that refer to solutions that are used for washing and disinfection (e.g., udders, eggs, and whole animals), and drenches that include solutions that are orally administered to livestock, usually with a dosing device. Solutions administered by injection are officially titled injections (see *Injections* ⟨1⟩).

Solutions intended for oral (gastrointestinal) administration usually contain flavorings and colorants to make the medication more attractive and palatable for the patient or consumer. When needed, they also may contain stabilizers to maintain chemical and physical stability and preservatives to prevent microbial growth.

STORAGE AND USE

Light-resistant containers should be considered when photolytic chemical degradation is a potential issue. To prevent water or solvent loss, solutions are stored in tight containers. Instructions to ensure proper dosing and administration must accompany the product

Sprays (Nasal, Pulmonary, or Solutions For Nebulization)

A spray is a preparation that contains a therapeutic agent(s) in either the liquid or solid state and is intended for administration as a fine mist of small aqueous droplets. The droplets may be generated by means other than the use of a volatile propellant (see *Aerosols*). The mech-

anism for droplet generation and the intended use of the preparation distinguish the various classes of sprays. A spray is composed of a pump, container, valve, actuator, and nozzle in addition to the formulation containing the drug(s), solvents, and excipients. Each component plays a role in determining the critical characteristics of the mist of fine droplets. Droplet size and size distribution, uniformity of delivery of dose, plume geometry, and droplet velocity are critical parameters that influence the efficiency of drug delivery. When the preparation is supplied as a multi-dose container, the addition of a suitable antimicrobial preservative may be necessary.

Spray formulations intended for nasal or pulmonary administration have an aqueous base. Nasal preparations may be solutions, suspensions, or emulsions intended for local or systemic effect. Nasal delivery may be employed for drugs with high hepatic extraction ratios. Pulmonary preparations typically are solutions, although appropriately sized suspension formulations are permissible. Preparations are usually isotonic and may contain excipients to control pH and viscosity.

Metered-dose sprays typically require manually depressing the top of the container to activate a metered valve system. Depending on the design of the formulation and the valve system, the droplets generated may be intended for immediate inhalation through the mouth and deposition in the pulmonary tree or for inhalation into the nose and deposition in the nasal cavity. These preparations are commonly known as metered-dose sprays. The design of the pump, container, valve, actuator, nozzle, and formulation are critical to the performance of the product.

Alternatively, sprays can be generated by package designs that do not accurately control the volume of formulation delivered. These presentations release the formulation as a fine mist of droplets upon physical manipulation of the package by the patient. This generally involves squeezing the sides of the container and expelling the formulation through the nozzle of the container.

Finally, liquid sprays may be generated from solutions by nebulization. This is a method for continuous generation of a fine mist of aqueous droplets from a drug-containing solution by application of the Venturi principle, ultrasonic energy, or other suitable mechanical means. The generated mist is directed to the patient for inhalation, sometimes with the aid of an appropriate tube or face mask. Although formulations for nebulization typically are solutions, they also may be fine suspensions or emulsions.

PACKAGING

Containers typically are made of a rigid plastic, but metal or glass may be suitable.

The nasal spray pump is designed to allow convenient one-handed operation. The nasal spray nozzle is designed so that it fits comfortably into the vestibule of the nasal cavity and allows the plume to be directed toward the appropriate region of the cavity.

LABELING AND USE

Typical warning statements include:

- All inhalation sprays should indicate: ''For Inhalation Administration Only. Keep out of the reach of children unless otherwise prescribed. Avoid spraying into the eyes.''
- All nasal sprays indicate: ''For Intranasal Administration Only''.

The device should contain a statement that patients should seek advice and instruction from a health care professional about the proper use of the device. Guid-

In-Process Revision

ance should be provided about the proper care and cleaning of the device to prevent introduction of microbes into the pulmonary airways.

Suppositories

Suppositories are dosage forms adapted for application into the rectum. They usually melt, soften, or dissolve at body temperature. A suppository may have a local protectant or palliative effect or may deliver an API for systemic or local action.

Suppository bases typically include cocoa butter, glycerinated gelatin, hydrogenated vegetable oils, mixtures of polyethylene glycols of various molecular weights, and fatty acid esters of polyethylene glycol. The suppository base can have a notable influence on the release of the API(s). Although cocoa butter melts quickly at body temperature, it is immiscible with body fluids and this inhibits the diffusion of fat-soluble APIs to the affected sites. Polyethylene glycol is a suitable base for some antiseptics. In cases when systemic action is desired, incorporating the ionized rather than the non-ionized form of the API may help maximize bioavailability. Although non-ionized APIs partition more readily out of water-miscible bases such as glycerinated gelatin and polyethylene glycol, the bases themselves tend to dissolve very slowly, which slows API release. Cocoa butter and its substitutes (e.g, *Hard Fat*) perform better than other bases for allaying irritation in preparations intended for treating internal hemorrhoids. Suppositories for adults are tapered at one or both ends and usually weigh about 2 g each.

PREPARATION

Cocoa butter suppositories have cocoa butter as the base and can be made by incorporating the finely divided API into the solid oil at room temperature and suitably shaping the resulting mass or by working with the oil in the melted state and allowing the resulting suspension to cool in molds. A suitable quantity of hardening agents may be added to counteract the tendency of some APIs (such as chloral hydrate and phenol) to soften the base. The finished suppository melts at body temperature.

A variety of vegetable oils, such as coconut or palm kernel, modified by esterification, hydrogenation, or fractionation, are used as cocoa butter substitutes to obtain products that display varying compositions and melting temperatures (e.g., *Hydrogenated Vegetable Oil* and *Hard Fat*). These products can be designed to reduce rancidity while incorporating desired characteristics such as narrow intervals between melting and solidification temperatures and melting ranges to accommodate formulation and climatic conditions.

APIs can be incorporated into glycerinated gelatin bases by addition of the prescribed quantities to a vehicle consisting of about 70 parts of glycerin, 20 parts of gelatin, and 10 parts of water.

Several combinations of polyethylene glycols that have melting temperatures that are above body temperature are used as suppository bases. Because release from these bases depends on dissolution rather than on melting, there are significantly fewer problems in preparation and storage than is the case for melting-type vehicles. However, high concentrations of higher molecular weight polyethylene glycols may lengthen dissolution time, resulting in problems with retention.

Several non-ionic surface-active agents closely related chemically to the polyethylene glycols can be used as suppository vehicles. Examples include polyoxyethylene sorbitan fatty acid esters and the polyoxyethylene stearates. These surfactants are used alone or in combination with other suppository vehicles to yield a wide range of melting temperatures and consistencies. A notable advantage of such vehicles is their water dispersibility. However, care must be taken with the use of surfactants

because they may either increase the rate of API absorption or interact with the API to reduce therapeutic activity.

Compounding suppositories using a suppository base typically involves melting the suppository base and dissolution or dispersion of the API in the molten base (see *Pharmaceutical Compounding—Nonsterile Preparations* ⟨795⟩). When compounding suppositories, the manufacturer or compounding professional prepares an excess amount of total formulation to allow the prescribed quantity to be accurately dispensed. In compounding suppositories, avoid caustic or irritating ingredients, carefully select a base that will allow the API to provide the intended effect, and in order to minimize abrasion of the rectal membranes, reduce solid ingredients to the smallest reasonable particle size. A representative number of the compounded suppositories should be weighed to confirm that none is less than 90% or more than 110% of the average weight of all units in the batch.

STORAGE AND USE

Suppositories typically are provided in unit-dose packaging with storage instructions to prevent melting of the suppository base. Suppositories with cocoa butter base require storage in well-closed containers, preferably at a temperature below 30°(controlled room temperature). Glycerinated gelatin suppositories require storage in tight containers, preferably at a temperature below 2°. Although polyethylene glycol suppositories can be stored without refrigeration, they should be packaged in tightly closed containers.

Include instructions about insertion procedures to ensure ease of use and absorption. Labels on polyethylene glycol suppositories should contain directions that they be moistened with water before insertion.

Suspensions

A suspension is a biphasic preparation consisting of solid particles dispersed throughout a liquid phase. Suspension dosage forms may be formulated for specific routes of administration such as oral suspensions, topical suspensions, or suspensions for aerosols (see *Aerosols*). Some suspensions are prepared and ready for use, and others are prepared as solid mixtures intended for reconstitution with an appropriate vehicle just before use. The term ''milk'' is sometimes used for suspensions in aqueous vehicles intended for oral administration (e.g., *Milk of Magnesia*). The term ''magma'' is often used to describe suspensions of inorganic solids, such as clays in water, that display a tendency toward strong hydration and aggregation of the solid, giving rise to gel-like consistency and thixotropic rheological behavior (e.g., *Bentonite Magma*). The term ''lotion'' may refer to a suspension dosage although the liquid phase in these preparations is commonly an emulsion intended for application to the skin (e.g., *Calamine Topical Suspension*; see *Emulsions*). Some suspensions are prepared in sterile form and are used as injectables (see *Injections* ⟨1⟩). Other sterile suspensions are for ophthalmic or otic administration. Suspensions generally are not injected intravenously, epidurally, or intrathecally unless the product labeling clearly specifies these routes of administration.

Limited aqueous solubility of the API(s) is the most common rationale for developing a suspension. Other potential advantages of a suspension include taste masking and improved patient compliance because of the more convenient dosage form. When compared to solutions, suspensions have improved chemical stability. Ideally, a suspension should contain small uniform particles that are readily suspended and easily re-dispersed following settling. Unless the dispersed solid is colloidal, the particulate matter in a suspension likely will settle to the bottom of the container upon standing. Such sedimentation may lead to caking and solidification of the

sediment and difficulty in re-dispersing the suspension upon agitation. To prevent such problems, manufacturers commonly add ingredients to increase viscosity and the gel state of the suspension or flocculation, including clays, surfactants, polyols, polymers, or sugars. Frequently, thixotropic vehicles are employed to counter particle-settling tendencies, but these vehicles must not interfere with pouring or re-dispersal. Additionally, the density of the dispersed phase and continuous phase may be modified to further control settling rate. For topical suspensions, rapid drying upon application is desirable.

The product is both chemically and physically stable throughout its shelf life. Temperature can influence the viscosity (and thus suspension properties and the ease of removing the dose from the bottle), and temperature cycling can lead to changes in the particle size of the dispersed phase via Ostwald ripening. When manufacturers conduct stability studies to establish product shelf life and storage conditions, they should cycle conditions (freeze/thaw) to investigate temperature effects.

All suspensions contain suitable antimicrobial agents to protect against bacterial, yeast, and mold contamination (see *Antimicrobial Effectiveness Testing* ⟨51⟩).

Suspensions for reconstitution are dry powder or granular mixtures that require the addition of water or a supplied formulated diluent before administration. This formulation approach is frequently used when the chemical or physical stability of the API or suspension does not allow sufficient shelf life for a preformulated suspension. Typically, these suspensions are refrigerated after reconstitution to increase their shelf life. For this type of suspension, the powder blend is uniform and the powder readily disperses when reconstituted. Taste of the reconstituted suspension is also an important attribute because many suspensions are used for pediatric populations.

Injectable suspensions generally are intended for either subcutaneous or intramuscular routes of administration and should have a controlled particle size, typically in the range of 5 μm or smaller. The rationale for the development of injectable suspensions includes poor API solubility, improved chemical stability, prolonged duration of action, and avoidance of first-pass metabolism. Care is needed in selecting the sterilization technique because it may affect product stability or alter the physical properties of the material.

PREPARATION

Suspensions are prepared by adding suspending agents or other excipients and purified water or oil to solid APIs and mixing to achieve uniformity. In the preparation of a suspension, the characteristics of both the dispersed phase and the dispersion medium should be considered. During development manufacturers should define an appropriate particle size distribution for the suspended material to minimize the likelihood of particle size changes during storage.

In some instances the dispersed phase has an affinity for the vehicle and is readily wetted upon its addition. For some materials the displacement of air from the solid surface is difficult, and the solid particles may clump together or float on top of the vehicle. In the latter case, a wetting agent is used to facilitate displacement of air from the powder surface. Surfactants, alcohol, glycerin, and other hydrophilic liquids can be employed as wetting agents when an aqueous vehicle will be used as the dispersion phase. These agents function by displacing the air in the crevices of the particles and dispersing the particles. In the large-scale preparation of suspensions, wetting of the dispersed phase may be aided by the use of high-energy mixing equipment such as colloid mills or other rotor–stator mixing devices.

After the powder has been wetted, the dispersion medium (containing the soluble formulation components such as colorants, flavorings, and preservatives) is added in portions to the powder, and the mixture is thoroughly

blended before subsequent additions of the vehicle. A portion of the vehicle is used to wash the mixing equipment free of suspended material, and this portion is used to bring the suspension to final volume and ensure that the suspension contains the desired concentration of solid matter. The final product may be passed through a colloid mill or other blender or mixing device to ensure uniformity. When appropriate, preservatives are included in the formulation of suspensions to protect against bacterial and mold contamination.

Suspensions are shaken before the dose is dispensed. Because of the viscosity of many suspension vehicles, air entrainment may occur during dosing. The formulation process allows evaluation of this possibility; adjustments in vehicle viscosity or the incorporation of low levels of antifoaming agents are common approaches to minimize air entrainment. Alternatively, specific instructions for shaking the formulation may be provided to minimize air incorporation and ensure accurate dosing.

PACKAGING AND STORAGE

Individual monographs specify the packaging and storage requirements for suspension products. Typically, the monograph will indicate a container type such as tight, well-closed, or light-resistant and may indicate storage conditions such as controlled room temperature. For additional information about meeting packaging requirements listed in the individual monographs, refer to *Containers—Glass* ⟨660⟩, *Containers—Plastic* ⟨661⟩, *Containers—Performance Testing* ⟨671⟩, *Good Packaging Practices* ⟨1177⟩, and the *General Notices* for statements about preservation, packaging, storage, and labeling.

Acceptable suspension of the particulate phase depends on the particle size of the dispersed phase as well as the viscosity and density of the vehicle. Clear instruction is provided regarding the appropriate storage temperature for the product because temperature can influence the viscosity and density (that affect suspension properties and the ease of removal of the dose from the bottle), and temperature cycling can lead to changes in particle size of the dispersed phase. Suspensions require storage in tight containers. Avoid freezing.

LABELING AND USE

Instructions to ensure proper dosing and administration must accompany the product. When labeling a suspension, consider any air that might be entrained in the preparation as a result of shaking, and avoid such entrainment. Compounded suspensions should indicate a beyond-use date that is calculated from the time of compounding. Suspensions are shaken well before use to ensure uniform distribution of the solid in the vehicles.

Tablets

Tablets are solid dosage forms in which the API is blended with excipients and compressed into the final dosage. Tablets are the most widely used dosage form in the U.S. Tablet presses use steel punches and dies to prepare compacted tablets by the application of high pressures to powder blends or granulations. Tablets can be produced in a wide variety of sizes, shapes, and surface markings. Capsule-shaped tablets are commonly referred to as caplets. Specialized tablet presses may be used to produce tablets with multiple layers or with specially formulated core tablets placed in the interior of the final dosage form. These specialized tablet presentations can delay or extend the release of the API(s) or physically separate incompatible APIs. Tablets may be coated by a variety of techniques to provide taste masking, protection of photo-labile API(s), prolonged or delayed release, or unique appearance (colors). When no deliberate effort has been made to modify the API release rate, tablets are referred to as immediate-release.

Tablet Triturates—Small, usually cylindrical, molded or compacted tablets. Tablet triturates traditionally were used as dispensing tablets in order to provide a convenient, measured quantity of a potent API for compounding purposes, but they are rarely used today.

Hypodermic Tablets—Molded tablets made from completely and readily water-soluble ingredients; formerly intended for use in making preparations for hypodermic injection. They may be administered orally or sublingually when rapid API availability is required, as in the case of *Nitroglycerin Sublingual Tablets*.

Bolus Tablets—Large, usually elongated, tablets intended for administration to large animals. Conventional tableting processes can be used to manufacture bolus tablets, but due to their size higher compression forces may be necessary.

Buccal Tablets—Intended to be inserted in the buccal pouch, where the API is absorbed directly through the oral mucosa. Few APIs are readily absorbed in this way (examples are nitroglycerin and certain steroid hormones).

Effervescent Tablets—Prepared by compaction and contain, in addition to the API(s), mixtures of acids (e.g., citric acid or tartaric acid) and carbonates and/or hydrogen carbonates. Upon contact with water, these formulations release carbon dioxide, producing the characteristic effervescent action.

Hard and Soft Chewable Tablets—Formulated and manufactured to produce a pleasant-tasting residue in the mouth and to facilitate swallowing. Hard chewable tablets are prepared by compaction, usually utilizing mannitol, sorbitol, or sucrose as binders and fillers, and contain colors and flavors to enhance their appearance and taste. Some chewable tablets may be swallowed without compromising delivery of the API. Chewable tablets are clearly labeled to indicate whether chewing is necessary to ensure reliable release of the API(s). Hard chewable tablets in veterinary medicine often have flavor enhancers like brewers yeast or meat/fish-based flavors. Soft chewable tablets are made by a molding or extrusion process, frequently with more than 10% water to help maintain a pliable, soft product.

Orally Disintegrating Tablets—Intended to disintegrate rapidly within the mouth to provide a fine dispersion before the patient swallows the resulting suspension. Some of these dosage forms have been formulated to facilitate rapid disintegration and are manufactured by conventional means or by using lyophilization or molding processes.

Sublingual Tablets—Intended to be inserted beneath the tongue, where the API is absorbed directly through the oral mucosa. As with buccal tablets, few APIs are extensively absorbed in this way, and much of the API is swallowed and is available for gastrointestinal absorption.

PREPARATION

Most compacted (compressed) tablets consist of the API(s) and a number of excipients. These excipients may include fillers (diluents), binders, disintegrating agents, lubricants, and glidants. Approved FD&C and D&C dyes or lakes, flavors, and sweetening agents also may be present.

Fillers or diluents are added when the quantity of API(s) is too small or the properties of the API do not allow satisfactory compaction in the absence of other ingredients. Binders impart adhesiveness to the powder blend and promote tablet formation and maintenance of API uniformity in the tableting mixture. Disintegrating agents facilitate reduction of the tablet into small particles upon contact with water or biological fluids. Lubricants reduce friction during the compaction and ejection cycles. Glidants improve powder fluidity, powder handling proper-

ties, and tablet weight control. Colorants are often added to tablet formulations for esthetic value or for product identification.

Tablets are prepared from formulations that have been processed by one of three general methods: wet granulation, dry granulation (roll compaction or slugging), and direct compression.

Wet Granulation—Involves the mixing of dry powders with a granulating liquid to form a moist granular mass that is dried and sized prior to compression. It is particularly useful in achieving uniform blends of low-dose APIs and facilitating the wetting and dissolution of poorly soluble, hydrophobic APIs.

Dry Granulations—Can be produced by passing powders between rollers at elevated pressure (roll compaction). Alternatively, dry granulation also can be carried out by the compaction of powders at high pressures on tablet presses, a process also known as slugging. In either case the compacts are sized before compression. Dry granulation improves the flow and handling properties of the powder formulation without involving moisture in the processing.

Direct Compression—Tablet processing involves dry blending of the API(s) and excipients followed by compression. The simplest manufacturing technique, direct compression is acceptable only when the API and excipients possess acceptable flow and compression properties without prior process steps.

Tablets may be coated to protect the ingredients from air, moisture, or light; to mask unpleasant tastes and odors; to improve tablet appearance; and to reduce dustiness. In addition, coating may be used to protect the API from acidic pH values associated with gastric fluids or to control the rate of drug release in the gastrointestinal tract.

The most common coating in use today is a thin film coating composed of a polymer that is derived from cellulose. Sugar coating is an alternative, less common approach. Sugar-coated tablets have considerably thicker coatings that are primarily sucrose with a number of inorganic diluents. A variety of film-coating polymers are available and enable the development of specialized release profiles. These formulations are employed to protect acid-labile APIs from the acidic stomach environment as well as to prolong the release of the API to reduce dosing frequency (see *Dissolution* ⟨711⟩ or *Disintegration* ⟨701⟩).

PACKAGING, STORAGE, AND LABELING

Individual monographs specify the packaging and storage requirements for tablet products. Typically, the monograph will indicate the container type such as tight, well-closed, or light-resistant. For additional information on meeting USP packaging requirements see *Containers—Glass* ⟨660⟩, *Containers—Plastic* ⟨661⟩ and *Containers—Performance Testing* ⟨671⟩. Effervescent tablets are stored in tightly closed containers or moisture-proof packs and are labeled to indicate that they should not be swallowed directly.

Tapes

A tape is a dosage form suitable for delivering APIs to the skin. It consists of an API(s) impregnated into a durable yet flexible woven fabric or extruded synthetic material that is coated with an adhesive agent. Typically the impregnated API is present in the dry state. The adhesive layer is designed to hold the tape securely in place without the aid of additional bandaging. Unlike transdermal patches, tapes are not designed to control the release rate of the API.

The API content of tapes is expressed as amount per surface area with respect to the tape surface exposed to the skin. The use of an occlusive dressing with the tape

enhances the rate and extent of delivery of the API to deeper layers of the skin and may result in greater systemic absorption of the API.

LABELING, STORAGE, AND USE

Label to indicate ''External Use Only''. Tapes are stored in tight containers protected from light and moisture. To employ the tape, one cuts a patch slightly larger than the area that will be treated. The backing paper is removed from the adhesive side, and the tape is applied to the skin. To ensure optimal adhesion, the tape should not be applied to folds in the skin. To minimize systemic absorption and to ensure good adhesion, tapes should be applied to dry skin.

GLOSSARY

This glossary provides definitions for terms in use in medicine and serves as a source of official names for official articles. Examples of general nomenclature forms for the more frequently encountered categories of dosage forms appear in *Nomenclature* ⟨1121⟩. In an attempt to be comprehensive, this glossary was compiled without the limits imposed by current preferred nomenclature conventions. To clearly identify/distinguish preferred from not preferred terms, entries indicate when a term is not preferred and direct the user to the current preferred term. When a term is described as an attribute of a dosage form, it should not be used in the official name for the dosage form.

AEROSOL: A dosage form consisting of a liquid or solid preparation packaged under pressure and intended for administration as a fine mist. The descriptive term aerosol also refers to the fine mist of small droplets or solid particles that are emitted from the product.

AROMATIC WATER (NOT PREFERRED; see *Solution*): A clear, saturated, aqueous solution of volatile oils or other aromatic or volatile substances.

AURAL (Auricular) (NOT PREFERRED; see *Otic*): For administration into, or by way of, the ear.

BEAD (NOT PREFERRED; see *Pellets*): A solid dosage form in the shape of a small sphere. In most products a unit dose consists of multiple beads.

BLOCKS: A large veterinary product intended to be licked by animals and containing the API(s) and nutrients such as salts, vitamins, and minerals.

BOLUS (NOT PREFERRED; see *Tablet*): A large tablet intended for administration to large animals.

CAPLET (NOT PREFERRED; see *Tablet*): Tablet dosage form in the shape of a capsule.

CAPSULE: A solid dosage form in which the API, with or without other ingredients, is filled into either a hard or soft shell. Most capsule shells are composed mainly of gelatin.

CHEWABLE: Attribute of a solid dosage form that is intended to be chewed before swallowing.

COATED: Attribute of a solid dosage form that is covered by deposition of an outer solid that is different in composition from the core material.

COLLODION (NOT PREFERRED; see *Solution*): A preparation that is a solution dosage form composed of pyroxilin dissolved in a solvent mixture of alcohol and ether and applied externally.

COLLODIAL DISPERSION: A system in which particles of colloidal dimension (i.e., typically between 1 nm and 1 μm) are distributed uniformly throughout a liquid.

CONCENTRATE: A liquid or solid preparation of higher concentration and smaller volume than the final dosage form; usually intended to be diluted prior to administration. The term continues to be used for veterinary preparations but is being phased out of *USP–NF* titles for human applications.

CONVENTIONAL-RELEASE (NOT PREFERRED; see *Immediate-Release*): Descriptive term for a dosage form in which no deliberate effort has been made to modify the release rate of the API. In the case of capsules and tablets, the inclusion or exclusion of a disintegrating agent is not interpreted as a modification.

CREAM: An emulsion dosage form often containing more than 20% water and volatiles or containing less than 50% hydrocarbons, waxes, or polyols as the vehicle for the API. Creams are generally intended for external application to the skin or mucous membranes.

DELAYED-RELEASE: A type of modified-release dosage form. A descriptive term for a dosage form deliberately modified to delay release of the API for some period of time after initial administration. Release of the API is prevented in the gastric environment but promoted in the intestinal environment; this term is synonymous with *Enteric-Coated* or *Gastro-Resistant*.

DENTAL: Descriptive term for a preparation that is applied to the teeth and/or gums for localized action.

DERMAL: Route of administration to the skin surface.

DOSAGE FORM: A formulation of the API(s) and excipients in quantities and physical form designed to allow the accurate and efficient administration of the API to the human or animal patient.

DRY POWDER INHALER: A dosage form consisting of a mixture of the API(s) and carrier; all components exist in a finely divided solid state that is mobilized into a fine mist upon the oral inhalation by the patient.

EFFERVESCENT: Attribute of an oral dosage form, frequently tablets or granules, containing ingredients that, when in contact with water, rapidly release carbon dioxide. The dosage form is dissolved or dispersed in water to initiate the effervescence prior to ingestion.

ELIXIR (NOT PREFERRED; see *Solution*): A preparation that typically is a clear, flavored, sweetened hydroalcoholic solution intended for oral use. The term is no longer used in *USP–NF* but is commonly encountered in compounding pharmacy practice.

EMOLLIENT: Attribute of a cream or ointment indicating an increase in the moisture content of the skin following application of bland, fatty, or oleaginous substances.

EMULSION: A dosage form consisting of a two-phase system composed of at least two immiscible liquids, one of which is dispersed as droplets (internal or dispersed phase) within the other liquid (external or continuous phase), generally stabilized with one or more emulsifying agents. Emulsion is not used as a dosage form term if a more specific term is applicable (e.g., *Cream*, *Lotion*, or *Ointment*).

ENTERIC-COATED (NOT PREFERRED; see *Delayed-Release*): Descriptive term for a solid dosage form in which a polymer coating has been applied to prevent the release of the API in the gastric environment.

EXCIPIENT: An ingredient of a dosage form other than an API.

EXTENDED-RELEASE: Descriptive term for a dosage form that is deliberately modified to protract the release rate of the API compared to that observed for an immediate-release dosage form. The term is synonymous with prolonged- or sustained-release. Many extended-release dosage forms have a pattern of release that begins with a ''burst effect'' that mimics an immediate release followed by a slower release of the remaining API in the dosage form.

FEED ADDITIVE: A preparation used in veterinary medicine that is mixed with an animal's food or water to deliver the API. Three types exist: type A medicated article, type B medicated feed, and type C medicated

feed. Only type C medicated feed preparations contain the API(s) in concentrations appropriate for administration directly to animals.

FILM: A term used to describe a thin, flexible sheet of material, usually composed of a polymer in an amorphous state. Films are applied to solid dosages for taste masking, product identification, and aesthetic purposes. Films also are employed as a means of oral administration of material in a rapidly dissolving form.

FOAM: An emulsion dosage form containing dispersed gas bubbles. When dispensed it has a fluffy, semisolid consistency.

GAS: One of the states of matter having no definite shape or volume and occupying the entire container when confined.

GASTRO-RESISTANT (NOT PREFERRED; see *Delayed-Release*): Descriptive term for a solid dosage form in which a polymer coating has been applied to prevent the release in the gastric environment.

GEL: A dosage form that is a semisolid dispersion of small inorganic particles or a solution of large organic molecules containing a gelling agent to provide stiffness. A gel may contain suspended particles.

GRANULES (NOT PREFERRED): A dosage form composed of dry aggregates of powder particles that may contain one or more APIs, with or without other ingredients. They may be swallowed as such, dispersed in food, or dissolved in water. Granules are frequently compacted into tablets or filled into capsules, with or without additional ingredients.

GUM: A dosage form in which the base consists of a pliable material that, when chewed, releases the API into the oral cavity.

HARD-SHELL CAPSULE (NOT PREFERRED; see *Capsules*): A type of capsule in which one or more APIs, with or without other ingredients, are filled into a two-piece shell. Most hard-shell capsules are composed mainly of gelatin and are fabricated prior to the filling operation.

IMMEDIATE-RELEASE: Descriptive term for a dosage form in which no deliberate effort has been made to modify the API release rate. In the case of capsules and tablets, the inclusion or exclusion of a disintegrating agent is not interpreted as a modification.

IMPLANT: A dosage form that is a solid or semisolid material containing the API, that is inserted into the body. The insertion process is invasive, and the material is intended to reside at the site for a period consistent with the design release kinetics or profile of the API(s).

INHALATION (BY INHALATION): A route of administration for aerosols characterized by dispersion of the API into the airways during inspiration.

BY INJECTION: A route of administration of a liquid or semisolid deposited into a body cavity, fluid, or tissue by use of a needle.

INSERT: A solid dosage form that is inserted into a body cavity other than the rectum. A suppository is an insert intended for application to the rectum (see *Suppository*).

INTRAOCULAR: A route of administration (by injection) for a sterile liquid within the eye.

IRRIGATION: A sterile solution or liquid intended to bathe or flush open wounds or body cavities.

JELLY (NOT PREFERRED; see *Gel*): A semisolid dispersion of small inorganic particles or a solution of large organic molecules containing a gelling agent to promote stiffness.

LIQUID: A dosage form consisting of a pure chemical in its liquid state. This dosage form term should not be applied to solutions. The term is not used in article names. When liquid is used as a descriptive term, it indicates a material that is pourable and conforms to its container at room temperature.

LOTION: An emulsion liquid dosage form applied to the outer surface of the body. Historically, this term has also been applied to suspensions and solutions.

LOZENGE: A solid dosage form intended to disintegrate or dissolve slowly in the mouth.

MODIFIED-RELEASE: A descriptive term for a dosage form with an API release pattern that has been deliberately changed from that observed for the immediate-release dosage form of the same API.

MOLDED TABLET (NOT PREFERRED; see *Tablet*): A tablet that has been formed by dampening the ingredients and pressing into a mold, then removing and drying the resulting solid mass.

MOUTHWASH (NOT PREFERRED; see *Solution*): Term applied to a solution preparation used to rinse the oral cavity.

NASAL: Route of administration (mucosal) characterized by deposition in the nasal cavity for local or systemic effect.

OCULAR (NOT PREFERRED; see *Intraocular*): Route of administration (by injection) indicating deposition of the API within the eye.

OINTMENT: A semisolid dosage form, usually containing less than 20% water and volatiles and more than 50% hydrocarbons, waxes, or polyols as the vehicle. This dosage form generally is for external application to the skin or mucous membranes.

OPHTHALMIC: A route of administration (mucosal) characterized by application of sterile preparation to the external parts of the eye.

ORAL: A route of administration (gastro-intestinal) characterized by deposition of a preparation into the mouth for absorption or action in the digestive tract.

ORALLY DISINTEGRATING: A descriptive term for a solid oral dosage form that disintegrates rapidly in the mouth.

ORO-PHARYNGEAL: A route of administration characterized by deposition of a preparation into the buccal cavity and/or pharyngeal region to exert a local or systemic effect.

OTIC: A route of administration (mucosal) characterized by deposition of a preparation into, or by way of, the ear. Sometimes referred to as *Aural* (*Aural* NOT PREFERRED).

PASTE: A semisolid dosage form containing a high percentage of finely dispersed solids with a stiff consistency. This dosage form is intended for application to the skin, oral cavity, or mucous membranes.

PELLET: A small solid dosage form of uniform, often spherical, shape. Spherical pellets are sometimes referred to as *Beads* (*Beads* NOT PREFERRED).

PILL (NOT PREFERRED but frequently incorrectly used to describe a *Tablet*): A solid spherical pharmaceutical dosage form, usually prepared by a wet massing technique.

PLASTER: A semisolid dosage form supplied on a support material for external application. Plasters are applied for prolonged periods to provide protection, support, or occlusion (for macerating action).

POWDER: A dosage form composed of a solid or mixture of solids reduced to a finely divided state and intended for internal or external use.

PROLONGED-RELEASE: NOT PREFERRED; see *Extended-Release*.

RECTAL: A route of administration (mucosal) characterized by deposition into the rectum to provide local or systemic effect.

RINSE: A liquid preparation used to cleanse by flushing.

SEMISOLID: Attribute of a material characterized by a reduced ability to flow or conform to its container at room temperature. A semisolid does not flow at low shear stress and generally exhibits plastic flow behavior.

SHAMPOO: A solution or suspension dosage form used to clean the hair and scalp. May contain an API intended for topical application to the scalp.

SOAP: The alkali salt(s) of a fatty acid or mixture of fatty acids used to cleanse the skin. Soaps used as dosage forms may contain an API intended for topical application to the skin. Soaps have also been used as liniments and enemas.

SOFT GEL CAPSULE (NOT PREFERRED; see *Capsule*): A specific capsule type characterized by increased levels of plasticizers producing a more pliable and thicker-walled material than hard gelatin capsules. Soft gel capsules are further distinguished because they are single-piece sealed dosages. Frequently used for delivering liquid compositions.

SOLUTION: A clear, homogeneous liquid dosage form that contains one or more chemical substances dissolved in a solvent or mixture of mutually miscible solvents.

SPIRIT (NOT PREFERRED; see *Solution*): A liquid dosage form composed of an alcoholic or hydroalcoholic solution of volatile substances.

SPRAY: Attribute that describes the generation of droplets of a liquid or solution to facilitate application to the intended area.

STENT, DRUG-ELUTING: A specialized form of implant used for extended local delivery of the API to the immediate location of stent placement.

STRIP (NOT PREFERRED; see *Tape*): A dosage form or device in the shape of a long, narrow, thin solid material.

SUBLINGUAL: A route of administration (mucosal) characterized by placement underneath the tongue and for release of the API for absorption in that region.

SUPPOSITORY: A solid dosage form in which one or more APIs are dispersed in a suitable base and molded or otherwise formed into a suitable shape for insertion into the rectum to provide local or systemic effect.

SUSPENSION: A liquid dosage form that consists of solid particles dispersed throughout a liquid phase.

SYRUP (NOT PREFERRED; see *Solution*): A solution containing high concentrations of sucrose or other sugars. This term is commonly used in compounding pharmacy.

TABLET: A solid dosage form prepared from powders or granules by compaction.

TAPE, MEDICATED: A dosage form or device composed of a woven fabric or synthetic material onto which an API is placed, usually with an adhesive on one or both sides to facilitate topical application.

TINCTURE (NOT PREFERRED; see *Solution*): An alcoholic or hydroalcoholic solution prepared from vegetable materials or from chemical substances.

TOPICAL: A route of administration characterized by application to the outer surface of the body.

TROCHE (NOT PREFERRED; see *Lozenge*): A solid dosage form intended to disintegrate or dissolve slowly in the mouth and usually prepared by compaction in a manner similar to that used for tablets.

URETHRAL: A route of administration (mucosal) characterized by deposition into the urethra.

VAGINAL: A route of administration (mucosal) characterized by deposition into the vagina.

VEHICLE: A term commonly encountered in compounding pharmacy that refers to a component for internal or external use that is used as a carrier or diluent in which liquids, semisolids, or solids are dissolved or suspended. Examples include water, syrups, elixirs, oleaginous liquids, solid and semisolid carriers, and proprietary products (see *Excipient*).

VETERINARY: Descriptive term for dosage forms intended for nonhuman use.■2S (*USP33*)

BRIEFING

〈**1231**〉 **Water for Pharmaceutical Purposes,** *USP 32* page 741. Although the majority of water used for production is *Purified Water* and *Water for Injection* that is produced on site (referred to as ''bulk water''), the Pharmaceutical Waters Expert Committee recognizes the need for and the use of commercially available ''packaged'' *Purified Water* and *Water for Injection* in some production environments. In addition, there are sterile waters such as *Sterile Purified Water* and *Sterile Water for Injection* (and *Inhalation* and *Irrigation*). As the tests and limits for these various types of waters have been updated in recent years, some of the terminology regarding ''bulk'', ''sterile'', and ''packaged'' needs to be updated and/or clarified. The proposed remedy is to distinguish between ''bulk'' water, ''sterile'' water, and ''packaged bulk'' water in the relevant monographs and general chapters. The term ''packaged waters'' has been used as a substitute for ''sterile waters'' and as a term to describe commercially available packages of *Purified Water* and *Water for Injection*. The Pharmaceutical Waters Expert Committee proposes that the term ''packaged waters'' be used for the packaged form of bulk *Purified Water* and *Water for Injection* that has been produced elsewhere. Requirements for packaged waters are contained in the *Purified Water* and *Water for Injection* monographs. Sterile waters, although they are also packaged articles, have their own unique monographs and uses. The Expert Committee is discouraging the use of the term ''packaged water'' to mean ''sterile water''.

There are companion changes in *Water Conductivity* 〈645〉 and the monographs for *Sterile Purified Water*, *Sterile Water for Injection*, *Sterile Water for Inhalation*, and *Sterile Water for Irrigation*. All changes align the use of these terms.

(PW: A. Hernandez-Cardoso.) RTS—C76228

INTRODUCTION

Water is widely used as a raw material, ingredient, and solvent in the processing, formulation, and manufacture of pharmaceutical products, active pharmaceutical ingredients (APIs) and intermediates, compendial articles, and analytical reagents. This general information chapter provides additional information about water, its quality attributes that are not included within a water monograph, processing techniques that can be used to improve water quality, and a description of minimum water quality standards that should be considered when selecting a water source.

This information chapter is not intended to replace existing regulations or guides that already exist to cover USA and International (ICH or WHO) GMP issues, engineering guides, or other regulatory (FDA, EPA, or WHO) guidances for water. The contents will help users to better understand pharmaceutical water issues and some of the microbiological and chemical concerns unique to water. This chapter is not an all-inclusive writing on pharmaceutical waters. It contains points that are basic information to be considered, when appropriate, for the processing, holding, and use of water. It is the user's responsibility to assure that pharmaceutical water and its production meet applicable governmental regulations, guidances, and the compendial specifications for the types of water used in compendial articles.

Control of the chemical purity of these waters is important and is the main purpose of the monographs in this compendium. Unlike other official articles, the bulk water monographs (*Purified Water* and *Water for Injection*) also limit how the article can be produced because of the belief that the nature and robustness of the purification process is directly related to the resulting purity. The chemical attributes listed in these monographs should be considered as a set of minimum specifications. More stringent specifications may be needed for some applications to ensure suitability for particular uses. Basic guidance on the appropriate applications of these waters is found in the monographs and is further explained in this chapter.

Control of the microbiological quality of water is important for many of its uses. ~~All~~

■Most■2S (*USP33*)

In-Process Revision

packaged forms of water that have monograph standards are required to be sterile because some of their intended uses require this attribute for health and safety reasons. USP has determined that a microbial specification for the bulk monographed waters is inappropriate and has not been included within the monographs for these waters. These waters can be used in a variety of applications, some requiring extreme microbiological control and others requiring none. The needed microbial specification for a given bulk water depends upon its use. A single specification for this difficult-to-control attribute would unnecessarily burden some water users with irrelevant specifications and testing. However, some applications may require even more careful microbial control to avoid the proliferation of microorganisms ubiquitous to water during the purification, storage, and distribution of this substance. A microbial specification would also be inappropriate when related to the ''utility'' or continuous supply nature of this raw material. Microbial specifications are typically assessed by test methods that take at least 48 to 72 hours to generate results. Because pharmaceutical waters are generally produced by continuous processes and used in products and manufacturing processes soon after generation, the water is likely to have been used well before definitive test results are available. Failure to meet a compendial specification would require investigating the impact and making a pass/fail decision on all product lots between the previous sampling's acceptable test result and a subsequent sampling's acceptable test result. The technical and logistical problems created by a delay in the result of such an analysis do not eliminate the user's need for microbial specifications. Therefore, such water systems need to be operated and maintained in a controlled manner that requires that the system be validated to provide assurance of operational stability and that its microbial attributes be quantitatively monitored against established alert and action levels that would provide an early indication of system control. The issues of water system validation and alert/action levels and specifications are included in this chapter.

TYPES OF WATER

There are many different grades of water used for pharmaceutical purposes. Several are described in *USP* monographs that specify uses, acceptable methods of preparation, and quality attributes. These waters can be divided into two general types: bulk waters, which are typically produced on site where they are used; and ~~packaged~~

■sterile■ 2S (*USP33*)
waters, which are produced, packaged, and sterilized to preserve microbial quality throughout their packaged shelf life. There are several specialized types of ~~packaged~~

■sterile■ 2S (*USP33*)
waters, differing in their designated applications, packaging limitations, and other quality attributes.

There are also other types of water for which there are no monographs. These are all bulk waters, with names given for descriptive purposes only. Many of these waters are used in specific analytical methods. The associated text may not specify or imply certain quality attributes or modes of preparation. These nonmonographed waters may not necessarily adhere strictly to the stated or implied modes of preparation or attributes. Waters produced by other means or controlled by other test attributes may equally satisfy the intended uses for these waters. It is the user's responsibility to ensure that such waters, even if produced and controlled exactly as stated, be suitable for their intended use. Wherever the term ''water'' is used within this compendia without other descriptive adjectives or clauses, the intent is that water of no less purity than *Purified Water* be used.

What follows is a brief description of the various types of pharmaceutical waters and their significant uses or attributes. *Figure 1* may also be helpful in understanding some of the various types of waters.

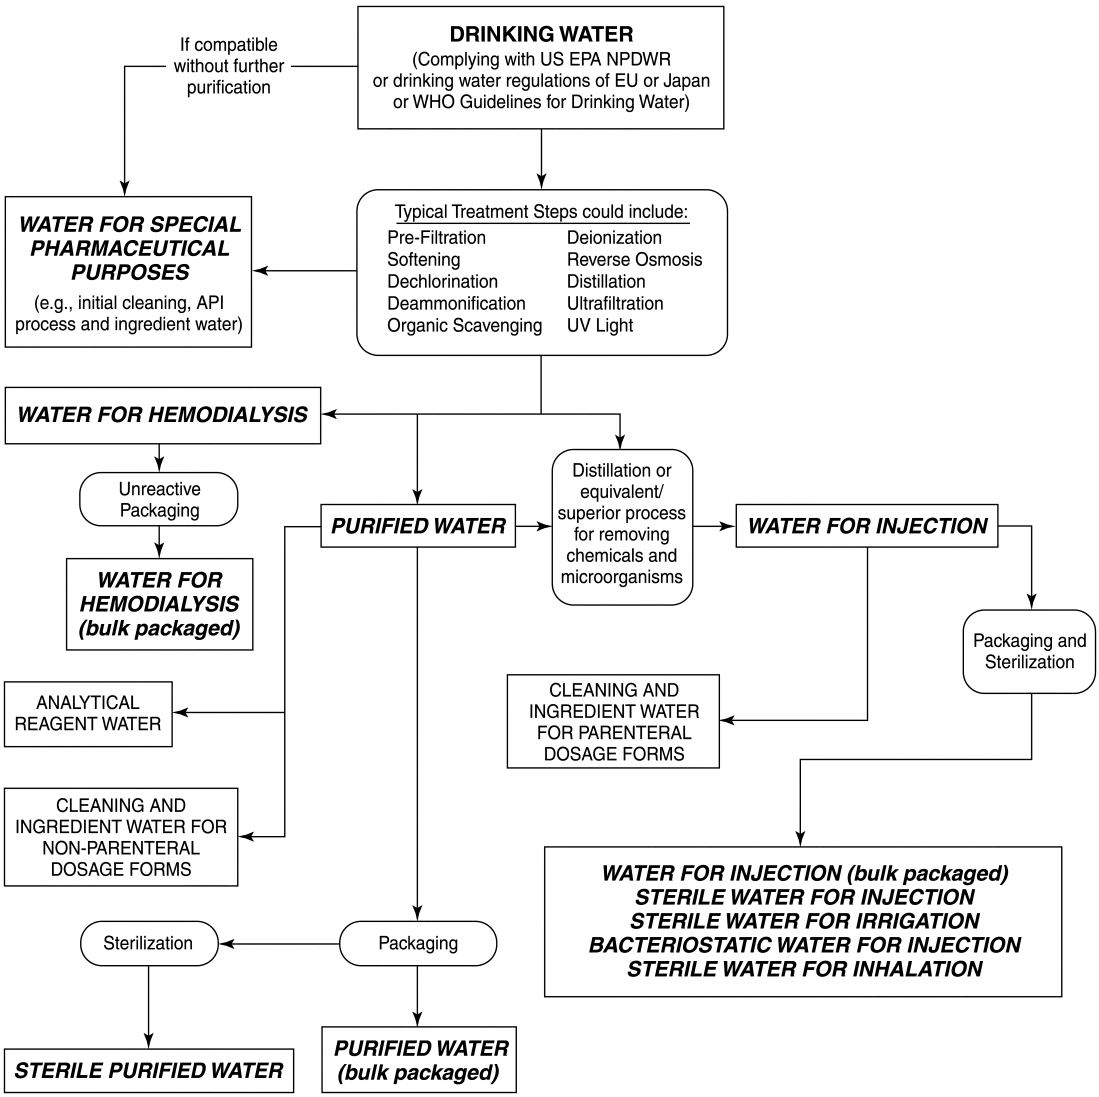

Figure 1. Water for pharmaceutical purposes.

Bulk Monographed Waters and Steam

The following waters are typically produced in large volume by a multiple-unit operation water system and distributed by a piping system for use at the same site. These particular pharmaceutical waters must meet the quality attributes as specified in the related monographs.

Purified Water—*Purified Water* (see the *USP* monograph) is used as an excipient in the production of nonparenteral preparations and in other pharmaceutical applications, such as cleaning of certain equipment and nonparenteral product-contact components. Unless otherwise specified, *Purified Water* is also to be used for all tests and assays for which water is indicated (see *General Notices and Requirements*). *Purified Water* is also referenced throughout the *USP–NF.* Regardless of the font and letter case used in its spelling, water complying with the *Purified Water* monograph is intended. *Purified Water* must meet the requirements for ionic and organic chemical purity and must be protected from microbial contamination. The minimal quality of source or feed water for the production of *Purified Water* is Drinking Water. This source water may be purified using unit operations that include deionization, distillation, ion exchange, reverse osmosis, filtration, or other suitable purification procedures. Purified water systems must be validated to reliably and consistently produce and distribute water of acceptable chemical and microbiological quality. Purified water systems that function under ambient conditions are particularly susceptible to the establishment of tenacious biofilms of microorganisms, which can be the source of undesirable levels of viable microorganisms or endotoxins in the effluent water. These systems require frequent sanitization and microbiological monitoring to ensure water of appropriate microbiological quality at the points of use.

The *Purified Water* monograph also allows bulk packaging for commercial use elsewhere. ~~When this is done, the required specifications are those of the packaged water *Sterile Purified Water,* except for *Sterility* and *Labeling*.~~

■■2S (*USP33*)
There is a potential for the occurrence of microbial contamination and other quality changes in this bulk packaged nonsterile water. Therefore, this form of *Purified Water* should be prepared and stored in a fashion that limits microbial growth and/or simply used in a timely fashion before microbial proliferation renders it unsuitable for its intended use. Also depending on the material used for packaging, there could be extractable compounds leaching into the water from the packaging. Though this article may meet its required chemical attributes, such extractables may render the water an inappropriate choice for some applications. It is the user's responsibility to ensure fitness for use of this packaged article when used in manufacturing, clinical, or analytical applications where the pure bulk form of the water is indicated.

Water for Injection—*Water for Injection* (see the *USP* monograph) is used as an excipient in the production of parenteral and other preparations where product endotoxin content must be controlled, and in other pharmaceutical applications, such as cleaning of certain equipment and parenteral product-contact components. The minimum quality of source or feed water for the generation of *Water for Injection* is Drinking Water as defined by the U.S. EPA, EU, Japan, or WHO. This source water may be pretreated to render it suitable for subsequent distillation (or whatever other validated process is used according to the monograph). The finished water must meet all of the chemical requirements for *Purified Water* as well as an additional bacterial endotoxin specification. Since endotoxins are produced by the kinds of microorganisms that are prone to inhabit water, the equipment and procedures used by the system to purify, store, and distribute *Water for Injection* must be designed to minimize or prevent microbial contamination as well as remove incoming endotoxins from the starting water. *Water for Injection* systems must be validated to reliably and consistently produce and distribute this quality of water.

The *Water for Injection* monograph also allows it to be packed in bulk for commercial use. ~~Required specifications include the test for *Bacterial endotoxins,* and those of the packaged water *Sterile Purified Water,* except for *Labeling*.~~

■■2S (*USP33*)
Bulk packaged *Water for Injection* is required to be sterile, thus eliminating microbial contamination quality changes. However, packaging extractables may render this water an inappropriate choice for some applications. It is the user's responsibility to ensure fitness for use of this packaged article when used in manufacturing, clinical, or analytical applications where the purer bulk form of the water is indicated.

Water for Hemodialysis—*Water for Hemodialysis* (see the *USP* monograph) is used for hemodialysis applications, primarily the dilution of hemodialysis concentrate solutions. It is produced and used on site and is made from EPA Drinking Water which has been further purified to reduce chemical and microbiological components. It may be packaged and stored in unreactive containers that preclude bacterial entry. The term ''unreactive containers'' implies that the container, especially its water contact surfaces, are not changed in any way by the water, such as by leaching of container-related compounds into the water or by any chemical reaction or corrosion caused by the water. The water contains no added antimicrobials and is not intended for injection. Its attributes include specifications for *Water conductivity, Total organic carbon* (or oxidizable substances), *Microbial limits,* and *Bacterial endotoxins.* The water conductivity and total organic carbon attributes are identical to those established for *Purified Water* and *Water for Injection;* however, instead of total organic carbon, the organic content may alternatively be measured by the test for *Oxidizable substances*. The *Microbial limits* attribute for this water is unique among the ''bulk'' water monographs, but is justified on the basis of this water's specific application that has microbial content requirements related to its safe use. The *Bacterial endotoxins* attribute is likewise established at a level related to its safe use.

Pure Steam—*Pure Steam* (see the *USP* monograph) is also sometimes referred to as ''clean steam''. It is used where the steam or its condensate would directly contact official articles or article-contact surfaces, such as during their preparation, sterilization, or cleaning where no subsequent processing step is used to remove any codeposited impurity residues. These *Pure Steam* applications include but are not limited to porous load sterilization processes, product or cleaning solutions heated by direct steam injection, or humidification of processes where steam injection is used to control the humidity inside processing vessels where the official articles or their in-process forms are exposed. The primary intent of using this quality of steam is to ensure that official articles or article-contact surfaces exposed to it are not contaminated by residues within the steam.

Pure Steam is prepared from suitably pretreated source water analogously to either the pretreatment used for *Purified Water* or *Water for Injection*. The water is vaporized with suitable mist elimination, and distributed under pressure. The sources of undesirable contaminants within *Pure Steam* could arise from entrained source water droplets, anticorrosion steam additives, or residues from the steam production and distribution system itself. The attributes in the *Pure Steam* monograph should detect most of the contaminants that could arise from these sources. If the official article exposed to potential *Pure Steam* residues is intended for parenteral use or other applications where the pyrogenic content must be controlled, the *Pure Steam* must additionally meet the specification for *Bacterial Endotoxins* ⟨85⟩.

These purity attributes are measured on the condensate of the article, rather than the article itself. This, of course, imparts great importance to the cleanliness of the *Pure Steam* condensate generation and collection process because it must not adversely impact the quality of the resulting condensed fluid.

Other steam attributes not detailed in the monograph, in particular, the presence of even small quantities of noncondensable gases or the existence of a superheated or dry state, may also be important for applications such as sterilization. The large release of energy (latent heat of condensation) as water changes from the gaseous to the liquid state is the key to

steam's sterilization efficacy and its efficiency, in general, as a heat transfer agent. If this phase change (condensation) is not allowed to happen because the steam is extremely hot and in a persistent superheated, dry state, then its usefulness could be seriously compromised. Noncondensable gases in steam tend to stratify or collect in certain areas of a steam sterilization chamber or its load. These surfaces would thereby be at least partially insulated from the steam condensation phenomenon, preventing them from experiencing the full energy of the sterilizing conditions. Therefore, control of these kinds of steam attributes, in addition to its chemical purity, may also be important for certain *Pure Steam* applications. However, because these additional attributes are use-specific, they are not mentioned in the *Pure Steam* monograph.

Note that less pure ''plant steam'' may be used for steam sterilization of nonproduct contact nonporous loads, for general cleaning of nonproduct contact equipment, as a nonproduct contact heat exchange medium, and in all compatible applications involved in bulk pharmaceutical chemical and API manufacture.

~~**Packaged**~~

▪**Sterile**▪ 2S (*USP33*) **Monographed Waters**

The following monographed waters are packaged forms of either *Purified Water* or *Water for Injection* that have been sterilized to preserve their microbiological properties. These waters may have specific intended uses as indicated by their names and may also have restrictions on packaging configurations related to those uses. In general, these ~~packaged~~

▪▪ 2S (*USP33*)
waters may be used in lieu of the bulk form of water from which they were derived. However, the user should take into consideration that the packaging and sterilization processes used for the articles may leach materials from the packaging material into the water over its shelf life, rendering it less pure than the original water placed into the package. The chemical attributes of these waters are still defined primarily by the wet chemistry methods and specifications similar to those formerly used for the bulk pharmaceutical waters prior to their replacement with water conductivity and total organic carbon (TOC). It is the user's responsibility to ensure fitness for use of this article when used in manufacturing, clinical, or analytical applications where the purer bulk form of the water is indicated.

Sterile Purified Water—*Sterile Purified Water* (see the *USP* monograph) is *Purified Water*, packaged and rendered sterile. It is used in the preparation of nonparenteral compendial dosage forms or in analytical applications requiring *Purified Water* where access to a validated *Purified Water* system is not practical, where only a relatively small quantity is needed, where ~~sterile~~

▪*Sterile*▪ 2S (*USP33*)
Purified Water is required, or where bulk packaged *Purified Water* is not suitably microbiologically controlled.

Sterile Water for Injection—*Sterile Water for Injection* (see the *USP* monograph) is *Water for Injection* packaged and rendered sterile. It is used for extemporaneous prescription compounding and as a sterile diluent for parenteral products. It may also be used for other applications where bulk *Water for Injection* or *Purified Water* is indicated but where ~~assess~~

▪access▪ 2S (*USP33*)
to a validated water system is either not practical or where only a relatively small quantity is needed. *Sterile Water for Injection* is packaged in single-dose containers not larger than 1 L in size.

Bacteriostatic Water for Injection—*Bacteriostatic Water for Injection* (see the *USP* monograph) is sterile *Water for Injection* to which has been added one or more suitable antimicrobial preservatives. It is intended to be used as a diluent in the preparation of parenteral products, most typically for multidose products that require repeated content withdrawals. It may be packaged in single-dose or multiple-dose containers not larger than 30 mL.

Sterile Water for Irrigation—*Sterile Water for Irrigation* (see the *USP* monograph) is *Water for Injection* packaged and sterilized in single-dose containers of larger than 1 L in size that allows rapid delivery of its contents. It need not meet the requirement under small-volume injections in the general test chapter *Particulate Matter in Injections* ⟨788⟩. It may also be used in other applications which do not have particulate matter specifications, where bulk *Water for Injection* or *Purified Water* is indicated but where access to a validated water system is not practical, or where somewhat larger quantities than are provided as *Sterile Water for Injection* are needed.

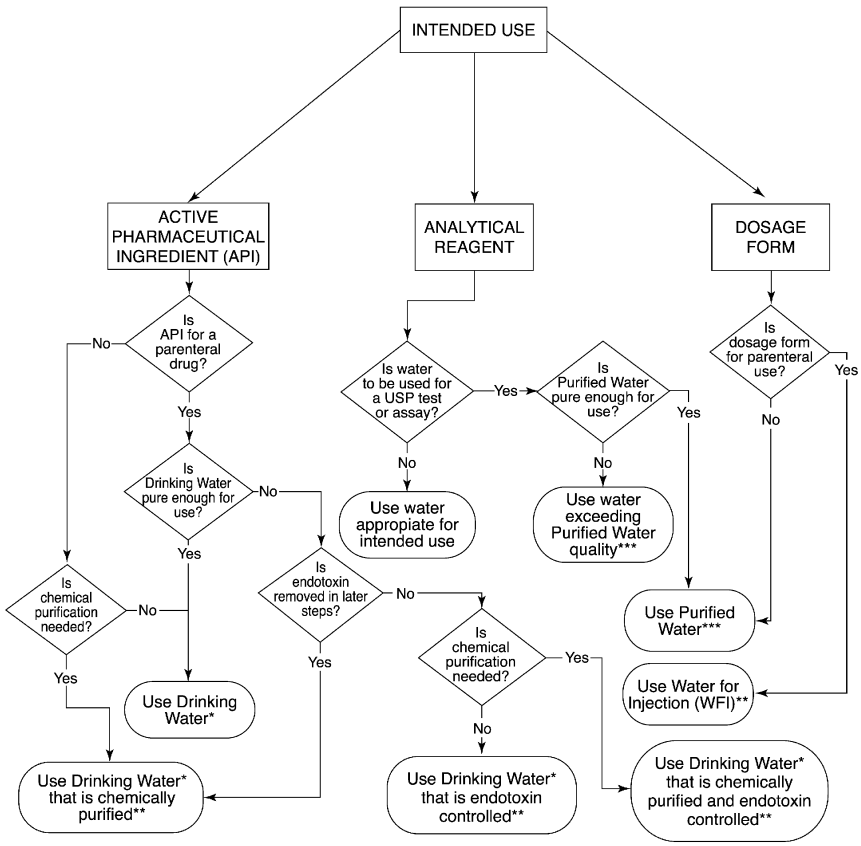
Sterile Water for Inhalation—*Sterile Water for Inhalation* (see the *USP* monograph) is *Water for Injection* that is packaged and rendered sterile and is intended for use in inhalators and in the preparation of inhalation solutions. It carries a less stringent specification for bacterial endotoxins than *Sterile Water for Injection* and therefore is not suitable for parenteral applications.

Nonmonographed Manufacturing Waters

In addition to the bulk monographed waters described above, nonmonographed waters can also be used in pharmaceutical processing steps such as cleaning, synthetic steps, or a starting material for further purification. The following is a description of several of these nonmonographed waters as cited in various locations within this compendia.

Drinking Water—This type of water can be referred to as Potable Water (meaning drinkable or fit to drink), National Primary Drinking Water, Primary Drinking Water, or National Drinking Water. Except where a singular drinking water specification is stated (such as the NPDWR [U.S. Environmental Protection Agency's National Primary Drinking Water Regulations as cited in 40 CFR Part 141]), this water must comply with the quality attributes of either the NPDWR, or the drinking water regulations of the European Union or Japan, or the WHO Drinking Water Guidelines. It may be derived from a variety of sources including a public water utility, a private water supply (e.g., a well), or a combination of these sources. Drinking Water may be used in the early stages of cleaning pharmaceutical manufacturing equipment and product-contact components. Drinking Water is also the minimum quality of water that should be used for the preparation of official substances and other bulk pharmaceutical ingredients. Where compatible with the processes, the allowed contaminant levels in Drinking Water are generally considered safe for use for official substances and other drug substances. Where required by the processing of the materials to achieve their required final purity, higher qualities of water may be needed for these manufacturing steps, perhaps even as pure as *Water for Injection* or *Purified Water*. Such higher purity waters, however, might require only selected attributes to be of higher purity than Drinking Water (see *Figure 2* below). Drinking Water is the prescribed source or feed water for the production of bulk monographed pharmaceutical waters. The use of Drinking Water specifications establishes a reasonable set of maximum allowable levels of chemical and microbiological contaminants with which a water purification system will be challenged. As seasonal variations in the quality attributes of the Drinking Water supply can occur, due consideration to its synthetic and cleaning uses must be given. The processing steps in the production of pharmaceutical waters must be designed to accommodate this variability.

In-Process Revision



* Drinking Water is water complying with US EPA NPDWR or drinking water regulations of EU or Japan or WHO drinking water guidelines.
** Water for sterile API's or dosage forms must first be rendered sterile if there is not a subsequent sterilization step in the process where used.
*** See guidance in this chapter where waters other than Purified Water are required by some USP tests and assays.

Note: All water systems should be validated with whatever microbial control is needed to suit the intended purposes of the water.

Figure 2. Selection of water for pharmaceutical purposes.

Hot Purified Water—This water is used in the preparation instructions for *USP–NF* articles and is clearly intended to be *Purified Water* that has been heated to an unspecified temperature in order to enhance solubilization of other ingredients. There is no upper temperature limit for the water (other than being less than 100°), but for each monograph there is an implied lower limit below which the desired solubilization effect would not occur.

Nonmonographed Analytical Waters

Both *General Notices and Requirements* and the introductory section to *Reagents, Indicators, and Solutions* clearly state that where the term ''water,'' without qualification or other specification, is indicated for use in analyses, the quality of water shall be *Purified Water.* However, numerous such qualifications do exist. Some of these qualifications involve methods of preparation, ranging from specifying the primary purification step to specifying additional purification. Other qualifications call for specific attributes to be met that might otherwise interfere with analytical processes. In most of these latter cases, the required attribute is not specifically tested. Rather, a further ''purification process'' is specified that ostensibly allows the water to adequately meet this required attribute.

However, preparation instructions for many reagents were carried forward from the innovator's laboratories to the originally introduced monograph for a particular *USP–NF* article or general test chapter. The quality of the reagent water described in these tests may reflect the water quality designation of the innovator's laboratory. These specific water designations may have originated without the innovator's awareness of the requirement for *Purified Water* in *USP–NF* tests. Regardless of the original reason for the creation of these numerous special analytical waters, it is possible that the attributes of these special waters could now be met by the basic preparation steps and current specifications of *Purified Water.* In some cases, however, some of the cited post-processing steps are still necessary to reliably achieve the required attributes.

Users are not obligated to employ specific and perhaps archaically generated forms of analytical water where alternatives with equal or better quality, availability, or analytical performance may exist. The consistency and reliability for producing these alternative analytical waters should be verified as producing the desired attributes. In addition, any alternative analytical water must be evaluated on an application-by-application basis by the user to ensure its suitability. Following is a summary of the various types of nonmonographed analytical waters that are cited in the *USP–NF.*

Distilled Water—This water is produced by vaporizing liquid water and condensing it in a purer state. It is used primarily as a solvent for reagent preparation, but it is also specified in the

execution of other aspects of tests, such as for rinsing an analyte, transferring a test material as a slurry, as a calibration standard or analytical blank, and for test apparatus cleaning. It is also cited as the starting water to be used for making *High Purity Water.* Because none of the cited uses of this water imply a need for a particular purity attribute that can only be derived by distillation, water meeting the requirements for *Purified Water* derived by other means of purification could be equally suitable where *Distilled Water* is specified.

Freshly Distilled Water—Also called ''recently distilled water'', it is produced in a similar fashion to *Distilled Water* and should be used shortly after its generation. This implies the need to avoid endotoxin contamination as well as any other adventitious forms of contamination from the air or containers that could arise with prolonged storage. It is used for preparing solutions for subcutaneous test animal injections as well as for a reagent solvent in tests for which there appears to be no particularly high water purity needed that could be ascribable to being ''freshly distilled''. In the ''test-animal'' use, the term ''freshly distilled'' and its testing use imply a chemical, endotoxin, and microbiological purity that could be equally satisfied by *Water for Injection* (though no reference is made to these chemical, endotoxin, or microbial attributes or specific protection from recontamination). For nonanimal uses, water meeting the requirements for *Purified Water* derived by other means of purification and/or storage periods could be equally suitable where ''recently distilled water'' or *Freshly Distilled Water* is specified.

Deionized Water—This water is produced by an ion-exchange process in which the contaminating ions are replaced with either H^+ or OH^- ions. Similarly to *Distilled Water, Deionized Water* is used primarily as a solvent for reagent preparation, but it is also specified in the execution of other aspects of tests, such as for transferring an analyte within a test procedure, as a calibration standard or analytical blank, and for test apparatus cleaning. Also, none of the cited uses of this water imply any needed purity attribute that can only be achieved by deionization. Therefore, water meeting the requirements for *Purified Water* that is derived by other means of purification could be equally suitable where *Deionized Water* is specified.

Freshly Deionized Water—This water is prepared in a similar fashion to *Deionized Water,* though as the name suggests, it is to be used shortly after its production. This implies the need to avoid any adventitious contamination that could occur upon storage. This water is indicated for use as a reagent solvent as well as for cleaning. Due to the nature of the testing, *Purified Water* could be a reasonable alternative for these applications.

Deionized Distilled Water—This water is produced by deionizing (see *Deionized Water*) *Distilled Water.* This water is used as a reagent in a liquid chromatography test that requires a high purity. Because of the importance of this high purity, water that barely meets the requirements for *Purified Water* may not be acceptable. *High Purity Water* (see below) could be a reasonable alternative for this water.

Filtered Distilled or Deionized Water—This water is essentially *Purified Water* produced by distillation or deionization that has been filtered through a 1.2-μm rated membrane. This water is used in particulate matter testing where the presence of particles in the water could bias the test results (see *Particulate Matter in Injections* ⟨788⟩). Because the chemical water purity needed for this test could also be afforded by water purification processes other than distillation or deionization, filtered water meeting the requirements for *Purified Water* but produced by means other than distillation or deionization could be equally suitable.

Filtered Water—This water is *Purified Water* that has been filtered to remove particles that could interfere with the analysis where the water is used. Where used for preparing samples for particulate matter testing (see *Particulate Matter in Injections* ⟨788⟩), though unspecified in monographs, water filtration should be through a 1.2-μm filter to be consistent with the general test chapter. Where used as a chromatography reagent, monograph-specified filter ratings range from 0.5 μm to unspecified.

High Purity Water—The preparation of this water is defined in *Containers—Glass* ⟨660⟩. It is water that is prepared by deionizing previously distilled water, and then filtering it through a 0.45-μm rated membrane. This water must have an in-line conductivity of not greater than 0.15 μS/cm (6.67 Megohm-cm) at 25°. For the sake of purity comparison, the analogous Stage 1 and 2 conductivity requirements for *Purified Water* at the same temperature are 1.3 μS/cm and 2.1 μS/cm, respectively. The preparation specified in *Containers—Glass* ⟨660⟩ uses materials that are highly efficient deionizers and that do not contribute copper ions or organics to the water, assuring a very high quality water. If the water of this purity contacts the atmosphere even briefly as it is being used or drawn from its purification system, its conductivity will immediately degrade, by as much as about 1.0 μS/cm, as atmospheric carbon dioxide dissolves in the water and equilibrates to bicarbonate ions. Therefore, if the analytical use requires that water purity remains as high as possible, its use should be protected from atmospheric exposure. This water is used as a reagent, as a solvent for reagent preparation, and for test apparatus cleaning where less pure waters would not perform acceptably. However, if a user's routinely available purified water is filtered and meets or exceeds the conductivity specifications of *High Purity Water,* it could be used in lieu of *High Purity Water.*

Ammonia-Free Water—Functionally, this water must have a negligible ammonia concentration to avoid interference in tests sensitive to ammonia. It has been equated with *High Purity Water* that has a significantly tighter Stage 1 conductivity specification than *Purified Water* because of the latter's allowance for a minimal level of ammonium among other ions. However, if the user's *Purified Water* were filtered and met or exceeded the conductivity specifications of *High Purity Water,* it would contain negligible ammonia or other ions and could be used in lieu of *High Purity Water.*

Carbon Dioxide-Free Water—The introductory portion of the *Reagents, Indicators, and Solutions* section defines this water as *Purified Water* that has been vigorously boiled for at least 5 minutes, then cooled and protected from absorption of atmospheric carbon dioxide. Because the absorption of carbon dioxide tends to drive down the water pH, most of the uses of *Carbon Dioxide-Free Water* are either associated as a solvent in pH-related or pH-sensitive determinations or as a solvent in carbonate-sensitive reagents or determinations. Another use of this water is for certain optical rotation and color and clarity of solution tests. Though it is possible that this water is indicated for these tests simply because of its purity, it is also possible that the pH effects of carbon dioxide containing water could interfere with the results of these tests. A third plausible reason that this water is indicated is that outgassing air bubbles might interfere with these photometric-type tests. The boiled water preparation approach will also greatly reduce the concentrations of many other dissolved gases along with carbon dioxide. Therefore, in some of the applications for *Carbon Dioxide-Free Water,* it could be the inadvertent deaeration effect that actually renders this water suitable. In addition to boiling, deionization is perhaps an even more efficient process for removing dissolved carbon dioxide (by drawing the dissolved gas equilibrium toward the ionized state with subsequent removal by the ion-exchange resins). If the starting *Purified Water* is prepared by an efficient deionization process and protected after deionization from exposure to atmospheric air, water that is carbon dioxide-free can be effectively made without the application of heat. However this deionization process does not deaerate the water, so if *Purified Water* prepared by deionization is considered as a substitute water in a test requiring *Carbon Dioxide-Free Water,* the user must verify that it is not actually water akin to *Deaerated Water* (discussed below) that is needed for the test. As indicated in *High Purity Water,* even brief contact with the atmosphere can allow small amounts of carbon dioxide to dissolve, ionize, and significantly degrade the conductivity and lower the pH. If the analytical use requires the water to remain as pH-neutral and as carbon dioxide-free as possible, even the analysis should be protected from atmospheric exposure. However, in most applications, atmospheric exposure during testing does not significantly affect its suitability in the test.

Ammonia- and Carbon Dioxide-Free Water—As implied by the name, this water should be prepared by approaches compatible with those mentioned for both *Ammonia-Free Water* and *Carbon Dioxide-Free Water.* Because the carbon dioxide-free attribute requires post-production protection from the atmosphere, it is appropriate to first render the water ammonia-free using the *High Purity Water* process followed by the boiling and carbon dioxide-protected cooling process. The *High Purity Water* deionization process for creating *Ammonia-Free Water* will also remove the ions generated from dissolved carbon dioxide and ultimately, by forced equilibration to the ionized state, all the dissolved carbon dioxide. Therefore, depending on its use, an acceptable procedure for making *Ammonia- and Carbon Dioxide-Free Water* could be to transfer and collect *High Purity Water* in a carbon dioxide intrusion-protected container.

Deaerated Water—This water is *Purified Water* that has been treated to reduce the content of dissolved air by ''suitable means''. In the *Reagents* section, approaches for boiling, cooling (similar to *Carbon Dioxide-Free Water* but without the atmospheric carbon dioxide protection), and sonication are given as applicable for test uses other than dissolution and drug release testing. Though *Deaerated Water* is not mentioned by name in *Dissolution* ⟨711⟩, suggested methods for deaerating dissolution media (which may be water) include warming to 41°, vacuum filtering through a 0.45-μm rated membrane, and vigorously stirring the filtrate while maintaining the vacuum. This chapter specifically indicates that other validated approaches may be used. In other monographs that also do not mention *Deaerated Water* by name, degassing of water and other reagents is accomplished by sparging with helium. *Deaerated Water* is used in both dissolution testing as well as liquid chromatography applications where outgassing could either interfere with the analysis itself or cause erroneous results due to inaccurate volumetric withdrawals. Applications where ambient temperature water is used for reagent preparation, but the tests are performed at elevated temperatures, are candidates for outgassing effects. If outgassing could interfere with test performance, including chromatographic flow, colorimetric or photometric measurements, or volumetric accuracy, then *Deaerated Water* should probably be used, whether called for in the analysis or not. The above deaeration approaches might not render the water ''gas-free''. At best, they reduce the dissolved gas concentrations so that outgassing caused by temperature changes is not likely.

Recently Boiled Water—This water may include recently or freshly boiled water (with or without mention of cooling in the title), but cooling prior to use is clearly intended. Occasionally it is necessary to use when hot. *Recently Boiled Water* is specified because it is used in a pH-related test or carbonate-sensitive reagent, in an oxygen-sensitive test or reagent, or in a test where outgassing could interfere with the analysis, such as specific gravity or an appearance test.

Oxygen-Free Water—The preparation of this water is not specifically described in the compendia. Neither is there an oxygen specification or analysis mentioned. However, all uses involve analyses of materials that could be sensitive to oxidation by atmospheric oxygen. Procedures for the removal of dissolved oxygen from solvents, though not necessarily water, are mentioned in *Polarography* ⟨801⟩ and *Spectrophotometry and Light-Scattering* ⟨851⟩. These procedures involve simple sparging of the liquid with an inert gas such as nitrogen or helium followed by inert gas blanketing to prevent oxygen reabsorption. The sparging times cited range from 5 to 15 minutes to an unspecified period. Some *Purified Water* and *Water for Injection* systems produce water that is maintained in a hot state and that is inert gas blanketed during its preparation and storage and distribution. Though oxygen is poorly soluble in hot water, such water may not be oxygen-free. Whatever procedure used for removing oxygen should be verified as reliably producing water that is fit for use.

LAL Reagent Water—This water is also referred to as endotoxin-free water. This is usually *Water for Injection,* which may have been sterilized. It is free from a level of endotoxin that would yield any detectable reaction or interference with the Limulus amebocyte lysate reagent used in the *Bacterial Endotoxins Test* ⟨85⟩.

Organic-Free Water—This water is defined by *Residual Solvents* ⟨467⟩ as producing no significantly interfering gas chromatography peaks. Referenced monographs specify using this water as the solvent for the preparation of standard and test solutions for the *Residual solvents* test.

Lead-Free Water—This water is used as a transferring diluent for an analyte in a *Lead* ⟨251⟩ test. Though no specific instructions are given for its preparation, it must not contain any detectable lead. *Purified Water* should be a suitable substitute for this water.

Chloride-Free Water—This water is specified as the solvent for use in an assay that contains a reactant that precipitates in the presence of chloride. Though no specific preparation instructions are given for this water, its rather obvious attribute is having a very low chloride level in order to be unreactive with this chloride sensitive reactant. *Purified Water* could be used for this water but should be tested to ensure that it is unreactive.

Hot Water—The uses of this water include solvents for achieving or enhancing reagent solubilization, restoring the original volume of boiled or hot solutions, rinsing insoluble analytes free of hot water soluble impurities, solvents for reagent recrystallization, apparatus cleaning, and as a solubility attribute for various *USP–NF* articles. In only one monograph is the temperature of ''hot'' water specified; so in all the other cases, the water temperature is less important, but should be high enough to achieve the desirable effect. In all cases, the chemical quality of the water is implied to be that of *Purified Water.*

Change to read:

CHEMICAL CONSIDERATIONS

The chemical attributes of *Purified Water* and *Water for Injection*

■in effect prior to *USP 23*■*2S (USP33)*
were specified by a series of chemistry tests for various specific and nonspecific attributes with the intent of detecting chemical species indicative of incomplete or inadequate purification. While these methods could have been considered barely adequate to control the quality of these waters, they nevertheless stood the test of time. This was partly because the operation of water systems was, and still is, based on on-line conductivity measurements and specifications generally thought to preclude the failure of these archaic chemistry attribute tests.

USP moved away from these chemical attribute tests to contemporary analytical technologies for the bulk waters *Purified Water* and *Water for Injection*. The intent was to upgrade the analytical technologies without tightening the quality requirements. The two contemporary analytical technologies employed were TOC and conductivity. The TOC test replaced the test for *Oxidizable substances* that primarily targeted organic contaminants. A multistaged *Conductivity* test which detects ionic (mostly inorganic) contaminants replaced, with the exception of the test for *Heavy metals,* all of the inorganic chemical tests (i.e., *Ammonia, Calcium, Carbon dioxide, Chloride, Sulfate*).

Replacing the heavy metals attribute was considered unnecessary because (a) the source water specifications (found in the NPDWR) for individual *Heavy metals* were tighter than the approximate limit of detection of the *Heavy metals* test for *USP XXII Water for Injection* and *Purified Water* (approximately 0.1 ppm), (b) contemporary water system construction materials do not leach heavy metal contaminants, and (c) test results for this attribute have uniformly been negative—there has not been a confirmed occurrence of a singular test failure (failure of only the *Heavy metals* test with all other attributes passing) since the current heavy metal drinking water standards have been in place. Nevertheless, since the presence of heavy metals

in *Purified Water* or *Water for Injection* could have dire consequences, its absence should at least be documented during new water system commissioning and validation or through prior test results records.

Total solids and *pH* ~~are~~

■were ■2S *(USP33)*
the only tests not covered by conductivity testing. The test for *Total solids* was considered redundant because the nonselective tests of conductivity and TOC could detect most chemical species other than silica, which could remain undetected in its colloidal form. Colloidal silica in *Purified Water* and *Water for Injection* is easily removed by most water pretreatment steps and even if present in the water, constitutes no medical or functional hazard except under extreme and rare situations. In such extreme situations, other attribute extremes are also likely to be detected. It is, however, the user's responsibility to ensure fitness for use. If silica is a significant component in the source water, and the purification unit operations could be operated or fail and selectively allow silica to be released into the finished water (in the absence of co-contaminants detectable by conductivity), then either silica-specific or a total solids type testing should be utilized to monitor and control this rare problem.

The *pH* attribute was eventually recognized to be redundant to the conductivity test (which included *pH* as an aspect of the test and specification); therefore, *pH* was dropped as a separate attribute test.

The rationale used by USP to establish its ~~conductivity specification~~

■*Purified Water* and *Water for Injection* conductivity specifications ■2S *(USP33)*
took into consideration the conductivity contributed by the two least conductive former attributes of *Chloride* and *Ammonia,* thereby precluding their failure had those wet chemistry tests been performed. In essence, the *Stage 3* conductivity specifications (see *Water Conductivity,*
■*Bulk Water* ■2S *(USP33)*
⟨645⟩) were established from the sum of the conductivities of the limit concentrations of chloride ions (from pH 5.0 to 6.2) and ammonia ions (from pH 6.3 to 7.0), plus the unavoidable contribution of other conductivity-contributing ions from water (H^+ and OH^-), dissolved atmospheric CO_2 (as HCO_3^-), and an electro-balancing quantity of either Na^+ ~~of~~

■or ■2S *(USP33)*
Cl^-, depending on the pH-induced ionic imbalance (see *Table 1*). The *Stage 2* conductivity specification is the lowest value on this table, 2.1 μS/cm. The *Stage 1* specifications, designed primarily for on-line measurements, were derived essentially by summing the lowest values in the contributing ion columns for each of a series of tables similar to *Table 1,* created for each 5° increment between 0° and 100°. For example purposes, the italicized values in *Table 1,* the conductivity data table for 25°, were summed to yield a conservative value of 1.3 μS/cm, the *Stage 1* specification for a nontemperature compensated, nonatmosphere equilibrated water sample that actually had a measured temperature of 25° to 29°. Each 5° increment in the table was similarly treated to yield the individual values listed in the table of *Stage 1* specifications (see *Water Conductivity,*
■*Bulk Water* ■2S *(USP33)*
⟨645⟩).

Table 1. Contributing Ion Conductivities of the Chloride–Ammonia Model as a Function of pH
(in atmosphere-equilibrated water at 25°)

In-Process Revision

As stated above, this rather radical change to utilizing a conductivity attribute as well as the inclusion of a TOC attribute allowed for on-line measurements. This was a major philosophical change and allowed major savings to be realized by industry. The TOC and conductivity tests can also be performed ''off-line'' in the laboratories using collected samples, though sample collection tends to introduce opportunities for adventitious contamination that can cause false high readings. The collection of on-line data is not, however, without challenges. The continuous readings tend to create voluminous amounts of data where before only a single data point was available. As stated under *Sampling Considerations,* continuous in-process data is excellent for understanding how a water system performs during all of its various usage and maintenance events in real time, but is too much data for QC purposes. Therefore, a justifiable fraction or averaging of the data can be used that is still representative of the overall water quality being used.

~~Packaged~~

■Packaged/sterile■2S (*USP33*)
waters present a particular dilemma relative to the attributes of conductivity and TOC. The package itself is the source of chemicals (inorganics and organics) that leach over time into the water and can easily be detected. The irony of organic leaching from plastic packaging is that when the *Oxidizable substances* test was the only ''organic contaminant'' test for both bulk and ~~packaged~~

■packaged/sterile■2S (*USP33*)
waters, that test's insensitivity to those organic leachables ~~rendered~~

■allowed■2S (*USP33*)
their presence in ~~packaged water at high concentrations (many times the TOC specification for bulk water) virtually undetectable~~

■packaged/sterile water to be quite high (possibly many times the TOC specification for bulk water).■2S (*USP33*)
Similarly, glass containers can also leach inorganics, such as sodium, which are easily detected by conductivity, but ~~are undetected by the wet chemistry tests for water (other than *pH* or *Total solids*)~~

■poorly detected by the former wet chemistry attribute tests.■2S (*USP33*)
Most of these leachables are considered harmless by current perceptions and standards at the rather significant concentrations present. Nevertheless, they effectively degrade the quality of the high-purity waters placed into these packaging ~~system~~

■systems.■2S (*USP33*)
Some packaging materials contain more leachables than others and may not be as suitable for holding water and maintaining its purity.

The attributes of conductivity and TOC tend to reveal more about the packaging leachables than they do about the water's original purity. These

■currently■2S (*USP33*)
''allowed'' leachables could render the ~~packaged~~

■packaged/sterile ■2S (*USP33*)
versions of originally equivalent bulk water essentially unsuitable for many uses where the bulk waters are perfectly adequate.

■Therefore, to better control the ionic packaging leachables, *Water Conductivity* ⟨645⟩ is divided into two sections. The first is titled *Bulk Water*, which applies to *Purified Water*, *Water for Injection*, *Water for Hemodialysis*, and *Pure Steam* and includes the three-stage conductivity testing instructions and specifications. The second is titled *Sterile Water*, which applies to *Sterile Purified Water*, *Sterile Water for Injection*, *Sterile Water for Inhalation*, and *Sterile Water for Irrigation*. The *Sterile Water* section includes conductivity specifications similar to the *Stage 2* testing approach because it is intended as a laboratory test, and these sterile waters were made from bulk water that already complied with the three-stage conductivity test. In essence, packaging leachables are the primary target ''analytes'' of the conductivity specifications in the *Sterile Water* section of *Water Conductivity* ⟨645⟩. The effect on potential leachables from different container sizes is the rationale for having two different specifications, one for small packages containing nominal volumes of 10 mL or less and another for larger packages. These conductivity specifications are harmonized with the *European Pharmacopoeia* conductivity specifications for *Sterile Water for Injection*. All monographed waters, except *Bacteriostatic Water for Injection*, have a conductivity specification that directs the user to either the *Bulk Water* or the *Sterile Water* section of *Water Conductivity* ⟨645⟩. For the sterile water monographs, this water conductivity specification replaces the redundant wet chemistry limit tests intended for inorganic contaminants that had previously been specified in these monographs.■2S (*USP33*)

BRIEFING

⟨2750⟩ Manufacturing Practices for Dietary Supplements, *USP 32* page 786. FDA published the final rule of *Current Good Manufacturing Practice in Manufacturing, Packaging, Labeling, or Holding Operations for Dietary Supplements* (cGMP) in June 2007, immediately after the submission to *Pharmacopeial Forum* of the previous revision of this chapter, which had incorporated the *Dietary Supplement and Nonprescription Drug Consumer Protection Act* (AER law). (For the previous revision, see page 1035 of *PF* 33(5) [Sept.–Oct. 2007].) The new cGMP regulations came into force on June 25, 2008, for com-

panies with 500 or more employees, and on June 25, 2009, for companies with 20 to 499 employees. By June 25, 2010, all companies must comply with the new rule.

Even though this chapter has provided stringent quality requirements since its first publication in 1993, updates are necessary in order to clarify its equivalencies to and stringencies against new regulations that provide more general instructions. For instance, the cGMP regulations include specific requirements relating to recordkeeping and documentation; plumbing design, installation, and maintenance; design, suitability, and maintenance of utensils and of automatic, mechanical, or electronic equipment; and control of packaging and labeling operations, including repackaging and relabeling operations.

Therefore, in order to address those differences, this proposed revision is much more explanatory and detailed in its guidance than the current chapter. These additional requirements in the revised chapter will help operators more easily ensure their product quality.

(DS-GC: Y. Tokiwa) RTS—C75199

Delete the following:

~~■As is indicated in the *General Notices* under *Significant Figures and Tolerances*, tolerances are based upon the consideration that the article is produced under recognized principles of good manufacturing practice. Many of the principles in this general information chapter are basic in that they apply equally to various types of products and levels of technology, and that they are derived from the current good manufacturing practices for drugs. However, the practical application of these principles to dietary supplements may be different.~~

~~The principles set forth in this chapter contain recommended minimum current good manufacturing practices for the methods to be used in, and the facilities and controls to be used for, the manufacture of a dietary supplement to assure that such a product meets the requirements of safety, and has the identity and strength and meets the quality and purity characteristics that it is represented to possess.~~

~~Establishments engaged solely in the harvesting, storage, or distribution of one or more ''raw agricultural commodities'' as defined in section 201(r)) of the Dietary Supplements Health and Education Act of 1994, which are ordinarily cleaned, prepared, treated, or otherwise processed before being marketed to the consuming public are excluded from this chapter.~~

~~A glossary of terms used in this general chapter is presented at the end.~~■2S (*USP33*)

Add the following:

■GENERAL PROVISIONS

The principles included in this chapter contain recommended minimum current good manufacturing practices for the methods to be used in, and the facilities and controls to be used for, the manufacture, holding, packaging, labeling, and distribution of dietary ingredients and dietary supplements. These principles are set forth to ensure that such products meet the requirements of safety, have the identity and strength, and meet the quality and purity characteristics that they are represented to possess.

Excluded from this chapter are establishments engaged solely in the harvesting, storage, or distribution of one or more ''raw agricultural commodities'' as defined in Section 201(r) of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321(r)), which are ordinarily cleaned, prepared, treated, or otherwise processed before being marketed to the consuming public.

The requirements pertaining to holding dietary ingredients and dietary supplements do not apply to holding those dietary supplements at a retail establishment for the sole purpose of direct retail sale to individual consumers. A retail establishment does not include a warehouse or other storage facility for a retailer or a warehouse or other storage facility that sells directly to individual consumers.

A glossary of terms used in this chapter is presented at the end.■2S (*USP33*)

ORGANIZATION AND PERSONNEL

Responsibilities of a Quality Control Unit

A quality control unit shall be established that has the responsibility and authority to approve or reject all raw materials, product containers, closures, in-process materials, packaging material, labeling, and finished dietary supplements, and the authority to review production records to ensure that no errors have occurred or, if errors have occurred, that they have been fully investigated. The quality control unit should be responsible for approving or rejecting products manufactured, processed, packed, or held under contract by another company.

Adequate laboratory facilities for the testing and approval (or rejection) of raw materials, product containers, closures, packaging materials, in-process materials,

■dietary ingredients,■2S (*USP33*)
and dietary supplements should be available to the quality control unit.

The quality control unit should have the responsibility for approving or rejecting all procedures or specifications that impact on the identity, strength, quality, and purity of the dietary supplement. All responsibilities and procedures applicable to the quality control unit shall be in writing.

■The designated person within the Quality Control Unit who conducts a material review and makes the disposition decision must, at the time of performance, document that material review and disposition decision.■2S (*USP33*)

Personnel Qualifications

Each person engaged in the manufacture of ~~a dietary supplement~~

■dietary ingredients and dietary supplements■2S (*USP33*) should have the proper education, training, and experience (or any combination thereof) needed to perform the assigned functions. Training should be in the particular operation(s) that the employee performs as they relate to the employee's functions.

Appropriate documentation of training shall be retained by the company.

Each person responsible for supervising the manufacture of ~~a dietary product~~

■a dietary ingredient, a dietary supplement, or both■2S (*USP33*) should have the proper education, training, and experience (or any combination thereof) to perform assigned functions in such a manner as to provide assurance that the product has the safety, identity, strength, quality, and purity that it is represented to possess.

An adequate number of qualified personnel to perform and supervise the manufacture of each ~~dietary product~~

■dietary ingredient, dietary supplement, or both■2S (*USP33*) product should be provided.

Personnel Responsibilities

The company management shall take all reasonable measures and precautions to ensure the following:

1. *Disease control.* Any person who, by medical examination or supervisory observation, is shown to have, or appears to have, an illness, open lesion, including boils, sores, or infected wounds, or any other abnormal source of microbial contamination by which there is a reasonable possibility of an in-process or finished ~~dietary product~~

   ■dietary ingredient or dietary supplement■2S (*USP33*) becoming adulterated, or processing equipment, utensils, or packaging materials becoming contaminated, shall be excluded from any operations which may be expected to result in such adulteration or contamination until the condition is corrected. Personnel shall be instructed to report such health conditions to their supervisors.
2. *Cleanliness.* All persons working in direct contact with raw materials, in-process or finished ~~dietary products~~

   ■dietary ingredients and dietary supplements,■2S (*USP33*) processing equipment, utensils, or packaging materials shall conform to hygienic practices while on duty to the extent necessary to protect against adulteration or contamination of such materials. The methods for maintaining cleanliness include, but are not limited to, the following:

   — Wearing outer garments suitable to the operation in a manner that protects against the adulteration of raw materials or of in-process or finished ~~dietary products~~

   ■dietary ingredients and dietary supplements,■2S (*USP33*) or contamination of processing equipment, utensils, or packaging materials;
   — Maintaining adequate personal cleanliness;
   — Removing cosmetics from parts of the body that may contact raw materials, in-process or finished ~~dietary products~~

   ■dietary ingredients and dietary supplements,■2S (*USP33*) equipment, utensils, or containers;
   — Washing hands thoroughly (and sanitizing if necessary to protect against contamination with undesirable microorganisms) in an adequate hand-washing facility before starting work, after each absence from the work station, and at any other time when the hands may have become soiled or contaminated;
   — Removing all unsecured jewelry and other objects that might fall into raw materials, in-process or finished ~~dietary products~~

   ■dietary ingredients and dietary supplements,■2S (*USP33*) equipment, or containers, and removing hand jewelry that cannot be adequately sanitized during periods in which in-process or finished product is manipulated by hand. If such hand jewelry and cosmetics cannot be removed, they may be covered by material that can be maintained in an intact, clean, and sanitary condition and that effectively protects against the adulteration of ~~dietary product~~

   ■dietary ingredients and dietary supplements■2S (*USP33*) or contamination of processing equipment, utensils or packaging materials;
   — Maintaining gloves, if they are used in raw materials or in in-process or finished product handling, in an intact, clean, and sanitary condition. The gloves should be of a material that adequately protects the product from contamination;
   — Wearing, where appropriate, in an effective manner, hair nets, caps, beard covers, or other effective hair restraints;
   — Storing clothing or other personal belongings in areas other than where in-process or finished product is exposed or where processing equipment or utensils are washed;
   — Confining the following actions to areas other than where in-process or finished product may be stored or exposed, or where processing equipment or utensils are washed: eating food, chewing gum, drinking beverages, or using tobacco; and
   — Taking any other necessary precautions to protect against adulteration of raw materials or of in-process or finished product, or contamination of processing equipment, utensils, or packaging materials with microorganisms or foreign substances, including, but not limited to, perspiration, hair, cosmetics, tobacco, chemicals, and medicines applied to the skin.

GROUNDS, BUILDINGS, AND FACILITIES

Grounds

The grounds about a ~~dietary product~~

■dietary ingredient■2S (*USP33*) manufacturing plant

■and a dietary supplement manufacturing plant■2S (*USP33*) under the control of the operator shall be kept in a condition that will protect against the adulteration of ~~dietary products~~

■dietary ingredients and dietary supplements.■2S (*USP33*) The methods for adequate maintenance of grounds include, but are not limited to, the following:

— Properly storing equipment, removing litter and waste, and cutting weeds or grass within the immediate vicinity of the plant building or structures that may constitute an attractant, breeding place, or harborage for pests;
— Maintaining roads, yards, and parking lots so that they do not constitute a source of adulteration in areas where product is exposed;
— Adequately draining areas that may contribute to product adulteration by seepage, foot-borne filth, or providing a breeding place for pests; and
— Operating systems for waste treatment and disposal in an adequate manner so that they do not constitute a source of adulteration in areas where product is exposed. If the plant grounds are bordered by grounds not under the operator's control and not maintained in the manner described above, care shall be exercised in the plant by inspection, extermination, or other means to exclude pests, dirt, and filth that may be a source of product adulteration.

Building Design

Any building or buildings used in the manufacture of ~~a dietary product~~

■a dietary ingredient, a dietary supplement, or both■2S (*USP33*) should be of suitable size and shall be constructed in such a manner that floors, walls, and ceilings may be adequately cleaned and kept clean and in good repair; that drips or condensates from fixtures, ducts, and pipes do not adulterate raw materials or in-process or finished ~~dietary product~~

■dietary ingredients and dietary supplements,■2S (*USP33*) or contaminate product containers, utensils, or packaging materials; and that aisles or working spaces are provided between equipment and walls and are adequately unobstructed and of adequate width to permit employees to perform their duties and to protect against adulterating in-process or finished product, or contaminating processing equipment with clothing or personal contact.

■Adequate screening or other protection against pests and insects should be installed, where necessary.■2S (*USP33*) The building should have adequate space for the orderly placement of equipment and materials to prevent mixups between different raw materials, product containers, closures, labeling, in-process materials, or finished products, and to prevent contamination. The flow of raw materials, product containers, closures, labeling, in-process materials, and products through the building or buildings should be designed to prevent contamination.

Operations should be performed within specifically defined areas of adequate size to prevent contamination or mixups or adulteration of in-process or finished ~~dietary product~~

■dietary ingredients and dietary supplements,■2S (*USP33*) or contamination of processing equipment, utensils, or packaging materials with microorganisms, chemicals, filth, or other extraneous materials. The potential for mixups and product adulteration may be reduced by adequate product safety controls and operating practices or effective design, including the separation of operations in which contamination is likely to occur, by one or more of the following means: location, time, partition, airflow, enclosed systems, or other effective means. There should be separate or defined areas as follows:

1. An area for the receipt, identification, storage, and withholding from use of components, product containers, closures, and labeling, pending the appropriate sampling, testing, or examination by the quality control unit before release for manufacturing or packaging;
2. An area for the storage of released components, product containers, closures, and labeling;
3. An area for storage of in-process materials;
4. An area for manufacturing and processing operations;
5. An area for packaging and labeling operations; and
6. An area for control and laboratory operations.

Any building used in the manufacture of ~~a dietary product~~

■a dietary ingredient or a dietary supplement■2S (*USP33*) shall permit the taking of proper precautions to protect dietary ingredients or dietary supplements in outdoor bulk fermentation vessels by any effective means, including the following:

(i) Using protective coverings,
(ii) Controlling areas over and around the vessels to eliminate harborages for pests,
(iii) Checking on a regular basis for pests and pest infestation, and
(iv) Skimming the fermentation vessels, as necessary.

Lighting

Adequate lighting shall be provided in all areas and should not expose bulk or finished product to adulteration or contamination. Adequate lighting should be provided in hand-washing areas, dressing and locker rooms, and toilet rooms, and in all areas where product is examined, processed, or stored and where equipment or utensils are cleaned; and such lighting should provide safety-type light bulbs, fixtures, skylights, or other glass suspended over exposed product in any step of preparation or otherwise protect against product adulteration in case of glass breakage.

Ventilation, Air Filtration, Air Heating, and Cooling

Adequate ventilation shall be provided, as well as equipment for adequate control over microorganisms, dust, humidity, and temperature when used in the manufacture of ~~a dietary product~~

■a dietary ingredient and a dietary supplement■2S (*USP33*) to minimize odors and vapors (including steam and noxious fumes) in areas where they may adulterate ~~dietary products~~

■dietary ingredients and dietary supplements;■2S (*USP33*) and to locate and operate fans and other air-blowing equipment in a manner that minimizes the potential for adulterating raw materials, in-process or finished ~~dietary products~~

■dietary ingredients and dietary supplements,■2S (*USP33*) or contaminating processing equipment, utensils, or packaging materials.

Plumbing

■The plumbing in the physical plant must be of an adequate size and design and be adequately installed and maintained to:

— Carry sufficient amounts of water to the required locations throughout the physical plant;

— Properly convey sewage and liquid disposable waste from the physical plant; and

— Avoid being a source of contamination to components, raw materials, dietary ingredients, dietary supplements, water supplies, or any contact surface, or creating an unsanitary condition.■2S (*USP33*)

Potable water at a suitable temperature, and under pressure as needed, should be supplied in a plumbing system free of defects that could contribute contamination to any ~~dietary product~~

■dietary ingredients and dietary supplements.■2S (*USP33*)
Potable water should meet the standards prescribed in the Environmental Protection Agency's Primary Drinking Water Regulations (40 CFR Part 141) or any state or local drinking water requirements that are more stringent. Water not meeting such standards should not be permitted in the potable water system for *Purified Water.* If potable water is to be used as a raw material, it should be further purified to satisfy compendial requirements.

Drains should be of adequate size and, where connected directly to a sewer, should have an air break or other mechanical device to prevent back-siphonage.

Sewage and Refuse

Sewage, trash, and other refuse in and from the building and immediate premises shall be disposed of in a safe and sanitary manner.

Washing and Toilet Facilities

Adequate washing facilities shall be provided, including hot and cold water, soap or detergent, air driers or single-service towels, and clean toilet facilities easily accessible to working areas.

General Maintenance and Sanitation

Any building used in the manufacture of ~~a dietary product~~

■a dietary ingredient, a dietary supplement, or both■2S (*USP33*)
should be maintained in a clean and sanitary condition and shall be kept in repair sufficient to prevent raw materials and in-process or finished ~~dietary products~~

■dietary ingredients and dietary supplements■2S (*USP33*)
from becoming adulterated. It shall be free of infestation by rodents, birds, insects, and other vermin. Trash and organic waste matter shall be held and disposed of in a timely and sanitary manner.

Cleaning compounds and sanitizing agents used in cleaning and sanitizing procedures shall be free from undesirable microorganisms and shall be safe and adequate under the conditions of use. Compliance with this requirement may be verified by any effective means, including purchase of these substances under a supplier's guarantee or certification, or examination of these substances for contamination. Only the following toxic materials may be used or stored in a plant where product is processed or exposed:

1. Those required to maintain clean and sanitary conditions;
2. Those necessary for use in laboratory testing procedures;
3. Those necessary for plant and equipment maintenance and operation; and
4. Those necessary for use in the plant's operations.

Written procedures assigning responsibility for sanitation and describing in sufficient detail the cleaning schedules, methods, equipment, and materials to be used in cleaning the building and facilities shall be required.

Toxic cleaning compounds, sanitizing agents, and pesticide chemicals shall be identified, used, held, and stored in a manner that protects against adulteration of raw materials or of in-process or finished product, or contamination of processing equipment or packaging materials. All relevant regulations promulgated by other federal, state, and local government agencies for the application, use or holding of these products should be followed.

No pests shall be allowed in any area of ~~a dietary product~~

■a dietary ingredient■2S (*USP33*)
manufacturing plant

■and a dietary supplement manufacturing plant.■2S (*USP33*)
Effective measures shall be taken to exclude pests from the processing areas and to protect against the adulteration by pests of product on the premises. The use of insecticides or rodenticides is permitted only under precautions and restrictions that will protect against the adulteration of raw materials, in-process or finished product, or contamination of processing equipment, utensils, or packaging materials.

Written procedures are also required for use of suitable rodenticides, insecticides, fungicides, fumigating agents, and cleaning and sanitizing agents. These procedures should be designed to prevent the contamination of equipment, raw materials, product containers, closures, packaging, labeling materials, or products. Rodenticides, insecticides, and fungicides should be registered and used in accordance with the Federal Insecticide, Fungicide, and Rodenticide Act.

Sanitation procedures shall apply to work performed by contractors or temporary employees as well as work performed by full-time employees during the ordinary course of operations.

Change to read:

EQUIPMENT

■AND UTENSILS■2S (*USP33*)

Equipment

■and utensils■2S (*USP33*)
used in the manufacture of ~~a dietary supplement~~

■dietary ingredients and dietary supplements■2S (*USP33*)
shall be of appropriate design

■or selection,■2S (*USP33*)
adequate size, and suitably located to facilitate operations for its intended use and for its cleaning and maintenance

■and to ensure that the specifications of dietary ingredients and dietary supplements are correct and are met.

Equipment and utensils include, but are not limited to, the following:

— Equipment used to hold or convey;
— Equipment used to measure;
— Equipment using compressed air or gas;
— Equipment used to carry out processes in closed pipes and vessels; and
— Equipment used in automatic, mechanical, or electronic systems.■2S (*USP33*)

Construction

All equipment

■and utensils■2S (*USP33*)
shall be: ~~constructed so that surfaces that contact raw materials, in-process materials, or finished products are not reactive, additive, or absorptive so as to alter the safety, identity, strength, quality, or purity of the product beyond the established requirements.~~

■— Constructed so that surfaces that contact raw materials, in-process materials, or finished products are not reactive, additive, or absorptive so as to alter the safety, identity, strength, quality, or purity of the product beyond the established requirements;
— Made of nontoxic materials;
— Designed and constructed to withstand the environment in which they are used; the action of raw materials, in-process materials, dietary ingredients, or dietary supplements; and, if applicable, cleaning compounds and sanitizing agents; and
— Maintained to protect raw materials, in-process materials, dietary ingredients, and dietary supplements from being contaminated by any source.

Equipment and utensils must have seams that are smoothly bonded or maintained to minimize the accumulation of dirt, filth, organic material, particles of raw materials, in-process materials, dietary ingredients, or dietary supplements, or any other extraneous materials or contaminants, in order to minimize the opportunity for growth of microorganisms.

Each freezer, refrigerator, and cold storage compartment used to hold raw materials, in-process materials, dietary ingredients, or dietary supplements

— Must be fitted with an indicating thermometer, temperature-measuring device, or temperature-recording device that shows, indicates, and records, or allows for recording by hand, the temperature accurately within the compartment; and
— Must have an automated device for regulating temperature or an automated alarm system to indicate a significant temperature change in a manual operation.■2S (*USP33*)

The design, construction, and use of equipment and utensils shall preclude the adulteration of raw materials, packaging materials, in-process materials, or finished product with any substances required for operation, such as: ~~lubricants, fuel, or any other contaminants such as metal fragments, contaminated water, etc.~~

■— Lubricants,
— Fuel,
— Coolants,
— Metal or glass fragments,
— Filth or any other extraneous material,
— Contaminated water, or
— Any other contaminants.

Instruments or controls used in the manufacturing, packaging, labeling, or holding of a dietary ingredient, a dietary supplement, or both; and instruments or controls that are used to measure, regulate, or record temperatures, hydrogen-ion concentration (pH), water activity, or other conditions, and to control or prevent the growth of microorganisms or other contamination must be:

— Accurate and precise,
— Adequately maintained, and
— Adequate in number for their designated uses.

For any automated, mechanical, or electronic equipment that is used to manufacture, package, label, or hold a dietary ingredient, a dietary supplement, or both:

— The suitability of the equipment must be determined by ensuring that the equipment is capable of operating satisfactorily within the operating limits required by the process;
— The equipment must be routinely calibrated, inspected, or checked to ensure proper performance. The quality control unit must approve these calibrations, inspections, or checks;
— The appropriate controls for automated, mechanical, and electronic equipment (including software for a computer-controlled process) must be established and used to ensure that any changes to the manufacturing, packaging, labeling, holding, or other operations are approved by the quality control unit and instituted only by authorized personnel; and
— The appropriate controls must be established and used to ensure that the equipment functions in accordance with its intended use. These controls must be approved by the quality control unit.

Compressed air or other gases introduced mechanically into or onto raw materials, in-process materials, dietary ingredients, dietary supplements, or contact surfaces, or that are used to clean any contact surface, must be treated in such a way that the raw material, in-process material, dietary ingredient, dietary supplement, or contact surface is not contaminated.■2S (*USP33*)

Cleaning and Maintenance

Equipment and utensils shall be cleaned, maintained, and sanitized at adequate intervals, between the manufacture of different batches of the same product and between the manufacture of different products, to prevent malfunctions or contamination that would alter the safety, identity, strength, quality, or purity of the product beyond the established requirements.

■In wet processing during manufacturing, all contact surfaces must be cleaned and sanitized, as necessary, to protect against the introduction of microorganisms into components, dietary ingredients, or dietary supplements. When cleaning and sanitizing is necessary, all contact surfaces must be cleaned and sanitized before use and after any interruption during which the contact surface may have become contaminated.

In a continuous production operation or in back-to-back consecutive operations, which involve different batches of the same dietary ingredient or dietary supplement, the contact surfaces must be adequately cleaned and sanitized.

The surfaces that do not come into direct contact with raw materials, in-process materials, dietary ingredients, or dietary supplements must be cleaned as frequently as necessary to protect against contaminating raw materials, in-process materials, dietary ingredients, and dietary supplements.

Single-service articles (such as utensils intended for one-time use, paper cups, and paper towels) must be:
— Stored in appropriate containers; and
— Handled, dispensed, used, and disposed of in a manner that protects against contamination of raw materials, in-process materials, dietary ingredients, dietary supplements, or any contact surface.

Cleaning compounds and sanitizing agents must be adequate for their intended use and safe under their conditions of use.

The portable equipment and utensils that have contact surfaces must be cleaned, sanitized, and then stored in a location and manner that protects them from contamination.■2S (*USP33*)

Written procedures for cleaning and maintaining equipment, including utensils, used in the manufacture of a product should be established and followed. These procedures should include, but are not necessarily limited to, the following:
— Assignment of responsibility for cleaning and maintaining equipment;
— Maintenance and cleaning schedules, including, where adequate, sanitizing schedules;
— A description in sufficient detail of the methods, equipment, and materials used in cleaning and maintenance operations, and the methods of disassembling and reassembling equipment, as necessary, to ensure proper cleaning and maintenance;
— Removal or obliteration of previous batch identification;
— Identification and protection of clean equipment from contamination before use;
— Inspection of equipment for cleanliness immediately before use;
— Regular calibration and inspection of equipment, or checking machines, to ensure proper performance and function

■must be conducted:

(a) Before first use; and

(b) At frequency specified in writing by supporting references.

— Instruments or controls that cannot be adjusted to agree with the reference standard must be repaired or replaced.■2S (*USP33*)

A written record of calibration, inspection, maintenance of equipment, and major equipment cleaning and use shall be maintained in individual equipment logs that show the date, product, and lot number of each batch processed. The persons performing the cleaning shall record in the log that the work was performed. Entries in the log should be in chronological order.

■The following is specified in order to keep records related to automated, or electric equipment:

— There must be backup file(s) of current software programs (and of outdated software that is necessary to retrieve records that are required to be retained, in accordance with the section *Records and Reports* in this chapter, when current software is not able to retrieve such records) and of data entered into computer systems used to manufacture, package, label, or hold dietary supplements.

(a) A backup file (e.g., a hard copy of data entered, diskettes, tapes, microfilm, or compact disks) must be an exact and complete record of the data entered.

(b) Backup software programs and data must be kept secure from alterations, inadvertent erasures, or loss.■2S (*USP33*)

Change to read:

RAW MATERIALS, PRODUCT CONTAINERS, AND CLOSURES

Written procedures describing in sufficient detail the receipt, identification, storage, handling, sampling, testing, and approval or rejection of raw materials, product containers, and closures should be provided.

Raw materials, product containers, and closures at all times should be handled and stored in a manner to prevent contamination.

Raw agricultural materials that contain soil or other contaminants shall be washed or cleaned as necessary. Water used for washing, rinsing, or conveying raw agricultural materials shall be safe and of adequate sanitary quality. Notwithstanding the general requirement for potable water, water may be reused for washing, rinsing, or conveying raw agricultural materials if it does not increase the level of contamination of such materials.

Bagged or boxed raw materials of product containers or closures should be stored off the floor and suitably spaced to permit cleaning and inspection.

Each lot should be appropriately identified as to its status (i.e., quarantined, approved, or rejected).

Receipt and Storage of Untested Raw Materials, Product Containers, and Closures

Written procedures shall be established and followed describing the receipt, identification, examination, handling, and sampling of raw materials. Upon receipt and before acceptance, each container or grouping of containers of raw materials, product containers, and closures should be examined visually for appropriate labeling as to contents, container damage, or broken seals, and for contamination. They are then stored under quarantine until they have been tested or examined, as appropriate, and released.

Raw materials shall be held in bulk, or in containers designed and constructed so as to protect against adulteration, and shall be held at such temperature and relative humidity and in such a manner as to prevent a dietary ingredient or dietary supplement from becoming adulterated. Frozen raw materials and other ingredients shall be kept frozen. If thawing is required prior to use, it shall be done in a manner that prevents the raw materials and other ingredients from becoming adulterated within the meaning of the Act.

Testing and Approval or Rejection

Each lot of raw materials, product containers, and closures should be sampled, tested, or examined, as appropriate, and released for use by the quality control unit. Based upon adequate process verification, in-process controls and statistical confidence, a skip-lot ~~sampling~~

■testing■2S (*USP33*)
plan is an alternative to

■fully■2S (*USP33*)
testing every batch

■provided that at least one identity test is conducted. ■2S (*USP33*)
An appropriate amount of each lot of raw materials should be reserved for 3 years beyond the shelf life appearing on the label of finished dietary supplements in which the raw materials were used. If adverse event reports are received (see the subsection *Adverse Event Reports*), the reserved raw materials should be kept for 6 years

■(serious events) or 3 years (nonserious events)■2S (*USP33*)
from the date the first report is received.

Representative samples should be collected for testing or examination. Sampling of botanicals should be in compliance with the provisions set in *Articles of Botanical Origin* ⟨561⟩. The number of containers sampled, and the amount of material taken from each container, should be based upon appropriate criteria such as statistical criteria for raw material variability, confidence levels, and degree of precision desired, the past quality history of the supplier, and the quantity needed for analysis and reserve where required. The following procedures should be used to collect the samples:

— The containers of raw materials selected should be cleaned, where necessary, by adequate means.
— The containers should be opened, sampled, and resealed in a manner designed to prevent contamination of their contents and contamination of other raw materials, product containers, or closures.

In-Process Revision

— These containers should be identified so that the following information can be determined: name of the material sampled, the lot number, the container from which the sample was taken, the date on which the sample was taken, and the name of the person who collected the sample.

Use the following procedure to examine and test the samples:

— At least one test should be conducted to verify the identity of each raw material of a product ~~if~~

■even in cases where■2S (*USP33*)
skip-lot testing is used. Such tests may include any appropriate test with established sufficient specificity to determine identity, including chemical and laboratory tests, gross organoleptic analysis, microscopic identification, or analysis of constituent markers.

— Each raw material should be tested for conformity with all appropriate written specifications for purity, strength, and quality. However, a report of analysis may be accepted from the supplier of a raw material, provided that the manufacturer establishes the reliability of the supplier's analyses and provided that at least one identity test is conducted on such raw material by the manufacturer.

— Containers and closures should be tested for conformance with all appropriate written procedures. However, a certificate of testing may be accepted from the supplier, provided that at least a visual identification is conducted on such containers or closures by the manufacturer.

— Each lot of a raw material, rework, product container, or closure that is liable to contamination with filth, insect infestation, or other extraneous adulterant should be examined against established specifications for such contamination and shall comply with any applicable Food and Drug Administration regulations and guidelines. Skip-lot examination should not apply in such cases.

— Each lot of a raw material that is liable to microbiological contamination that is objectionable in view of its intended use shall be subjected to microbiological tests before use. Raw materials either shall not contain levels of microorganisms that may produce food poisoning or other disease in humans, or shall be otherwise treated during manufacturing operations so that they no longer contain levels that would cause the product to be adulterated within the meaning of the Act. In lieu of such testing by the manufacturer, a guarantee or certification of analysis may be accepted from the supplier of a component provided that the manufacturer establishes the reliability of the supplier's analysis.

— Raw materials and other ingredients susceptible to adulteration with aflatoxin, other natural toxins, pesticides, or heavy metals shall comply with current Food and Drug Administration regulations, guidelines, and action levels for poisonous or deleterious substances and the requirements in *Articles of Botanical Origin* ⟨561⟩, or in each monograph, before these materials or ingredients are incorporated into a finished dietary ingredient or dietary supplement. Compliance with this requirement may be accomplished by analyzing these materials and ingredients for aflatoxins and other natural toxins; or, in lieu of such testing by the manufacturer, a guarantee or certification of analysis may be accepted from the supplier of a raw material provided that the manufacturer establishes the reliability of the supplier's analysis.

— Any lot of raw material, product container, or closure that meets the appropriate written specifications of identity, strength, quality, and purity and related tests may be approved and released for use. Any lot of such material that does not meet such specifications should be rejected.

Use of Approved Raw Materials, Product Containers, and Closures

Raw materials, product containers, and closures approved for use should be rotated so that the oldest approved stock is used first. Deviation from the requirement is permitted if such deviation is temporary and adequate.

Retesting of Approved Raw Materials, Product Containers, and Closures

Raw materials, product containers, and closures should be retested or reexamined, as appropriate, for identity, strength, quality, and purity and approved or rejected by the quality control unit after a specified time in storage or as necessary, e.g., after exposure to air, heat, or other conditions that might adversely affect the raw material, product container, or closure or after storage of active and inactive ingredients and in-process materials for long periods of time.

Rejected Raw Materials, Product Containers, and Closures

Rejected raw materials, product containers, and closures should be identified and controlled under a quarantine system that prevents their use in manufacturing or processing operations for which they are unsuitable.

Change to read:

PRODUCTION AND PROCESS CONTROLS

Written Procedures

Written procedures should be provided for production and process controls designed to ensure that the

■dietary ingredients and■2S (*USP33*)
dietary supplements have the identity, strength, quality, and purity they are represented to possess. These procedures should be drafted, reviewed, and approved by the appropriate organizational units and reviewed and approved by the quality control unit. These production and process control procedures should be followed in the execution of the various production and process control functions and should be documented at the time of performance. Any deviation from the written procedures should be recorded and justified.

(1) All operations in the receiving, inspecting, transporting, segregating, preparing, manufacturing, packaging, and storing of ~~dietary products~~

■dietary ingredients and dietary supplements ■2S (*USP33*)
shall be conducted in accordance with adequate sanitation principles.

(2) All reasonable precautions shall be taken to ensure that production procedures do not contribute adulteration from any source. Chemical, microbial, or extraneous-material testing procedures shall be used where necessary to identify sanitation failures or possible product adulteration.

(3) All product that has become contaminated to the extent that it is adulterated within the meaning of the Act shall be rejected, or if permissible, treated or processed to eliminate the contamination.

(4) All product manufacturing, including packaging and storage, shall be conducted under such conditions and controls as are necessary to minimize the potential for the growth of microorganisms, or for the adulteration of raw materials, in-process materials, and finished product.

(5) Measures taken to destroy microorganisms, reduce the microbial load, or prevent the growth of undesirable microorganisms, particularly those of public health significance, shall be adequate under the conditions of manufacture, handling, and distribution to prevent dietary supplements and ingredients from being adulterated within the meaning of the Act. These measures shall also comply with current regulations affecting dietary supplement products and ingredients.

(6) Work-in-process shall be handled in a manner that protects against adulteration.

■(7) In-process material must be held under appropriate conditions of temperature, humidity, and light.■2S (*USP33*)

(8) Effective measures shall be taken to protect finished dietary ingredients and dietary supplements from adulteration by raw materials, in-process materials, or refuse. When raw materials, in-process materials or refuse are unprotected, they shall not be handled simultaneously in a receiving, loading, or shipping area if that handling could result in adulterated ~~dietary products~~

■dietary ingredients and dietary supplements.■2S (*USP33*)
Dietary ingredients and dietary supplements transported by conveyor shall be protected against adulteration as necessary.

(9) Effective measures shall be taken as necessary to protect against the inclusion of metal or other extraneous material in product. Compliance with this requirement may be accomplished by using sieves, traps, magnets, electronic metal detectors, or other suitable effective means.

(10) Mechanical manufacturing steps such as cutting, sorting, inspecting, shredding, drying, grinding, blending, and sifting shall be performed so as to protect dietary ingredients and dietary supplements against adulteration. Compliance with this requirement may be accomplished by providing adequate physical protection of ~~dietary products~~

■dietary ingredients and dietary supplements■2S (*USP33*)
from contact with adulterants. Protection may be provided by adequate cleaning and sanitizing of all processing equipment between each manufacturing step.

(11) Heat blanching, when required in the preparation of a ~~dietary product~~

■dietary ingredient or a dietary supplement,■2S (*USP33*)
should be effected by heating the product to the required temperature, holding it at this temperature for the required time, and then either rapidly cooling the material or passing it to subsequent manufacturing without delay. Thermophilic growth and contamination in blanchers should be minimized by the use of adequate operating temperatures and by periodic cleaning. Where the blanched product is washed before filling, potable water shall be used.

(12) Intermediate of dehydrated ~~dietary products~~

■dietary ingredients and dietary supplements■2S (*USP33*)
that rely on the control of water (a_w) for preventing the growth of undesirable microorganisms shall be processed to and maintained at a safe moisture level. Compliance with this requirement may be accomplished by any effective means, including employment of one or more of the following practices:
(i) Monitoring the water activity (a_w) of the material;
(ii) Controlling the soluble solids–water ratio in finished product; and
(iii) Protecting finished product from moisture pickup, by use of a moisture barrier or by other means, so that the water activity (a_w) of the product does not increase to an unsafe level.

(13) Dietary ingredients and dietary supplements that rely principally on the control of pH for preventing the growth of undesirable microorganisms shall be monitored and maintained at an appropriate pH. Compliance with this requirement may be accomplished by any effective means, including employment of one or more of the following practices:
(i) Monitoring the pH and water activity, if appropriate, of raw materials, in-process material, and finished product; and
(ii) Controlling the amount of acid added to the product.

(14) When ice is used in contact with ~~dietary products~~

■dietary ingredients and dietary supplements,■2S (*USP33*)
it shall be made from potable water, and shall be used only if it has been manufactured in accordance with current good manufacturing practice

■in manufacturing, packing, or holding human food■2S (*USP33*)
as outlined in 21 CFR Part 110.

Charge-In of Raw Materials

Written production and control procedures should include the following, which are designed to ensure that the dietary supplements have the identity, strength, quality, and purity they are represented to possess:

— The batch should be formulated with the intent to provide not less than 100 percent of the labeled or established amount of dietary ingredient.
— Raw materials for product manufacturing should be weighed, measured, or subdivided as appropriate and the appropriate signatures recorded in the batch record.
— Actual yields and percentages of theoretical yield should be determined at appropriate phases of processing.

Material scheduled for rework shall be identified as such.

Equipment Identification

All compounding and storage containers, processing lines, and major equipment used during the production of a batch of a product should be properly identified to indicate their contents and, when necessary, the phase of processing of the batch.

Sampling and Testing of In-Process Materials, ~~and Dietary Products~~

■Dietary Ingredients, and Dietary Supplements■2S (*USP33*)

To ensure batch uniformity and integrity of dietary supplements, written procedures should be established and followed that describe the in-process controls and tests or examinations to be conducted on appropriate samples of in-process materials. Based upon process verification, in-process controls, and statistical confidence, a skip-lot ~~sampling~~

■testing■2S (*USP33*)

In-Process Revision

plan is an alternative to testing every batch

■of finished products provided that at least one representative measure is performed.■2S (*USP33*)
Control procedures should be established to monitor the output of those manufacturing processes that may be responsible for causing variability in the characteristics of in-process material and the finished product. Such control procedures may include, but are not limited to, the following, where appropriate:
— Friability
— Weight variation
— Disintegration time
— Dissolution time
— Clarity, completeness, or pH of solutions

■— Blend uniformity■2S (*USP33*)

In-process specifications for such characteristics should be consistent with finished product specifications. Examination and testing of samples should ensure that the in-process material and dietary supplement conform to the established specifications.

In-process materials should be tested for identity, strength, quality, and purity as adequate, and approved or rejected by the quality control unit during the production process, e.g., at commencement or completion of significant phases or after storage for long periods.

Rejected or adulterated in-process materials should be identified and controlled under a quarantine system designed to prevent their use in manufacturing or processing operations for which they are unsuitable and to prevent the adulteration of other products.

Change to read:

LABELING AND PACKAGING

Materials Examination and Usage Criteria

Written procedures should be provided describing in sufficient detail the receipt, identification, storage, handling, sampling, examination, or testing of labeling and packaging materials

■or products received for packaging or labeling. Each immediate container or grouping of immediate containers in a shipment of product received for packaging or labeling, or of packaging and labeling materials, must be visually examined for appropriate content label, container damage, or broken seals to determine whether the container condition may have resulted in contamination or deterioration of the received product. The supplier's invoice, guarantee, or certification in a shipment of the received product must be visually examined to ensure that the received product is consistent with the purchase order.■2S (*USP33*)
Labeling and packaging materials

■or products received for packaging or labeling■2S (*USP33*) should be ~~representatively sampled and examined or tested upon receipt and before use in packaging or labeling of a product.~~

■quarantined until:

— Representative samples of each unique shipment, and of each unique lot within each unique shipment, of received product for packaging or labeling, or of packaging and labeling materials, are collected;
— The quality control unit reviews and approves the documentation to determine whether the received product for packaging or labeling, or packaging and labeling materials meet the specifications; and
— The quality control unit approves the received product for packaging or labeling, or packaging and labeling materials, and releases for use from quarantine.■2S (*USP33*)

~~Any labeling or packaging materials meeting appropriate written specifications may be approved and released for use.~~

■■2S (*USP33*)
Those that do not meet such specifications should be

■identified and■2S (*USP33*)
rejected to prevent their use in operations for which they are unsuitable.

A record should be kept of each shipment received of each different labeling and packaging material,

■or each different received product for packaging or labeling,■2S (*USP33*)
indicating receipt, date of examination or testing, and whether accepted or rejected.

■Each unique lot within each unique shipment of received product for packaging or labeling, or of packaging and labeling materials, must be identified in a manner that allows the recipient to trace the lot to the supplier, the date received, the name of the received product, the status of the received product (e.g., quarantined, approved, or rejected), and to the product that was packaged or labeled and distributed.

This unique identifier must be used whenever the disposition of each unique lot within each unique shipment of the received product for packaging or labeling, or of packaging and labeling materials, is recorded.■2S (*USP33*)

Labels and other labeling materials for each different product, strength, product type, or quantity of contents should be stored separately ~~with suitable identification .~~

■under conditions that will protect against contamination and deterioration and avoid mixups.■2S (*USP33*)
Only authorized personnel should have access to the storage area.

▪Packaging and labels must be held under appropriate conditions so that the packaging and labels are not adversely affected (e.g. contamination, deterioration). ▪2S (*USP33*)

Gang printing of labeling to be used for different products or different strengths of the same product (or labeling of the same size and identical or similar format or color schemes) should be minimized. If gang printing is employed, packaging and labeling operations should provide for special control procedures, taking into consideration sheet layout, stacking, cutting, and handling during and after printing.

Printing devices on, or associated with, manufacturing lines used to imprint labeling upon the product unit label or case should be monitored to ensure that all imprinting conforms to the print specified in the batch production record.

Obsolete and outdated labels, labeling, ~~and~~

▪▪2S (*USP33*)
other packaging materials,

▪and products received for packaging or labeling▪2S (*USP33*)
should be destroyed and documented.

Labeling Issuance

Strict control should be exercised over labeling issued for use in product labeling operations. The control procedures employed should be in writing with sufficient detail.

Labeling materials issued for a batch should be carefully examined for identity and conformity to the labeling specified in the master ~~or~~

▪and▪2S (*USP33*)
batch production records.

Procedures should be used to reconcile the quantities of labeling issued, used, and returned, and should require evaluation of discrepancies found. If discrepancies are found between the quantity of product finished and the quantity of labeling issued and are outside preset limits based on historical operating data, such discrepancies should be investigated.

Returned labeling should be maintained and sorted in a manner to prevent mixups and provide proper identification.

All excess labeling bearing lot or control numbers should be destroyed and documented.

Operations

Written procedures designed to ensure that correct labels, labeling, and packaging materials are used for dietary supplements should incorporate the following features:

— Prevention of mixups and cross-contamination by physical or spatial separation from operations on other products;
— Identification of the product with a lot or control number;
— Examination of packaging and labeling materials for suitability and correctness before packaging operations, and documentation of such examination in the batch production record; and
— Inspection of the packaging and labeling facilities immediately before use to ensure that all products have been removed from previous operations. Inspection should also be made to ensure that packaging and labeling materials not suitable for subsequent operations have been removed. Results of the inspection should be documented in the batch production records.

▪Relabeling and Repackaging

— Dietary ingredients and dietary supplements may be repackaged or relabeled only after the quality control unit has approved such repackaging or relabeling.
— A representative sample of each batch of repackaged or relabeled dietary ingredients and dietary supplements must be examined to determine whether the repackaged or relabeled dietary ingredients and dietary supplements meet all established specifications.
— The quality control unit must approve or reject each batch of repackaged or relabeled dietary ingredients and dietary supplements before its release for distribution.▪2S (*USP33*)

Tamper-Resistant Packaging

REQUIREMENTS

Each manufacturer and packer who packages a dietary supplement for retail sale shall package the product in a tamper-resistant package, if this product is accessible to the public while held for sale. A tamper-resistant package is one having an indicator or barrier to entry which, if breached or missing, can reasonably be expected to provide visible evidence to consumers that tampering has occurred. To reduce the likelihood of substitution of a tamper-resistant feature after tampering, the indicator or barrier to entry is required to be distinctive by design or by the use of an identifying characteristic (e.g., a pattern, name, registered trademark, logo, or picture). For purposes of this section, the term ''distinctive by design'' means that the packaging cannot be duplicated with commonly available materials or through commonly available processes. A tamper-resistant package may involve an immediate-container and closure system, or secondary-container or carton system, or any combination of systems intended to provide a visual indication of package integrity. The tamper-resistant feature should be designed to remain intact when handled in a reasonable manner during manufacture, distribution, and retail display.

LABELING

Each retail package of a dietary supplement covered by this section shall bear a statement that is prominently placed so that consumers are alerted to the specific tamper-resistant feature of the package. The labeling statement should be so placed that it will be unaffected if the tamper-resistant feature of the packaging is breached or missing. If the tamper-resistant feature chosen to meet the requirement above is one that uses an identifying characteristic, that characteristic should be referred to in the labeling statement. For example, the labeling statement on a bottle with a shrink band could say ''For your protection, this bottle has an imprinted seal around the neck.''

Dietary Supplement ~~Inspection~~ ■Examination■2S (*USP33*)

Packaged and labeled products should be examined during finishing operations to ensure that containers and packages in the lot have the correct label. A representative sample of units should be collected at the completion of finishing operations and visually examined for correct labeling. Results of these examinations should be recorded in the batch production or control records.

Contact Information

The manufacturer, packer, or distributor of dietary supplements is required to comply with the current labeling requirements in the law that also include a domestic address or phone number through which an adverse event report for a dietary supplement may be received.

Shelf Life

Dietary supplements should bear a date indicative of their shelf life, determined by appropriate testing, to ensure that they meet applicable standards of identity, strength, quality, and purity at or before the labeled shelf-life date.

Shelf life should be related to any storage conditions stated on the labeling.

Change to read:

QUALITY CONTROL OPERATIONS

The establishment of any specifications, standards, sampling plans, test procedures, or other laboratory control mechanisms required by this chapter, including any change in such specifications, standards, sampling plans, test procedures, or other laboratory control mechanisms, shall be drafted by the appropriate organizational unit and reviewed and approved by the quality control unit. The requirements in this section should be followed and documented at the time of performance. Any deviation from the written specifications, standards, sampling plans, test procedures, or other laboratory control mechanisms shall be recorded and justified.

Quality control operations include the establishment of scientifically sound and appropriate specifications, standards, sampling plans, and test procedures designed to ensure that raw materials, product containers, closures, in-process materials, labeling,

■products received for labeling and packaging operations as dietary supplements,■2S (*USP33*)

and finished products conform to adequate standards of identity, strength, quality, and purity. These controls include the following:

— Determination of conformance to appropriate written specifications for the acceptance of each lot within each shipment of raw materials, product containers, closures, and labeling used in the manufacture of ~~dietary products~~ ■dietary ingredients and dietary supplements, and of products received for labeling and packaging operations as dietary supplements.■2S (*USP33*)
(The specifications include a description of the sampling and testing procedures used. Samples should be representative and adequately identified. Such procedures also require appropriate retesting of any raw material, product container, or closure that is subject to deterioration.) Based upon adequate process verification, in-process controls, and statistical confidence, a skip-lot ~~sampling~~ ■testing■2S (*USP33*)
plan is an alternative to testing every batch, ■excluding raw materials, which require 100% identity testing.■2S (*USP33*)

— Determination of conformance to written specifications and a description of sampling and testing procedures for in-process materials. (Such samples should be representative and properly identified.)
— Determination of conformance to written descriptions of sampling procedures and appropriate specifications for finished products. (Such samples should be representative and properly identified.)
— The calibration of instruments, at suitable intervals, in accordance with an established written program containing specific directions, schedules, limits for accuracy and precision, and provisions for remedial action in the event that accuracy and/or precision limits are not met. Instruments not meeting established specifications shall not be used until repaired.

Testing and Release for Distribution

There should be appropriate laboratory determination of satisfactory conformance to specifications for the finished product, including the identity and strength prior to release. Based upon adequate process verification, in-process controls, or statistical confidence, a skip-lot or composite ~~sampling~~ ■testing■2S (*USP33*)
plan is an alternative to testing every batch.

There should be appropriate laboratory testing, as necessary, of each batch of dietary supplement required to be free of objectionable microorganisms. The accuracy, linearity, sensitivity, specificity, and precision of test methods employed by the firm, when they differ from compendial methods, should be established and documented.

Written procedures should describe any sampling and testing plans, which should include the method of sampling and the number of units per batch to be tested.

Products failing to meet established standards or specifications and any other relevant quality control criteria should be rejected. Rejected or adulterated ~~dietary products~~ ■dietary ingredients and dietary supplements■2S (*USP33*)
shall be identified, stored, and disposed of in a manner that protects against the adulteration of the other products. Reprocessing may be performed. Prior to acceptance and use, reprocessed material must meet established standards, specifications, and any other relevant criteria. Written procedures shall be established and followed prescribing the method for reprocessing batches or operations start-up materials that do not conform to finished goods standards or specifications. Finished goods manufactured using such materials shall meet all established purity, composition, and quality standards.

Stability Testing

There should be a written protocol designed to assess the stability characteristics of dietary supplements. The results of such testing should be used in determining appropriate storage conditions and shelf life. This protocol should include the following:

— Sample size and test intervals based on statistical criteria for each attribute should be examined to ensure valid estimates of stability;
— Storage conditions for samples retained for testing;
— Reliable, meaningful, and specific test methods should be used; and

— The dietary supplement should be tested in the same type of container–closure system as that in which the dietary supplement is marketed.

An adequate number of batches of each dietary supplement should be tested to determine an adequate shelf life, and a record of these data should be maintained. Accelerated studies combined with basic stability information on the raw materials, dietary supplements, and container-closure systems may be used to support tentative shelf life if full shelf-life studies are not available. Simplified stability testing procedures may be used where data from similar product formulations are available to support a shelf-life estimation of a new product. Where data from accelerated studies are used to project a tentative shelf life date that is beyond a date supported by actual shelf-life studies, stability studies should be conducted, including dietary supplement testing at appropriate intervals, until the tentative shelf life is verified or the adequate shelf life is determined.

Reserve Samples

An appropriately identified reserve sample that is representative of each lot or batch of dietary supplement should be retained and stored under conditions consistent with product labeling until at least 3 years after the shelf life of the product. The reserve sample should be stored in the same immediate container-closure system in which the finished product is marketed or in one that has essentially the same characteristics. The reserve sample consists of at least twice the quantity necessary to perform all the required tests. If an adverse event report is received, the reserve samples of dietary supplements and dietary ingredients from the same lot or batch must be analyzed by an appropriate procedure to confirm their identity and determine any adulteration or contamination. The recovered samples associated with adverse event reports from consumers, distributors, or both should also be analyzed, following the same method used for the reserved samples, if available. The results should be reported with other required information to the federal authority, using the required form. The reserve samples from a particular lot or batch associated with an adverse event report should be held for 6 years

■(serious events) or 3 years (nonserious events)■2S (*USP33*) from the date when the first adverse event report is received by the manufacturer, packer, or distributor.

Change to read:

RECORDS AND REPORTS

Any record for production, control,

■quality control operations,■2S (*USP33*) or distribution that is required to be maintained and is specifically associated with a batch of a product should be retained for at least 3 years after the shelf life of the batch.

Records should be maintained for all raw materials, product containers, closures, and labeling for at least 3 years after the shelf life of the last lot of product incorporating the raw material or using the container, closure, or labeling.

Master Production and Control Records

To ensure uniformity from batch to batch, master production and control records for each product should be prepared, dated, and signed by one person and independently checked, dated, and signed by a second person from the quality control unit.

Master production and control records should include the following:

— The name and strength of the product;

— The name and weight or measure of each dietary ingredient per unit or portion or per unit of weight or measure of the product, and a statement of the total weight or measure of any dosage unit;

— A complete list of raw materials designated by names or codes sufficiently specific to indicate any special quality characteristic;

— An accurate statement of the weight or measure of each raw material, using the same weight system (metric, avoirdupois, or apothecary) for each raw material;

— A statement concerning any calculated excess of raw material;

— A statement of theoretical weight or measure at appropriate phases of processing;

— A statement of theoretical yield, including the maximum and minimum percentages of theoretical yield beyond which investigation is required;

— A description of the product containers, closures, and packaging materials, including a specimen or copy of each label and all other labeling signed and dated by the person or persons responsible for approval of such labeling or, in lieu of specimens or copies of each label or other labeling, a positive identification of all labeling used; and

— Complete manufacturing and control instructions, ~~sampling and testing procedures, specifications,~~

■testing procedures, acceptance limits,■2S (*USP33*) special notations, and precautions to be followed.

■— Specific actions necessary in order to perform and verify points, steps, or stages in the manufacturing process where control is necessary to ensure the quality of dietary ingredients and dietary supplements, and to ensure that dietary ingredients and dietary supplements are packaged and labeled as specified in the master production record.

(a) Such specific actions must include verifying the weight or measure of any component and verifying the addition of any component; and

(b) For manual operations, such specific actions must include:

(i) One person weighing or measuring a component and another person verifying the weight or measure; and

(ii) One person adding the component and another person verifying the addition.

Corrective action plans for use when a specification is not met.■2S (*USP33*)

Batch Production and Control Records

Batch production and control records should be prepared for each batch of product produced and should include complete information relating to the production and control of each batch. These records should be reviewed and signed by a second person from the quality control unit. These records should

In-Process Revision

include accurate reproduction of the appropriate master production or control record and documentation that each significant step in the manufacture, processing, packing, or holding of the batch was accomplished, including the following:

— Dates;
— Identity of individual major equipment and lines used;
— Specific identification of each batch of raw material or in-process material used;
— Weights and measures of raw materials used in the course of processing;
— In-process and laboratory control results;
— Inspection of the packaging and labeling areas before and after use;
— A statement of the actual yield and a statement of the percentage of theoretical yield at appropriate phases of processing;
— Description of product containers and closures used;
— Complete labeling control records, including: ~~specimens or copies of all labeling used or identification of all labeling used;~~

■(a) The unique identifier assigned to packaging and labels used, the quantity of the packaging and labels used, and, when label reconciliation is required, reconciliation of any discrepancies between issuance and use of labels; and

(b) An actual or representative label, or a cross-reference to the physical location of the actual or representative label specified in the master manufacturing record;■2S (*USP33*)

— Any sampling performed;
— Identification of the persons performing and directly supervising or checking any step in the operation;
— Any investigation made; ~~and~~
— ~~Results of examinations made.~~

■— The results of any tests or examinations conducted on packaged and labeled dietary supplements (including repackaged or relabeled dietary supplements), or a cross-reference to the physical location of such results;

— Documentation at the time of performance that quality control personnel:

(a) Reviewed the batch production record, including:

(i) Review of any required monitoring operation, and

(ii) Review of the results of any tests and examinations, including tests and examinations conducted on components, in-process materials, finished batches of dietary supplements, and packaged and labeled dietary ingredients and dietary supplements;

(b) Approved or rejected any reprocessing or repackaging;

(c) Approved and released, or rejected, the batch for distribution, including any reprocessed batch; and

(d) Approved and released, or rejected, the packaged and labeled dietary supplement, including any repackaged or relabeled dietary supplement;

— Documentation at the time of performance of any required material review and disposition decision; and
— Documentation at the time of performance of any reprocessing.

Records for Raw Materials, Packaging, and Labels and for Product Received for Packaging or Labeling as a Dietary Supplement

The following records must be made and retained:

— Written procedures for fulfilling the requirements for raw materials, packaging, and labels and for product received for packaging or labeling;
— Receiving records (including records such as certificates of analysis, suppliers' invoices, and suppliers' guarantees) for components, packaging, and labels and for products received for packaging or labeling; and
— Documentation that the requirements of *Raw Materials, Labeling and Packaging* were met:

(a) The person who performs the required operation must document, at the time of performance, that the required operation was performed; and

(b) The documentation must include:

(i) The date of receipt of the raw materials, packaging, labels, or products received for packaging or labeling as a dietary supplement;

(ii) The initials of the person performing the required operation;

(iii) The results of any tests or examinations conducted on raw materials, packaging, or labels, and of any visual examination of product received for packaging or labeling as a dietary supplement; and

(iv) Any material review and disposition decision conducted on raw materials, packaging, labels, or products received for packaging or labeling as a dietary supplement.■2S (*USP33*)

Laboratory Records

Laboratory records should include complete data derived from all tests necessary to ensure compliance with established specifications and standards, including examinations and assays, as follows:

— A description of the sample received for testing with identification of source (that is, location from where sample was obtained), quantity, lot number or other distinctive code, and date sample was taken.
— A statement of each method used in the testing of the sample.
— A statement of the weight or measure of sample used for each test, where appropriate.
— A complete record of all data secured in the course of each test, including all graphs, charts, and spectra from laboratory instrumentation, properly identified to show the specific raw material, product container, closure, in-process material, or finished product, and lot tested.
— A record of all calculations performed in connection with the test, including units of measure, conversion factors, and equivalency factors.
— A statement of the results of tests and how the results compare with established standards of identity, strength, quality, and purity for the raw material, product container, closure, in-process material, or finished product tested.
— The initials or signature of the person who performs each test and the date(s) the tests were performed.

Complete records should be maintained of any modification of an established method employed in testing. Such records should include the reason for the modification and data to verify that the modification produced results that are at least as accurate and reliable for the material being tested as the established method.

Complete records should be maintained of any testing and standardization of laboratory reference standards, reagents, and standard solutions, the periodic calibration of laboratory instruments, and all stability testing performed. Any deviation should be reviewed and signed by the management of the quality control unit.

▪Quality Control Operation Records

The following records must be made and retained:

— Written procedures for the responsibilities of the quality control operations, including written procedures for conducting a material review and making a disposition decision and written procedures for approving or rejecting any reprocessing;
— Written documentation, at the time of performance, that quality control personnel performed the review, approval, or rejection requirements, by recording the following:
  (i) Date on which the review, approval, or rejection was performed; and
  (ii) Signature of the person performing the review, approval, or rejection; and
— Documentation of any material review and disposition decision and follow-up. Such documentation must be included in the appropriate batch production record and must include:
  (i) Description of the investigation into the cause of the deviation from the specification or the unanticipated occurrence;
  (ii) Evaluation of whether the deviation or unanticipated occurrence has resulted in, or could lead to, a failure to ensure the quality of the dietary supplement or a failure to package and label the dietary supplement as specified in the master manufacturing record;
  (iii) Identification of the action(s) taken to correct, and prevent a recurrence of, the deviation or the unanticipated occurrence;
  (iv) Explanation of the actions taken with the raw material, dietary supplement, packaging, or label;
  (v) A scientifically valid reason for any reprocessing of a dietary supplement that is rejected or any treatment or in-process adjustment of a component that is rejected; and

(vi) The signatures of (1) the individual(s) designated to perform the quality control operation, who have conducted the material review and made the disposition decision; and in addition, (2) each qualified individual who has provided information relevant to that material review and disposition decision.■2S (*USP33*)

Distribution Records

Distribution records should contain the name and strength of the product, name and address of the consignee, date and quantity shipped, and lot or control number of the finished product.

Record Keeping

The manufacturer, packer, or distributor of dietary supplements must keep all required records, as shown in this chapter, for 3 years beyond the shelf life of dietary supplements associated with those records. If adverse event reports are received, those records must be kept for additional 6 years from the date when the first report is received. All records must be accessible by the regulatory authority when requested.

■Records must be kept as original records, as true copies (such as photocopies, microfilm, microfiche, or other accurate reproductions of the original records), or as electronic records.

All electronic records must comply with part 11 of Code of Federal Regulations Title 21 (21 CFR part 11).

If reduction techniques are used, such as microfilming, suitable reader and photocopying equipment must be readily available to auditors and inspectors.■2S (*USP33*)

Complaint Files

Written procedures describing the handling of all written and oral complaints regarding a dietary supplement shall be established and followed. These procedures should include provisions for review by the quality control unit of any complaint involving the possible failure of a product to meet any of its specifications and a determination as to the need for an investigation.

Each complaint should be recorded in a file designed especially for dietary supplement complaints. Written records should be maintained until at least 3 years after the shelf life of the product, or 3 years after the date when the complaint was received, whichever is longer.

The written record should include the following information, where known: the name and strength of the product, lot number, name of complainant, nature of complaint, and reply to complainant.

If an investigation is necessary, the written record should include the findings of the investigation and follow-up.

■The review and investigation of the product complaint by a qualified person, the review by quality control personnel about whether to investigate a product complaint, and the findings and follow-up action of any investigation performed must extend to all relevant batches and records.■2S (*USP33*)

Adverse Event Reports

■Adverse event reports include reports on any health-related adverse event associated with the use of a dietary supplement that is adverse. It includes both nonserious and serious adverse event reports.

The manufacturer, packer, or distributor of a dietary supplement (called the *responsible person*) whose name appears on the label shall be responsible for keeping a report of all nonserious adverse events along with any related records (e.g., records of communications with the person who reported the nonserious event). All such records of nonserious adverse events should be kept for 6 years.■2S (*USP33*)

~~The manufacturer, packer, or distributor of a dietary supplement (responsible person)~~

■The responsible person■2S (*USP33*) whose name appears on the label shall also be responsible for reporting any serious adverse event reported to it, and associated with a dietary supplement that is marketed and used in the same country, to the regulatory authority as soon as appropriate, but no later than 15 business days after receipt of the report, using the appropriate form as defined by the regulation

■(http://www.fda.gov/Food/DietarySupplements/Alerts/ucm111110.htm).■2S (*USP33*)
A serious adverse event is an event that results in

■any of following:■2S (*USP33*)

1. Death,
2. A life-threatening experience,
3. Inpatient hospitalization,
4. A persistent or significant disability or inability,
5. A congenital anomaly or birth defect, or
6. A condition that requires, according to reasonable medical judgment, a medical or surgical intervention to prevent one of the five outcomes listed above.

A retailer whose name appears on the label as a distributor may, by agreement, authorize the manufacturer or packer to submit the required reports to the regulatory authority, as long as the retailer directs all received adverse event reports to the manufacturer or packer. Each serious adverse event report should include a copy of the product's label, the information described in the preceding section *Complaint Files*, and if possible, the contact information of the complainant; daily intake; alcohol consumption and amount; use of prescription medicine

and OTC medicine, including a daily dose; and other medical information. The information associated with personal identification and medical records should be obtained only for the reports and kept safe from disclosure. Any new medical information that is related to an already submitted serious adverse event report that is received within 1 year of the initial report shall be submitted to the regulatory authority as soon as appropriate, but no later than 15 business days after receipt of the information. The records related to each report of ~~an~~

■a serious■2S *(USP33)*
adverse event received by the manufacturer, packer, or retailer should be maintained for 6 years. The authorized person who is designated by the regulatory authority should be permitted access to those records.

RETURNED AND SALVAGED PRODUCTS

Returned Dietary Supplements

Returned products should be identified as such and held. If the conditions under which returned ~~dietary products~~

■dietary ingredients and dietary supplements■2S *(USP33)*
have been held, stored, or shipped before or during their return, or if the condition of the product, its container, carton, or labeling, as a result of storage or shipping, casts doubt on the safety, identity, strength, quality, or purity of the product, the returned product should be destroyed unless examination, testing, or other investigations prove the product meets appropriate standards of safety, identity, strength, quality, or purity. The returned products associated with adverse events must be destroyed after a sufficient sample of products is stored for the purpose of further investigation only. The products related to the adverse event that have been returned should be kept for 6 years

■(serious events) or 3 years (nonserious events)■2S *(USP33)*
from the date when the first report is received. A product may be reprocessed provided that the subsequent product meets adequate standards, specifications, and characteristics. Records of returned products should be maintained and should include the name and label potency of the product, lot number (or control number or batch number), reason for the return, quantity returned, date of disposition, and ultimate disposition of the returned product. If the reason for a product being returned implicates associated batches, an appropriate investigation is necessary.

Dietary Supplement Salvaging

Products that have been involved in adverse events or subjected to improper storage conditions, including extremes in temperature or humidity, smoke, fumes, pressure, age, or radiation due to natural disasters, fires, accidents, or equipment failures should not be salvaged and returned to the marketplace. Whenever there is a question whether products have been subjected to such conditions, salvaging operations may be conducted only if there is (a) evidence from laboratory tests and assays that the products meet all applicable standards of identity, strength, quality, and purity, and (b) evidence that the products and their associated packaging were not subjected to improper storage conditions as a result of the disaster or accident. Organoleptic examinations should be accepted only as supplemental evidence that the dietary supplement meets appropriate standards of identity, strength, quality, and purity. Records including name, lot number, and disposition should be maintained for salvaged products. If the products are involved in adverse events, the instructions described in the preceding section *Records and Reports* should be followed.

Defect Action Levels

Some dietary ingredients and dietary supplements, even when produced under current good manufacturing practice, contain natural or unavoidable defects that at low levels are not hazardous to health. The Food and Drug Administration establishes maximum levels for these defects in ~~dietary products~~

■dietary ingredients and dietary supplements■2S *(USP33)*
produced under current good manufacturing practice and uses these levels in deciding whether to recommend regulatory action.

Defect action levels are established for ~~dietary products~~

■dietary ingredients and dietary supplements■2S *(USP33)*
whenever it is necessary and feasible to do so. These levels are subject to change upon the development of new technology or the availability of new information.

Compliance with defect action levels does not excuse violation of the requirement in section 402(a)(4) of the Act that ~~dietary products~~

■dietary ingredients and dietary supplements■2S *(USP33)*
shall not be prepared, packed, or held under unsanitary conditions or the requirements in this part that ~~dietary product~~ manufacturers, distributors, and holders

■of both dietary ingredients and dietary supplements■2S *(USP33)*
shall observe current good manufacturing practice. Evidence indicating that such a violation exists causes ~~a dietary product~~

■a dietary ingredient and a dietary supplement■2S *(USP33)*
to be adulterated within the meaning of the Act, even though the amounts of natural or unavoidable defects are lower than the currently established defect action levels. The manufacturer, distributor, and holder of ~~a dietary product~~

■a dietary ingredient or a dietary supplement■2S *(USP33)*
shall at all times utilize quality control operations that reduce natural or unavoidable defects to the lowest level currently feasible.

The mixing of a dietary ingredient or dietary supplement containing defects above the current defect action level with another lot of dietary ingredient or dietary supplement is not permitted and renders the final product adulterated within the meaning of the Act, regardless of the defect level of the final product.

A compilation of the current defect action levels for natural or unavoidable defects in ~~dietary products~~

■dietary ingredients and dietary supplements■2S *(USP33)*
that present no health hazard may be obtained upon request from the Industry Activities Staff (HFS-565), Center for Food Safety and Applied Nutrition, U.S. Food and Drug Administration, 5100 Paint Branch Parkway, College Park, MD 20740-3835.

GLOSSARY

Act means Federal Food, Drug and Cosmetic Act (United States Code [U.S.C.] Title 21, Chapter 9).

Acceptance criteria is the product specifications and acceptance or rejection criteria, such as acceptable quality level and unacceptable quality level, with an associated sampling plan, that are necessary for making a decision to accept or reject a lot or batch (or any other convenient subgroups of manufactured units).

Adequate means that which is needed to accomplish the intended purpose in keeping with good public health practice.

Adverse event means any health-related event that is adverse and that is associated with the use of a dietary supplement.

Adverse event report means a report of an adverse event (see definition above). (See also *Serious adverse event report.)*

Batch is a specific quantity of a finished product or other material that is intended to have uniform character and quality, within specified limits, and is produced according to a single manufacturing order during the same cycle of manufacture.

Blanching means a prepackaging heat treatment of ~~a dietary product~~

■a dietary ingredient and a dietary supplement■2S (*USP33*)

for a sufficient time and at a sufficient temperature to partially or completely inactivate the naturally occurring enzymes and to effect other physical or biochemical changes in the product.

Composition is (1) the identity of a dietary ingredient or dietary supplement, and (2) the concentration of a dietary ingredient (e.g., weight or other unit of use/weight or volume), or the potency or activity of one or more dietary ingredients, as indicated by appropriate procedures.

Dietary ingredient is an ingredient intended for use or used in a dietary supplement that is

— a vitamin;

— a mineral;

— an herb or other botanical;

— an amino acid;

— a dietary substance for use by humans to supplement the diet by increasing the total dietary intake, or a concentrate, metabolite, constituent, extract; or

— a combination of any of the foregoing ingredients.

~~*Dietary product* means either a dietary ingredient or dietary supplement as defined in this chapter.~~

■■2S (*USP33*)

Dietary supplement is a product (other than tobacco) that is intended to supplement the diet and that bears or contains one or more of the following dietary ingredients: a vitamin, a mineral, an herb or other botanical, an amino acid, a dietary substance for use by humans to supplement the diet by increasing the total daily intake, or a concentrate, metabolite, constituent, extract or combination of these ingredients, that is intended for ingestion in a pill, capsule, tablet or liquid form, that is not represented for use as a conventional food or as the sole item of a meal or diet, and that is labeled as a dietary supplement, and includes products such as new drug, certified antibiotic, or licensed biologic that was marketed as a dietary supplement or food before approval, certification, or license unless a sanitary authority waives this provision.

Inactive ingredient is any raw material other than a dietary ingredient.

In-process material is any material fabricated, compounded, blended, ground, extracted, sifted, sterilized, or processed in any other way that is produced for, and used in, the preparation of the dietary supplement.

Lot is a batch, or a specific identified portion of a batch, having uniform character and quality within specified limits.

Lot number, control number, or *batch number* is any distinctive combination of letters, numbers, or symbols, or any combination of them from which the complete history of the manufacture, processing, packing, holding, and distribution of a batch or lot of finished dietary ingredient, dietary supplement, or other material can be determined.

Manufacture or *manufacturing* includes all operations associated with the production of ~~dietary products~~

■dietary ingredients and dietary supplements,■2S (*USP33*) including packaging and labeling operations, testing, and quality control of a dietary ingredient or dietary supplement.

Microorganisms means yeast, molds, bacteria, and viruses and includes, but is not limited to, species having public health significance. The term ''undesirable microorganisms'' includes those microorganisms that are of public health significance, that subject ~~a dietary product~~

■a dietary ingredient or a dietary supplement■2S (*USP33*) to decomposition, that indicate that a dietary ingredient or dietary supplement is contaminated with filth, or that otherwise may cause ~~a dietary product~~

■a dietary ingredient or a dietary supplement■2S (*USP33*) to be adulterated within the meaning of the Act. Occasionally in these regulations, the adjective ''microbial'' is used instead of an adjectival phrase containing the word ''microorganism.''

Pest refers to any objectionable animals or insects including, but not limited to, bird, rodents, flies, and larvae.

Plant means the building or facility or parts thereof, used for or in connection with the manufacturing, packaging, labeling, or holding of ~~a dietary product~~

■a dietary ingredient and a dietary supplement.■2S (*USP33*)

Process evaluation is a set of tests performed on a process intended to evaluate its capacity to consistently produce the results that it is intended for.

Quality control operation is a planned and systematic procedure for taking all actions necessary to prevent ~~a dietary product~~

■a dietary ingredient and a dietary supplement■2S (*USP33*) from being adulterated.

Quality control unit is any person or organizational element designated by the firm to be responsible for the duties relating to quality control operations.

Raw material is any ingredient intended for use in the manufacture of a dietary ingredient or dietary supplement, including those that may not appear in such finished product. (A dietary ingredient is a raw material when considering the manufacture of a dietary supplement.)

Representative sample is a sample that consists of a number of units that are drawn based on rational criteria such as random sampling and is intended to ensure that the sample accurately portrays the material being sampled.

Rework is a clean, unadulterated material that has been removed from processing for reasons other than unsanitary conditions or that has been successfully reconditioned by reprocessing and that is suitable for use in the manufacture of ~~a dietary product~~

■a dietary ingredient or a dietary supplement.■2S (*USP33*)

Sanitizing is to adequately treat equipment, containers, or utensils by a process that is effective in destroying vegetative cells of microorganisms of public health significance and in substantially reducing other undesirable microorganisms but without affecting the product or its safety for the consumer.

Serious adverse event report means a report of an adverse event that is termed *serious* because it meets certain criteria (see the subsection *Adverse Event Reports*). ~~The new law~~

■The Dietary Supplement and Nonprescription Drug Consumer Protection Act■*2S (USP33)* requires manufacturers and distributors of dietary supplements and OTC drugs to report all serious adverse events to the Secretary of the Food and Drug Administration (FDA). This is an entirely new requirement for dietary supplements.

Shall is used to state requirements that must be met under the provisions of this guideline.

Shelf life is the period of time after manufacturing in which the dietary supplement is ensured to meet applicable standards of identity, strength, quality, and purity.

Shelf-life (*Use by*) *date* is the date beyond which the dietary supplement is no longer ensured to meet applicable standards of identity, strength, quality, and purity.

Should is used to state recommended or advisory procedures or identify recommended equipment.

Skip-lot ~~*sampling*~~ ■*testing (or sampling)*■*2S (USP33)* is a reduced level of ~~sampling or testing~~

■testing (or sampling)■*2S (USP33)* for a particular specified parameter(s) based upon one or more of the following:

— Statistical analysis of an adequate quantity of historical test data;
— Statistical confidence in the capability of the manufacturing process as determined by suitable verification; or
— Ongoing monitoring of the process using recognized statistical process control (SPC) techniques.

Strength means the concentration of the active substance (weight/weight, weight/volume, or unit of use/volume or weight basis); and/or the potency, that is, the activity of the product as indicated by appropriate laboratory tests.

Water activity (a_w) is a measure of the free moisture in a dietary ingredient or dietary supplement and is the quotient of the water vapor pressure of the substance divided by the vapor pressure of pure water at the same temperature.

REAGENTS, INDICATORS, AND SOLUTIONS

Reagent Specifications

BRIEFING

Cobalt Chloride, *USP 32* page 816. It is proposed to correct the CAS number of this reagent.

(HDQ: M. Marques.) RTS—C75911

Change to read:

Cobalt Chloride *(Cobaltous Chloride),* $CoCl_2 \cdot 6H_2O$—**237.93** ~~[7646-79-9]~~

■[*7791-13-1*]■2S *(USP33)*
—Use ACS reagent grade.

BRIEFING

Oxygen Certified Standard. It is proposed to add this new reagent used in the monograph for *Medical Air*.

(HDQ: M. Marques.) RTS—C61164

Add the following:

■**Oxygen Certified Standard**—A suitable 99.99% oxygen certified standard is available from most suppliers of specialty gases.■2S *(USP33)*

BRIEFING

Tetramethylbenzidine. It is proposed to add this new reagent used in developing reagent B in the tests for *Limit of Propanolamine* and *Degradation Products* in the *Cyclophosphamide* monograph, which appears elsewhere in this issue of *PF*.

(HDQ: M. Marques) RTS—C73270

Add the following:

■**Tetramethylbenzidine,** *(4-(4-Amino-3,5-dimethylphenyl)-2,6-dimethylaniline; 3,3′,5,5′ Tetramethylbenzidine; 3,3′5,5′-Tetramethyl-[1,1′-biphenyl] 4,4′-diamine)* $C_{16}H_{20}N_2$—**240.34** [*54827-17-7*]—Use a suitable grade.■2S *(USP33)*

Test Solutions

BRIEFING

Lead Subacetate TS, *USP 32* page 866. It is proposed to simplify the preparation of this *Test solution* harmonizing with the text in the *British Pharmacopoeia*.

(HDQ: M. Marques.) RTS—C75914

Change to read:

Lead Subacetate TS~~ Triturate 14 g of lead monoxide to a smooth paste with 10 mL of water, and transfer the mixture to a bottle, using an additional 10 mL of water for rinsing. Dissolve 22 g of lead acetate in 70 mL of water, and add the solution to the lead oxide mixture. Shake it vigorously for 5 minutes, then set it aside, shaking it frequently, during 7 days. Finally filter, and add enough recently boiled water through the filter to make 100 mL.~~

■Dissolve 40.0 g of lead acetate in 90 mL of carbon dioxide-free water. Adjust with 10 M sodium hydroxide to a pH of 7.5, centrifuge, and use the clear supernatant solution. It contains NLT 16.7% (w/w) and NMT 17.4% (w/w) of Pb in a form corresponding to the formula $C_8H_{14}O_{10}Pb_3$. The solution remains clear when stored in a well-closed container.■2S *(USP33)*

BRIEFING

Starch TS, *USP 32* page 869. It is proposed to include the information about using commercially available solutions stabilized with compounds other than mercury salts.

(HDQ: M. Marques.) RTS—C75665

Change to read:

Starch TS—Mix 1 g of soluble starch with 10 mg of red mercuric iodide and sufficient cold water to make a thin paste. Add 200 mL of boiling water, and boil for 1 minute with continuous stirring. Cool, and use only the clear solution. [NOTE—Commercially available, stabilized starch indicator solutions may be used,

■including mercury-free solutions preserved with other compounds such as salicylic acid.]■2S (*USP33*)

Chromatographic Columns (Packings)

BRIEFING

L## (Emtricitabine, Chirobiotic V). It is proposed to add this new column designation used to validate the test for *Organic Impurities* in the USP Pending Monograph *Emtricitabine*.

(HDQ: M. Marques) RTS—C76702

Add the following:

■**L## (Emtricitabine, Chirobiotic V)**—Vancomycin glycopeptide covalently bonded to silica particles, 100 Angstroms, about 5 μm in diameter.■2S (*USP33*)

REFERENCE TABLES

BRIEFING

Container Specifications for Capsules and Tablets, *USP 32* page 881, page 4014 of the *First Supplement*, and page 992 of *PF* 35(4) [July–Aug. 2009].

(HDQ) RTS—C34840; C44029; C55687; C61270

The following table is provided as a reminder for the pharmacist engaged in the typical dispensing situation who already is acquainted with the *Packaging and Storage* requirements set forth in the individual monographs. It lists the capsules and tablets that are official in the *United States Pharmacopeia* and indicates the relevant tight (T), well-closed (W), and light-resistant (LR) specifications applicable to containers in which the drug that is repackaged should be dispensed.

This table is not intended to replace, nor should it be interpreted as replacing, the definitive requirements stated in the individual monographs.

BRIEFING

Description and Relative Solubility of USP and NF Articles, *USP 32* page 890, page 4014 of the *First Supplement*, page 817 of *PF* 34(3) [May–June 2008], page 1565 of *PF* 34(6) [Nov.–Dec. 2008], page 188 of *PF* 35(1) [Jan.–Feb. 2009], page 464 of *PF* 35(2) [Mar.–Apr. 2009], page 651 of *PF* 35(3) [May–June 2009], and page 993 of *PF* 35(4) [July–Aug. 2009].

(HDQ) RTS—C42827; C44029; C58037; C61270; C62478; C64233; C65585; C67219; C67224; C68840; C69714; C72216

Add the following:

■**Clenbuterol Hydrochloride:** White or almost white, crystalline powder. Soluble in water and in alcohol, slightly soluble in acetone. It melts with decomposition at 173°.■2S (*USP33*)

Add the following:

■**Diethyl Sebacate:** A colorless to slightly yellow liquid. Miscible with alcohol, with ether, with other organic solvents, and with most fixed oils; insoluble or practically insoluble in water. *NF category*: Flavors and perfumes.■2S (*USP33*)

Add the following:

■**Docetaxel:** White or almost white, crystalline powder. Freely soluble in acetone; soluble in methanol; practically insoluble in water.■2S (*USP33*)

Add the following:

■**Dofetilide:** White to off-white powder. Soluble in 0.1 N sodium hydroxide, in acetone, and in 0.1 N hydrochloric acid; very slightly soluble in water and in isopropyl alcohol.■2S (*USP33*)

Add the following:

■**L-Glutamic Acid Hydrochloride:** A white, crystalline powder. 1 g dissolves in about 3 mL of water. It is almost insoluble in alcohol and in ether. Its solutions are acid to litmus. *NF Category*: Flavors and perfumes.■2S (*USP33*)

Change to read:

Hydrochlorothiazide: White, or practically white, practically odorless, crystalline powder. ~~Slightly soluble in water;~~

■■2S (*USP33*)
Freely soluble in sodium hydroxide solution, in *n*-butylamine, and in dimethylformamide;

■very slightly soluble in water;■2S (*USP33*)
sparingly soluble in methanol; insoluble in ether, in chloroform, and in dilute mineral acids.

Add the following:

■**Levetiracetam:** White to almost white powder. Very soluble in water; soluble in acetonitrile; practically insoluble in hexane.■2S (*USP33*)

Add the following:

▪**Partially-Neutralized Methacrylic Acid and Ethyl Acrylate Copolymer:** White or almost white, free-flowing powder. Freely soluble in alcohol, in methanol, and in a 40 g/L solution of sodium hydroxide; soluble in solutions at pH values above pH 5.5 under salt formation; practically insoluble in ethyl acetate and in acidic aqueous solutions. *NF category*: Coating agent; film-forming agent.■2S (*USP33*)

Add the following:

▪**Methylpyrrolidone:** A clear, colorless liquid. Miscible with water and with most organic solvents including alcohol, ketones, and aromatic and chlorinated hydrocarbons. Boiling point: about 202°. Refractive index: about 1.469.■2S (*USP33*)

Add the following:

▪**Orlistat:** White to off-white fine powder or fine powder with lumps. Freely soluble in chloroform; very soluble in methanol and in alcohol; practically insoluble in water.■2S (*USP33*)

Add the following:

▪**Hydrogented Polydextrose:** Off-white to light tan-colored solid. Very soluble in water; soluble in alcohol; slightly soluble in glycerin and in propylene glycol. *NF category*: Bulking agent; coating agent; humectant; tablet binder; suspending and/or viscosity-increasing agent. ■2S (*USP33*)

Add the following:

▪**Riluzole:** White to slightly yellow powder or crystalline powder. Freely soluble in acetonitrile, in alcohol and in methylene chloride; slightly soluble in hexane; very slightly soluble in water.■2S (*USP33*)

Pending Proposals

(Items from earlier numbers of *PF* that have not yet been adopted and become official)

In order for an item to be adopted into the *USP–NF* and become officially binding, it must first be proposed and published in the *Pharmacopeial Forum (PF)* to allow the public an opportunity to review and comment upon it. When an item is adopted, it is published in the *USP–NF,* its *Supplements,* an *IRA* , or a *Revision Bulletin.* Those items that have not yet been adopted are marked as *Pending Proposals.*

The *Pending Proposals* list contains these items separated into the following categories: General Notices and Requirements; *USP* monographs; Dietary Supplements Monographs; General Chapters; Reagents; Indicators; and Solutions; Reference Tables; Excipients; and *NF* Monographs. Each entry in the *Pending Proposals* list contains the monograph title and the citation of the most recent publication of the monograph. Reprints of *PF* proposals may be purchased from USP by sending a written request for information to custsvc@usp.org.

To check the status of a *Pending Proposal,* please contact USP as directed below.

- The briefing accompanying the monograph or general chapter lists the names of the Scientific Liaisons responsible for the proposed revisions. The contact information (phone number and email) for the Scientific Liaison is available in the *Staff Directory* section of *How to Use PF.* For *USP–NF Online* subscribers, the name and contact information for the assigned Scientific Liaison is available in the *Auxiliary Information* portion of each monograph.
- Call USP at 301-816-8344 and ask to speak with the Scientific Liaison assigned to the monograph or general chapter of interest.
- Submit questions by email to stdsmonographs@usp.org. Please indicate the name of the monograph or general chapter in the subject line of the email.

Following these lists the reader will find the *Canceled Proposals* list. These are items that were published in *PF* and were pending, but have since been canceled. This list contains cumulative entries for the six issues per volume of *PF* [i.e., 35(1) through 35(6)]. Note that canceled proposals may be republished in *PF* to be considered for future adoption into the *USP–NF.*

Acetaminophen and Tramadol Hydrochloride Tablets (new)	35	1	56
Acetylcysteine—*USP Reference standards, Assay*	31	3	726
Medical Air—*Identification* (add); *Assay; Inorganic Impurities—Carbon Dioxide, Carbon Monoxide, Sulfur Dioxide, Limit of Nitric Acid and Nitrogen Dioxide; Packaging and Storage; Labeling*	35	4	828
Albumin Human—*Definition, Packaging and storage, Expiration date, Labeling, USP Reference standards* (add), *Identification A, B* (add), *Bacterial endotoxins* (add), *Safety* (add), *Sterility* (add), *pH* (add), *Molecular size distribution* (add), *Heat stability* (add), *Incubation* (add) *Prekallikrein activator* (add), *Protein content* (add), *Heme content* (add), *Potassium content* (add), *Sodium content* (add)	31	5	1338
Albuterol Tablets—*Assay*	31	3	726
Alendronate Sodium Tablets—*Dissolution*	35	1	59
Alprazolam Tablets—*Assay*	33	1	41
Alumina, Magnesia, and Calcium Carbonate Chewable Tablets (new)	29	6	1836
Amifostine—*X-ray diffraction* (delete)	34	5	1136
Amiodarone Hydrochloride (new)	34	6	1429
Amlodipine Besylate—*Chemical information, Definition, Labeling* (add), *Water*	34	5	1136
Amlodipine Besylate Tablets (new)	35	1	62
Amphetamine Sulfate—*USP Reference standards, Identification, Chromatographic purity* (delete), *Related compounds* (add), *Organic volatile impurities* (delete), *Assay*	34	4	902
Amphetamine Sulfate Tablets—*Identification, Assay*	34	4	904
Ampicillin—*Definition, USP Reference standards, Related compounds* (add), *Assay*	34	5	1140
Ampicillin Sodium—*Dimethylaniline*	35	1	65

Pending Proposals (*continued*)

(Items from earlier numbers of *PF* that have not yet been adopted and become official)

Title and Proposal	PF Volume, Issue, and Page Numbers of Pending Proposals Vol.	No.	Page(s)
Aprotinin (new)	31	3	732
Aprotinin Injection (new)	31	3	736
Articaine Hydrochloride (new)	35	3	544
Aspirin—*Readily carbonizable substances*	34	5	1143
Atenolol—*Identification B*	35	3	545
Atenolol Tablets—*Dissolution*	35	1	66
Atorvastatin Calcium (new)	35	1	66
Atovaquone Oral Suspension—*Assay*	34	2	247
Atracurium Besylate Injection—*Related compounds*	34	4	905
Atropine Sulfate—*Identification C* (add); *Organic Impurities—Other Alkaloids* (delete), *Procedure* (add); *Melting Range or Temperature* (delete); *Optical Rotation* (delete); *Optical Rotation* (add); *Acidity* (delete); *Packaging and Storage; USP Reference Standards*	35	4	829
Aurothioglucose Injectable Suspension—*Bacterial endotoxins* (add), *Sterility* (add)	34	4	906
Azithromycin—*USP Reference standards, Limit of related substances* (delete), *Related compounds* (add)	34	3	559
Azithromycin for Injection (new)	34	3	562
Azithromycin Tablets (new)	34	5	1143
Aztreonam for Injection—*Assay*	34	4	906
Balsalazide Disodium (new)	35	4	830
Balsalazide Disodium Capsules (new)	35	4	832
Benzethonium Chloride—*Identification B, C* (delete), *Identification B* (add), *USP Reference Standards* (add)	35	4	833
Benzocaine—*Readily carbonizable substances*	34	5	1147
Benzoic Acid—*Readily carbonizable substances*	34	5	1147
Benzoin—*Botanic characteristics, Identification*	35	1	70
Bicalutamide Tablets—*Labeling, Dissolution*	34	5	1147
Bisoctrizole (new)	32	2	309
Bleomycin for Injection—*Identification A, B* (add), *Other requirements*	34	5	1150
Budesonide—*Limit of 11-ketobudesonide, Related compounds*	35	3	539
Buspirone Hydrochloride—*Content of chloride*	31	3	742
Caffeine—*Identification B, Melting range* (delete), *Readily carbonizable substances* (delete), *Other alkaloids* (delete)	34	5	1150
Camphor—*Water*	31	3	742
Capecitabine—*Assay, Organic Impurities*	35	4	834
Capecitabine Tablets—*Assay, Dissolution, Organic Impurities*	35	4	835
Carbidopa—*Specific rotation*	35	1	73
Carbidopa and Levodopa Extended-Release Tablets (new)	34	6	1433
Carmustine (new)	35	3	546
Carmustine for Injection (new)	35	3	548
Cefazolin Sodium—*Chemical information, Related compounds* (add)	34	6	1438
Cefixime for Oral Suspension—*Water* (delete)	34	6	1441
Ceftazidime Injection—*USP Reference standards, Pyrogen* (delete), *Bacterial endotoxins* (add)	34	4	907
Ceftiofur Hydrochloride (new)	34	4	908
Ceftiofur Sodium (new)	34	4	912
Chloral Hydrate—*Readily carbonizable substances*	34	5	1150
Ciprofloxacin—*Identification B*	35	4	837
Ciprofloxacin Hydrochloride—*Identification B*	35	4	839
Ciprofloxacin Injection—*Identification A*	35	4	840
Ciprofloxacin Ophthalmic Solution—*Identification A*	35	4	842
Ciprofloxacin Tablets—*Identification A, B* (delete)	35	4	843
Citalopram Hydrobromide—*Identification, Related compounds*	34	4	917
Citalopram Tablets—*Identification A, Uniformity of Dosage Units, Organic Impurities*	35	4	844
Anhydrous Citric Acid *(Harmonization)—Sulfate*	31	3	749
Anhydrous Citric Acid—*Readily carbonizable substances*	34	5	1150
Citric Acid Monohydrate *(Harmonization)—Sulfate*	31	3	750
Citric Acid Monohydrate—*Readily carbonizable substances*	34	5	1151
Citric Acid, Magnesium Oxide, and Sodium Carbonate Irrigation—*USP Reference standards, Assay for citric acid (delayed implementation to January 1, 2009)*	31	2	394
Cladribine—*Specific rotation, Related compounds*	33	1	49
Clarithromycin Tablets—*Dissolution*	35	1	73
Clavulanate Potassium—*Limit of aliphatic amines, Limit of 2-ethylhexanoic acid*	34	6	1441
Climbazole (new)	33	5	891

Pending Proposals (*continued*)

(Items from earlier numbers of *PF* that have not yet been adopted and become official)

Title and Proposal	PF Volume, Issue, and Page Numbers of Pending Proposals Vol.	No.	Page(s)
Clindamycin Palmitate Hydrochloride—*Chemical information, Assay*	34	6	1442
Clopidogrel Tablets—*Related compounds*	33	1	50
Cloprostenol Injection (new)	34	4	918
Cloprostenol Sodium (new)	34	4	920
Cocaine—*Readily carbonizable substances*	34	5	1151
Cocaine Hydrochloride—*Readily carbonizable substances*	34	5	1151
Codeine—*Readily carbonizable substances*	34	5	1151
Codeine Sulfate—*Readily carbonizable substances*	34	5	1151
Dalteparin Sodium (new)	30	5	1598
Dantrolene Sodium Capsules—*Packaging and storage*	34	5	1151
Dapsone—*Assay*	31	3	750
Deferoxamine Mesylate—*Definition, Identification* (delete), *A* (add), *B* (add), *Assay, Organic Impurities—Procedure* (add), *Packaging and Storage*	35	4	847
Human Acellular Dermal Matrix (new)	35	3	558
Microsized Human Acellular Dermal Matrix (new)	35	3	561
Desmopressin Nasal Spray Solution (new)	31	4	1059
Dextroamphetamine Sulfate—*Definition, USP Reference standards, Identification, Chromatographic purity* (delete), *Related compounds* (add), *Organic volatile impurities* (delete), *Assay*	34	4	921
Dextrose—*Harmonization*	34	6	1585
Diazepam Extended-Release Capsules—*USP Reference standards, Assay*	32	2	330
Diclazuril (new)	35	1	73
Diclofenac Sodium Delayed-Release Tablets—*Dissolution*	35	2	271
Dicyclomine Hydrochloride—*Readily carbonizable substances*	34	5	1152
Didanosine for Oral Solution—*Assay*	34	6	1443
Dihydroxyaluminum Sodium Carbonate Chewable Tablets (new)	29	6	1873
Disulfiram—*Assay, Inorganic Impurities—Selenium*	35	4	848
Dolasetron Mesylate—*Impurities*	35	2	272
Dopamine Hydrochloride—*Readily carbonizable substances*	34	5	1152
Doxazosin Mesylate—*Assay*	34	5	1152
Dronabinol Capsules—*Definition, Assay, USP Reference Standards*	35	3	549
Ecamsule Solution (new)	34	5	1153
Egg Phospholipids (new)	31	3	757
Endotoxin Indicator for Depyrogenation (new)	34	6	1444
Enrofloxacin (new)	34	4	924
Ensulizole—*USP Reference Standards*	35	4	849
Epirubicin Hydrochloride (new)	35	2	273
Erythromycin Pledgets—*Identification* (add), *Other requirements*	34	5	1157
Sterile Erythromycin Ethylsuccinate—*Identification* (add), *Other requirements*	34	5	1158
Esomeprazole Magnesium—*Identification B, Other Components—Content of Magnesium, Optical Rotation* (delete)	35	3	550
Esterified Estrogens—*Identification, Free steroids, Assay*	32	6	1678
Esterified Estrogens Tablets—*USP Reference standards, Assay*	32	6	1680
Ethotoin Tablets—*USP Reference standards, Assay*	32	2	332
Famotidine Injection (new)	32	2	333
Famotidine for Oral Suspension—*Uniformity of dosage units*	34	5	1158
Fenofibrate—*Definition, Assay*	35	2	275
Fentanyl (new)	34	3	602
Fexofenadine Hydrochloride Tablets—*Dissolution*	34	4	931
Fluconazole Injection (new)	35	3	552
Fluconazole Tablets (new)	34	4	932
Fludarabine Phosphate for Injection—*Related compounds*	34	4	933
Flurazepam Hydrochloride—*Identification*	31	3	766
Fluvestrant (new)	33	5	99
Gabapentin Tablets—*Labeling* (add), *Dissolution*	34	4	934
Galantamine Tablets—*Labeling* (add), *Dissolution*	34	6	1452
Glimepiride Tablets—*Dissolution*	33	3	411
Glutaral Concentrate—*Specific gravity*	31	3	766
Glyburide and Metformin Hydrochloride Tablets—*Identification A*	34	5	1163
Goserelin Acetate (new)	32	3	792
Granisetron Hydrochloride Injection (new)	34	4	935
Granisetron Hydrochloride Oral Suspension (new)	34	6	1454
Granisetron Hydrochloride Tablets (new)	34	4	937
Halazone—*Readily carbonizable substances*	34	5	1163

Pending Proposals (*continued*)

Helium—*Identification A* (delete), *B* (delete), *Identification* (add), *Assay, Inorganic Impurities—Carbon Monoxide, Odor, Packaging and Storage, Labeling* (add)	35	4	850
Heparin Sodium (entire monograph revised)	35	2	257
Heparin Sodium Injection (entire monograph revised)	35	2	266
Hydromorphone Hydrochloride Oral Solution (new)	35	4	851
Hydroxychloroquine Sulfate Tablets—*Identification*	34	4	940
Hydroxypropyl Cellulose Ocular System—*Assay*	35	4	852
Ibuprofen—*Chromatographic purity*	34	4	941
Ibuprofen Tablets—*Limit of ibuprofen related compound C*	34	4	941
Imipramine Hydrochloride—*Melting range* (delete)	34	5	1164
Biphasic Isophane Insulin Human Suspension (new)	31	4	1033
Human Insulin Isophane Suspension and Human Insulin Injection—*Soluble insulin human content*	34	4	941
Irbesartan—*Limit of azide*	34	5	1164
Itraconazole (new)	34	4	947
Ketoprofen Extended-Release Capsules (new)	34	4	951
Lactic Acid—*Readily carbonizable substances*	34	5	1164
Lamivudine and Zidovudine Tablets (new)	35	2	277
Levothyroxine Sodium—*Organic Impurities—Procedure 1, Procedure 2* (add), *Packaging and Storage, Labeling* (add), *USP Reference Standards*	35	3	555
Levothyroxine Sodium Oral Powder—*Identification* (add)	34	4	954
Levothyroxine Sodium Tablets—*Definition, Identification*	34	4	954
Lindane—*Assay*	34	2	280
Liothyronine Sodium Tablets—*Identification*	34	4	955
Liotrix Tablets—*Identification*	34	4	955
Lisinopril Tablets—*Dissolution*	34	4	956
Lisinopril and Hydrochlorothiazide Tablets (new)	34	4	956
Loratadine Orally Disintegrating Tablets (new)	34	3	624
Loratadine and Pseudoephedrine Sulfate Extended-Release Tablets (new)	32	6	1715
Losartan Potassium Tablets (new)	34	5	1164
Losartan Potassium and Hydrochlorothiazide Tablets (new)	34	6	1455
Magnesium Carbonate and Citric Acid for Oral Solution—*USP Reference standards* (add), *Content of anhydrous citric acid, Other requirements (delayed implementation to January 1, 2009)*	31	2	419
Magnesium Citrate Oral Solution—*USP Reference standards* (add), *Assay for anhydrous citric acid (delayed implementation to January 1, 2009)*	31	2	420
Magnesium Citrate for Oral Solution—*USP Reference standards* (add), *Content of anhydrous citric acid, Other requirements (delayed implementation to January 1, 2009)*	31	2	421
Mannitol—*Harmonization*	34	6	1588
Mannitol Injection—*Labeling*	32	2	263
Megestrol Acetate Oral Suspension—*Dissolution*	35	1	75
Meloxicam—*Impurities, Procedure 1*	35	2	278
Mesna (new)	34	5	1168
Metformin Hydrochloride Extended-Release Tablets—*Dissolution*	35	1	76
Methylbenzethonium Chloride—*Identification B* (delete), *C* (delete), *D* (delete), *B* (add); *USP Reference Standards* (add)	35	4	853
Methylcellulose (new)—*Stage 6 Harmonization*	35	3	683
Methylcellulose Ophthalmic Solution—*Identification*	31	3	780
Methylcellulose Oral Solution—*Identification*	31	3	780
Methylcellulose Tablets—*Identification*	31	3	780
Methylene Blue Injection, Veterinary (new)	34	6	1461
Metronidazole Benzoate—*USP Reference standards, Related compounds*	31	3	781
Midazolam (new)	34	4	961
Midazolam Injection (new)	34	3	635
Minocycline Periodontal System (new)	34	4	963
Mirtazapine—*USP Reference standards, Water, Chromatographic purity, Assay*	34	4	964
Misoprostol (new)	35	3	564
Mometasone Furoate Cream—*Packaging and storage, Related compounds* (add), *Assay*	35	1	82
Mometasone Furoate Ointment—*Packaging and storage, Related compounds* (add), *Assay*	35	1	84

Pending Proposals (*continued*)

Mometasone Furoate Topical Solution—*Packaging and storage, Related compounds* (add), *Assay*	35	1	87
Morantel Tartrate—*pH*	32	6	1735
Morphine Sulfate Extended-Release Capsules—*Assay, Organic Impurities—Procedure, USP Reference Standards*	35	3	565
Moxifloxacin Hydrochloride (new)	34	5	1170
Moxifloxacin Ophthalmic Solution (new)	34	5	1173
Mupirocin Nasal Ointment (new)	34	4	966
Mycophenolate Mofetil—*Identification, Melting range* (delete), *Related compounds, Assay*	35	1	89
Mycophenolate Mofetil Capsules (new)	35	4	854
Mycophenolate Mofetil Tablets (new)	35	4	856
Naratriptan Hydrochloride Oral Suspension (new)	35	1	90
Nefazodone Hydrochloride—*Identification*	35	3	540
Nevirapine Oral Suspension—*Organic Impurities—Procedure*	35	4	857
Nateglinide (new)	34	6	1463
Nateglinide Tablets (new)	35	2	281
Niacinamide—*Readily carbonizable substances*	34	5	1176
Nitrofurantoin—*Packaging and storage*	35	1	92
Nitrofurantoin Capsules—*Packaging and storage*	35	1	92
Nitrofurantoin Oral Suspension—*Packaging and storage*	35	1	92
Nitrofurantoin Tablets—*Packaging and storage*	35	1	92
Nitrous Oxide—*Definition; Identification A, B* (delete), *C* (delete); *Assay; Inorganic Impurities—Ammonia, Nitric Oxide, Nitrogen Dioxide, Halogens, Carbon Monoxide, Carbon Dioxide; Water; Packaging and Storage; Labeling* (add)	35	4	859
Norethindrone Acetate—*Chromatographic purity*	34	4	969
Norethynodrel (delete entire monograph)	35	1	92
Octisalate—*Assay*	34	4	970
Ofloxacin—*Chromatographic purity* (delete), *Related compounds* (add)	30	4	1274
Ofloxacin Tablets—*Uniformity of dosage units*	34	6	1467
Olanzapine Tablets (new)	35	2	282
Olopatadine Hydrochloride (new)	35	3	567
Olopatadine Hydrochloride Ophthalmic Solution (new)	35	3	568
Ondansetron Hydrochloride—*Limit of ondansetron related compound D, Assay*	32	1	126
Ondansetron Tablets (new)	34	4	971
Ondansetron Orally Disintegrating Tablets—*Labeling* (add), *Disintegration, Dissolution, Water* (delete)	34	6	1467
Oseltamivir Phosphate (new)	34	6	1468
Oseltamivir Phosphate Capsules (new)	34	6	1471
Oxaliplatin (new)	34	4	973
Oxaliplatin Injection (new)	35	2	284
Oxaliplatin for Injection (new)	34	6	1473
Oxazepam Capsules—*Dissolution*	35	2	286
Oxcarbazepine (new)	34	5	1177
Oxcarbazepine Tablets (new)	34	6	1478
Oxybutynin Chloride Tablets—*Dissolution*	35	1	93
Oxycodone Hydrochloride—*USP Reference standards, Limit of oxycodone related compound A (14-hydroxycodeinone) and oxycodone related compound C (codeinone)* (add), *Chromatographic purity*	34	6	1480
Oxycodone Hydrochloride Extended-Release Tablets—*Related compounds*	31	4	1104
Oxygen—*Identification—Procedure, B* (delete); *Assay; Inorganic Impurities—Carbon Dioxide, Carbon Monoxide; Packaging and Storage; Labeling*	35	4	861
Oxygen 93 Percent—*Identification A, B* (delete); *Assay; Inorganic Impurities—Carbon Dioxide, Carbon Monoxide; Packaging and Storage; Labeling*	35	4	862
Oxymetazoline Hydrochloride Nasal Solution—*pH*	33	5	932
Pamidronate Disodium—*Alcohol content* (delete)	34	5	1179
Pamidronate Disodium for Injection—*Definition*	33	1	81
Pancuronium Bromide Injection (new)	32	4	1097
Pantoprazole Oral Suspension (new)	35	4	863
Paricalcitol—*Identification, Assay*	33	2	252

Pending Proposals (*continued*)

(Items from earlier numbers of *PF* that have not yet been adopted and become official)

Pectin—*Chemical information; Definition; Identification—A, B, C, D* (delete), *Procedure* (add); *Assay—Methoxy Groups* (name change), *Galacturonic Acid, Methoxy Groups* (add); *Impurities—Lead, Procedure 1, Procedure 2* (add), *Procedure 3* (add); *Microbial Enumeration Tests; Packaging and Storage; Labeling; USP Reference Standards* (add)	35	2	287
Penicillamine Capsules—*Dissolution*	31	2	436
Pentamidine Isethionate (new)	35	3	570
Pentobarbital—*Identification B* (delete), *C, Assay, Organic Impurities—Procedure, Melting Range or Temperature* (delete)	35	4	864
Pentobarbital Sodium—*Labeling* (add), *USP Reference standards, Other requirements* (add)	31	1	73
Permethrin (new)	32	4	1100
Permethrin Cream (new)	34	1	103
Petrolatum (new)—*Harmonization*	28	2	569
White Petrolatum (new)—*Harmonization*	28	2	570
Liquefied Phenol—*Identification* (add), *Other requirements*	35	1	93
Phenytoin Chewable Tablets (new)	29	6	1965
Physostigmine—*Readily carbonizable substances*	34	5	1179
Physostigmine Salicylate—*Readily carbonizable substances*	34	5	1179
Physostigmine Sulfate—*Readily carbonizable substances*	34	5	1179
Pilocarpine Hydrochloride—*Readily carbonizable substances*	34	5	1179
Pilocarpine Nitrate—*Readily carbonizable substances*	34	5	1179
Piperacillin and Tazobactam for Injection (new)	34	4	980
Potassium and Sodium Bicarbonates and Citric Acid Effervescent Tablets for Oral Solution—*USP Reference standards* (add), *Assay for anhydrous citric acid (delayed implementation to January 1, 2009)*	31	2	440
Potassium Bitartrate—*Heavy metals*	34	5	1180
Potassium Citrate Extended-Release Tablets—*USP Reference standards* (add), *Assay (delayed implementation to January 1, 2009)*	31	2	443
Potassium Citrate and Citric Acid Oral Solution—*USP Reference standards* (add), *Assay for citrate (delayed implementation to January 1, 2009)*	31	2	444
Potassium Iodide Delayed-Release Tablets—*Identification* (add), *Other requirements*	34	6	1481
Potassium Iodide Oral Solution—*Definition*	31	3	786
Potassium Sodium Tartrate—*Limit of ammonia*	31	3	787
Pralidoxime Chloride for Injection—*Identification A, B, C* (add), *Other requirements*	34	5	1180
Pravastatin Sodium Tablets—*USP Reference standards, Related compounds*	34	5	1180
Praziquantel Tablets—*Dissolution*	35	2	291
Primidone—*Identification B, C* (delete), *Assay, Organic Impurities—Procedure, Melting Range or Temperature* (delete), *USP Reference Standards*	35	3	571
Primidone Tablets—*Assay, Organic Impurities—Procedure* (add), *USP Reference Standards*	35	3	573
Promethazine Hydrochloride and Codeine Phosphate Oral Solution (new)	35	2	292
Promethazine Hydrochloride and Dextromethorphan Hydrobromide Oral Solution (new)	35	2	295
Promethazine and Phenylephrine Hydrochloride Oral Solution (new)	35	2	298
Promethazine and Phenylephrine Hydrochloride and Codeine Phosphate Oral Solution (new)	35	2	301
Propafenone Hydrochloride—*USP Reference standards, Chromatographic purity* (delete), *Related compounds* (add)	35	1	94
Propoxyphene Hydrochloride—*Definition, Assay, Organic Impurities—Procedure, Melting Range or Temperature* (delete)	35	4	865
Propoxyphene Hydrochloride Capsules—*Identification B* (delete), *Identification C*	35	3	574
Psyllium Husk—*Impurities—Heavy Metals* (add), *Procedure 3* (add)	35	2	304
Pyrantel Pamoate—*USP Reference standards, Related compounds*	34	6	1482
Quinapril Tablets—*Related compounds*	34	5	1182
Ramipril—*Definition, Assay*	31	3	787
Ramipril Capsules (new)	35	4	867
Oral Rehydration Salts—*USP Reference standards* (add), *Assay for citrate (delayed implementation to January 1, 2009)*	31	5	1399
Repaglinide Tablets—*Loss on Drying* (delete)	35	2	306

Tamsulosin Hydrochloride (new)	35	3	578
Tamsulosin Hydrochloride Capsules (new)	34	5	1193
Telmisartan (new)	35	3	580
Telmisartan Tablets (new)	35	3	581
Terazosin Capsules (new)	35	4	872
Terazosin Tablets (new)	35	4	874
Terbinafine Oral Suspension (new)	35	1	96
Terbutaline Oral Suspension (new)	35	1	97
Terbutaline Sulfate Inhalation Aerosol—*USP Reference standards, Assay*	31	2	450
Terconazole (new)	34	4	991
Thiabendazole Chewable Tablets (new)	29	6	1991
Thimerosal—*Readily carbonizable substances*	34	5	1197
Thioguanine—*USP Reference standards, Identification, Limit of guanine*	34	2	305
Thioridazine Hydrochloride—*Identification*	31	3	798
Tiagabine Hydrochloride Oral Suspension (new)	35	1	98
Ticlopidine Hydrochloride (new)	35	3	582
Ticlopidine Hydrochloride Tablets (new)	35	3	584
Tilmicosin—*Definition, Related compounds, Assay*	31	3	798
Tioconazole—*Assay*	35	4	875
Tizanidine Tablets—*Dissolution*	35	3	585
Topiramate Tablets (new)	34	5	1197
Tramadol Hydrochloride (new)	34	5	1200
Tramadol Hydrochloride Tablets (new)	31	2	462
Tranexamic Acid (new)	34	6	1484
Tranylcypromine Sulfate (new)	35	2	314
Tranylcypromine Tablets (new)	35	3	587
Trenbolone Acetate—*Definition, USP Reference standards, Identification, Chromatographic purity* (delete), *Limit of trenbolone acetate 17α-isomer* (delete), *Related compounds* (add), *Assay*	35	1	100
Tretinoin Gel—*Identification, Assay*	34	6	1485
Triamcinolone Acetonide—*USP Reference standards, Assay*	31	3	800

Pending Proposals (*continued*)

(Items from earlier numbers of *PF* that have not yet been adopted and become official)

Title and Proposal	***PF Volume, Issue, and Page Numbers of Pending Proposals***		
	Vol.	***No.***	***Page(s)***
Tricitrates Oral Solution—*USP Reference standards* (add), *Assay for citrate (delayed implementation to January 1, 2009)*	31	2	465
Tromethamine—*Melting Range or Temperature*	35	2	316
Tryptophan—*Chromatographic purity* (add), *Limit of tryptophan related compound A* (add)	33	6	1214
Tylosin Injection (new)	34	5	1205
Ursodiol Capsules—*Dissolution*	31	3	800
Ursodiol Tablets—*Identification, Assay*	35	4	876
Valacyclovir Hydrochloride (new)	35	3	589
Valacyclovir Tablets (new)	35	4	878
Valganciclovir Tablets (new)	33	1	89
Valproic Acid Capsules—*Disintegration* (delete)	35	3	591
Valrubicin—*Definition, USP Reference standards, Identification, Loss on drying* (delete), *Water* (add), *Limit of residual solvents* (delete), *Related compounds, Assay*	35	1	103
Valrubicin Intravesical Solution—*USP Reference standards, Related compounds*	34	6	1486
Vancomycin Hydrochloride—*Identification, Inorganic Impurities—Heavy Metals* (add), *Organic Impurities—Procedure: Limit of Monodechlorovancomycin, Sterility Tests* (add), *Bacterial Endotoxins Test* (add), *Composition of Vancomycin, Labeling* (add)	35	4	879
Vancomycin Hydrochloride Capsules—*Identification*	34	6	1487
Sterile Vancomycin Hydrochloride—(delete the entire monograph)	34	1	112
Vancomycin Hydrochloride for Injection—*Definition, Identification* (add), *Assay, Uniformity of Dosage Units* (add), *Inorganic Impurities—Heavy Metals* (delete), *pH* (add), *Water Determination* (add), *Composition of Vancomycin, Other Requirements, Labeling* (add)	35	4	881
Vasopressin—*Chemical information, Definition, USP Reference standards, Oxytocic activity* (delete), *Water* (add), *Acetic acid content* (add), *Assay*	34	4	994
Vasopressin Injection—*Assay*	34	4	995
Vinblastine Sulfate for Injection—*Identification* (add), *Other requirements*	34	4	995
Vincristine Sulfate Injection—*Identification*	35	1	106
Vincristine Sulfate for Injection—*Identification*	35	1	106
Pure Steam (new)	31	2	467
Water for Hemodialysis—*Bacterial endotoxins*	31	2	468
Water for Injection—*Definition, Bacterial Endotoxins Test, Water Conductivity, Sterility Tests* (add), *Packaging and Storage* (add), *Labeling* (add)	35	2	316
Purified Water—*Definition, Packaging and Storage* (add), *Labeling* (add)	35	2	317
Sterile Water for Inhalation—*Definition*	35	4	883
Sterile Water for Injection—*Oxidizable substances*	31	3	803
Sterile Water for Irrigation—*Oxidizable substances*	31	3	804
Sterile Purified Water—*Oxidizable substances*	31	3	804
Xylose—*USP Reference standards, Identification, Chromatographic purity, Assay*	34	4	995
Ziprasidone Hydrochloride (new)	35	3	592
Zolpidem Tartrate (new)	34	6	1487
Zolpidem Tartrate Extended-Release Tablets (new)	35	3	595
Zolpidem Tartrate Tablets (new)	35	4	883
Zonisamide (new)	34	6	1489
Dietary Supplements Monographs			
Acesulfame Potassium—*Packaging and storage* (add), *Limit of fluoride*	31	3	811
N-Acetyltyrosine (new)	35	1	107
Ashwagandha (new)	35	4	885
Powdered Ashwagandha (new)	35	4	886
Powdered Ashwagandha Extract (new)	35	4	888
Boswellia Serrata (new)	35	4	890
Boswellia Serrata Extract (new)	35	4	891
Calcium and Vitamin D with Minerals Tablets—*Assay for calcium; Assay for copper; Assay for magnesium; Assay for manganese; Assay for zinc; Assay for calcium, copper, magnesium, manganese, and zinc, Method 2* (add)	34	6	1491
Crypthecodinium Cohnii Oil (new)	35	4	892

In-Process Revision

Pending Proposals (*continued*)

STAGE 4 HARMONIZATION

This section contains monographs or chapters undergoing harmonization by the Pharmacopeial Discussion Group (PDG). The PDG consists of the United States Pharmacopeia (USP), the European Pharmacopoeia (EP), and the Japanese Pharmacopoeia (JP). The process of harmonization consists of several steps (Stages 1 through 7, as defined below). Stage 4 drafts are available for comments. Below are descriptions of the developmental Stages as defined by the United States Pharmacopeia, the European Pharmacopoeia, and the Japanese Pharmacopoeia.

Stage 1: Identification The PDG identifies items to be harmonized and designates a coordinating pharmacopeia for each item. The PDG distributes the work by consensus among the three participating pharmacopeias. Harmonization may be carried out retrospectively for existing monographs or chapters, or prospectively for new monographs or chapters.

Stage 2: Investigation The investigation process conducted by the coordinating pharmacopeia results in the preparation of a Stage 3 draft monograph or chapter accompanied by a report giving the rationale for the proposal and including validation data where appropriate. This report is based on input that comes from users, authorities, producers, associations, literature, experts, and staff.

Stage 3: Proposal The Stage 3 draft is reviewed and commented on by the other two pharmacopeias. The coordinating pharmacopeia reviews those comments, prepares a harmonized Stage 4 draft, and sends it to the other two participating pharmacopeias.

Stage 4: Official Inquiry The Stage 4 draft is published in the Forum of each pharmacopeia. In *PF,* this stage appears as OFFICIAL INQUIRY STAGE 4 in the *Harmonization* section. Each pharmacopeia analyzes the comments it receives and submits the consolidated comments to the coordinating pharmacopeia, which then reviews those comments, prepares a harmonized Stage 5A draft, and sends it to the other two participating pharmacopeias.

Stage 5: Consensus

A. Provisional

The Stage 5A draft is reviewed and commented on by the other two pharmacopeias. When consensus is reached, a CONSENSUS STAGE 5B document is prepared by the coordinating pharmacopeia.

B. Final

The Stage 5B draft (consensus document) is sent by the coordinating pharmacopeia to the other two participating pharmacopeias for final approval.

Stage 6: Adoption Each pharmacopeia incorporates the harmonized Stage 5B draft according to its own procedure. Adopted items are published by the three pharmacopeias in their Supplements or, where applicable, in a new edition of their Pharmacopeias.

Stage 7: Date of Implementation The pharmacopeias inform each other of the date of implementation in the particular region.

MONOGRAPHS (USP)

BRIEFING

Petrolatum. The United States Pharmacopeia is the coordinating pharmacopeia for the international harmonization of the compendial standards for the Petrolatum monograph, as part of the process of international harmonization of monographs and general analytical methods of the European, Japanese, and United States pharmacopeias. The following monograph, which represents the **OFFICIAL INQUIRY STAGE 4** document, is based on comments from the European and Japanese pharmacopeias. Changes from the existing USP monograph include the following:

1. *Definition*. The term "stabilizer" has been replaced by "antioxidant" at the request of the EP to provide a limitation on a single type of additive.
2. *Identification*. Added an infrared absorption requirement.
3. *Packaging and Storage*. Added the statement, "protected from light" based on comments received.
4. *Labeling*. Added the statement, "Where the labeling indicates the consistency, determine compliance using the test for *Consistency*." The test for *Consistency*, which measures a functionality parameter of the article, is not intended to be a required test in this harmonized monograph. Therefore, the proposed *Labeling* wording is intended to indicate that the test for *Consistency* in the harmonized monograph is to be used to determine consistency values if such values are reported in the labeling for the article.
5. *Specific Gravity*. Deleted based on comments that the wide test limits are not suitable to characterize the article.
6. *Melting Range or Temperature*. On the basis of comments from the EP, the range is widened from 38°–60° to 40°–75° to better reflect the global market.
7. *Polycyclic Aromatic Hydrocarbons*. On the basis of requests from global regulatory authorities, a new test has been added based on the existing EP monograph.

(EM2: Kevin Moore.) RTS—C76301

Add the following:

Petrolatum

DEFINITION

Petrolatum is a purified mixture of semisolid hydrocarbons obtained from petroleum. It may contain a suitable antioxidant.

IDENTIFICATION

- **INFRARED ABSORPTION** ⟨**197F**⟩

IMPURITIES

Inorganic Impurities

- **RESIDUE ON IGNITION**

  Sample: 2 g

  Analysis: Heat the *Sample* in an open porcelain or platinum dish over a Bunsen flame.

  Acceptance criteria: It volatilizes without emitting an acrid odor and yields NMT 0.1% of residue.

Organic Impurities

- **PROCEDURE 1: ORGANIC ACIDS**

  Sample solution: 20.0 g of Petrolatum in 100 mL of neutralized alcohol and water (1:1). Agitate thoroughly, and heat to boiling.

  Analysis: Add 1 mL of phenolphthalein TS, and titrate rapidly with 0.1 N sodium hydroxide VS, with vigorous agitation to the production of a sharp pink endpoint, noting the color change in the alcohol-water layer.

  Acceptance criteria: NMT 400 µL of 0.1 N sodium hydroxide is required.

- **PROCEDURE 2: POLYCYCLIC AROMATIC HYDROCARBONS**

  Sample solution: 1.0 g of Petrolatum in 50 mL of hexane that has been previously shaken twice with 10 mL of dimethyl sulfoxide

  Reference solution: 6.0 mg/L of USP Napthalene RS in dimethyl sulfoxide

  Analysis: Transfer the *Sample solution* to a 125-mL separating funnel with unlubricated ground-glass parts (stopper, stopcock). Add 20 mL of dimethyl sulfoxide. Shake vigorously for 1 min and allow to stand until two clear layers are formed. Transfer the lower layer to a second separating funnel. Repeat the extraction with a further 20 mL of dimethyl sulfoxide. Shake vigorously the combined lower layers with 20 mL of hexane for 1 min. Allow to stand until two clear layers are formed. Separate the lower layer and dilute with dimethyl sulfoxide to 50.0 mL. Measure the absorbance over the range 260–420 nm using a path length of 4 cm and as compensation liquid the clear lower layer obtained by vigorously shaking 10 mL of dimethyl sulfoxide with 25 mL of hexane for 1 min. Measure the absorbance of the *Reference solution* at the maximum at 278 nm using a path length of 4 cm and dimethyl sulfoxide as compensation liquid.

  Acceptance criteria: At no wavelength in the range of 260–420 nm does the absorbance of the *Sample solution* exceed that of the *Reference solution* at 278 nm, corresponding to NMT 300 ppm.

SPECIFIC TESTS

- **COLOR**

  Sample: 10 g

  Analysis: Melt the *Sample* on a steam bath, and pour 5 mL of the liquid into a clear-glass 15- × 150-mm test tube, keeping the petrolatum melted.

  Acceptance criteria: The petrolatum is not darker than a solution made by mixing 3.8 mL of ferric chloride CS and 1.2 mL of cobaltous chloride CS in a similar tube, the comparison of the two being made in reflected light against a white background, the petrolatum tube being held directly against the background at such an angle that there is no fluorescence.

- **MELTING RANGE OR TEMPERATURE,** *Class III* ⟨**741**⟩**:** 40°–75°
- **CONSISTENCY**

  Apparatus: A penetrometer fitted with a polished cone-shaped metal plunger weighing 150 g, having a detachable steel tip of the following dimensions: the tip of the cone has an angle of 30°, the point being truncated to a diameter of 0.381 ± 0.025 mm, the base of the tip is 8.38 ± 0.05 mm in diameter, and the length of the tip is 14.94 ± 0.05 mm. The remaining portion of the cone has an angle of 90°, is 28 mm in height, and has a maximum diameter at the base of 65 mm. The containers for the test are flat-bottom metal cylinders that are 100 ± 6 mm in diameter and NLT 65 mm in height. They are constructed of at least 1.6-mm (16-gauge) metal, and are provided with well-fitting, water-tight covers.

Sample: Petrolatum

Analysis: Place the required number of containers in an oven, and bring them and a quantity of *Sample* to a temperature of 82 ± 2.5°, pour the *Sample* into one or more of the containers, filling to within 6 mm of the rim. Cool to 25 ± 2.5° over a period of NLT 16 h, protected from drafts. Two h before the test, place the containers in a water bath at 25 ± 0.5°. If the room temperature is below 23.5° or above 26.5°, adjust the temperature of the cone to 25 ± 0.5° by placing it in the water bath.

Without disturbing the surface of the substance under test, place the container on the penetrometer table, and lower the cone until the tip just touches the top surface of the test substance at a spot 25–38 mm from the edge of the container. Adjust the zero setting and quickly release the plunger, then hold it free for 5 s. Secure the plunger, and read the total penetration from the scale. Make three or more trials, each so spaced that there is no overlapping of the areas of penetration. Where the penetration exceeds 20 mm, use a separate container of the test substance for each trial. Read the penetration to the nearest 0.1 mm. Calculate the average of the three or more readings, and conduct further trials to a total of 10 if the individual results differ from the average by more than ±3%.

Acceptance criteria: The final average of the trials is NLT 10.0 mm and NMT 30.0 mm, indicating a consistency value of 100–300.

- **ALKALINITY**

Sample: 35 g

Analysis: Introduce the *Sample* into a suitable beaker, add 100 mL of boiling water, cover, and place on a stirring hotplate maintained at the boiling point of water. After 5 min, allow the phases to separate. Draw off the separated water into a casserole, wash the petrolatum further with two 50-mL portions of boiling water, and add the washings to the casserole. To the pooled washings, add 1 drop of phenolphthalein TS, and boil.

Acceptance criteria: The solution does not acquire a pink color.

- **ACIDITY:** If the addition of phenolphthalein TS in the test for *Alkalinity* produces no pink color, add 0.1 mL of methyl orange TS.

Acceptance criteria: No red or pink color is produced.

- **FIXED OILS, FATS, AND ROSIN**

Sample: 10 g

Analysis: Digest the *Sample* with 50 mL of 5 N sodium hydroxide at 100° for 30 min. Separate the water layer, and acidify it with 5 N sulfuric acid.

Acceptance criteria: No oily or solid matter separates.

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in well-closed containers, protected from light.
- **LABELING:** Label it to indicate the name and proportion of any added antioxidant. Where the labeling indicates the consistency, determine compliance using the test for *Consistency*.
- **USP REFERENCE STANDARDS** ⟨**11**⟩

USP Napthalene RS

- **DESCRIPTION AND SOLUBILITY**

Petrolatum: Unctuous yellowish to light amber mass, having not more than a slight fluorescence even after being melted. Is transparent in thin layers. Is free or practically free from odor and taste. Freely soluble in benzene, in carbon disulfide, in chloroform, and in turpentine oil; soluble in ether, in solvent hexane, and in most fixed and volatile oils; practically insoluble in cold and hot alcohol and in cold dehydrated alcohol; insoluble in water.

BRIEFING

White Petrolatum. The United States Pharmacopeia is the coordinating pharmacopeia for the international harmonization of the compendial standards for the White Petrolatum monograph, as part of the process of international harmonization of monographs and general analytical methods of the European, Japanese, and United States pharmacopeias. The following monograph, which represents the **OFFICIAL INQUIRY STAGE 4** document, is based on comments from the European and Japanese pharmacopeias. Changes from the existing USP monograph include the following:

1. *Definition*. The term "stabilizer" has been replaced by "antioxidant" at the request of the EP to provide a limitation on a single type of additive.
2. *Identification*. Added an infrared absorption requirement.
3. *Packaging and Storage*. Added the statement, "protected from light" based on comments received.
4. *Labeling*. Added the statement, "Where the labeling indicates the consistency, determine compliance using the test for *Consistency*." The test for *Consistency*, which measures a functionality parameter of the article, is not intended to be a required test in this harmonized monograph. Therefore, the proposed *Labeling* wording is intended to indicate that the test for *Consistency* in the harmonized monograph is to be used to determine consistency values if such values are reported in the labeling for the article.
5. *Specific Gravity*. Deleted based on comments that the wide test limits are not suitable to characterize the article.
6. *Melting Range or Temperature*. On the basis of comments from the EP, the range is widened from 38°–60° to 40°–75° to better reflect the global market.
7. *Polycyclic Aromatic Hydrocarbons*. On the basis of requests from global regulatory authorities, a new test has been added based on the existing EP monograph.

(EM2: Kevin Moore.) RTS—C76302

Add the following:

White Petrolatum

DEFINITION

White Petrolatum is a purified mixture of semisolid hydrocarbons obtained from petroleum. It may contain a suitable antioxidant.

IDENTIFICATION

- **INFRARED ABSORPTION** ⟨**197F**⟩

IMPURITIES

Inorganic Impurities

- **RESIDUE ON IGNITION**

Sample: 2 g

Analysis: Heat the *Sample* in an open porcelain or platinum dish over a Bunsen flame.

Acceptance criteria: It volatilizes without emitting an acrid odor and yields NMT 0.1% of residue.

Organic Impurities

- **PROCEDURE 1: ORGANIC ACIDS**

Sample solution: 20.0 g of White Petrolatum in 100 mL of neutralized alcohol and water (1:1). Agitate thoroughly, and heat to boiling.

Analysis: Add 1 mL of phenolphthalein TS, and titrate rapidly with 0.1 N sodium hydroxide VS, with vigorous agitation to the production of a sharp pink endpoint, noting the color change in the alcohol-water layer.

Acceptance criteria: NMT 400 µL of 0.1 N sodium hydroxide is required.

- **PROCEDURE 2: POLYCYCLIC AROMATIC HYDROCARBONS**

Sample solution: 1.0 g of White Petrolatum in 50 mL of hexane that has been previously shaken twice with 10 mL of dimethyl sulfoxide

Reference solution: 6.0 mg/L of USP Naphthalene RS in dimethyl sulfoxide

Analysis: Transfer the *Sample solution* to a 125-mL separating funnel with unlubricated ground-glass parts (stopper, stopcock). Add 20 mL of dimethyl sulfoxide. Shake vigorously for 1 min and allow to stand until two clear layers are formed. Transfer the lower layer to a second separating funnel. Repeat the extraction with a further 20 mL of dimethyl sulfoxide. Shake vigorously the combined lower layers with 20 mL of hexane for 1 min. Allow to stand until two clear layers are formed. Separate the lower layer and dilute with dimethyl sulfoxide to 50.0 mL. Measure the absorbance over the range of 260–420 nm using a path length of 4 cm and as compensation liquid the clear lower layer obtained by vigorously shaking 10 mL of dimethyl sulfoxide with 25 mL of hexane for 1 min. Measure the absorbance of the *Reference solution* at the maximum at 278 nm using a path length of 4 cm and dimethyl sulfoxide as compensation liquid.

Acceptance criteria: At no wavelength in the range of 260–420 nm does the absorbance of the *Sample solution* exceed that of the *Reference solution* at 278 nm, corresponding to NMT 300 ppm.

SPECIFIC TESTS

- **COLOR**

Sample: 10 g

Analysis: Melt the *Sample* on a steam bath, and pour 5 mL of the liquid into a clear-glass 15- × 150-mm test tube, keeping the White Petrolatum melted.

Acceptance criteria: The White Petrolatum is not darker than a solution made by mixing 1.6 mL of ferric chloride CS and 3.4 mL of water in a similar tube, the comparison of the two being made in reflected light against a white background, the White Petrolatum tube being held directly against the background at such an angle that there is no fluorescence.

- **MELTING RANGE OR TEMPERATURE,** *Class III* ⟨**741**⟩**:** 40°–75°
- **CONSISTENCY**

Apparatus: A penetrometer fitted with a polished cone-shaped metal plunger weighing 150 g, having a detachable steel tip of the following dimensions: the tip of the cone has an angle of 30°, the point being truncated to a diameter of 0.381 ± 0.025 mm, the base of the tip is 8.38 ± 0.05 mm in diameter, and the length of the tip is 14.94 ± 0.05 mm. The remaining portion of the cone has an angle of 90°, is 28 mm in height, and has a maximum diameter at the base of 65 mm. The containers for the test are flat-bottom metal cylinders that are 100 ± 6 mm in diameter and NLT 65 mm in height. They are constructed of at least 1.6-mm (16-gauge) metal, and are provided with well-fitting, water-tight covers.

Sample: White Petrolatum

Analysis: Place the required number of containers in an oven, and bring them and a quantity of *Sample* to a temperature of 82 ± 2.5°, pour the *Sample* into one or more of the containers, filling to within 6 mm of the rim. Cool to 25 ± 2.5° over a period of NLT 16 h, protected from drafts. Two h before the test, place the containers in a water bath at 25 ± 0.5°. If the room temperature is below 23.5° or above 26.5°, adjust the temperature of the cone to 25 ± 0.5° by placing it in the water bath.

Without disturbing the surface of the substance under test, place the container on the penetrometer table, and lower the cone until the tip just touches the top surface of the test substance at a spot 25–38 mm from the edge of the container. Adjust the zero setting and quickly release the plunger, then hold it free for 5 s. Secure the plunger, and read the total penetration from the scale. Make three or more trials, each so spaced that there is no overlapping of the areas of penetration. Where the penetration exceeds 20 mm, use a separate container of the test substance for each trial. Read the penetration to the nearest 0.1 mm. Calculate the average of the three or more readings, and conduct further trials to a total of 10 if the individual results differ from the average by more than ±3%.

Acceptance criteria: The final average of the trials is NLT 10.0 mm and NMT 30.0 mm, indicating a consistency value of 100–300.

- **ALKALINITY**

Sample: 35 g

Analysis: Introduce the *Sample* into a suitable beaker, add 100 mL of boiling water, cover, and place on a stirring hotplate maintained at the boiling point of water. After 5 min, allow the phases to separate. Draw off the separated water into a casserole, wash the White Petrolatum further with two 50-mL portions of boiling water, and add the washings to the casserole. To the pooled washings, add 1 drop of phenolphthalein TS, and boil.

Acceptance criteria: The solution does not acquire a pink color.

- **ACIDITY:** If the addition of phenolphthalein TS in the test for *Alkalinity* produces no pink color, add 0.1 mL of methyl orange TS.

Acceptance criteria: No red or pink color is produced.

- **FIXED OILS, FATS, AND ROSIN**

Sample: 10 g

Analysis: Digest the *Sample* with 50 mL of 5 N sodium hydroxide at 100° for 30 min. Separate the water layer, and acidify it with 5 N sulfuric acid.

Acceptance criteria: No oily or solid matter separates.

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in well-closed containers, protected from light.
- **LABELING:** Label it to indicate the name and proportion of any added antioxidant. Where the labeling indicates the consistency, determine compliance using the test for *Consistency*.
- **USP REFERENCE STANDARDS** ⟨**11**⟩

USP Napthalene RS

- **DESCRIPTION AND SOLUBILITY**

White Petrolatum: White or faintly yellowish, unctuous mass, transparent in thin layers even after cooling to 0°. Freely soluble in benzene, in carbon disulfide, and in chloroform; soluble in ether, in solvent hexane, and in most fixed and volatile oils; slightly soluble in cold or hot alcohol, and in cold dehydrated alcohol; insoluble in water.

STAGE 6 HARMONIZATION

This section contains monographs or chapters undergoing harmonization by the Pharmacopeial Discussion Group (PDG). The PDG consists of the United States Pharmacopeia (USP), the European Pharmacopoeia (EP), and the Japanese Pharmacopoeia (JP). The process of harmonization consists of several steps (Stages 1 through 7, as defined below). This section includes Stage 6 adopted text which is provided for information. USP cannot incorporate public comments at Stage 6 without consulting PDG partners. Below are descriptions of the developmental Stages as defined by the United States Pharmacopeia, the European Pharmacopoeia, and the Japanese Pharmacopoeia.

Stage 1: Identification The PDG identifies items to be harmonized and designates a coordinating pharmacopeia for each item. The PDG distributes the work by consensus among the three participating pharmacopeias. Harmonization may be carried out retrospectively for existing monographs or chapters, or prospectively for new monographs or chapters.

Stage 2: Investigation The investigation process conducted by the coordinating pharmacopeia results in the preparation of a Stage 3 draft monograph or chapter accompanied by a report giving the rationale for the proposal and including validation data where appropriate. This report is based on input that comes from users, authorities, producers, associations, literature, experts, and staff.

Stage 3: Proposal The Stage 3 draft is reviewed and commented on by the other two pharmacopeias. The coordinating pharmacopeia reviews those comments, prepares a harmonized Stage 4 draft, and sends it to the other two participating pharmacopeias.

Stage 4: Official Inquiry The Stage 4 draft is published in the Forum of each pharmacopeia. In *PF*, this stage appears as OFFICIAL INQUIRY STAGE 4 in the *Harmonization* section. Each pharmacopeia analyzes the comments it receives and submits the consolidated comments to the coordinating pharmacopeia, which then reviews those comments, prepares a harmonized Stage 5A draft, and sends it to the other two participating pharmacopeias.

Stage 5: Consensus

A. Provisional

The Stage 5A draft is reviewed and commented on by the other two pharmacopeias. When consensus is reached, a CONSENSUS STAGE 5B document is prepared by the coordinating pharmacopeia.

B. Final

The Stage 5B draft (consensus document) is sent by the coordinating pharmacopeia to the other two participating pharmacopeias for final approval.

Stage 6: Adoption Each pharmacopeia incorporates the harmonized Stage 5B draft according to its own procedure. Adopted items are published by the three pharmacopeias in their Supplements or, where applicable, in a new edition of their Pharmacopeias.

Stage 7: Date of Implementation The pharmacopeias inform each other of the date of implementation in the particular region.

STIMULI TO THE REVISION PROCESS

This section may contain the following:

- reports or statements of Expert Committees
- original research reports
- evaluations of new and existing pharmacopeial methods
- commentaries
- articles relevant to compendial issues.

These items are published to stimulate discussion and continual review of Pharmacopeial standards. Generally, if an Expert Committee publishes an article on which they are specifically seeking comment, this will be clearly stated in the article. Readers may submit comments on issues raised in this section, but comment is not as critical as that for the *In-Process Revision* section. Readers interested in submitting comments should see *Instructions to Authors.*

INSTRUCTIONS TO AUTHORS

Contributions in the form of original research reports, evaluations of new and existing compendial methods, and other commentaries and articles relevant to drug standards or to *USP–NF* revision will be considered for publication in *Pharmacopeial Forum* under the section *Stimuli to the Revision Process*. Manuscripts are received with the explicit understanding that they have not been published previously in any language or medium and that they are not simultaneously under consideration by any other publication.

All manuscripts are subject to review by USP headquarters staff, Committee members, or qualified outside referees, and if accepted for publication they will be subject to editing by USP staff. Accepted manuscripts become the property of the USP Convention (USPC) and may not be subsequently published elsewhere without written permission from the USPC. Authors are also responsible for obtaining permission for reprinting any illustrations that have been published elsewhere.

Abstract—Include an abstract of not more than 250 words stating the purpose and the results or conclusions of the article.

Style and Usage—*Stimuli* articles generally follow the current *Chicago Manual of Style* except in scientific usage (numbers, abbreviations, etc.). For the latter, authors should use the current *AMA Manual of Style* or the current *ACS Style Guide*. Authors may usefully consult a current copy of *Pharmacopeial Forum*.

References—Consult the current *AMA Manual of Style*, which is generally consistent with the National Library of Medicine's *Recommended Formats for Bibliographic Citation*. A current copy of *Pharmacopeial Forum* will offer examples of reference formats.

Copyright—Copyright transfer documents will be sent to authors after manuscripts have been accepted for publication.

Contact Person—USP will designate a Scientific Liaison in the Documentary Standards Division as the corresponding author. This ensures that USP receives all comments generated by the *Stimuli* article. Authors should contact the Scientific Liaison if they would like to receive copies of comments generated by their *Stimuli* articles.

Submission Instructions—Manuscripts must be submitted both as an electronic file and as a printed copy of the electronic file. Submit the text in Microsoft® Word or another current word-processing application. The preferred format for graphics submitted electronically is tagged image file format (TIFF). Photocopies are not acceptable. Manuscripts submitted for publication should be addressed to:

General Chapter Management in the 2010–2015 Cycle

USP General Chapter Project Team, Prescription–Nonprescription Stakeholder Forum[a]; Susan de Mars, Darrell R. Abernethy, William F. Koch, Angela G. Long, Anthony J. DeStefano, and Roger L. Williams, *USP*[b]

ABSTRACT This *Stimuli* article summarizes approaches that the United States Pharmacopeial Convention (USP) intends to advance for revision of General Chapters in the 2010 to 2015 and subsequent cycles. The article represents in part the work of USP General Chapter Project Team of the Prescription–Nonprescription Stakeholder Forum and in part USP staff under the direction of the Chair of the Council of Experts. It is designed to inform and guide incoming chairs of the new USP Council of Experts in the 2010–2015 cycle. It is also intended to inform the public at large of the value and complexity of USP's General Chapters, which now number approximately 300. With this *Stimuli* article, USP announces plans for a General Chapter Redesign project that can incorporate some or all of the elements presented in this *Stimuli* article. Comments are welcome.

INTRODUCTION

Information about General Chapters in the *United States Pharmacopeia* (*USP*) appears on the USP Web site at http://www.usp.org/USPNF/submitMonograph/generalChapterWorkplans.html. General Chapters in *USP* support *USP* monographs as well as monographs in the *National Formulary* (*NF*), Pending Monographs (http://www.usp.org/standards/pending/guidelines.html) and Non-US monographs (http://www.usp.org/standards/international/guidelines.html). They also support dietary supplement monographs and thus will be reproduced in their entirely along with such monographs in USP's new *Dietary Supplement Compendium* (http://www.usp.org/products/dietarySupplementsCompendium/). They should conform increasingly with the General Tests and Assays of USP's *Food Chemicals Codex*. The interpretation and application of General Chapters is governed by the *General Notices and Requirements (General Notices)* of *USP* (*1*).

CURRENT STATUS AND OPPORTUNITIES FOR IMPROVEMENT

The basis for many of the General Chapters in *USP* was and to some extent remains to conserve text for print versions of *USP* and *NF* and to allow commonly used procedures to be updated across multiple monographs without the need to individually revise each monograph. The Council of Experts thus might advance a General Chapter when it could be called out in more than a few (e.g., five) monographs. USP's General Chapters are divided roughly into physical and chemical test categories. The numbering system for General Chapters has little underlying logic, although pursuant to the *General Notices*, General Chapters numbered below 1000 generally are considered required and General Chapters above 1000 are considered informative. General Chapters that support only dietary supplements monographs are numbered above 2000. The lack of consistent approaches over time has led to *USP* General Chapters that are not well organized and are not always consistent when viewed singly or collectively. Some attempts in this and the prior cycle were made to advance a more consistent approach. This *Stimuli* article summarizes these approaches and advances more as a means of informing and guiding both the Council of Experts and USP's stakeholders (manufacturers, compounding professionals, conformity assessment bodies, practitioners, and patients) toward a more consistent and logical presentation and understanding of General Chapters. A more structured, comprehensive set of approaches is expected to produce a more uniform and useful set of General Chapters for all of USP's compendia.

CURRENT STRUCTURE AND PRESENTATION OF GENERAL CHAPTERS

General Chapters below 1000—General Chapters numbered below 1000 in *USP* usually are called out in a monograph and thus are considered a requirement for the analyst in executing one or more monograph tests. Even where not specifically referred to in a monograph, these General Chapters may be a requirement under provisions in USP's *General Notices*. In addition, at times an enforcing body such as the US Food and Drug Administration (FDA) may consider these General Chapters a requirement regardless of whether they are referenced in monographs or the *General Notices*.

General Chapters above 1000—As noted above, USP generally intends General Chapters numbered above 1000 not to be required and instead are considered informative. However, if specifically referred to in a monograph or in a required General Chapter, such text may become mandatory. In addition, informative chapters can be made enforceable by being adopted officially by an enforcing body or being included in a manufacturer's

[a] See Appendix for the names of USP General Chapter Project Team of the Prescription–Nonprescription Stakeholder Forum.

[b] Correspondence should be addressed to: Anthony J. DeStefano, PhD, Vice President, General Chapters, US Pharmacopeial Convention, 12601 Twinbrook Parkway, Rockville, MD 20852-1790; tel. 301.816.6303; e-mail ajd@usp.org.

or compounding professional's Standard Operating Procedures. Despite USP's intent that these generally not be required, questions and concerns about their enforceability remain because of their inclusion in *USP* and *NF*, which are in their entirety official compendia of the United States.

In this cycle, as part of the *General Notices* revision made official in *USP 32*, the idea emerged that informative text might be moved out of *USP* into a companion volume that would not be part of an official compendium of the United States. Such text would be elaborated through the USP Council of Experts and would serve analysts in understanding and executing the tests of USP's compendia. No decision has been reached as of the date of this *Stimuli* article about whether to advance a separate volume of informative text, which may be considered in a subsequent revision to the *General Notices*.

Classification/Taxonomy of General Chapters—As a means of bringing more clarity and order to *USP*'s General Chapters, staff working with the Council of Experts created a 13-chart guide to General Chapters. The charts sort chapters by article and topic categories. Within each chart General Chapters use the ICH categories of universal tests (description, identification, assay, and impurities) and specific tests (e.g., physicochemical characterization, equipment, or water content) to group General Chapters. Although the charts may not be specifically useful to an analyst using a single monograph, they do present a number of coherent views of the purpose and utility of General Chapters in *USP*. In this context, the charts are designed to support and inform drug development and drug registration decision-making.

General Chapters by Analytical Procedures/Methods—Although General Chapters may cover a broad array of topics, required General Chapters should speak to one or more tests, procedures, and acceptance criteria. A procedure is the series of steps followed by the analyst in conducting a compendial test. In turn, a procedure can rely on any of several analytical methods. Methods can be grouped as shown in *Table 1* and are closely related to the procedures of a monograph.

GENERAL CHAPTERS PROJECT TEAM

Project Teams are established under the Prescription–Nonprescription Stakeholder Forum in accordance with the Rules and Procedures of the Council of Experts. In 2006, the Chair of the Council of Experts formed the General Chapters Project Team to review General Chapters. The team focused on the chapters assigned to the 10 Expert Committees that make up the 2005–2010 General Chapters Collaborative Group as well as the excipient chapters, resulting in the examination of more than 200 of the 300 existing General Chapters. The purpose of the Project Team was twofold: first to understand which General Chapters or parts thereof should remain or become required; second to determine which General Chapters should be updated. To facilitate decision-making, the Project Team established criteria against which to make decisions for each of the assigned General Chapters. These criteria are presented in *Figure 1.*

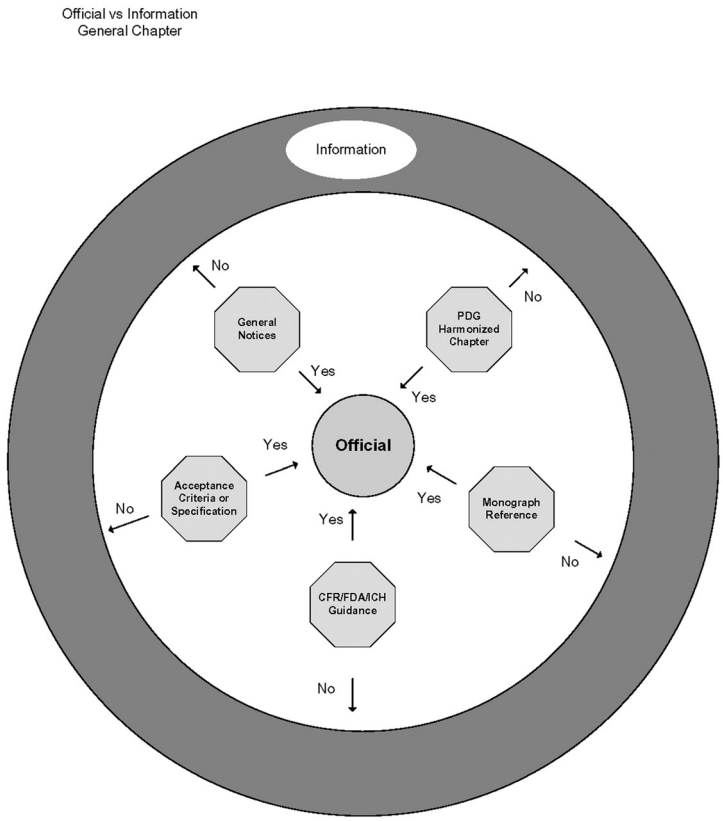

Figure 1. Project Team Decision Wheel for the Assessment of General Chapter Content Categorization.

Project Team members reviewed each of a set of assigned chapters and provided a recommendation about whether the contained standards should be included in the required series or should be considered informative. The team recommended reallocation of text for approximately 25% of the reviewed General Chapters and made recommendations with respect to the state of the technology of many of the chapters. This information will be used in the 2010–2015 cycle as input to revise content in General Chapters, moving text between required and informative General Chapters where needed according to specified criteria and providing guidance to the new Expert Committees with regard to technology considered out of date or no longer useful.

FUTURE OPPORTUNITIES: OBJECTIVES

Overall, USP expects that all General Chapters in USP compendia will be clear, concise, and highly useful to the analyst when considered alone in the performance of a monograph test and also collectively as a general representation of modern measurement science. Words should be kept to a minimum with careful editing for clarity. General Chapters that are informative should provide more general information without specifying procedures and acceptance criteria for official articles. Required and informative chapters can form comprehensive sets of overarching and interrelated text. The interrelationship between General Chapters should be clearly presented and carefully described. Specific opportunities to achieve this desired state through the General Chapter Redesign are presented in this section of the *Stimuli* article.

General Chapters Grouped According to Development/Registration Topics—General Chapters might be grouped by drug development topics according to relevant parts of the ICH Common Technical Document. This grouping could take into account all of the ICH Quality guidance documents. To some extent this has already occurred in current versions of *USP* and *NF*; e.g., the aforementioned charts are usually developed along the lines of the ICH Quality documents, and the concluding Monograph Redesign project provides a framework for *USP*'s monographs directed toward the control elements defined in ICH Module 3.

General Chapters Grouped According to Compendial Topics—*USP*'s General Chapters might be grouped according to compendial topic (*Table 2*).

Required General Chapters—USP intends that required General Chapters will be brief and will focus on procedures and acceptance criteria where needed for tests of a monograph. This may lead to the redesign of current below 1000 General Chapters, with the intent of editing and reformatting without necessarily changing the contained standard.

Informative General Chapters—USP intends that General Chapters above 1000 will be entirely informational and will not contain monograph-related requirements. Topics that might be covered in informational chapters include:

- Background, theory, and future directions/applications
- Areas that need standards, e.g., nanotechnology
- Safety approaches and information
- Guidance chapters for good food and drug practices
- Drug development and registration documents
- Supply chain management documents, including GMP analyses and comparisons
- Comparisons across the USP compendia.

Evaluation of Existing General Chapters—A key objective of the evaluation of a General Chapter is a critical assessment of both the quality of the science and its presentation. Chapter evaluation and follow-up recommendations for the next cycle will involve a series of decisions based on the current state of the chapter and its impact. These evaluations will be done independently by the Project Team, USP Staff, and the appropriate Expert Committees (see *Table 3*).

General Chapter Information Database—USP possesses the following information regarding the history, current status, and impact of each chapter. This information comprises a database that will be made available on the USP Web site.

1. Official status [e.g., Official, Official in *Pharmacopeial Forum* (*PF*), New in *PF*, or In Development]
2. If official, original official date and most recent official revision
3. Most recent publication in *PF*
4. Chapter impact—number of monographs referencing each chapter
5. Associated reference standards
6. Harmonization status
7. Responsible liaison
8. Current Expert Committee assignment.

Templates—USP's monograph redesign approach was based on a standardized template. USP expects this template will be useful for General Chapters as well, particularly for the procedural chapters considered required and thus will be closely allied with monographs. Templates are also expected to be useful in defining groups of General Chapters that speak to a common topic (see *Table 4*). The overall goal will be to provide continuity and consistency in General Chapter texts.

Harmonization—Intensive efforts during the past several decades have emphasized the importance of harmonizing General Chapters with other compendia. Harmonized tests, procedures, and acceptance criteria greatly assist an increasingly global pharmaceutical industry in developing one set of approaches applicable in multiple geographies. This approach also facilitates and leads to an internationally recognized reference measurement system for drugs. This will result in fewer required methods, increased testing efficiency, facilitation of global method transfers, and an advance toward modern measurement science.

These opportunities will require significant time and effort. With strong focus and a commitment from both USP and its stakeholders, the intent is to close the General Chapter Redesign project at the end of the 2015 cycle.

THE COUNCIL OF EXPERTS

The Council of Experts and its Expert Panels in the coming cycle are critical to the success of the General Chapter Redesign project. The methods undergirding the procedures of compendial text will fall primarily to three Expert Committees with focus on physical, chemical, and biological procedures. However, all Expert Committees will necessarily be involved in the overall effort. Careful staff support will be needed in the following areas.

Expert Committee Assignments/Reassignments—The number of Expert Committees has been reduced in the 2010–2015 cycle with the intent of creating topic-specific Expert Panels when needed (www.usp.org/pdf/EN/aboutUSP/expertCommitteeFocusAreas.pdf). Reassignment of work from Expert Committees in the current cycle to Expert Committees in the 2010–2015 cycle appears on the USP Web site at www.usp.org/USPNF/submitMonograph/generalChapterWorkplans.html.

Work Plan Establishment and Tracking—USP staff will provide Expert Committees devoted to consideration of General Chapters with a comprehensive set of information about each General Chapter as a means of defining work plans and to determine the need for and assignments of Expert Panels. Specific steps in the process are suggested in *Table 5*.

CONCLUSION AND NEXT STEPS

USP's General Chapters are key to the scientific progress of USP's compendia. Through recent *Stimuli* articles USP envisions an approach according to which future monographs might contain criteria for good procedures (*2*) with elimination of the step-by-step procedures that characterize current monographs. Acceptable procedures might be declared equivalent or better based on well-designed and -reviewed studies (*3*). The general approach relies on well-characterized reference materials that are certifiable through careful collaborative studies. The approach is in accord with modern principles of metrology (*4*) and also paves the way for further compen-

dial harmonization (*5*). General Chapters are integral to the advancement of this approach and to other scientific advances.

USP offers this *Stimuli* now to solicit comments on the proposed General Chapter Redesign initiative via the *Pharmacopeial Forum* process. As appropriate, comments will be incorporated into the project and used to inform newly elected chairs of the Council of Experts following the USP Convention elections in April 2010. Taken together with the impressive advances of the current cycle, the General Chapter Redesign Project may be considered a capstone in a series of efforts—*General Notices* revision, Monograph Redesign, and allied efforts—that advance USP's documentary and reference material standards to meet challenges of the 21st century to ensure access to good quality medicines for patients and consumers.

Transfer of Analytical Procedures: A Proposal for a New General Information Chapter

Oscar Quattrocchi,[a] Greg Martin,[a] Dennis Runser,[a] Robert Iser,[b] Fred Xi,[a] Horacio Pappa[c]

ABSTRACT This *Stimuli* article presents the basis of a new General Information Chapter on method transfer. This Chapter continues a series of chapters devoted to providing guidance for the quality of the data-acquisition process (i.e., qualification, validation, and verification). The purpose of the procedure transfer process is to qualify the receiving laboratory to perform an analytical procedure that was developed in another laboratory. This concept is similar to the verification process described in USP General Information Chapter *Verification of Compendial Procedures* ⟨1226⟩. A section in the Chapter describes differences and similarities between verification and transfer. This *Stimuli* article aims to initiate discussion and solicit stakeholder comments.

INTRODUCTION

The testing of a pharmaceutical ingredient, in-process intermediate, or finished product is critical in establishing the quality of the final pharmaceutical product. The transfer of analytical procedures (TAP), also referred to as method transfer, is the documented process that qualifies a laboratory (the receiving unit) to use an analytical test procedure that originates in another laboratory (the transferring unit, also named the sending unit), thus ensuring that the receiving unit has the procedure knowledge and ability to perform the transferred analytical procedure as intended.

The purpose of this article is to summarize the types of transfers that may occur, including the possibility of waiver of any verification, and to outline the components of a transfer protocol. It is not the intent of this article to go into any detail about statistical methods. A summary of approaches for the statistically similar problem of comparison of procedures has been published (*1*). That article may become one or more General Chapters and, if so, would be referenced by any General Chapter that is developed regarding method transfer. Also, this Chapter does not encompass the transfer of microbiological or biological procedures.

TYPES OF TRANSFERS OF ANALYTICAL PROCEDURES

TAP can be performed and demonstrated by several approaches. The most common is comparative testing performed on homogeneous lots of the target material from standard production batches or samples intentionally prepared for the test (e.g., by spiking relevant accurate amounts of known impurities into samples). Other approaches include covalidation between laboratories, the complete or partial validation of the analytical procedures by the receiving unit, and the transfer waiver, which is an appropriately justified omission of the transfer process. It is possible to initiate and even finalize the transfer before the validation process is completed. However, the lack of complete knowledge about the variables of the procedure and particularly its robustness may complicate the transfer process by adding more variables to a system that should be as simple as possible.

Comparative Testing

Comparative testing is the most common method for TAP and requires the analysis of one or more samples of the same lot by both the transferring and the receiving units. Such analysis is based on an agreed and preapproved transfer protocol that provides the details of the procedure, the samples that will be used, and the predetermined acceptance criteria. The data generated by both parties are compared to the acceptance criteria in order to assess the equivalence of results between the transferring and the receiving units.

Covalidation between Two or More Laboratories

The laboratory that performs the validation of an analytical procedure is, by definition, qualified to run that method. Manufacturers can involve the receiving unit in an interlaboratory qualification, including them as a part of the validation team and thereby obtaining data for the assessment of reproducibility. This assessment is made using a preapproved transfer protocol that provides the details of the procedure, the samples to be used, and the predetermined acceptance criteria. In such cases it may not be necessary to perform the complete validation because the method transfer exercise is aimed at evaluating laboratory-to-laboratory capability, not at establishing the primary validation and statistical strength of the analytical method itself. General Information Chapter *Validation of Compendial Procedures* ⟨1225⟩ provides useful guidance about which characteristics are appropriate for testing.

[a] USP General Chapter Expert Committee member.

[b] FDA Liaison. The opinions expressed in this paper do not necessarily reflect the views or opinions of FDA.

[c] Correspondence should be addressed to: Horacio Pappa, PhD, Senior Scientist, US Pharmacopeia, 12601 Twinbrook Parkway, Rockville, MD 20852-1790; tel. 301.816.8319; e-mail hp@usp.org.

Method Verification or Revalidation

Method verification or revalidation is another acceptable approach for transfer of a validated procedure. TAP is conceptually similar to ⟨1226⟩, although the Chapters' objectives reflect some differences in the process and documentation. General Information Chapter ⟨1226⟩ deals with the transfer of a pharmacopeial procedure from the compendia to a receiving unit. When successful, TAP demonstrates a similar transfer process between the transferring unit that is responsible for the development and validation of the procedure and the receiving unit. In both cases the procedures to be transferred and the acceptance criteria are closely related to the development and the validation processes. The main difference between them resides in the nature of the sample. In a TAP, the sample typically is the same for all units involved. For the transfer of a compendial procedure (⟨1226⟩) a single sample may be evaluated only within one or more operational units that compare performance against an existing monograph or a single compendial test standard.

After a laboratory has performed a successful verification or validation, the laboratory has gained the skill and knowledge necessary to perform the test. This approach is more time-consuming than comparative testing, and manufacturers also may find it more difficult to observe bias between different sites, operators, and instruments.

Transfer Waiver

The conventional TAP may be omitted under certain circumstances. In those cases, the receiving unit is considered to be qualified to use the analytical test procedures without comparison and generation of interlaboratory comparative data. The following list, though not necessarily exhaustive, gives examples that may justify the waiver of the TAP:

- The receiving unit has already used the procedure for a significant amount of time and has gained the necessary skills and knowledge.
- The new product has a composition comparable to that of an existing product and/or the concentration of active ingredient is similar to that of an existing product and is analyzed by procedures for which the receiving unit already has experience.
- The analytical procedure is the same or closely similar to a procedure already in use.
- The personnel in charge of the development and validation moved to the receiving unit.

ELEMENTS RECOMMENDED FOR THE TRANSFER OF ANALYTICAL PROCEDURES

Several elements, many of which are interrelated, are recommended for a successful TAP using the comparative testing approach. When appropriate and as a part of pre-transfer activities, the transferring unit should provide training to the receiving unit, or the receiving unit should run the procedures and identify any issues that may need to be resolved before signing the transfer protocol. Training should be documented.

The transferring unit, often the development unit, is responsible for providing the analytical procedure, any necessary development, validation reports, and documents, as well as for providing the necessary training and assistance to the receiving unit whenever necessary during the transfer. The receiving unit may be a Quality Control unit, another intracompany facility, another company, or a contract research organization, among others. The receiving unit provides qualified staff or properly trains the staff before the transfer, ensures that the facilities and instrumentation are properly calibrated and qualified as needed, and verifies that the laboratory systems are in compliance with applicable regulations and in-house general laboratory procedures. Both the transferring and receiving units should compare and discuss data and any deviations from the protocol. This discussion addresses any necessary corrections or updates to the final report and the analytical procedure as necessary to reproduce the procedure.

PREAPPROVED PROTOCOL

A well-designed protocol should be discussed, agreed upon, and documented before the implementation of TAP. The document expresses a consensus between the parties, indicating an intended execution strategy, and may include each party's requirements and responsibilities. The protocol should describe the objective; the scope; the responsibilities of the transferring and the receiving units; the materials and instruments to be used; the analytical procedure; the experimental design; and the acceptance criteria for all the tests and/or methods included in the transfer. Based on the validation data and procedural knowledge, the transfer protocol should identify the specific procedure characteristics that will be verified and the analysis that will be used to evaluate acceptable outcomes from the transfer exercise.

The acceptance criteria, also based on validation documents, should include the comparability criteria for results from all study sites. These criteria may be based on the difference between mean values and should be accompanied by an estimation of the variability, e.g., percent relative standard deviation for each site and/or a statistical method for the comparison of the means (e.g., two one-sided *t* tests for intersite similarity) for assay and content uniformity tests. The same parameters, with appropriate adjustment in relation to the specification limit, may be used for impurities and degradation products. Dissolution can be evaluated by a comparison of the dissolution profiles using the similarity factor f_2 or by comparison of data at the specified time points as described previously for the assay.

The laboratories should provide a rationale for any procedure not included as well as any transfer waiver. The materials, standards, samples, and instruments that will be used should be described, along with the associated parameters.

Whenever possible, a set of real samples and aged samples should be evaluated to examine potential problems related with differences in sample preparation equipment.

The documentation section of the transfer protocol may include report forms to ensure consistent recording of results and to improve consistency between laboratories. This section should contain the additional information that will be included with the results, such as chromatograms, spectra, and deviation reports. The protocol also explains how any deviation from the acceptance criteria will be managed.

THE ANALYTICAL PROCEDURE

The procedure is written with sufficient detail and explicit instructions to allow a trained analyst to perform it without difficulty. A pre-transfer meeting between the transferring and the receiving units is helpful to clarify any issues and answer any questions regarding the transfer process. If complete or partial validation data exist, they should be available to the receiving unit, along with any technical details required to perform the test in question. In some cases it may be useful for the individuals who were involved with the initial development or validation to be on-site during the transfer. The number of batches, replicates, and injection sequences in the case of liquid or gas chromatography should be clearly expressed, and, in the case of dissolution testing, the number of individual dosage units should be stipulated.

METHOD TRANSFER REPORT

When the TAP is successfully completed the scientists involved should prepare a Transfer Report that describes the results obtained in relation to the acceptance criteria, along with conclusions that confirm that the receiving unit is now qualified to run the procedure. Failure to meet the acceptance criteria does not constitute an out-of-specification (OOS) result and does not require a formal OOS investigation. However, any result that fails to meet the predetermined acceptance criteria should be properly investigated and documented. Any deviations should be discussed and justified. The issues that contributed to failure to achieve the predicted acceptance criteria should be corrected, including training or further clarification of the analytical procedure. When the acceptance criteria are not met, the procedure cannot be transferred. Then remedial steps must be taken until the acceptance criteria are met.

Visible Particulates in Injections—A History and a Proposal to Revise *USP* General Chapter *Injections* ⟨1⟩

Russell E. Madsen,[a] Roy T. Cherris,[b] John G. Shabushnig,[a] and Desmond G. Hunt[c,d]

ABSTRACT This *Stimuli* article provides a history of visual inspection practices and requirements for parenteral products in the United States. It includes a sampling plan and test for products that have been 100% inspected as part of the manufacturing process and criteria by which a product can be considered ''essentially free'' from visible particulates. The proposed test alone is insufficient for batch release testing—a complete program for the control and monitoring of particulate matter remains an essential prerequisite. The proposal is generally harmonized with the Particulate Contamination: Visible Particles section of the *European Pharmacopoeia* and the Foreign Insoluble Matter Test for Injections in the *Japanese Pharmacopoeia*. The objectives of this *Stimuli* article are to initiate discussion and to solicit public comments that will be considered by the Ad Hoc Advisory Panel—Visual Inspection of Parenterals and subsequently the Parenteral Products: Industrial Expert Committee. The Expert Committee will consider recommendations from the Advisory Panel regarding the proposed revision.

THE NEED TO INSPECT

Visual inspection of parenteral products is driven by the need to minimize the introduction of unintended particulate matter to patients during the delivery of injectable medications. Such inspection also offers the opportunity to reject nonconforming units, such as those with cracks or incomplete seals, that pose a risk to the sterility of the product. The desire to detect these defects at a very low frequency and the randomness of their occurrence have resulted in the current expectation that each finished unit be inspected (100% inspection).

Human visual performance is critical to the assessment of visible particles. The threshold for human vision is generally accepted to be 50 μm. The detection process is probabilistic; i.e., the probability of detection increases with increasing particle size. Analysis of inspection results pooled from several studies involving different groups of inspectors shows that the probability of detection for a single 50-μm particle in clear solution in a 10-mL vial with diffuse illumination between 2000 and 3000 lux is slightly greater than 0%. This probability increases to approximately 40% for a 100-μm particle and becomes greater than 95% for particles 200 μm and larger (*1*).

Many animal studies have been conducted to determine the fate of intravenous particles of differing size and composition (*1–4*). Most studies have focused on subvisible particles that have a diameter of less than 50 μm. The smallest of these particles (approximately 1 μm in diameter) are often trapped in the liver, lungs, and spleen. Intravenous infusion of particles larger than the internal diameter of capillaries may be clinically significant because the particles may increase the risk of foreign particle embolism (*5*, *6*). Larger particles generally do not migrate far from the injection site. The most common response observed is the formation of emboli and granulomas. Although they help explain the physiological response to particulate matter, the large number of particles employed in these studies (e.g., 10^9 particles/kg/injection) provides little guidance about the risk of delivering small numbers of particles to patients.

Several reviews describe the effect on patients of particles in parenterals (*7–13*). Garvin and Gunner were among the first to express concern about the effects of particles in patients (*14*, *15*). Ethical considerations preclude controlled human studies on the effect of particulates in human patients. Some anecdotal information can be obtained from studies that involve intravenous drug abusers (*16–18*). In these case studies, solid oral dosages often are ground up and injected as a slurry. Pulmonary foreign body emboli and granulomas were observed in these patients. Again, the clinical risks of particles administered in other settings are difficult to infer from these observations because of the large number of foreign particles and the uncontrolled conditions in which they were administered.

Even though an estimated 15 billion injectable doses of medicines are dispensed each year (*19*), no reports of adverse events associated with the injection of individual visible particles have been found. Although zero defects is the desired goal and should drive continuous process improvement, it is not a workable acceptance criterion for visible particulate matter because of current packaging components and processing capability. The US Pharmacopeial Convention (USP) has adopted the terminology of ''essentially free'' to recognize this current state. As we move forward, a more precise definition is desirable to prevent misunderstanding and to aid in communication of this important quality attribute.

HISTORY OF INSPECTION STANDARDS

In 1915 *USP IX* described the need for injectable compounds to be true solutions. In 1916, the *National Formulary* (*NF IV*) included six monographs for parenteral products and specified the method of preparation, but neither Compendium provided guidance with respect to solution clarity.

The first appearance of ''solution clarity'' and freedom from contaminants for parenterals occurred in 1936 in *NF VI*. A requirement for clarity in injectable solutions specified: ''Aqueous ampule solutions are to be clear; i.e., when observed over a bright light, they shall be substantially free from precipitate, cloudiness or turbidity, specks or flecks, fibers or cotton hairs, or any undissolved material.''

The requirement for visual clarity of parenteral products began in 1942. This was before USP's acquisition of *NF* and required coordination between USP and the American Pharmaceutical Association, the publisher of *NF* at that time. The two compendia that were official at the time,*NF VII* and *USP XII*, were coordinated in response to the need to define and control the quality of injectable products purchased in support of the military during World War II. Together, the compendia introduced the term ''substantially free'' to describe the need for control of particle contamination. *NF VII* stated: ''Aqueous solutions are to be clear; i.e., when observed over a bright light, they shall be substantially free from precipitate, cloudiness, or turbidity, specks or flecks, fibers or cotton hairs, or any undissolved material. Substantially free shall be construed to mean a preparation which is free from foreign bodies that would be readily discernible by the unaided eye when viewed through a light reflected from a 100-watt Mazda lamp using as a median a ground glass and a background of black and white'' (*20*).

USP XII stated ''Appearance of Solutions or Suspensions—Injections which are solutions of soluble medicaments must be clear, and free of any turbidity or undissolved material which can be detected readily without magnification when the solution is examined against black and white backgrounds with a bright light reflected from a 100-watt Mazda lamp or its equivalent'' (*21*).

Both *USP* and *NF* used the same test procedure; however the *USP* procedure was more rigorous because it omitted the qualifying adverb ''substantially.'' These directives were used by FDA in its role as the Quality Control Office for all pharmaceuticals purchased by the Armed Forces during World War II. On the basis of these requirements, FDA rejected many lots of injectable solutions offered to fulfill government contracts.

In 1947, *USP XIII* published requirements for clarity of solutions (*22*): ''Clarity of Solutions—Water for Injection, pharmacopeial Injections or pharmacopeial Solutions of medicament, intended for parenteral administration, unless exempted by individual monographs, must be substantially free of any turbidity or undissolved material which can be detected readily without accessory magnification (except for such optical correction as may be required to establish normal vision), when the solution is examined against a black background and against a light which at a point ten inches below the source provides an intensity of illumination not less than 100 and not more than 350 foot candles. This intensity of illumination may be obtained from a 100-watt, inside-frosted incandescent lamp operating at rated voltage, or from fluorescent lamps, or from any equivalent source of light.''

Following adverse observations during an FDA inspection of Bristol Laboratories, a finding of particle contamination in ampules was tested in court (*23*). The FDA inspector, guided by the ''clarity'' requirement as described in *USP XIII*, found particle-contaminated ampules in six accepted stocks from Bristol Laboratories. As a result of this inspection, the company was served with an FDA injunction and request for recall.

Bristol Laboratories challenged the results of the test by preparing a blinded test group of 150 ampules containing 1.5 mL sterile saline. This test group included 38 ampules that the FDA inspector had rejected as contaminated with particles. The case came to trial in 1949. At the conclusion of the government's testimony, the court granted the defendant's motion for dismissal. When on the witness stand, the FDA expert witness was asked to replicate the inspection using the test group and passed 36 out of 38 previously rejected containers. The case was dismissed on the grounds ''1) that the standards involved were indefinite and 2) that the evidence was insufficient to show such violation of the Act as would warrant the granting of the relief prayed for (destruction of the ampules)''(*23*).

From 1955 through 1970, *USP XV* through *USP XVIII* provided guidance about visual inspection of injections. For example, *USP XV* noted: ''Every care should be exercised in the preparation of injections to prevent contamination with micro-organisms and foreign material. Good pharmaceutical practice also requires that each Injection, in its final container, be subjected individually to visible inspection.'' *USP XVI* and *USP XVII* said: ''Every care should be exercised in the preparation of injections to prevent contamination with micro-organisms and foreign material. Good pharmaceutical practice also requires that each Injection, in its final container, be subjected individually to visible inspection whenever the nature of the container permits.''

In 1959, Fed. Std. No. 00142, Parenteral Preparations, was issued by the United States Navy Bureau of Medicine and Surgery (BuMed) and became mandatory for all Federal agencies. The standard was applicable to sterile parenteral preparations in final containers intended for human consumption. The standard was superseded in 1966 by Fed. Std. No. 142a. The standard provided requirements for clarity of solutions as well as limits for visible particulate matter as follows:

Section S6.2.1 *Clarity of solutions*. Applicable to type I, class 1; type II, class 1; type II, class 3; and solutions of dry solids (type IV, class 1). Solutions of parenteral preparations shall be clear and free from undissolved or particulate matter within the limits permitted in the classification of defects and the applicable acceptable quality level (AQL), when examined without accessory magnification (except for such optical correction as may be required to establish normal vision) against a black background and against a white background and

illumination from a light which at a point 25.4 centimeters (10 inches) from its source, provides an intensity of illumination of not less than 100 and not more than 350 foot-candles. Some biological products need not be clear and entirely free from turbidity, provided this is characteristic of the product. The clarity standards for such products shall be judged on an item-for-item basis with the characteristic properties of the product considered in each case.

NOTE—This standard was applied as a final test to samples of finished products, not to 100% on-line inspection, and the sampling was in accordance with MIL-STD-105.

For aqueous solutions (type I, class 1), the ''solution not clear'' defect was classified as Major A, Inspection Level II and the AQL (percent defective) as 1.0. Therefore, in a 30,000 unit batch, 315 units would be inspected; if only 7 or fewer contained visible particulate matter, the batch would pass the Clarity of Solution Test. Thus, at the time, agencies of the Federal government, including FDA, would deem this level to be acceptable and in compliance with the meaning of the USP term ''essentially free.''

Fed. Std. No. 142a was amended in 1970. It is not known when this standard was abandoned, but the significance of Fed. Std. No. 142a is that it provided government-endorsed acceptance limits for the presence of ''visible'' particles. Parenteral product quality acceptance levels were based on the limitations of sterile-product manufacturing capability at that time. Solomon Pflag, BuMed director in 1968, noted, ''Within the framework of the technology available on the subject of particulate matter, Military Services have been highly successful in the procurement of quality parenterals'' (*24*).

Fed. Std. No. 142a could serve as a model on which to frame a practical visible particulate matter acceptance level reflecting the improvement in present parenteral manufacturing technology.

USP XIX, Supplement 1, initiated the philosophical requirement for a zero-defect quality standard for foreign matter and particles (*25*): ''Every care should be exercised in the preparation of injections to prevent contamination. Good pharmaceutical practice also requires that each Injection, in its final container, be subjected individually to a physical inspection, whenever the nature of the container permits, and that every container whose contents show evidence of contamination with visible foreign material be rejected.'' This requirement was repeated verbatim in *USP XX* in 1980 (*26*).

In 1995, *USP XXIII* repeated the requirement for a zero-defect quality standard for foreign matter and particles (*27*): ''Every care should be exercised in the preparation of all products intended for injection, to prevent contamination with microorganisms and foreign material.'' This revision returned to the view expressed in *USP XIX Revision 1* that the response to particle contamination in injectable fluids must be a graded one. Only one phrase was changed: The previous use of the term *substantially free* was replaced by the term *essentially free*. In response to various publications and comments since 1980, a graded response to the inspection for visible particles appeared in *USP XXIII*, *Particulate Matter in Injections* ⟨788⟩: ''Particulate matter consists of mobile, randomly sourced, extraneous substances...that cannot be quantitated by chemical analysis due to the small amount of material that it represents and to its heterogeneous composition. Injectable solutions, including solutions constituted from sterile solids intended for parenteral use, should be essentially free from particles that can be observed on visual inspection.'' This requirement remains basically unchanged since the printing of *USP XIV* (*28*).

The requirements regarding ''visible particulates'' in the pharmacopeias of countries that participate in the International Conference on Harmonization are somewhat different, as shown below.

General Chapter ⟨1⟩ in *USP 31* states: ''Each final container of all parenteral preparations shall be inspected to the extent possible for the presence of observable foreign and particulate matter (hereafter termed 'visible particulates') in its contents. The inspection process shall be designed and qualified to ensure that every lot of all parenteral preparations is essentially free from visible particulates'' (*29*). No inspection method is specified.

The *Japanese Pharmacopoeia* states: ''Unless otherwise specified, Injections meet the requirements of the *Foreign Insoluble Matter Test for Injections* ⟨6.06⟩'' (*30*). Two inspection methods are described. Method 1 ''is applied to injections either in solutions, or in solution constituted from sterile drug solids'' and contains the following instructions: ''Clean the exterior of containers, and inspect with the unaided eyes at a position of light intensity of approximately 1000 lux under an incandescent lamp: Injections must be clear and free from readily detectable foreign insoluble matter. As to Injections in plastic containers for aqueous injections, the inspection should be performed with the unaided eyes at a position of light intensity at approximately 8000 to 10,000 lux, with an incandescent lamp at appropriate distances above and below the container.'' Method 2 ''is applied to injections with constituted solution'' and contains the following instructions: ''Clean the exterior of the containers, and dissolve the contents with constituted solution or with water for injection carefully, avoiding any contamination with extraneous foreign substances. The solution thus constituted must be clear and free from foreign insoluble matter that is clearly detectable when inspected with the unaided eyes at a position of light intensity of approximately 1000 lux, right under an incandescent lamp.''

The *European Pharmacopoeia* states ''Solutions for injection, examined under suitable conditions of visibility, are clear and practically free from particles'' (*31*). The inspection is described as follows: ''Gently swirl or invert the container...and observe for about 5 s in front of the white panel. Repeat the procedure in front of the black panel. Record the presence of any particles.''

BASIS FOR THE PROPOSAL

The proposal (see Draft Text for Consideration, below) is based on Fed. Std. No. 142a, which was used successfully for more than a decade to ensure the quality of sterile parenteral products delivered to the US government, and on the results of Parenteral Drug Association (PDA) surveys that assessed current practices in the inspection

of parenteral products. Fed. Std. No. 142a classified the defect as Major A, Inspection Level II and the AQL (percent defective) as 1.0. From the 2008 PDA Survey of Visual Inspection Practices (2), the median value for the AQL for Major defects (most often associated with particulate matter) is 0.65%.

The proposed inspection conditions have been harmonized with those specified in the *European Pharmacopeia*, with a recommendation to use a high-frequency ballast with the fluorescent lamps to reduce flicker and associated inspector fatigue.

The proposal uses a General Inspection Level II sampling plan, as found in American National Standards Institute/American Society for Quality (ANSI/ASQ) Z1.4, as a release test for product that has been 100% inspected during manufacturing and a fixed sample size of 60 units when there is a need to re-evaluate a batch that has been released and is in distribution (*33*). The re-evaluation, or ''field'' sample size is applicable to batch sizes greater than 600 units. The 60-sample plan is similar to an ANSI/ASQ Z1.4 Special Level S-4 inspection with an AQL of 0.65%, covering sample size code letters G (n = 32) for batches between 1201 and 10,000, H (n = 50) for batches between 10,001 and 35,000, or J (n = 80) for batches between 35,001 and 500,000. It has an AQL of 0.60%. A batch with 2.8 defective units per hundred would be accepted 50% of the time. For comparison, an ANSI/ASQ Z1.4 General Level II inspection at a comparable AQL (0.65%) would accept a batch with 1.3 defective units per hundred 50% of the time. The re-evaluation sampling plan does not require abnormally high levels of retained samples, and, with the exception of powders and/or freeze-dried products, it is nondestructive.

DRAFT TEXT FOR CONSIDERATION

Definitions

ESSENTIALLY FREE *[Insert at the end of the Definitions section of* ⟨1⟩ *Injections]*:

Where used in this Chapter, the term essentially free *means that when the batch of Injection is inspected as described herein, no more than the specified number of units may be observed to contain visible particulates.*

Visible Particulates in Injections *[Insert as a subheading under Foreign and Particulate Matter]*:

This test is intended to be applied to product that has been 100% inspected as part of the manufacturing process; it is not sufficient for batch release testing alone, and a complete program for the control and monitoring of particulate matter remains an essential prerequisite. This includes dry sterile solids for injection when reconstituted as directed in the labeling. Other methods that have been demonstrated to achieve the same or better sensitivity for visible particulates may be used as an alternative to the one described below.

Injections shall be clear and free from visible particulates when examined without magnification (except for optical correction as may be required to establish normal vision) against a black background and against a white background with illumination that at the inspection point has an intensity between 2000 and 3750 lux. This may be achieved through the use of two 15-W fluorescent lamps (e.g., F15/T8). The use of a high-frequency ballast to reduce flicker from the fluorescent lamps is recommended. Higher illumination intensity is recommended for examination of product in containers other than those made from clear glass.

Before performing the inspection, remove any adherent labels from the container and wash and dry the outside. The unit to be inspected shall be gently swirled, ensuring that no air bubbles are produced, and inspected for approximately 5 s against each of the backgrounds. The presence of any particles should be recorded.

For batch-release purposes, sample and inspect the batch using ANSI/ASQ Z1.4 General Inspection Level II, single sampling plans for normal inspection, AQL 0.65. Not more than the specified number of units contains visible particulates.

For product in distribution, sample and inspect 60 units. Not more than one unit contains visible particulates.

NOMENCLATURE

This section includes supplements to the latest edition of the *USP Dictionary of USAN and International Drug Names* that incorporate new United States Adopted Names (USAN) and revisions to existing Dictionary names. Also listed are Proposed and Recommended International Nonproprietary Names (INN) when they have been announced by the World Health Organization.

Possible names suggested for use as USAN and INN are listed for public review and comment along with information on how nonproprietary names are devised. In addition, readers may find articles relevant to current compendial nomenclature issues that also occasionally report on related matters pertaining to USAN and INN.

Nomenclature

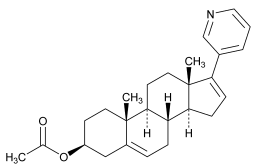
USP Dictionary of USAN and International Drug Names
2009 USP DICTIONARY SUPPLEMENT 3

IMPORTANT—Save this Supplement. This and all supplements appearing in *PF* are needed to keep the 2009 edition of the USP Dictionary (USPD) up-to-date. The cumulative contents of the supplements to the current (2009) edition will be included in the next complete edition of the Dictionary.

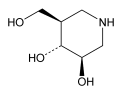
Newly Approved United States Adopted Names (USAN), Released for Publication

The following are newly established United States Adopted Names (USAN). These names will not be listed cumulatively; see preceding and succeeding numbers of *PF* for other new USAN to supplement the Dictionary main volume.

Abiraterone Acetate [*2009*] (a′′ bir a′ ter one ac′ e tate). $C_{26}H_{33}NO_2$. 391.50. [Abiraterone is INN and BAN.] (1) Androsta-5,16-dien-3-ol, 17-(3-pyridinyl)-, acetate (ester), (3β)-; (2) 17-(Pyridin-3-yl)androsta-5,16-dien-3β-yl acetate. *CAS-154229-18-2; CAS-154229-19-3* [abiraterone]. *Castration-resistant prostate cancer.* ✧*CB7630*



Afegostat [*2008*] (a feg′ oh stat). $C_6H_{13}NO_3$. 147.20. (1) 3,4-Piperidinediol, 5-(hydroxymethyl)-, (3*R*,4*R*,5*R*)-; (2) (3*R*,4*R*,5*R*)-5-(Hydroxymethyl)piperidine-3,4-diol. *CAS-169105-89-9. Treatment of Gaucher disease.*



Afegostat Tartrate [*2009*] (a feg′ oh stat tar′ trate). $C_6H_{13}NO_3.C_4H_6O_6$. 297.30. (1) 3,4-Piperidinediol, 5-(hydroxymethyl)-, (3*R*,4*R*,5*R*)-, (2*R*,3*R*)-2,3-dihydroxybutanedioate (1:1); (2) (3*R*,4*R*,5*R*)-5-(Hydroxymethyl)piperidine-3,4-diol hydrogen (2*R*,3*R*)-2,3-dihydroxybutanedioate (salt). *CAS-919364-56-0. Treatment of Gaucher disease.* ✧*AT2101*

Arhalofenate [*2008*] (ar′′ hal oh fen′ ate). $C_{19}H_{17}ClF_3NO_4$. 415.80. Teglarinad Chloride [*2009*] (teg lar′ i nad klor′ ide). $C_{30}H_{43}Cl_2N_5O_8$. 672.60. (1) Pyridinium, 4-[[[[6-(4-chlorophenoxy)hexyl]amino](cyanoamino)methylene]amino]-1-(3-oxo-2,4,7,10,13,16-hexaoxaheptadec-1-yl)-, chloride; (2) 4-({*N*-[6-(4-Chlorophenoxy)hexyl]-*N*′-cyanocarbamimidoyl}amino)-1-(3-oxo-2,4,7,10,13,16-hexaoxaheptadecan-1-yl)pyridinium chloride. *CAS-432037-57-5*. *Antineoplastic.* ✧*GMX1777; EB1627*

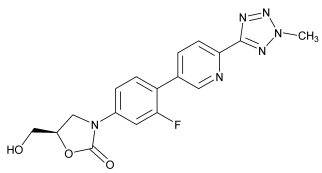
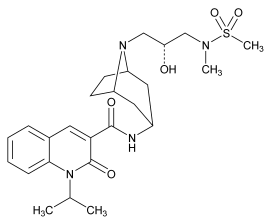
Tiomolibdate Diammonium [*2008*] (tye′′ oh moe lib′ date). $H_8MoN_2S_4$. 260.30. (1) Molybdate(2-), tetrathioxo-, ammonium (1:2), (*T-4*)-; (2) Diammonium tetrathiomolybdate. *CAS-15060-55-6*. *Anticopper drug.* Coprexa (Pipex Therapeutics) ✧*ATTM; TM; NSC-714598*

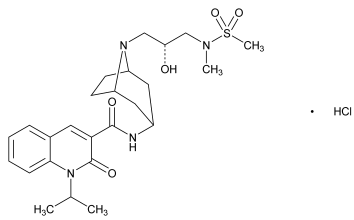
Torezolid [*2009*] (tore ez′ oh lid). $C_{17}H_{15}FN_6O_3$. 370.30. (1) 2-Oxazolidinone, 3-[3-fluoro-4-[6-(2-methyl-2*H*-tetrazol-5-yl)-3-pyridinyl]phenyl]-5-(hydroxymethyl)-, (5*R*)-; (2) (5*R*)-3-{3-Fluoro-4-[6-(2-methyl-2*H*-tetrazol-5-yl)pyridin-3-yl]-phenyl}-5-(hydroxymethyl)oxazolidin-2-one.*CAS-856866-72-3*. *Antibiotic.* ✧*TR-700*



Velusetrag [*2008*] (vel′′ u set′ rag). $C_{25}H_{36}N_4O_5S$. 504.60. (1) 3-Quinolinecarboxamide, 1,2-dihydro-*N*-[(3-*endo*)-8-[(2*R*)-2-hydroxy-3-[methyl(methylsulfonyl)amino]propyl]-8-azabicyclo[3.2.1]oct-3-yl]-1-(1-methylethyl)-2-oxo-; (2) *N*-[(1*R*,3*R*,5*S*)-8-{(2*R*)-2-Hydroxy-3-[methyl(methylsulfonyl)amino]propyl}-8-azabicyclo[3.2.1]oct-3-yl]-1-(1-methylethyl)-2-oxo-1,2-dihydroquinoline-3-carboxamide.*CAS-866933-46-2*. *Treatment of constipation.* ✧*TD-5108*



Velusetrag Hydrochloride [*2008*] (vel′′ u set′ rag hye′′ droe klor′ ide). $C_{25}H_{36}N_4O_5S.HCl$. 541.10. (1) 3-Quinolinecarboxamide, 1,2-dihydro-*N*-[(3-*endo*)-8-[(2*R*)-2-hydroxy-3-[methyl(methylsulfonyl)amino]propyl]-8-azabicyclo[3.2.1]oct-3-yl]-1-(1-methylethyl)-2-oxo-, monohydrochloride; (2) *N*-[(1*R*,3*R*,5*S*)-8-{(2*R*)-2-Hydroxy-3-[methyl(methylsulfonyl)amino]propyl}-8-azabicyclo[3.2.1]oct-3-yl]-1-(1-methylethyl)-2-oxo-1,2-dihydroquinoline-3-carboxamide hydrochloride. *CAS-866933-51-9*. *Treatment of constipation.*



Zalutumumab [*2009*] (zal′′ ue toom′ ue mab). $C_{6512}H_{10068}N_{1732}O_{2032}S_{46}$. (1) Immunoglobulin G1, anti-(human epidermal growth factor receptor)(human monoclonal 2F8 heavy chain), disulfide with human monoclonal 2F8 κ-chain, dimer; (2) Immunoglobulin G1, anti-(human epidermal growth factor receptor (receptor tyrosine-protein kinase ErbB-1)); human monoclonal 2F8 g1 heavy chain (228-214′)-disulfide with human monoclonal 2F8 κ light chain dimer (234-234′′:237-237′′)-bisdisulfide. Molecular weight is approximately 146,600 daltons. *CAS-667901-13-5*. INN. *Treatment of cancer.* ✧*HuMax-EGFr, 2F8*

Proposed and Recommended International Nonproprietary Names

International Nonproprietary Names (INN) are devised by the World Health Organization (WHO).

Under its charter, WHO is empowered simply to recommend specific actions or procedures to its Member States. This limitation is incorporated into the WHO program concerned with the selection of international nonproprietary names for pharmaceutical substances, in that WHO first publishes the selected names as proposals (''Proposed International Nonproprietary Names''). For a period of four months from the date of publication of *WHO Drug Information,* comments and objections may be submitted by the Member States or other interested parties. In general, an objection reflects a belief that the proposed name may be confused with a preexisting name, perhaps in only a restricted area in which the party has a proprietary interest in the form of trademark rights. In the event that no objection is received, WHO lists and publishes the names as recommendations (''Recommended International Nonproprietary Names''), which the Member States then recognize as the sole or preferred nonproprietary name for use within their respective territories.

Proposed International Nonproprietary Names–List 100

The following 56 names have been selected by WHO as Proposed International Nonproprietary Names. This list, with chemical names, descriptions and molecular formulae, appears in *WHO Drug Information,* Vol. 22, No. 4, 2008.

Suggested INN	Category
Adarotene	*Antineoplastic*
Afamelanotide	*Melanocortine receptor agonist*
Alisporivir	*Antiviral*
Amenamevir	*Antiviral*
Atigliflozin	*Antihyperglycemic*
Balapiravir	*Antiviral*
Beloranib	*Antineoplastic*
Blinatumomab	*Antineoplastic*
Canosimibe	*Antihyperlipidemic*
Cixutumumab	*Antineoplastic*
Coleneuramide	*Neuroprotective agent*
Cositecan	*Antineoplastic*
Cutamesine	*s Receptor ligand*
Davunetide	*Neuroprotective agent*
Delafloxacin	*Antibiotic*
Dirucotide	*Autoimmune disorders*
Dutogliptin	*Antihyperglycemic*
Elotuzumab	*Antineoplastic*
Farletuzumab	*Antineoplastic*
Fidaxomicin	*Antibiotic*
Figitumumab	*Antineoplastic*
Fosbretabulin	*Antineoplastic*
Fostamatinib	*Antineoplastic*
Indeglitazar	*Antihyperglycemic*
Ingenol Mebutate	*Antineoplastic*
Laninamivir	*Antiviral*
Lesogaberan	*GABA receptor agonist*
Limiglidole	*Antihyperglycemic*
Lotilibcin	*Antibiotic*
Macimorelin	*Growth hormone release stimulating peptide*
Namitecan	*Antineoplastic*
Necitumumab	*Antineoplastic*
Oportuzumab Monatox	*Antineoplastic*
Panobacumab	*Antibacterial (against Pseudomonas aeruginosa)*
Pozanicline	*Nicotinic acetylcholine receptor partial agonist/agonist*
Ramucirumab	*Antineoplastic*
Regorafenib	*Antineoplastic*
Riferminogene Pecaplasmid	*Gene therapy product, stimulates angiogenesis*
Robatumumab	*Antineoplastic*
Racotumomab	*Antineoplastic*
Selumetinib	*Antineoplastic*
Serlopitant	*Neurokinin (NK1) receptor antagonist*
Siltuximab	*Antineoplastic*
Sobetirome	*Antihyperlipidemic*
Sofinicline	*Nicotinic acetylcholine receptor partial agonist/agonist*
Solanezumab	*Neuroprotective agent*
Taberminogene Vadenovec	*Gene therapy product, treatment of arterial restenosis*
Tarafenacin	*Muscarinic receptor antagonist*
Telcagepant	*Antimigraine*
Tilivapram	*Phosphodiesterase IV inhibitor*
Toceranib	*Antineoplastic*
Tozasertib	*Antineoplastic*
Vanutide Cridificar	*Neuroprotective agent*
Vedolizumab	*Immunomodulator*
Voreloxin	*Antineoplastic*
Zicronapine	*Antipsychotic*

Recommended International Nonproprietary Names–List 61

The following 68 names have been selected by WHO as Recommended International Nonproprietary Names. This list, with chemical names, descriptions and molecular formulae, appears as prepublication list 61 on the WHO website.

Levomefolic Acid
Aderbasib
Adoprazine
Alipogene Tiparvovec
Apricoxib
Bafetinib
Bederocin
Befiradol
Bevasiranib
Catridecacog
Citatuzumab Bogatox
Conatumumab
Custirsen
Danusertib
Darotropium Bromide
Demiditraz
Denenicokin
Derquantel
Disitertide
Drinabant
Dulanermin
Edoxaban
Elagolix
Elesclomol
Entinostat
Eprotirome
Esreboxetine
Etaracizumab
Foravirumab
Ibipinabant
Intiquinatine
Lancovutide
Larazotide
Lensiprazine
Levomilnacipran
Linagliptin
Lixisenatide
Macitentan
Melogliptin
Mimopezil
Mipomersen
Niraxostat
Olesoxime
Ombrabulin
Otenabant
Palifosfamide
Palovarotene
Radezolid
Rafivirumab
Retaspimycin
Saracatinib
Semagacestat
Semuloparin Sodium
Sivifene
Talarozole
Talmapimod
Tanezumab
Tasimelteon
Tasisulam
Taspoglutide
Tecovirimat
Teneligliptin
Tildipirosin
Tosedostat
Troplasminogen Alfa
Ustekinumab
Vadimezan
Velneperit

Nomenclature

INDEX

This is a cumulative directory for the content of all issues of *PF* beginning with *PF* 35(1).

[*Note—This index covers Vol. 35 No. 1, pp. 1–218; Vol. 35 No. 2, pp. 219-498; Vol. 35 No. 3, pp. 499-784; Vol. 35 No. 4, pp. 785-1050; Vol. 35 No. 5, pp. 1051-1408.*]

CHROMATOGRAPHIC COLUMNS USED IN *USP–NF* AND *PHARMACOPEIAL FORUM*

This is an update based on the proposals published in this issue of *PF*.

Chromatographic Columns Used in *USP-NF* and *Pharmacopeial Forum*
Sept.–Oct. 2009

ANASTROZOLE (DSD Mgh #4650)

PF	LGS#	Reagent Brand	Type of Test	Comments
34(2)	L42	HiChrom RPB-250A	Assay and Related Compounds	3.2 mm × 10 cm, 5μm. Manufacturer: HiChrom

AZTREONAM (DSD Mgh #6772)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	G43	OVI-G43	Limit of	Limit of alcohol. 0.53 mm × 30 m, 3 μm. Manufacturer: Supelco

DEFEROXAMINE MESYLATE (DSD Mgh #22400)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(4)	L1	ZORBAX ODS	Assay and Related Compounds	4.6 mm × 7.5 cm, 3.5 μm. Alternative column Zorbax Eclipse XDB C18. Manufacturer: Agilent Technologies

DICLOFENAC SODIUM EXTENDED-RELEASE TABLETS (DSD Mgh #24972)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L7	ZORBAX C8	Organic Impurities	4.6 mm × 25 cm. Manufacturer: Agilent Technologies

DOCETAXEL (DSD Mgh #27795)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L1	Sunfire C18	Assay and Related Compounds	4.6 mm × 15 cm, 3.5 μm. Manufacturer: Waters Corp.

DOFETILIDE (DSD Mgh #27968)

PF	LGS#	Reagent Brand	Type of Test	Comments
0(0)	L7	Nova-Pak C8	Assay	3.9 mm × 15 cm, 4 μm. Manufacturer: Waters Corp.
0(0)	L1	Symmetry C-18	Organic Impurities	3.9 mm × 15 cm, 5 μm. Manufacturer: Waters Corp.

FEXOFENADINE HYDROCHLORIDE TABLETS (DSD Mgh #852)

PF	LGS#	Reagent Brand	Type of Test	Comments
0(0)	L1	Spherisorb ODS-2	Dissolution	Dissolution Test 3. 4.6 mm × 10 cm, 5 μm. Manufacturer: Waters Corp.

HYDROGENATED POLYDEXTROSE (DSD Mgh #2982)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L39	Ultrahydrogel 250	Molecular Weight Limit	7.8 mm × 30 cm. Manufacturer: Waters
35(5)	L17	Aminex HPX-87H	Assay and Limit of	Limit of monomers. 7.8 mm × 30 cm. Guard column Cation H cartridge, catalog # 125-0129, Bio-Rad. Manufacturer: BIO-RAD Laboratories

LEVETIRACETAM (DSD Mgh #2646)

PF	LGS#	Reagent Brand	Type of Test	Comments
0(0)	L1	YMC-Pack ODS-AQ	Assay and Related Compounds	4.6 mm × 15 cm, 3 μm. Manufacturer: YMC Co., Inc.
0(0)	L51	Chiralpak AD	Limit of	Limit of Levetiracetam-*R*-enantiomer. 4.6 mm × 25 cm, 10 μm. Manufacturer: Chiral Technologies, Inc.
0(0)	L1	XTerra RP 18	Limit of	Limit of Levetiracetam Related Compound B. 4.6 mm × 25 cm, 5 μm. Manufacturer: Waters Corp.

MEFLOQUINE HYDROCHLORIDE (DSD Mgh #48040)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L1	LiChrospher 100 RP-18	Assay	4.0mm × 25 cm, 5 μm. Manufacturer: Merck KGaA

ORLISTAT (DSD Mgh #58790)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L7	Superspher 60 RP-Select B	Limit of	Limit of Orlistat Related Compound D. 4.0 mm × 25 cm. 5 μm Manufacturer: Merck KGaA

OXACILLIN SODIUM (DSD Mgh #59030)

PF	LGS#	Reagent Brand	Type of Test	Comments
20(1)	L11	MicroBondapak Phenyl	Assay	4 mm × 30 cm. Manufacturer: Waters Corp

PARTIALLY-NEUTRALIZED METHACRYLIC ACID AND ETHYL ACRYLATE COPOLYMER (DSD Mgh #4428)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L1	AQUASIL C18	Organic Impurities and Limit of	Limit of methacrylic acid and ethyl acrylate. 4 mm × 12.5 cm, 5 μm. Alternative column: Zorbax SB-AQ, 4.6 mm × 15 cm, 5 μm. Manufacturer: Agilent. Manufacturer: Thermo Scientific

POLYDEXTROSE (DSD Mgh #66235)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L39	Ultrahydrogel 250	Molecular Weight Limit	7.8 mm × 30 cm, 6 μm. Manufacturer: Waters
35(5)	L17	Aminex HPX-87H	Assay and Limit of	Limit of monomers. 7.8 mm × 30 cm. Guard-column Cation H cartridge, manufacturer Bio-Rad, cat # 125-0129 Manufacturer: BIO-RAD Laboratories

RACTOPAMINE HYDROCHLORIDE SUSPENSION (DSD Mgh #1278)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L1	Supelcosil LC-18-DB	Assay	4.6 mm × 15 cm, 5 μm. Manufacturer: Supelco, Inc.
35(5)	L1	Supelcosil LC-18-DB	Organic Impurities	4.6 mm × 25 cm, 5 μm. Manufacturer: Supelco, Inc.
35(5)	L1	APEX ODS	Diastereoisomer Ratio	4.6 mm × 25 cm, 5 μm. Manufacturer: Phenomenex

TELMISARTAN AND HYDROCHLOROTHIAZIDE TABLETS (DSD Mgh #37985)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L1	Inertsil ODS	Dissolution	3 mm × 6 cm, 5 μm. Manufacturer: GL Sciences
35(5)	L1	Inertsil ODS	Assay and Organic Impurities	4.0 mm × 12.5 cm, 5 μm. Manufacturer: GL Sciences

TRICLOSAN (DSD Mgh #85150)

PF	LGS#	Reagent Brand	Type of Test	Comments
22(3)	G3	DB-17	Assay and Related Compounds	Alternative column AT-50, 0.53 mm × 15 cm, 1 μm Manufacturer: J & W Scientific

ZIDOVUDINE ORAL SOLUTION (DSD Mgh #89518)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L1	Hypersil BDS C-18	Organic Impurities	4.6 mm × 10 cm, 3 μm. Manufacturer: Thermo Scientific

ZOLPIDEM TARTRATE TABLETS (DSD Mgh #89990)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(4)	L1	Spherisorb ODS1	Assay and Related Compounds	4.6 mm × 15 cm, 5 μm. Manufacturer: Waters Corp.

Table of Contents*

PHARMACOPEIAL FORUM VOL. 35 NO. 6 **NOV.–DEC. 2009**

* The *USP–NF* (*USP 33–NF 28*), the *Supplement* (*Supp*), or the *Interim Revision Announcement* (*IRA*) for which the revision proposal is targeted is shown in parentheses next to each proposed item.

THE JOURNAL OF STANDARDS DEVELOPMENT AND OFFICIAL COMPENDIA REVISION

Please address comments on *Pharmacopeial Forum* content to
USP Executive Secretariat
12601 Twinbrook Parkway,
Rockville, MD 20852
execsec@usp.org

Pharmacopeial Forum is covered in *Current Contents/Life Sciences* and in the *Science Citation Index (SCI),* in *International Pharmaceutical Abstracts*, and in *Current Awareness in Biological Sciences.*

The United States Pharmacopeial Convention comprises representatives from colleges and national and state organizations of medicine and pharmacy. It publishes the U.S. Pharmacopeia and National Formulary, the legally recognized compendia of standards for drugs and products of other health care technologies. The USP and NF include assays and tests for the determination of strength, quality, and purity and requirements for packaging and labeling.

This publication was paginated using Advent 3B2 Publishing Software.

Printed in USA by United Book Press, Inc., Baltimore, MD

ISSN: 0363-4655

STANDARDS DEVELOPMENT

This section presents an overview of the public review and comment process, conducted through *Pharmacopeial Forum* (*PF*), for the development of official standards in the *United States Pharmacopeia* and the *National Formulary* (*USP–NF*).

USP publishes *PF* on a bimonthly basis to provide an opportunity to review and comment on the new or revised standards.

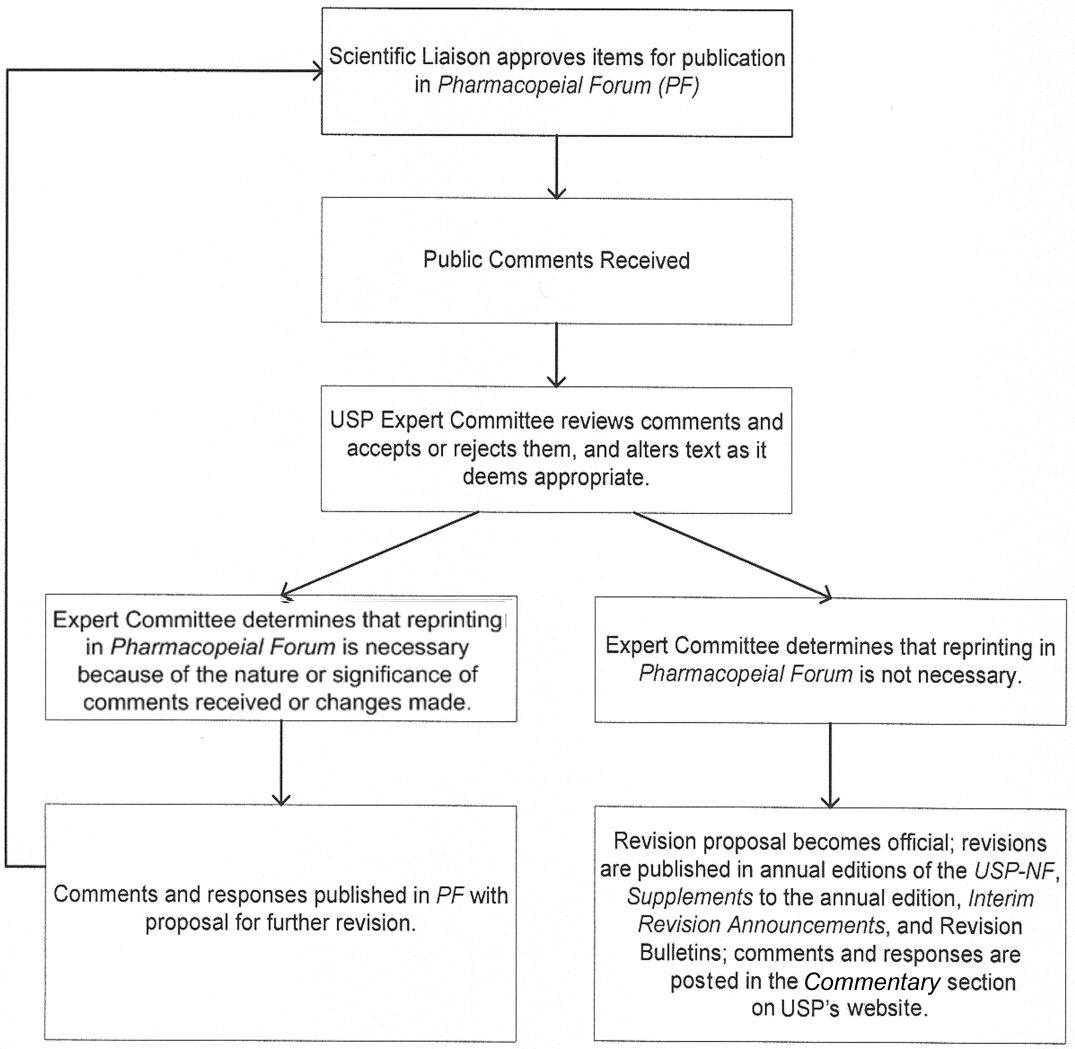
PF includes the following:

1. **Proposed Revisions**—New or revised standards targeted for adoption through USP's typical Revision Process. USP's Revision Process calls for publication of a proposed revision in *PF* for a 90-day notice and comment period. After the comment period and subsequent review of comments and approval by the relevant USP Expert Committee, the official standard is published in the next *USP–NF* or *Supplement*. If comments received are significant, or if the Expert Committee's consideration of comments results in significant additional changes, the Expert Committee may determine that reprinting in *PF* is necessary prior to the revision becoming official. See the *In-Process Revision* section for current proposed revisions.
2. **Accelerated Revisions**—New or revised standards that become official through an accelerated process in accordance with USP's Guideline on Accelerated Revisions (available on the USP website) (e.g., *Interim Revision Announcements*, *Revision Bulletins*, and *Errata*). Accelerated Revisions allow for a revision to become official prior to the next *USP–NF* or *Supplement* and do not always require notice and comment. *Interim Revision Announcements* are first presented for a 60-day public comment period in the *Proposed Interim Revision Announcement* section before becoming official in a later *PF* in the *Interim Revision Announcements* section of the *PF*. Note that *Revision Bulletins* appear only on the USP website.

USP welcomes comments and data on proposed revisions. Comments, along with USP's responses, will be published in the *Commentary* section of the USP website (www.usp.org).

The chart below shows the public review and comment process and its relationship to standards development.

Public Review and Comment Process for *USP-NF* Standards Development



Questions on the process should be addressed to Director, Executive Secretariat, United States Pharmacopeia, 12601 Twinbrook Parkway, Rockville, MD 20852 (e-mail: execsec@usp.org).

HOW TO USE *PF*

''How to Use PF'' describes the various parts of *Pharmacopeial Forum*, lists the *Committee Designations*, and includes the *Staff Directory*.

The contents of the various sections of *PF* are briefly described below. A more detailed description of each section is provided at the beginning of that section. A general description of the types and amount of information expected in a *Request for Revision* is available in the *Guideline for Submitting Requests for Revision to the USP–NF* on the USP website (www.usp.org/USPNF/submitMonograph/subGuide.html).

Proposed and Adopted Revisions to the *USP–NF*

Section	Content	How Readers Can Respond
Proposed Interim Revision Announcement Accelerated Revision targeted to become official in an upcoming *PF.*	Proposals for *Interim Revision Announcements (IRAs)* that will be published as official in a future *Pharmacopeial Forum.* BRIEFING: Scientific rationale for proposed changes. May include other information useful to the analyst, such as the brand name of the column used in developing the proposed procedure and the USP Scientific Liaison who handled the issue.	Review material and send comments within 60 days of the *PF* publication where the standard was proposed (or per the Briefing). Direct comments to the USP Scientific Liaison (see the *Staff Directory*) identified at the end of the Briefing.
Interim Revision Announcement Official Accelerated Revision (on the first day of the second month, unless otherwise indicated).	Standards that have been adopted and will become official on the date that is specified in the section's introductory page or within parentheses following a particular item. New or revised text is marked by the symbols •.	Review material to see whether affected by any of the changes. Note date when standards become official, and ensure compliance.
Errata Accelerated Revision.	Corrections to official standards that will be printed in *USP–NF.*	Review material to see whether affected by any changes.
In-Process Revision Revisions for public review and comment.	Proposals for standards that will be published as official in a future *USP–NF* book or *Supplement*. BRIEFING: Scientific rationale for proposed changes. May include other information useful to the analyst, such as the brand name of the column used in developing the proposed procedure and the appropriate USP Scientific Liaison.	Review material and send comments. Comment deadlines are found at the end of the *Policies and Announcements* section. Direct comments to the USP Scientific Liaison (see the *Staff Directory*) identified at the end of the Briefing. For general inquiries or in cases where a Scientific Liaison is not identified, use the general USP telephone number 301-881-0666 or fax number 301-998-6839.
Previous PF Proposals	Proposals from previous *PF*s that did not advance to official status in an official USP publication. This section is cumulative.	Review material to track pending proposals.
Canceled Proposals	Items that were published in *PF* and were pending, but have since been canceled. Note that canceled proposals may be republished to be considered in the future for adoption in *USP–NF.*	Review material to track canceled proposals.

Proposed and Adopted Revisions to the *USP–NF* *(Continued)*

Section	Content	How Readers Can Respond
Stage 4 Harmonization Items the Pharmacopeial Discussion Group (PDG) is working to internationally harmonize.	BRIEFING: Scientific rationale for the potential inclusion or change or for the proposed change. Stage 4 is available for comment.	Review material and provide comments to the appropriate Scientific Liaison cited in the Briefing. Individuals who wish to correspond with the European and Japanese Pharmacopoeias concerning monographs in the Official Inquiry and Consensus stages of international harmonization should address their comments to the coordinating pharmacopoeia, with a copy to USP, for a given article. The addresses for the European (PhEur) and Japanese (JP) pharmacopoeias are as follows: PhEur Secretariat Ms. Lynn Kelso-Eleuterio Central Secretariat European Pharmacopoeia Department European Directorate for the Health Care Council of Europe 7, Allée Kastner CS 30026 67081 Strasbourg France Tel: +33 (3) 88 41 31 48 Fax: +33 (3) 88 41 27 71 lynn.kelso@edqm.eu JP Secretariat Dr. Shigenori Harada Quality Expert Pharmaceuticals and Medical Devices Agency (PMDA) Shin-kasumigaseki Building 3-3-2, Kasumigaseki, Chiyoda-ku Tokyo, 100-0013 Japan Phone: +81-3-3506-9431 Fax: +81-3-3506-9440 harada-shigenori@pmda.go.jp
Stage 6 Harmonization Items the Pharmacopeial Discussion Group (PDG) is working to internationally harmonize.	Stage 6 is the final official harmonized standard and is not available for comment. This information is published for informational purposes only. New or revised text to Stage 6 documents is marked with symbols that indicate the publication in which the book or *Supplement* becomes official.	Review material to see whether affected by any changes.

Other Sections

Expert Committee Designations
Names of the Expert Committees (comprising volunteer scientific experts) that work with USP staff on the development of standards

Staff Directory
Names of key USP Standards Division staff members, including Scientific Liaisons, with contact information

Policies and Announcements
- General scientific and policy issues affecting *USP–NF* standards and processes
- Update on standards-related issues being considered by USP
- Guidelines on how to comment
- Publication and comment schedules

Stimuli to the Revision Process
- Articles on standards development issues authored by the USP Council of Experts, USP staff, or other interested parties
- Discussions of issues on which USP desires public input prior to further development

Nomenclature
- Latest adopted United States Adopted Names (USAN) and International Nonproprietary Names (INN) for drugs
- Revisions to existing names as a supplement to the *USP Dictionary of USAN and International Drug Names*
- Suggested, proposed, and recommended USAN and INN
- Information on how nonproprietary drug names are devised
- Articles relevant to compendial nomenclature issues

Index
Cumulative directory for the content of all issues of *PF* beginning with *PF* 35(1)

Chromatographic Columns Used in USP–NF and Pharmacopeial Forum
Update of chromatographic columns based on the proposals published in this issue of *PF*

POLICIES AND ANNOUNCEMENTS

This section provides general information resources for *USP–NF* standards and processes. Information resources include announcements on scientific and policy issues currently under consideration, schedules for USP publications, and schedules for comment periods for proposed standards.

CALL FOR CANDIDATES FOR 2010–2015 COUNCIL OF EXPERTS, ITS EXPERT COMMITTEES, AND ITS EXPERT PANELS. APPLICATION DEADLINE FOR COMMITTEE CHAIRS: DECEMBER 18, 2009. In accordance with the Bylaws of the USP Convention, USP is issuing a Call for Candidates for the 2010–2015 Council of Experts (COE). The 2010–2015 COE includes Expert Committees in the areas of Nomenclature, Small Molecules, Biologics and Biotechnology, Excipients, General Chapters, Reference Standards, Compounding, Food Ingredients, and Dietary Supplements. In the 2010–2015 cycle, USP is expanding the number of Expert Panels that report to Expert Committees.

The deadline for applications for the COE (Expert Committee Chairs) is **December 18, 2009**. The deadline for applications for Expert Committee members is **May 15, 2010**. Recruitment for Expert Panel members will begin in July 2010 and will be continuous.

These Expert Committees and Panels are aligned with the new USP Strategic Plan, which focuses on expanding and enhancing USP's core compendial and standards-setting activities. The ability to add Expert Panels according to USP's needs introduces flexibility and scalability into USP's activities. USP plans to continue to attract a global base of experts and therefore encourages any qualified individual to apply. Importantly, this approach also enables USP to closely align its documentary and Reference Standards activities for a more efficient standards-setting process.

Specific Expert Committees and Expert Panels for which USP is seeking candidates are listed at USP's nominations website (www.usp.org/goto/nominate).

For further information, please contact Nelufar Mohajeri, Director, Volunteer Affairs and Compendial Initiatives (nym@usp.org or nominate@usp.org).

USP POSTS COMMENTARY TO INTERIM REVISION ANNOUNCEMENTS ON THE USP WEBSITE. In order to maintain transparency for revisions made to proposed Interim Revision Announcements that become official in the *Pharmacopeial Forum*, USP posts commentary for the proposed *Interim Revision Announcements* on the *Revisions and Commentary* web page on the date that the official standard is released in *Pharmacopeial Forum*. Note that commentary to *In-Process Revisions* is posted on the *Revisions and Commentary* web page under the final book or supplement where the official standard appears. *Commentary* is not part of the official text of the monograph and is not intended to be enforceable by regulatory authorities. Rather, it explains the basis of the Expert Committee's response to public comments. If there is a difference between the contents of the *Commentary* section and the official monograph, the text of the official monograph prevails. In case of a dispute or question of interpretation, the language of the official text, alone and independent of the *Commentary* section, shall prevail.

CUMULATIVE EDITIONS. *USP–NF* is available in print, CD, and online formats. For the CD and online formats, each new edition or *Supplement* integrates content from all previous editions to date.

***PHARMACOPEIAL FORUM* PUBLIC REVIEW and COMMENT PERIOD DEADLINES.** The USP welcomes and encourages interested parties to submit comments and data regarding potential, proposed, or adopted (official) standards. In accordance with the Rules and Procedures of the 2005–2010 Council of Experts, USP has implemented a 90-day comment period by providing a deadline for each issue of *PF* unless otherwise stated in the individual briefing. The listing of comment period deadlines and the targeted official publications appears below.

Pharmacopeial Forum	Comment Deadline	Targeted Official Publication	Release Date	Official Date
PF 35(2)	June 15, 2009	*USP 33–NF 28 1st Supplement*	February 2010	August 1, 2010
PF 35(3)	August 15, 2009			
PF 35(4)	October 15, 2009	*USP 33–NF 28 2nd Supplement*	June 2010	December 1, 2010
PF 35(5)	December 15, 2009			
PF 35(6)	February 15, 2010	*USP 34–NF 29*	November 2010	May 1, 2011
PF 36(1)	March 31, 2010			

All official revisions are published in the annual edition or *Supplements* to *USP–NF* (twice yearly). Between these publications, official revisions are published in *PF* in the *Interim Revision Announcement* section and incorporated in the upcoming *USP–NF* or *Supplement*. They may also be published as *Revision Bulletins* on www.usp.org in the ''New Official Text'' section. The official publication in which an *Interim Revision Announcement* (*IRA*) is incorporated will depend upon publication deadlines. The electronic version of *USP–NF* is updated as each *Supplement* becomes available and therefore contains all official text up to and including the contents of the latest *Supplement*. The table below outlines the publications and their release and official dates, and the *USP–NF* or *Supplement* that supersedes them.

Publication Schedules

Publication	Release Date	Official Date	Superseded by
IRA [*PF* 35(2)]	March 1, 2009	April 1, 2009	*2nd Supplement to USP 32–NF 27*
IRA [*PF* 35(3)]	May 1, 2009	June 1, 2009	*USP 33–NF 28*
2nd Supplement to USP 32–NF 27	June 1, 2009	December 1, 2009	*USP 33–NF 28*
IRA [*PF* 35(4)]	July 1, 2009	August 1, 2009	*1st Supplement to USP 33–NF 28*
IRA [*PF* 35(5)]	September 1, 2009	October 1, 2009	*1st Supplement to USP 33–NF 28*
IRA [*PF* 35(6)]	November 1, 2009	December 1, 2009	*2nd Supplement to USP 33–NF 28*
USP 33–NF 28	November 1, 2009	May 1, 2010	*1st Supplement to USP 33–NF 28*
IRA [*PF* 36(1)]	January 1, 2010	February 1, 2010	*2nd Supplement to USP 33–NF 28*
1st Supplement to USP 33–NF 28	February 1, 2010	August 1, 2010	*2nd Supplement to USP 33–NF28*

PRIORITY NEW MONOGRAPH ITEMS. The following list contains monographs USP is seeking for drug substances and drug products that are, or will be, off patent within 5 years. Monographs are marked ''Received'' upon receipt of a monograph proposal. This list has been updated as of June 24, 2009.

Monograph sponsors should consult USP's Guideline for Submitting Requests for Revision to the *USP–NF* at http: // www . usp . org / USPNF / submit Monograph / subGuide.html.

For additional information, contact Randy Kiser, MS, MBA, rwk@usp.org.

Small Molecules (Drug Substances)—As of June 24, 2009

1. Acamprosate Calcium	2. Acrivastine	3. Adapalene
4. Aldesleukin	5. Alemtuzumab	6. Allopurinol Sodium
7. Alosetron Hydrochloride	8. Aminopromazine Fumarate	9. Aminopterin Sodium
10. Amlexanox	11. Amlodipine Maleate	12. Amrinone Lactate
13. Anagrelide Hydrochloride ***(Received)***	14. Artemether	15. Auranofin
16. Azacitidine	17. Azelaic Acid ***(Received)***	18. Azelastine Hydrochloride
19. Bemotrizinol	20. Bentoquatam	21. Benzphetamine Hydrochloride
22. Bepridil Hydrochloride	23. Besifloxacin	24. Bismuth Tribromophenate
25. Bivalirudin ***(Received)***	26. Bromfenac Sodium	27. Butenafine Hydrochloride
28. Caffeine Citrate	29. Calcium Trisodium Pentetate	30. Calfactant
31. Camphorated Metacresol	32. Candesartan Cilexetil ***(Received)***	33. Carbaspirin Calcium
34. Ceftibuten	35. Cerivastatin Sodium	36. Cevimeline Hydrochloride ***(Received)***
37. Chlophedianol Hydrochloride	38. Chlorpheniramine Tannate	39. Cidofovir
40. Cisatracurium Besylate	41. Climbazole	42. Codeine Polistirex
43. Colfosceril	44. Copper Undecylenate	45. Cysteamine Bitartrate
46. Dalfopristin	47. Decitabine	48. Deserpidine
49. Desogestrel	50. Desonide ***(Received)***	51. Diethanolamine Methoxycinnamate
52. Difenoxin Hydrochloride	53. Doconazol	54. Domiphen Bromide
55. Doripenem	56. Entacapone ***(Received)***	57. Epoprostenol Sodium ***(Received)***
58. Esmolol Hydrochloride ***(Received)***	59. Estazolam	60. Estramustine Phosphate Sodium

Small Molecules (Drug Substances)—As of June 24, 2009 *(Continued)*

61. Ethanolamine Oleate	62. Ethyl 4-[Bis(Hydroxypropyl)] Amino-benzoate	63. Etomidate ***(Received)***
64. Etoposide Phosphate	65. Exemestane	66. Famciclovir ***(Received)***
67. Felbamate ***(Received)***	68. Ferric Hexacyanoferrate (Prussian Blue)	69. Ferric Sodium Gluconate
70. Fluoromethane F 18	71. Fomepizole	72. Fosfomycin Tromethamine ***(Received)***
73. Gadobenate Dimeglumine	74. Gadofosveset Trisodium	75. Gadopentetic Acid
76. Gadoxetate Disodium	77. Gallium Nitrate	78. Glyceryl Aminobenzoate
79. Guanidine Hydrochloride	80. Halobetasol Propionate ***(Received)***	81. Haloperidol Decanoate ***(Received)***
82. Hydrocodone Polistirex	83. Ibutilide Fumarate	84. Iloperidone
85. Imipramine Pamoate	86. Imiquimod	87. Iodamide Meglumine
88. Isosulfan Blue	89. Lactulose	90. Latanoprost ***(Received)***
91. Lepirudin	92. Levobetaxolol Hydrochloride	93. Levocetirizine Dihydrochloride
94. Levomethadyl Acetate	95. Lodoxamide Tromethamine	96. Lomustine ***(Received)***
97. Loteprednol Etabonate	98. Loxapine Hydrochloride	99. Lubiprostone
100. Melphalan Hydrochloride	101. Memantine Hydrochloride	102. Mequinol
103. Methotrexate Sodium	104. Methoxycinnamate	105. Methyl Nicotinate
106. Metipranolol Hydrochloride	107. Mibefradil Dihydrochloride	108. Midazolam Hydrochloride
109. Mifepristone	110. Milrinone Lactate	111. Misoprostol Oil
112. Mivacurium Chloride	113. Moexipril Hydrochloride	114. Montelukast Sodium
115. Nabilone	116. Nalbuphine Hydrochloride	117. Nalmefene Hydrochloride
118. Nedocromil Sodium	119. Nefopam	120. Nelarabine
121. Nelfinavir Mesylate	122. Nepafenac	123. Nesiritide Citrate
124. Nevirapine Hemihydrate	125. Nicardipine Hydrochloride ***(Received)***	126. Nilutamide
127. Olsalazine Sodium ***(Received)***	128. Oxiconazole Nitrate	129. Paliperidone
130. Pemirolast Potassium	131. Pemoline	132. Perindopril Erbumine
133. Phenylephrine Tannate	134. Pioglitazone Hydrochloride ***(Received)***	135. Pipecuronium Bromide
136. Piperonyl Butoxide	137. Pirbuterol Acetate	138. Pirbuterol Acetate ***(Received)***
139. Podofilox	140. Poractant Alfa	141. Porfimer Sodium
142. Pramiprexole Dihydrochloride ***(Received)***	143. Prasterone	144. Proguanil Hydrochloride
145. Pyrilamine Tannate	146. Pyrithione Zinc	147. Quetiapine Fumarate ***(Received)***
148. Quinupristin	149. Rabeprazole Sodium	150. Ranitidine
151. Rifapentine	152. Rivastigmine Tartrate ***(Received)***	153. Rizatriptan Benzoate
154. Ropinirole Hydrochloride ***(Received)***	155. Rostaporfin	156. Sertaconazole Nitrate
157. Silodosin	158. Sodium Phenylbutyrate	159. Spirapril Hydrochloride
160. Streptozocin	161. Sulfacytine	162. Sulfosalicylic Acid
163. Tazarotene	164. Tegaserod Maleate	165. Tenofovir Disoproxil Fumarate ***(Received)***
166. Tiludronate Disodium	167. Tiopronin	168. Tolvaptan
169. Toremifene Citrate	170. Trastuzumab	171. Trypan Blue
172. Unithiol	173. Venlafaxine Hydrochloride ***(Received)***	174. Voriconazole ***(Received)***
175. Zafirlukast	176. Zaleplon ***(Received)***	177. Zinc Trisodium Pentetate
178. Zoledronic Acid		

Small Molecules (Drug Products)—As of June 24, 2009

1. Acamprosate Calcium Delayed-Release Tablets	2. Acetaminophen and Tramadol Hydrochloride Tablets	3. Acetaminophen, Butalbital, Caffeine, and Codeine Phosphate Capsules
4. Acetaminophen, Clemastine Fumarate, and Pseudoephedrine Hydrochloride Tablets	5. Acetazolamide Extended-Release Capsules	6. Acetylcysteine Injection
7. Acrivastine and Pseudoephedrine Hydrochloride Capsules	8. Adapalene and Benzoyl Peroxide Gel	9. Adapalene Topical Gel
10. Adapalene Topical Solution	11. Albuterol Extended-Release Tablets	12. Albuterol for Inhalation
13. Albuterol Oral Solution	14. Aldesleukin for Injection	15. Alendronate Sodium Oral Solution
16. Allopurinol for Injection	17. Alosetron Tablets	18. Amantadine Hydrochloride Tablets
19. Aminophylline Extended-Release Tablets	20. Aminopromazine Fumarate and Neomycin Sulfate Tablets	21. Aminopromazine Fumarate Injection
22. Aminopromazine Fumarate Tablets	23. Aminopterin Sodium Tablets	24. Amlexanox Oral Paste
25. Amlodipine and Benazepril Hydrochloride Capsules ***(Received)***	26. Amlodipine Besylate Tablets	27. Amlodipine Maleate Tablets
28. Amoxicillin and Clavulanate Potassium Chewable Tablets	29. Amoxicillin Chewable Tablets	30. Amrinone Lactate Injection
31. Anagrelide Hydrochloride Capsules ***(Received)***	32. Anastrozole Tablets	33. Anecortave Acetate Injectable Suspension
34. Anhydrous Lactose for Inhalation	35. Anisotropine Methylbromide Tablets	36. Artemether and Lumefantrine Tablets
37. Articaine Hydrochloride and Epinephrine Bitartrate Injection	38. Atovaquone and Proguanil Hydrochloride Tablets	39. Atovaquone Tablets
40. Atropine and Pralidoxime Chloride Injection	41. Auranofin Capsules	42. Avobenzone, Ecamsule, and Octocrylene Cream
43. Avobenzone, Ecamsule, Octocrylene, and Titanium Dioxide Cream	44. Azacitidine for Injectable Suspension	45. Azatadine Maleate and Pseudoephedrine Sulfate Extended-Release Tablets
46. Azelastine Hydrochloride Metered-Dose Nasal Solution	47. Azelastine Hydrochloride Ophthalmic Solution	48. Azithromycin for Injection ***(Received)***
49. Azithromycin Tablets ***(Received)***	50. Benazepril Hydrochloride and Hydrochlorothiazide Tablets	51. Bentoquatam Topical Suspension
52. Benzocaine and Cetylpyridinium Chloride Lozenges	53. Benzocaine and Menthol Lotion	54. Benzphetamine Hydrochloride Tablets
55. Bepridil Tablets	56. Besifloxacin Ophthalmic Suspension	57. Betaxolol and Pilocarpine Hydrochloride Ophthalmic Suspension
58. Bismuth Tribromophenate Ointment	59. Bivalirudin for Injection ***(Received)***	60. Bromfenac Sodium Ophthalmic Solution
61. Brompheniramine Maleate, Dextromethorphan Hydrobromide, and Pseudoephedrine Hydrochloride Oral Solution	62. Brompheniramine Maleate, Phenylpropanolamine Hydrochloride, and Codeine Phosphate Syrup	63. Buffered Didanosine for Oral Solution
64. Bupivacaine and Lidocaine Hydrochlorides Injection	65. Buprenorphine Hydrochloride Injection	66. Buspirone Hydrochloride Capsules

INTERIM REVISION ANNOUNCEMENT

In this section readers will find the following:
- The list of new USP Reference Standards that have become available
- The list of assays or tests that are adopted but held in abeyance pending availability of required USP Reference Standards
- Newly adopted (official) revisions to the *USP–NF* that become official before the official date of the next *Supplement* or that were not ready for adoption by the closing date for the upcoming *Supplement*. (The official date for these revisions is stated on the next page.)
- Errata

Readers should review this section to determine if they are affected by any of the changes.

Symbols—New text is enclosed in symbols and set off from the current official text as shown in the following example: •new text•.

Where the symbols appear together with no enclosed text, such as ••, it means that text has been deleted and no new text was proposed to replace it. In all revisions, the closing symbol is accompanied by an identifier that indicates the issue of a given *PF* volume.

Errata—Errata are considered to be text, erroneously published in the *USP–NF* or its *Supplements,* that does not accurately reflect the intended official requirements of the Council of Experts. Beginning with *PF* 35(2), Errata will be published both in the *Pharmacopeial Forum* and on the usp.org website. At the end of the *Interim Revision Announcement* section in this publication is a list of errata and corrections to *USP 32–NF 27*. The page number indicates where the item is found in *USP–NF.* Errata are updated as necessary in each *Pharmacopeial Forum* issue and monthly on the usp.org website. This information will also be cumulative in future *Supplements,* and will appear in its corrected form in the next annual edition of *USP–NF.* The list of Errata has been relocated to www.usp.org, where updates will be posted monthly.

INTERIM REVISION ANNOUNCEMENT to *USP 32* and to *NF 27*

By authority of the United States Pharmacopeial Convention, Inc.
Prepared by the Council of Experts and published by the Board of Trustees

Duane M. Kirking, Pharm.D., Ph.D.,
Chair, USP Board of Trustees,
USP Trustee At-Large

Roger L. Williams, M.D., *Chief Executive Officer*
and *Chairman, USP Council of Experts*

Susan de Mars, J.D., *Chief Documentary Standards Officer* and *General Counsel*
William F. Koch, Ph.D., FACB, *Chief Standards Acquisitions* and *Metrology Officer*

Released November 1, 2009 **Official December 1, 2009**

Inquiries regarding *USP–NF* can be addressed to the USP Executive Secretariat, 12601 Twinbrook Parkway, Rockville, MD 20852, USA (execsec@usp.org).

New USP Reference Standards

The following USP Reference Standards, which were not available when the associated monograph was made official, have since become available. The respective official date of each *USP 32* or *NF 27* standard, test, or assay requiring the use of the following USP Reference Standards is indicated in parentheses after the name of the Reference Standard. Note that the official date is six months after publishing in this PF.

USP *S*-Adenosyl-L-homocysteine RS (March 1, 2010)
USP Fludeoxyglucose Related Compound B RS (May 1, 2010)
USP Alpha Lipoic Acid RS (March 1, 2010)
USP Lypressin RS (March 1, 2010)
USP Propylene Glycol Dilaurate RS (May 1, 2010)
USP Valrubicin RS (March 1, 2010)
USP Vasopressin RS (March 1, 2010)

Unavailable First-Time Official USP Reference Standards

The official dates of any *USP 32* or *NF 27* standards, tests, or assays requiring the use of the following new USP Reference Standards are postponed until further notice pending availability of the respective Reference Standards. This listing was updated as of August 10, 2009. Please refer to the current USP Catalog for a more up-to-date availability list. The USP Catalog can be accessed on-line at http://www.uspcatalog.com.

USP Acarbose RS
USP Acarbose System Suitability Mixture RS
USP Albumin Human RS
USP Alteplase RS
USP Amifostine RS
USP Amifostine Thiol RS
USP Antithrombin III Human RS
USP Aprotinin RS
USP Aprotinin System Suitability RS
USP Copolymer Polypropylene RS
USP Diethylstilbestrol Diphosphate RS
USP Powdered *Echinacea pallida* Extract RS
USP Eucatropine Hydrochloride RS
USP Gonadorelin Hydrochloride RS
USP Hemoglobin RS
USP Maritime Pine Extract RS
USP Menotropins RS
USP Oleyl Oleate RS
USP Sargramostim RS
USP Sincalide RS
USP Valrubicin Related Compound A RS

ERRATA

Following is a list of errata and corrections to *USP–NF*. The page number indicates where the item is found and in which official or pending official publication of *USP–NF*. If necessary, this list will be updated with every issue of *PF*. This information will also be available as a cumulative table in future *Supplements* and will appear in its corrected form in a future annual edition of *USP–NF*. Errata are considered to be items erroneously published that have not received the approval of the Council of Experts and that do not reflect the official requirement. USP staff is available to respond to questions regarding the accuracy of a particular requirement by calling 1-800-822-USPC.

***USP32–NF27* Page**	**Title**	**Section**	**Description**
45	⟨11⟩ *USP Reference Standards*	*USP Enzacamene RS*	Change to: ''USP Methyl Benzylidine Camphor RS.'' and place in alphabetical order.
145	⟨381⟩ *Elastomeric Closures for Injections*	*Physicochemical Tests*	Line 1 under *Volatile Sulfides, Requirement*: Change ''Any black stain on the paper produced by *Solution S* is not more intense than that produced by the control solution.'' to: Any black stain on the paper produced by the test solution is not more intense than that produced by the control solution.
500	⟨1056⟩ *Biotechnology-Derived Articles—Polyacrylamide Gel Electrophoresis*	*Characteristics of Polyacrylamide Gels for Protein Electrophoresis*	Line 5 under *Electrophoretic Separation, Sample Buffer 2*: Change ''a final 100 μM DTT concentration.'' to: a final 100 mM DTT concentration.
2257	*Enzacamene*	*USP Reference standards*	Line 1 under *USP Reference standards* ⟨11⟩: Change ''USP Enzacamene RS.'' to: USP Methyl Benzylidene Camphor RS.
		Assay	Line 2 under *Assay, Standard preparation*: Change ''USP Enzacamene RS'' to: USP Methyl Benzylidene Camphor RS Line 7 under *Assay, Procedure*: Change ''USP Enzacamene RS'' to: USP Methyl Benzylidene Camphor RS

4288	*Tylosin Injection*	*Content of tylosins*	Line 1: Change ''*Sodium perchlorate solution*—Prepare a 200 g per L solution. Adjust with 1 N hydrochlorid acid to a pH of 2.5 ± 0.1, and filter. *Mobile phase*—Prepare a mixture of *Sodium perchlorate solution* and acetonitrile (3:2). Degas, and make adjustments if necessary (see *System Suitability* under *Chromatography* ⟨621⟩).'' to: *Sodium perchlorate solution*—Prepare a 184 g per L solution. *Mobile phase*—Prepare a mixture of *Sodium perchlorate solution* and acetonitrile (3:2). Adjust with 1 N hydrochlorid acid to a pH of 2.5 ± 0.1, and filter. Make adjustments if necessary (see *System Suitability* under *Chromatography* ⟨621⟩).

PROPOSED INTERIM REVISION ANNOUNCEMENTS

This section includes proposals for *Interim Revision Announcements* (*IRAs*) that will be published as official *USP* or *NF* standards. There is a 60-day comment period for these proposals, beginning on the 15th of the first month of this *Pharmacopeial Forum*. The approved official text will be published in a future *Pharmacopeial Forum* and additionally in the ''New Official Text'' section of USP's web site (www.usp.org). Readers should review material in this section and provide comments to the Scientific Liaison (use the *Staff Directory* to find the contact information). Information on how to comment is found in the *Policies and Announcements* section. It is important to send comments promptly so that the Expert Committee members can consider readers' input as they are deciding whether to advance standards to official status.

Each proposal is preceded by a Briefing that indicates the proposed revisions.

Proposed IRA

IN-PROCESS REVISION

This section contains proposals for adoption as official *USP* or *NF* standards (either proposed *new* standards or proposed *revisions* of current *USP* or *NF* standards). These may be any of the following: (1) proposed revisions placed directly under *In-Process Revision,* or (2) modifications of revisions previously proposed under *In-Process Revision*. Readers should review material in this section and provide comments to the staff liaison (use the *Staff Directory* to find the contact information). Information on how to comment is found in the *Policies and Announcements* section. It is important to send comments promptly so that the Committee members can consider readers' input as they are deciding whether to advance standards to official status.

Briefings Each Proposal is preceded by a Briefing in the following format:

BRIEFING

Name of Item, citations of the most recent USP publications in which this item appeared. Rationale for the revision. Other relevant information. (For example, if a chromatographic method is being proposed, column specifications and retention times for compounds of interest.) Finally, the Committee designation (see *How to Use PF*), the name of the scientific staff liaison who handled the particular issue, and the USP tracking correspondence number, as shown in the example below:

(DSI: D. Sarma.) RTS—C55678

Symbols Proposed revisions are shown with language proposed for deletion or replacement crossed off. Because of the redesign of monographs, any proposed new text with revisions for *USP 33–NF 28* and beyond will be set off from the current official text by shading where the symbols surround the text changes. Standards that become official as *Interim Revision Announcements (IRAs)* in *Pharmacopeial Forum* will continue to identify changed text in a larger font (print edition only). All *USP–NF* revisions use the following symbols that indicate the final destination of the official text: •new text• if slated for an *IRA*; ▲new text▲ if slated for *USP–NF*; and ■new text■ if slated for a *Supplement* to *USP–NF*. The same symbols *not* set off by an extra paragraph break and enclosing text with no increase in type size indicate recent revisions that are already official. Where the symbols appear together with no enclosed text, such as ••, or ■■, or ▲▲, it means that text has been deleted and no new text was proposed to replace it.

In all revisions, the closing symbol is accompanied by an identifier that indicates the particular *IRA* or *Supplement* or indicates the *USP* or *NF* as the publication where the revision will appear if approved. For example, •2 indicates that the revision is proposed for the *Interim Revision Announcement* that will appear in issue 2 of a given *PF* volume, ■2S (*USP 32*) indicates that the proposed revision is slated for the *Second Supplement to USP 32*, and ▲*USP33* and ▲*NF28* indicates that the revisions are proposed for *USP 33* and *NF 28*, respectively.

Official Title Changes Where the specification ''***Monograph title change***'' is found, it indicates that the official title stated after that specification will be substituted for the former title in the appropriate places throughout that monograph once this revision becomes official.

USP MONOGRAPHS

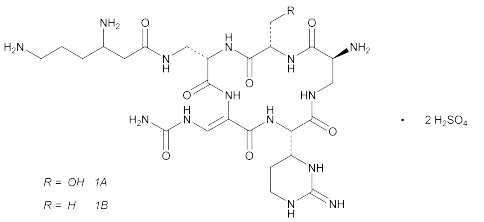
BRIEFING

Capreomycin Sulfate, *USP 32* page 1777. On the basis of comments received, the following revisions are proposed:

- *Identification* test *B*, based on chromatographic retention times, is added.
- The test for *Capreomycin 1 Content* is revised, because the analytical column required for this method is no longer available. The revised test is based on a method validated with the Spherisorb CN brand of L10 column. The typical retention time for capreomycin 1A is 7 min. Relative retention times are provided in the method.

(MD-ANT: A. Wise.) RTS—C68831

Capreomycin Sulfate



Capreomycin, sulfate [1405-37-4].

$C_{25}H_{44}N_{14}O_8$ 668.71
Capreomycin 1A (free base);
3,6-Diamino-*N*-({(2*S*,5*S*,11*S*,15*S*,*Z*)-15-amino-2-(hydroxymethyl)-11-[(*R*)- iminohexahydropyrimidin-4-yl] -3,6,9,12,16-pentaoxo-8-(ureidomethylene)-1,4,7,10,13-pentaazacyclohexadecan-5-yl}methyl)hexanamide [37290-35-6].

$C_{25}H_{44}N_{14}O_7$ 652.71
Capreomycin 1B (free base);
3,6-Diamino-*N*-({(2*S*,5*S*,11*S*,15*S*,*Z*)-15-amino-11-[(*R*)-iminohexahydropyrimidin-4-yl]-2-methyl-3,6,9,12,16-pentaoxo-8-(ureidomethylene)-1,4,7,10,13-pentaazacyclohexadecan-5-yl}methyl)hexanamide [33490-33-4].

DEFINITION

Capreomycin Sulfate is the disulfate salt of capreomycin, a polypeptide mixture produced by the growth of *Streptomyces capreolus*, suitable for parenteral use. It has a potency equivalent to NLT 700 µg and NMT 1050 µg of capreomycin/mg.

IDENTIFICATION

- **A. IDENTIFICATION TESTS—GENERAL,** *Sulfate* ⟨**191**⟩

Add the following:

▲• **B.** The retention times of the major peaks of the *Sample solution* correspond to those of the *System suitability solution*, as obtained in the test for *Capreomycin 1 Content*.▲*USP34*

ASSAY

- **PROCEDURE:** Proceed as directed in *Antibiotics—Microbial Assays* ⟨81⟩ for capreomycin.

Acceptance criteria: 700–1050 µg/mg

IMPURITIES

Inorganic Impurities

In-Process Revision

BRIEFING

Capreomycin for Injection, *USP 32* page 1777. On the basis of comments received, the following revisions are proposed:

- The *Identification* test is deleted from the *Other Requirements* section and included in a new *Identification* section as *Identification* test *A. Identification* test *B*, based on chromatographic retention times, is added.
- The test for *Capreomycin 1 Content* is revised, because the analytical column required for this method is no longer available. The revised test is based on a method validated with the Spherisorb CN brand of L10 column. The typical retention time for capreomycin 1A is 7 min. Relative retention times are provided in the method.

(MD-ANT: A. Wise.) RTS—C68831

Capreomycin for Injection

DEFINITION

Capreomycin for Injection contains an amount of Capreomycin Sulfate equivalent to NLT 90.0% and NMT 115.0% of the labeled amount of capreomycin.

IDENTIFICATION

Add the following:

▲• **A. IDENTIFICATION TESTS—GENERAL,** *Sulfate* ⟨**191**⟩▲*USP34*

Add the following:

▲• **B.** The retention times of the major peaks of the *Sample solution* correspond to those of the *System suitability solution*, as obtained in the test for *Capreomycin 1 Content.*▲*USP34*

ASSAY

- **PROCEDURE:** Proceed as directed in *Antibiotics—Microbial Assays* ⟨81⟩ for Capreomycin.
  Acceptance criteria: 90.0%–115.0%

IMPURITIES

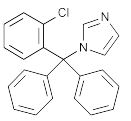
BRIEFING

Clotrimazole, *USP 32* page 1997. On the basis of data received the following revisions are proposed:

1. *Assay* and *Organic Impurities, Procedure 2: Limit of Clotrimazone Related Compound A*: Replace methanol with acetonitrile in the *Mobile phase* in order to increase the resolution between clotrimazole and clotrimazole related compound A while providing cleaner baseline noise and better peak responses. The preparations of the solutions have been revised for ease of use. The procedures are based on analyses performed with the Merck Purospher Star RP 18e brand of L1 column.
2. *Identification:* Replace the TLC *Identification* test with an analysis based on the *Assay* retention time.
3. *Internal standard:* The internal standard has been eliminated from the *Assay* method. The validation data demonstrates that use of an internal standard is not required for this application. This change has the added benefit of alleviating the burden of dealing with testosterone propionate, which is a controlled substance.

(MD-AA: M. Puderbaugh, B. Davani.) RTS—C56870

Clotrimazole



$C_{22}H_{17}ClN_2$ 344.84
1*H*-Imidazole, 1-[(2-chlorophenyl)diphenylmethyl]-;
1-(*o*-Chloro-α,α-diphenylbenzyl)imidazole [23593-75-1].

DEFINITION
Clotrimazole contains NLT 98.0% and NMT 102.0% of $C_{22}H_{17}ClN_2$, calculated on the dried basis.

BRIEFING

Dactinomycin for Injection, *USP 32* page 2054. On the basis of comments received, the *Definition* and *Identification* test *B* are updated to current USP convention.

(MD-ANT: A. Wise.) RTS—C68501

In-Process Revision

Dactinomycin for Injection

DEFINITION

Change to read:

Dactinomycin for Injection is a sterile mixture of Dactinomycin and Mannitol. It contains NLT 90.0% and NMT 120.0% of the labeled amount of $C_{62}H_{86}N_{12}O_{16}$. ~~the labeled amount being 0.5 mg in each container.~~ ▲*USP34*

[**CAUTION—**Great care should be taken to prevent inhaling particles of Dactinomycin and exposing the skin to it.]

IDENTIFICATION

- **A. PROCEDURE**

Standard solution: 25 µg/mL of USP Dactinomycin RS in methanol
Sample solution: 25 µg/mL of dactinomycin in methanol
Acceptance criteria: The UV absorption spectrum of the *Sample solution* exhibits maxima and minima at the same wavelengths as the *Standard solution*, concomitantly measured.
Ratio: A_{240}/A_{445}, 1.30–1.50

Change to read:

- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ~~and both chromatograms compare qualitatively.~~ ▲*USP34*

ASSAY

- **PROCEDURE**

[NOTE—Use freshly prepared *Standard solution* and *Sample solution*, protected from light.]
Mobile phase: Acetonitrile and water (3:2)
Standard solution: 250 µg/mL of USP Dactinomycin RS in *Mobile phase*
Sample solution: 250 µg/mL of dactinomycin from Dactinomycin for Injection diluted with *Mobile phase*. Filter, if necessary, to obtain a clear solution.
Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 254 nm
Column: 3.9-mm × 30-cm; packing L1
Flow rate: 2.5 mL/min
Injection size: 10 µL
System suitability
Sample: *Standard solution*
[NOTE—The retention time for dactinomycin is 6 min.]
Suitability requirements
Column efficiency: NLT 1200 theoretical plates
Tailing factor: NMT 2
Relative standard deviation: NMT 3.0%
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_{62}H_{86}N_{12}O_{16}$ taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response of the *Sample solution*
r_S = peak response of the *Standard solution*
C_S = concentration of USP Dactinomycin RS in the *Standard solution* (µg/mL)
C_U = nominal concentration of dactinomycin in the *Sample solution* (µg/mL)
Acceptance criteria: 90.0%–120.0%

SPECIFIC TESTS

- **pH** ⟨**791**⟩**:** 5.5–7.5, in the solution constituted as directed in the labeling
- **LOSS ON DRYING** ⟨**731**⟩**:** Dry a sample in a vacuum at a pressure not exceeding 5 mm of mercury at 60° for 3 h: it loses NMT 4.0% of its weight.
- **OTHER REQUIREMENTS:** It meets the requirements under *Injections* ⟨1⟩.
- **BACTERIAL ENDOTOXINS TEST** ⟨**85**⟩**:** It contains NMT 100.0 USP Endotoxin Units/mg of dactinomycin.
- **STERILITY TESTS** ⟨**71**⟩**:** It meets the requirements when tested as directed for *Test for Sterility of the Product to be Examined*, *Membrane Filtration*, each container being constituted aseptically by injecting Sterile Water for Injection through the stopper, and the entire contents of all the containers being collected aseptically with the aid of 200 mL of *Fluid A* before filtering.
- **CONSTITUTED SOLUTION:** At the time of use, it meets the requirements for *Injections* ⟨1⟩, *Constituted Solutions*.

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in light-resistant *Containers for Sterile Solids* as described under *Injections* ⟨1⟩.
- **LABELING:** Label it to include the statement "Protect from light."
- **USP REFERENCE STANDARDS** ⟨**11**⟩
USP Dactinomycin RS
USP Endotoxin RS

BRIEFING

Diltiazem Hydrochloride Tablets, *USP 32* page 2164. It is proposed to change the wavelength used in the *Dissolution* test from 240 nm to 237 nm, where the maximum absorbance occurs.

(BPC: M. Marques.) RTS—C78512

Diltiazem Hydrochloride Tablets

DEFINITION

Diltiazem Hydrochloride Tablets contain NLT 90.0% and NMT 110.0% of the labeled amount of diltiazem hydrochloride ($C_{22}H_{26}N_2O_4S \cdot HCl$).

IDENTIFICATION

- **A. PROCEDURE**

Indicator solution: Transfer 17.4 g of ammonium thiocyanate and 2.8 g of cobalt chloride to a 100-mL volumetric flask, add 50 mL of water, and sonicate for 10 min. Dilute with water to volume.
Analysis: Finely powder 1 Tablet, and transfer to a 15-mL screw-capped test tube. Add 10 mL of 0.1 N hydrochloric acid, shake, and filter. Add 2 mL of *Indicator solution* to 2 mL of the filtrate, and shake. Add 5 mL of chloroform, and shake.
Acceptance criteria: A blue color develops in the chloroform layer.

- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

ASSAY

- **PROCEDURE**

Solution A: Dissolve 1.16 mg/mL of *d*-10-camphorsulfonic acid in 0.1 M sodium acetate, and adjust with 0.1 N sodium hydroxide to a pH of 6.2.
Mobile phase: Acetonitrile, methanol, and *Solution A* (25:25:50)
Standard solution: 1.2 mg/mL of USP Diltiazem Hydrochloride RS in methanol
Sample solution: Transfer to a 500-mL volumetric flask an equivalent to 600 mg of diltiazem hydrochloride from NLT 20

In-Process Revision

finely powdered Tablets. Add 200 mL of methanol, and sonicate for 1 h. Cool, and dilute with methanol to volume. Centrifuge a 25-mL aliquot at 3500 rpm for 15 min, and use the clear supernatant.

System suitability solution: 12 µg/mL each of USP Diltiazem Hydrochloride RS and USP Desacetyl Diltiazem Hydrochloride RS, in methanol

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

Mode: LC

Detector: UV 240 nm

Column: 3.9-mm × 30-cm; packing L1

Flow rate: 1.6 mL/min

Injection size: 10 µL

System suitability

Samples: *Standard solution* and *System suitability solution*

[NOTE—The relative retention times for desacetyl diltiazem and diltiazem are about 0.65 and 1.0, respectively.]

Suitability requirements

Resolution: NLT 3 between desacetyl diltiazem and diltiazem, *System suitability solution*

Column efficiency: NLT 1200 theoretical plates for the diltiazem peak, *System suitability solution*

Relative standard deviation: NMT 2.0%, *Standard solution*

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of $C_{22}H_{26}N_2O_4S \cdot HCl$ in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*

r_S = peak response from the *Standard solution*

C_S = concentration of USP Diltiazem Hydrochloride RS in the *Standard solution* (mg/mL)

C_U = nominal concentration of diltiazem hydrochloride in the *Sample solution* (mg/mL)

Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS

Change to read:

- **DISSOLUTION** ⟨**711**⟩

Medium: Water; 900 mL

Apparatus 2: 75 rpm

Time: 30 min and 3 h

Detector: UV ~~240~~▲237▲*USP34* nm

Sample solution: Sample per *Dissolution* ⟨711⟩. Dilute with *Medium* to a concentration that is similar to the *Standard solution*.

Standard solution: USP Diltiazem Hydrochloride RS in *Medium*

Tolerances: Use the following acceptance criteria for the 30-min time point: at S_1 no unit is more than Q; at S_2 the average value is equal to or less than Q, and no unit is greater than Q + 10%; at S_3 the average value is equal to or less than Q, and NMT 2 units are more than Q + 10%, and no unit is more than Q + 25%. Use the criteria in *Dissolution* ⟨711⟩, *Acceptance Table* for the 3-h time point. NMT 60% (Q) of the labeled amount of $C_{22}H_{26}N_2O_4S \cdot HCl$ is dissolved in 30 min, and NLT 75% (Q) is dissolved in 3 h.

- **UNIFORMITY OF DOSAGE UNITS** ⟨**905**⟩**:** Meet the requirements

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in tight, light-resistant containers.

- **USP REFERENCE STANDARDS** ⟨**11**⟩

USP Desacetyl Diltiazem Hydrochloride RS

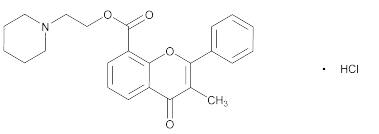
USP Diltiazem Hydrochloride RS

BRIEFING

Flavoxate Hydrochloride, *USP 32* page 2378. On the basis of comments and validated methods received, it is proposed to replace the current *Organic Impurities* test with a more selective, gradient elution HPLC method. The liquid chromatographic procedure is based on analyses performed using an Inertsil ODS brand of L1 column. The typical retention times for flavoxate, flavoxate related compound A, flavoxate related compound B, and flavoxate related compound C are 7.5, 21, 26, and 27.5 min, respectively.

(MD-PP: H. Ramanathan, R. Ravichandran.) RTS—C69182

Flavoxate Hydrochloride



$C_{24}H_{25}NO_4 \cdot HCl$ 427.92

4*H*-1-Benzopyran-8-carboxylic acid, 3-methyl-4-oxo-2-phenyl-, 2-(1-piperidinyl)ethyl ester, hydrochloride;

2-Piperidinoethyl 3-methyl-4-oxo-2-phenyl-4*H*-1-benzopyran-8-carboxylate hydrochloride [3717-88-2].

DEFINITION

Flavoxate Hydrochloride contains NLT 98.0% and NMT 102.0% of $C_{24}H_{25}NO_4 \cdot HCl$, calculated on the dried basis.

IDENTIFICATION

- **A. INFRARED ABSORPTION** ⟨**197K**⟩
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.
- **C. IDENTIFICATION TESTS—GENERAL,** *Chloride* ⟨**191**⟩**:** A solution of 10 mg/mL meets the requirements of the silver nitrate precipitate.

ASSAY

- **PROCEDURE**

Solution A: Mixture of 1.0 g of sodium hexanesulfonate in 650 mL of water, 1 mL of triethylamine, and 1.0 mL of phosphoric acid

Mobile phase: Add 350 mL of acetonitrile to *Solution A*.

Standard solution: 50 µg/mL of USP Flavoxate Hydrochloride RS in *Mobile phase*

Sample solution: 50 µg/mL of Flavoxate Hydrochloride in *Mobile phase*

BRIEFING

Glyburide and Metformin Hydrochloride Tablets, *USP 32* page 2511 and page 1163 of *PF* 34(5) [Sept.–Oct. 2008]. It is proposed to revise the test for *Dissolution* to indicate that the *Sample solution* could be diluted with *Medium*, if necessary.

(BPC: M. Marques.) RTS—C78915

Glyburide and Metformin Hydrochloride Tablets

DEFINITION

Glyburide and Metformin Hydrochloride Tablets contain NLT 90.0% and NMT 110.0% of the labeled amounts of glyburide ($C_{23}H_{28}ClN_3O_5S$) and metformin hydrochloride ($C_4H_{11}N_5 \cdot HCl$).

IDENTIFICATION

Change to read:

- **A. GLYBURIDE:** ~~*Infrared Absorption* ⟨197K⟩—Prepare the test specimen as follows. Grind 5 Tablets to a fine powder. Add 25 mL of water, and shake for 5 minutes. Add 25 mL of chloroform, and shake for an additional 5 minutes. Centrifuge at 2500 rpm for 5 minutes. Transfer the lower chloroform layer to another container, evaporate the solvent under a stream of nitrogen, and dry the extract at 60° for 3 hours: the IR absorption spectrum of a potassium bromide dispersion prepared from the residue so obtained exhibits maxima only at the same wavelengths as that of a similar preparation of USP Glyburide RS.~~ ■The retention time of the glyburide peak of the *Sample solution* corresponds to that of the major peak of the *Standard solution*, as obtained in the *Assay* for *Glyburide*.■2S (*USP32*)
- **B. METFORMIN HYDROCHLORIDE:** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay* for *Metformin Hydrochloride*.

ASSAY

- **GLYBURIDE**

Solution A: 28 mg/mL of monobasic ammonium phosphate

Mobile phase: Acetonitrile and *Solution A* (40:60). Adjust with 1 N sodium hydroxide to a pH of 5.3.

Diluent: Acetonitrile and water (50:50)

Standard stock solution: 0.25 mg/mL of USP Glyburide RS in acetonitrile and water. [NOTE—Dissolve in the acetonitrile and dilute with water to volume. Use volumes of each such that the final ratio of acetonitrile to water is 1:1.]

Standard solution: 0.025 mg/mL of USP Glyburide RS in *Diluent*, from *Standard stock solution*

System suitability solution 1: Prepare a solution containing 0.025 mg/mL of USP Glyburide Related Compound A RS in *Diluent*. Transfer 50 µL of this solution to a 50-mL volumetric flask, and dilute with *Standard solution* to volume.

System suitability solution 2: 5.0 mg/mL of USP Metformin Hydrochloride RS in *System suitability solution 1*

Sample solution: Dissolve NLT 5 Tablets in *Diluent* by stirring with a magnetic stirring bar for a least 1 h. Dilute to obtain a solution containing 0.025 mg/mL of glyburide, based on the label claim. Centrifuge a portion of this solution at 3000 rpm for 10 min and use the clear supernatant. [NOTE—Retain a portion of this solution for the *Assay* for *Metformin Hydrochloride*.]

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

In-Process Revision

Mode: LC
Detector: UV 230 nm
Column: 4.6-mm × 15-cm; 5-µm packing L7
Temperature: 40°
Flow rate: 1.2 mL/min
Injection size: 100 µL

System suitability
Sample: *System suitability solution 2*
[NOTE—The relative retention time for the peak due to glyburide related compound A is about 0.30 with respect to glyburide.]
Suitability requirements
Capacity factor, k′: NLT 7 for the peak due to glyburide
Column efficiency: NLT 3000 theoretical plates for the peak due to glyburide
Relative standard deviation: NMT 1.5% for the peak due to glyburide; NMT 10% for the peak due to glyburide related compound A

Analysis
Samples: *Standard solution* and *Sample solution*
Record the chromatograms for about 1.25 times the retention time of the glyburide peak. Calculate the percentage of $C_{23}H_{28}ClN_3O_5S$ in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of USP Glyburide RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of glyburide in the *Sample solution* (mg/mL)

Acceptance criteria: 90.0%–110.0% of glyburide label claim

- **METFORMIN HYDROCHLORIDE**

Solution A: Transfer 1.0 g each of sodium heptanesulfonate and sodium chloride to a 2000-mL volumetric flask. Add 1800 mL of water, and adjust with 0.06 M phosphoric acid to a pH of 3.85. Dilute with water to volume.
Mobile phase: Acetonitrile and *Solution A* (10:90)
Diluent: Acetonitrile and water (1:40)
Standard solution: 0.25 mg/mL of USP Metformin Hydrochloride RS in *Diluent*. [NOTE—Sonicate to achieve complete dissolution, if necessary.]
System suitability stock solution: 25 µg/mL each of USP Metformin Related Compound B RS and USP Metformin Related Compound C RS in *Diluent*
System suitability solution: Transfer 0.5 mL of *System suitability stock solution* to a 50-mL volumetric flask, and dilute with *Standard solution* to volume.
Sample solution: Dilute with water a portion of the retained *Sample solution* from the *Assay* for *Glyburide* to obtain 0.25 mg/mL of metformin hydrochloride based on the label claim.
Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 218 nm
Column: 3.9-mm × 30-cm; 10-µm packing L1
Temperature: 30°
Flow rate: 1 mL/min
Injection size: 5 µL

System suitability
Sample: *System suitability solution*
[NOTE—The relative retention times for metformin related compound B, metformin, and metformin related compound C (this impurity can have a variable retention time) are about 0.86, 1.0, and 2.1–2.3, respectively.]
Suitability requirements
Resolution: NLT 1.5 between metformin related compound B and metformin
Tailing factor: 0.8–2.0 for the metformin peak
Relative standard deviation: NMT 1.5% for the metformin peak and NMT 10% for each of the peaks due to metformin related compound B and metformin related compound C

Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_4H_{11}N_5 \cdot HCl$ in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of USP Metformin Hydrochloride RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of metformin hydrochloride in the *Sample solution* (mg/mL)

Acceptance criteria: 90.0%–110.0% of metformin label claim

PERFORMANCE TESTS

Change to read:

- **DISSOLUTION** ⟨**711**⟩

Glyburide
Medium: 0.05 M boric acid and 0.05 M potassium chloride solution. Prepare by dissolving 3.09 g of boric acid and 3.73 g of potassium chloride in 250 mL of water, adjust with 1 N sodium hydroxide to a pH of 9.5, and dilute with water to 1 L; 500 mL.
Apparatus 2: 75 rpm
Time: 30 min
Standard solution: Transfer 10 mg of USP Glyburide RS to a 100-mL volumetric flask. Dissolve in 20 mL of acetonitrile, and dilute with *Medium* to volume. Dilute further with *Medium* to obtain a solution having a glyburide concentration, in mg/mL, of L/500 where L is the label claim, in mg, of glyburide.
Sample solution: Sample per *Dissolution* ⟨711⟩. Pass a portion of the solution under test through a 0.45-µm polypropylene filter or a 1-µm glass fiber filter. ▲Dilute with *Medium*, if necessary.▲*USP34*
Solution A: 28.7 mg/mL of monobasic ammonium phosphate in water
Mobile phase: *Solution A* and acetonitrile (1:1). Adjust with 1 N sodium hydroxide to a pH of 5.3.
Chromatographic system

System suitability
Sample: *Standard solution*
Suitability requirements
Column efficiency: NLT 5000
Tailing factor: 0.8–2.0
Relative standard deviation: NMT 2%

Analysis
Samples: *Standard solution* and *Sample solution*
Determine the percentage of $C_{23}H_{28}ClN_3O_5S$ dissolved:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of the *Standard solution* (mg/mL)
C_U = nominal concentration of glyburide in the *Sample solution* (mg/mL)

Tolerances: NLT 85% (Q) of the labeled amount of glyburide is dissolved.

Metformin hydrochloride
Medium: 0.05 M phosphate buffer, pH 6.8. Prepare by dissolving 6.8 g of monobasic potassium phosphate in 1000 mL of water, and adjust with 0.2 N sodium hydroxide to a pH of 6.8 ± 0.1; 1000 mL.

Apparatus 2: 50 rpm
Time: 30 min
Standard solution: Dissolve a quantity of USP Metformin Hydrochloride RS in *Medium*. Dilute further, if necessary, with *Medium* to obtain a solution having a metformin hydrochloride concentration, in mg/mL, of L/1000 where L is the label claim, in mg, of metformin hydrochloride.
Sample solution: Sample per *Dissolution* ⟨711⟩. Pass a portion of the solution under test through a 0.45-µm polypropylene filter or a 1-µm glass fiber filter. ▲Dilute with *Medium*, if necessary.▲*USP34*
Spectrometric conditions
(See *Spectrophotometry and Light-Scattering* ⟨851⟩.)
Mode: UV-Vis
Analytical wavelength: 232 nm
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_4H_{11}N_5 \cdot HCl$ dissolved:

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times 100$$

A_U = absorbance of the *Sample solution*
A_S = absorbance of the *Standard solution*
C_S = concentration of USP Metformin Hydrochloride RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of metformin hydrochloride in the *Sample solution* (mg/mL)
Tolerances: NLT 85% (Q) of the labeled amount of metformin hydrochloride is dissolved.

- **UNIFORMITY OF DOSAGE UNITS ⟨905⟩:** Meet the requirements for *Weight Variation* for metformin hydrochloride and for *Content Uniformity* for glyburide

IMPURITIES

Organic Impurities

- **PROCEDURE 1: GLYBURIDE**

Solution A, Mobile phase, Diluent, and **Chromatographic system:** Proceed as directed in the *Assay* for *Glyburide*.
Standard solution: Dilute 1.0 mL of *Standard solution* from the *Assay* for *Glyburide* with *Diluent* to 100 mL.
Sample solution: Use the *Sample solution* from the *Assay* for *Glyburide*.
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of each glyburide impurity in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times F \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of USP Glyburide RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of glyburide in the *Sample solution* (mg/mL)
F = relative response factor, use 0.8 for glyburide related compound A, and use 1.0 for all other impurities
Acceptance criteria
[NOTE—Disregard any peak less than 0.05%, and disregard any peak observed in the blank.]
Glyburide related compound A: NMT 1.0%
Any other individual impurities: NMT 0.2%
Total impurities: NMT 0.50%, excluding glyburide related compound A

- **PROCEDURE 2: METFORMIN HYDROCHLORIDE**

Solution A, Mobile phase, and **Chromatographic system:** Proceed as directed in the *Assay* for *Metformin Hydrochloride*.
Sample solution: Use the *Sample solution* from the *Assay* for *Metformin Hydrochloride*.
Analysis
Sample: *Sample solution*
Calculate the percentage of each impurity in the portion of Tablets taken:

$$\text{Result} = (r_U/r_T) \times 100$$

r_U = peak response for each impurity from the *Sample solution*
r_T = sum of the responses of all peaks from the *Sample solution*
Acceptance criteria
[NOTE—Disregard any peak less than 0.05%, and disregard any peak observed in the blank.]
Individual impurities: NMT 0.1%
Total impurities: NMT 0.5%

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in tight, light-resistant containers, and store at controlled room temperature.

USP Metformin Related Compound C RS

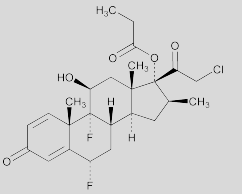
BRIEFING

Halobetasol Propionate. Because there is no existing *USP* monograph for this drug substance, a new monograph based on validated methods of analysis is being proposed. The liquid chromatographic procedures in the *Assay* and test for *Organic Impurities* are based on analyses performed with a Waters Symmetry Shield RP18 brand of L1 column. The typical retention time for halobetasol is about 10.5 min.

(MD-CCA: H. Ramanathan, C. Anthony.) RTS—C49074

Add the following:

▲Halobetasol Propionate



$C_{25}H_{31}ClF_2O_5$ 484.96
Pregna-1,4-diene-3,20-dione, 21-chloro-6,9-difluoro-11-hydroxy-16-methyl-17-(1-oxopropoxy)-, (6α,11β,16β)-;
21-Chloro-6α,9-difluoro-11β,17-dihydroxy-16β-methylpregna-1,4-diene-3,20-dione 17-propionate [66852-54-8].

DEFINITION

Halobetasol Propionate contains NLT 98.0% and NMT 102.0% of $C_{25}H_{31}ClF_2O_5$, calculated on the dried basis.

IDENTIFICATION

- **A. INFRARED ABSORPTION ⟨197K⟩**
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

BRIEFING

Lithium Carbonate Tablets, *USP 32* page 2798. It is proposed to add more information on the surfactant and *Surfactant solution* used in the *Dissolution* test.

(BPC: M. Marques.) RTS—C78922

Lithium Carbonate Tablets

DEFINITION
Lithium Carbonate Tablets contain NLT 95.0% and NMT 105.0% of the labeled amount of Li_2CO_3.

IDENTIFICATION
A portion of the powdered Tablets meets the requirements of the following tests.
- **A.** It effervesces upon the addition of an acid, yielding a colorless gas that, when passed into calcium hydroxide TS, immediately causes a white precipitate to form.
- **B.** When moistened with hydrochloric acid, it imparts an intense crimson color to a nonluminous flame.

ASSAY
- **PROCEDURE**

Standard solution: Transfer 30 mg of USP Lithium Carbonate RS to a 100-mL volumetric flask, and add 20 mL of water and 0.5 mL of hydrochloric acid. Shake until dissolved, and dilute with water to volume. Pipet 20 mL of the resulting solution into a 1000-mL volumetric flask, add 800 mL of water and 20 mL of a suitable surfactant solution, and dilute with water to volume.

Sample solution: Powder NLT 20 Tablets. Transfer a portion of powder, nominally equivalent to 600 mg of lithium carbonate, into a 1000-mL volumetric flask. Add water and hydrochloric acid (40:5), shake until the solid is well disintegrated, and dilute with water to volume. Pipet 10 mL of the resulting solution into a 1000-mL volumetric flask, add 800 mL of water and 20 mL of the surfactant solution, and dilute with water to volume.

Spectrometric conditions
Mode: Flame photometer
Analytical wavelength: About 671 nm
[NOTE—Adjust the instrument with the surfactant solution.]

Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of Li_2CO_3 in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of the *Standard solution* (mg/mL)
C_U = nominal concentration of lithium carbonate in the *Sample solution* (mg/mL)

Acceptance criteria: 95.0%–105.0%

BRIEFING

Methylphenidate Hydrochloride Extended-Release Tablets, *USP 32* page 2950 and page 1162 of *PF* 35(5) [Sept.–Oct. 2009]. It is proposed to clarify the concentration of the *Standard solution* to be used in the *System suitability* in *Dissolution Test 2*.

(BPC: M. Marques.) RTS—C79246

Methylphenidate Hydrochloride Extended-Release Tablets

DEFINITION
Methylphenidate Hydrochloride Extended-Release Tablets contain NLT 90.0% and NMT 110.0% of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$).

IDENTIFICATION
- **A. INFRARED ABSORPTION**

Sample specimen: Place a portion of powdered Tablets, equivalent to 100 mg of methylphenidate hydrochloride, in a 100-mL beaker. Add 20 mL of chloroform, stir for 5 min, and filter, collecting the filtrate. Evaporate the filtrate to about 5 mL. Add ethyl ether slowly, with stirring, until crystals form. Filter the crystals, wash with ethyl ether, and dry at 80° for 30 min.

Acceptance criteria: The IR absorption spectrum of a mineral oil dispersion of the crystals so obtained exhibits maxima only at the same wavelengths as that of a similar preparation of USP Methylphenidate Hydrochloride RS.

Add the following:

■• **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the test for *Organic Impurities*.■2S *(USP33)*

ASSAY

• **PROCEDURE**

Acetate buffer: Dissolve 1.64 g of anhydrous sodium acetate in 900 mL of water. Adjust with acetic acid to a pH of 4.0, and dilute with water to 1000 mL.

Mobile phase: Methanol, acetonitrile, and *Acetate buffer* (4:3:3)

Internal standard solution: 0.4 mg/mL of phenylephrine hydrochloride in *Mobile phase*

Standard stock solution: 0.2 mg/mL of USP Methylphenidate Hydrochloride RS in *Mobile phase*

Standard solution: Transfer 10.0 mL of *Standard stock solution* to a glass-stoppered, 25-mL conical flask, add 5.0 mL of *Internal standard solution*, and mix.

Sample stock solution: 0.2 mg/mL of methylphenidate hydrochloride from powdered Tablets (NLT 20 Tablets) in *Mobile phase*. [NOTE—Sonicate for 15 min.]

Cool to room temperature, dilute with *Mobile phase* to volume, and mix. Pass a portion of this solution through a suitable membrane filter, discarding the first portion of the filtrate. [NOTE—Avoid the use of glass filters. Polypropylene filters are suitable for use.]

Sample solution: Transfer 10.0 mL of the clear filtrate to a glass-stoppered, 25-mL conical flask, and add 5.0 mL of *Internal standard solution*.

Chromatographic system

(See *Chromatography* ⟨621⟩*, System Suitability*.)

Mode: LC

Detector: UV 210 nm

Column: 4.6-mm × 25-cm; packing L10

Flow rate: 1.5 mL/min

Injection size: 50 µL

System suitability

Sample: *Standard solution*

[NOTE—The relative retention times for phenylephrine hydrochloride and methylphenidate hydrochloride are 0.8 and 1.0, respectively.]

Suitability requirements

Resolution: NLT 2.0 between the analyte and internal standard peaks

Relative standard deviation: NMT 2.0% from the peak response ratios of the analyte to the internal standard

Analysis

Samples: *Standard solution and Sample solution*

Calculate the percentage of $C_{14}H_{19}NO_2 \cdot HCl$ in the portion of Tablets taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

R_U = peak response ratio of the analyte to the internal standard from the *Sample solution*

R_S = peak response ratio of the analyte to the internal standard from the *Standard solution*

C_S = concentration of the *Standard solution* (mg/mL)

C_U = nominal concentration of the *Sample solution* (mg/mL)

Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS

Change to read:

• **DISSOLUTION** ⟨**711**⟩

Procedure for a pooled sample

Test 1

Medium: Water; 500 mL

Apparatus 2: 50 rpm

Time: 1, 2, 3.5, 5, and 7 h

Sample solution: Use portions of the solution under test passed through suitable 0.45-µm filter. [NOTE—Do not use glass fiber filters.]

Analysis: Determine the amount of $C_{14}H_{19}NO_2 \cdot HCl$ dissolved by using the procedure in the *Assay*, making any necessary volumetric adjustments.

Tolerances: The percentages of the labeled amount of $C_{14}H_{19}NO_2 \cdot HCl$ dissolved at the times specified conform to *Acceptance Table 2*.

Time (h)	Amount Dissolved
1	25%–45%
2	40%–65%
3.5	55%–80%
5	70%–90%
7	NLT 80

Test 2 (for products labeled for dosing every 24 h)**:** If the product complies with this test, the labeling indicates that it meets USP *Dissolution Test 2*.

Medium: Acidified water (adjust with phosphoric acid to a pH of 3); 50 mL, at 37 ± 0.5°

Apparatus 7 (see *Drug Release* ⟨724⟩)**:** 30 cycles/min; 2–3 cm amplitude

Use *Sample Preparation A* using a metal coil sample holder (*Figure 4d*). Place 1 Tablet in the holder with the Tablet orifice facing down, and cover the top of the holder with Parafilm™. At the end of each specified test interval, the systems are transferred to the next row of new test tubes containing 50 mL of fresh *Medium*.

Times: 1-h intervals for a duration of 10 h

Determine the percentages of the labeled amount of $C_{14}H_{19}NO_2 \cdot HCl$ dissolved by using the following method.

Dilution medium: Mixture of acetonitrile and *Medium* (1:3)

Standard stock solution: 0.3 mg/mL USP Methylphenidate Hydrochloride RS in *Dilution medium*

Standard solutions: Prepare at least six solutions by making serial dilutions of the *Standard stock solution* in *Dilution medium* to bracket the expected drug concentration range.

Solution A: Dissolve 2.0 g of 1-octanesulfonic acid sodium salt in 700 mL of water, mix well, and adjust with phosphoric acid to a pH of 3.0.

Mobile phase: Mixture of acetonitrile and *Solution A* (3:7)

Chromatographic system

(See *Chromatography* ⟨621⟩*, System Suitability*.)

Mode: LC

Detector: UV 220 nm

Column: 3.2-mm × 5-cm; 5-µm packing L1

Flow rate: 1 mL/min

Column temperature: 30°

Injection size: 25 µL

System suitability

Sample: ▲Middle range concentration of the▲*USP34* *Standard solution*

Suitability requirements

Tailing factor: NMT 2

Capacity factor: NMT 2

In-Process Revision

Relative standard deviation: NMT 2% from the peak response of the analyte; NMT 2% of the retention time of the analyte

Analysis

Samples: *Standard solutions* and the solution under test

Construct a calibration curve by plotting the peak response versus the concentration of the *Standard solutions*. Determine the amount of $C_{14}H_{19}NO_2 \cdot HCl$ in each interval by linear regression analysis of the standard curve.

Tolerances: The percentages of the labeled amount of $C_{14}H_{19}NO_2 \cdot HCl$ dissolved at the times specified conform to *Acceptance Table 2*.

Time (h)	Amount Dissolved
1	12%–32%
4	40%–60%
10	NLT 85%
Average from 3 to 6 h	9%–15%/h

Calculate the average percentage released from 3 to 6 h:

$$\text{Result} = (Y - X)/3$$

Y = cumulative drug released from 0 to 6 h
X = cumulative drug released from 0 to 3 h

• **UNIFORMITY OF DOSAGE UNITS ⟨905⟩:** Meet the requirements

IMPURITIES

Add the following:

■Organic Impurities

• **PROCEDURE**

Mobile phase: Dissolve 2 g of 1-octanesulfonic acid in 730 mL of water. Adjust with phosphoric acid to a pH of 2.7. Mix with 270 mL of acetonitrile.

Solution A: Acidified water. Adjust with phosphoric acid to a pH of 3.

Diluent A: Acetonitrile and *Solution A* (1:3)

Diluent B: Acetonitrile and methanol (1:1)

System suitability solution: 80 µg/mL of USP Methylphenidate Hydrochloride RS, 1 µg/mL of methylphenidate hydrochloride erythro isomer from USP Methylphenidate Hydrochloride Erythro Isomer Solution RS and 2 µg/mL of USP Methylphenidate Related Compound A RS, in *Diluent A*

Standard solution: 0.2 µg/mL of USP Methylphenidate Hydrochloride RS, 0.5 µg/mL of methylphenidate hydrochloride erythro isomer from USP Methylphenidate Hydrochloride Erythro Isomer Solution RS and 1.5 µg/mL of USP Methylphenidate Related Compound A RS, in *Diluent A*

Sample stock solution: Dissolve 10 Tablets in 20% of total volume in *Diluent B*. Stir for 4 h. Dilute with *Solution A* to volume.

Sample solution: 0.1 mg/mL of methylphenidate hydrochloride in *Solution A*, from *Sample stock solution*. [NOTE—Centrifuge before chromatographic analysis.]

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

Mode: LC

Detector: UV 210 nm

Column: 3.9-mm × 15-cm column; 5-µm packing L1

Flow rate: 1 mL/min

Injection size: 25 µL

Temperature: 30°

Run time: 2 times the retention time of methylphenidate

System suitability

Sample: *System suitability solution*

Suitability requirements

Tailing factor: NMT 2.0 for methylphenidate peak

Resolution: NLT 6.0 between methylphenidate and erythro isomer peaks

Relative standard deviation: NMT 2.0% for methylphenidate peak and NMT 4.0% each for methylphenidate related compound A and erythro isomer peaks

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of methylphenidate related compound A or erythro isomer in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = response of methylphenidate related compound A or erythro isomer from the *Sample solution*
r_S = response of methylphenidate related compound A or erythro isomer from the *Standard solution*
C_S = concentration of USP Methylphenidate Related Compound A RS or methylphenidate hydrochloride erythro isomer, in the *Standard solution* (mg/mL)
C_U = nominal concentration of methylphenidate hydrochloride in the *Sample solution* (mg/mL)

Calculate the percentage of any unspecified degradation product in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = response of each impurity from the *Sample solution*
r_S = response of USP Methylphenidate Hydrochloride RS from the *Standard solution*
C_S = concentration of USP Methylphenidate Hydrochloride RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of methylphenidate hydrochloride in the *Sample solution* (mg/mL)

Acceptance criteria

Individual impurities: See *Impurity Table 1*.

Total impurities: NMT 2.5%

Impurity Table 1

Name	Relative Retention Time	Acceptance Criteria, NMT (%)
Methylphenidate related compound A[a]	0.47	1.5
Erythro isomer[b]	0.65	0.5
Methylphenidate hydrochloride	1.0	—
Any unspecified degradation product	—	0.2

[a] α-Phenyl-2-piperidineacetic acid.
[b] Methyl (*RS,SR*)-2-phenyl-2-(piperidin-2-yl) acetate.

USP Metolazone RS

BRIEFING

Mycophenolate Mofetil for Injection. A new *USP* monograph for this dosage form, based on validated methods of analysis, is being proposed. The liquid chromatographic procedures in the *Assay* and in the test for *Organic Impurities* are based on analyses performed with the Inertsil-Phenyl, 5-µm brand of L11 column. The typical retention time for mycophenolate mofetil is about 27 min.

(MD-OOD: F. Mao. MSA: R. Tirumalai.) RTS—C38804

In-Process Revision

Add the following:

▲Mycophenolate Mofetil for Injection

DEFINITION

Mycophenolate Mofetil for Injection contains an amount of Mycophenolate Mofetil Hydrochloride equivalent to NLT 90.0% and NMT 110.0% of the labeled amount of mycophenolate mofetil ($C_{23}H_{31}NO_7$).

IDENTIFICATION

- The retention time of the major peak in the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

ASSAY

- **PROCEDURE**

[NOTE—Protect solutions from light.]

Buffer 1: Transfer 10 mL of triethylamine into a 1000-mL volumetric flask containing about 950 mL of water and mix. Adjust with phosphoric acid to a pH of 7.2, and dilute with water to volume.

Buffer 2: Transfer 10 mL of triethylamine into a 1000-mL volumetric flask containing about 950 mL of water and mix. Adjust with phosphoric acid to a pH of 3.0, and dilute with water to volume.

Solution A: *Buffer 1* and water (4:9)

Diluent: Acetonitrile, *Buffer 2*, and water (7:4:9)

Mobile phase: Acetonitrile and *Solution A* (3:7)

Standard stock solution: Transfer a known quantity of USP Mycophenolate Mofetil RS in a suitable volumetric flask, add acetonitrile equivalent to about 10% of the final volume, and sonicate for about 5 min or until the solid dissolves. Dilute with *Diluent* to volume to obtain a solution containing a known concentration of 1.0 mg/mL of USP Mycophenolate Mofetil RS.

Standard solution: 0.4 mg/mL of USP Mycophenolate Mofetil RS in *Diluent*, from *Standard stock solution*

Sample solution: Constitute each of the containers of Mycophenolate Mofetil for Injection with 14 mL of 5% Dextrose Injection. Quantitatively transfer the contents of all vials, the combined contents of which are equivalent to about 2 g of mycophenolate mofetil, to a 200-mL volumetric flask, and dilute with water to volume. Transfer 4.0 mL of this solution to a 100-mL volumetric flask, and dilute with *Diluent* to volume.

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

Mode: LC

Detector: UV 249 nm

Column: 4.6-mm × 25-cm; 5-µm packing L11

Column temperature: 45°

Autosampler temperature: 5°

Flow rate: 1.5 mL/min

Injection size: 10 µL

System suitability

Sample: *Standard solution*

Suitability requirements

Tailing factor: NMT 2.0

Relative standard deviation: NMT 2.0%

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of $C_{23}H_{31}NO_7$ in the portion of Mycophenolate Mofetil for Injection taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*
r_S = peak response from the *Standard solution*
C_S = concentration of mycophenolate mofetil in the *Standard solution* (mg/mL)
C_U = nominal concentration of mycophenolate mofetil in the *Sample solution* (mg/mL)

Acceptance criteria: 90.0%–110.0%

BRIEFING

Mycophenolate Mofetil for Oral Suspension. A new *USP* monograph for this dosage form, based on validated methods of analysis, is being proposed. The liquid chromatographic procedures in the *Assay* and in the test for *Organic Impurities* are based on analyses performed with the Inertsil-Phenyl, 5-µm brand of L11 column. The typical retention time for mycophenolate mofetil is about 25 min.

(MD-OOD: F. Mao. BPC: M. Marques.) RTS—C38804

Add the following:

▲Mycophenolate Mofetil for Oral Suspension

DEFINITION
Mycophenolate Mofetil for Oral Suspension is a dry mixure of mycophenolate mofetil and one or more suitable buffers, colors, diluents, and flavors. It contains NLT 90.0% and NMT 110.0% of the labeled amount of mycophenolate mofetil ($C_{23}H_{31}NO_7$).

IDENTIFICATION
- The retention time of the major peak in the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

ASSAY
- **PROCEDURE**
  [NOTE—Protect solutions from light.]
  Buffer 1: Pipet 10 mL of triethylamine into a 1000-mL volumetric flask containing about 950 mL of water, and mix. Adjust with phosphoric acid to a pH of 7.2, and dilute with water to volume.
  Buffer 2: Pipet 10 mL of triethylamine into a 1000-mL volumetric flask containing about 950 mL of water, and mix. Adjust with phosphoric acid to a pH of 3.0, and dilute with water to volume.
  Solution A: *Buffer 1* and water (4:9)
  Extraction solvent: Acetonitrile, *Buffer 2*, and water (13:4:9)
  Diluent: Acetonitrile, *Buffer 2*, and water (7:4:9)
  Mobile phase: Acetonitrile and *Solution A* (3:7)
  Standard stock solution: 4 mg/mL of USP Mycophenolate Mofetil RS in *Extraction solvent*. Sonicate to aid the dissolution.
  Standard solution: 0.4 mg/mL of USP Mycophenolate Mofetil RS in *Diluent*, from the *Standard stock solution*
  Sample stock solution: Constitute Mycophenolate Mofetil for Oral Suspension as directed on the label. Prepare a composite sample by mixing NLT 4 bottles of the constituted Mycophenolate Mofetil for Oral Suspension. Transfer a volume of the composite sample so obtained, equivalent to 800 mg of mycophenolate mofetil, to a 200-mL volumetric flask, and dilute with *Extraction solvent* to volume.
  Sample solution: Transfer 5.0 mL of *Sample stock solution* to a 50-mL volumetric flask, and dilute with *Diluent* to volume. Pass through a 45-µm filter.
  Chromatographic system
  (See *Chromatography* ⟨621⟩*, System Suitability*.)
  Mode: LC
  Detector: UV 249 nm
  Column: 4.6-mm × 25-cm; 5-µm packing L11
  Column temperature: 45°
  Autosampler temperature: 5°
  Flow rate: 1.5 mL/min
  Injection size: 20 µL
  System suitability
  Sample: *Standard solution*
  Suitability requirements
  Tailing factor: NMT 2.0
  Relative standard deviation: NMT 2.0%, *Standard solution*
  Analysis
  Samples: *Standard solution* and *Sample solution*
  Calculate the percentage of $C_{23}H_{31}NO_7$ in the portion of Mycophenolate Mofetil for Oral Suspension taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

  r_U = peak response from the *Sample solution*
  r_S = peak response from the *Standard solution*
  C_S = concentration of mycophenolate mofetil in the *Standard solution* (mg/mL)
  C_U = nominal concentration of mycophenolate mofetil in the *Sample solution* (mg/mL)
  Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS
- **DISSOLUTION** ⟨**711**⟩
  [NOTE—Prepare all solutions in low-actinic glassware.]
  Medium: 0.1 N hydrochloric acid; 900 mL, deaerated.
  Apparatus 2: 40 rpm
  Time: 20 min
  Standard solution: 0.278 mg/mL of USP Mycophenolate Mofetil RS in *Medium*.
  Sample solution: Reconstitute Mycophenolate Mofetil for Oral Suspension according to the labeling instructions. Shake well. Use a separate 3-mL syringe for each vessel. Withdraw 2 mL of suspension. Remove air bubbles from the syringe. Adjust the volume to 1.2 mL and accurately weigh the filled syringe. Operate the apparatus, holding the syringe above the surface of the medium, at a location that is halfway between the paddle shaft and the vessel wall. Carefully introduce the sample to the vessel over a 5–10 sec period. Weigh the empty syringe and determine the weight of the sample (g). At the time specified, withdraw an aliquot and immediately pass through a suitable 10-µm filter, discarding the first few mL.
  Spectrometric conditions
  Mode: UV
  Analytical wavelength: 304 nm
  Cell: 0.2 cm
  Blank: *Medium*
  Analysis
  Samples: *Standard solution* and *Sample solution*
  Calculate the percentage of the labeled amount of mycophenolate mofetil dissolved:

$$\text{Result} = (A_U/A_S) \times (C_S/L) \times (V_1/V_2) \times 100$$

  A_U = absorbance of the *Sample solution*
  A_S = absorbance of the *Standard solution*

In-Process Revision

C_S = concentration of mycophenolate mofetil in the *Standard solution* (mg/mL)
L = suspension label claim of mycophenolate mofetil (mg/mL)
V_1 = volume of *Medium*, 900 (mL)
V_2 = volume of sample (mL), weight (g) of the sample divided by the density of the suspension (g/mL)

Tolerances: NLT 80% (Q) of the labeled amount of mycophenolate mofetil is dissolved.

- **UNIFORMITY OF DOSAGE UNITS ⟨905⟩:** Meets the requirements
- **DELIVERABLE VOLUME ⟨798⟩:** Meets the requirements

ASSAY

- **PROCEDURE**

[NOTE—Use vigorous shaking and very brief sonication to dissolve the substance to be examined. Inject the *Sample solution* within 20 min of preparation. Polypropylene HPLC autosampler vials should be used.]

Buffer: Weigh 2.72 g of monobasic potassium phosphate (anhydrous) and 1.80 g of 1-pentanesulfonic acid sodium salt into a suitable container. Add 2000 mL of water, and mix well to completely dissolve all solids. Transfer 0.5 mL of triethylamine to the buffer solution, and mix thoroughly. Adjust the pH of the solution to 4.3 ± 0.05 by dropwise addition of phosphoric acid.

Mobile phase: Methanol and *Buffer* (3:17)

Oxaliplatin standard stock solution: 0.5 mg/mL of USP Oxaliplatin RS in water

Oxaliplatin related compound B standard stock solution: Transfer USP Oxaliplatin Related Compound B RS to a suitable volumetric flask, add 25% of the final volume of methanol, and sonicate for approximately 2 min to disperse the solids. Add approximately 65% of the final volume of 0.001 M nitric acid, and sonicate for an additional 30 min to dissolve the solids. Allow to cool if necessary. Dilute with 0.001 M nitric acid to volume, and mix to obtain a solution having a known concentration of about 0.125 mg/mL. [NOTE—USP Oxaliplatin Related Compound B RS is converted to (*SP*-4-2)-diaqua[(1*R*,2*R*)-cyclohexane-1,2-diamine-*N*,*N*′]platinum in solution preparation.]

Oxaliplatin related compound C standard stock solution: 0.1 mg/mL of USP Oxaliplatin Related Compound C RS in water

System suitability solution: 2 mg/mL of Oxaliplatin in 0.005 M sodium hydroxide. Allow this solution to stand at room temperature for at least 5 days. Transfer 10 mL of this solution, 10 mL of *Oxaliplatin related compound B standard stock solution,* and 5 mL of *Oxaliplatin related compound C standard stock solution* into a 100-mL volumetric flask, and dilute with water to volume. [NOTE—The preparation of the *System suitability solution* forms the diaquodiaminocyclohexaneplatinum dimer.]

Standard solution: 0.1 mg/mL of Oxaliplatin in water, from *Oxaliplatin standard stock solution*

Sample solution: 0.1 mg/mL of Oxaliplatin in water

Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 210 nm
Column: 4.6-mm × 25-cm column; 5-µm packing L1
Flow rate: 1 mL/min
Injection size: 50 µL

System suitability
Samples: *System suitability solution* and *Standard solution*
[NOTE—The relative retention times, measured with respect to oxaliplatin, of oxaliplatin related compounds C and B and diaquodiaminocyclohexaneplatinum dimer are about 0.8, 2.7, and 6, respectively.]
Suitability requirements
Resolution: NLT 2.0 between oxaliplatin and oxaliplatin related compound C, *System suitability solution*
Tailing factor: Between 0.8 and 2.0 for the oxaliplatin peak, *System suitability solution*
Relative standard deviation: NMT 2.0% for the oxaliplatin peak, *Standard solution*

Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of $C_8H_{14}N_2O_4Pt$ in the portion of Oxaliplatin taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = response from the *Sample solution*
r_S = response from the *Standard solution*
C_S = concentration of USP Oxaliplatin RS in the *Standard solution* (mg/mL)
C_U = concentration of Oxaliplatin in the *Sample solution* (mg/mL)

Acceptance criteria: 98.0%–102.0% on the dried basis

IMPURITIES

Inorganic Impurities

- **LIMIT OF SILVER**

Sample stock solution: Dissolve 100 mg of Oxaliplatin, weighed, in 50 mL of water to obtain a solution having a concentration of 2 mg/mL.

Sample solution: 1 mg/mL of Oxaliplatin in 0.5 M nitric acid from *Sample stock solution*

Standard stock solution: Dilute a commercially available silver nitrate atomic absorption standard solution containing 1000 ppm of silver in 0.5 M nitric acid quantitatively, and stepwise if necessary, with 0.5 M nitric acid to obtain a 10-ppb solution.

Standard solution 1: Mix 20 µL of the *Sample stock solution* and 8 µL of the *Standard stock solution*, and dilute with 0.5 M nitric acid to 40 µL.

Standard solution 2: Mix 20 µL of the *Sample stock solution* and 16 µL of the *Standard stock solution,* and dilute with 0.5 M nitric acid to 40 µL.

Spectrometric conditions
(See *Spectrophotometry and Light-Scattering* ⟨851⟩.)
Mode: Atomic absorption spectrophotometry
Analytical wavelength: Silver emission line of 328.1 nm
Lamp: Silver hollow–cathode
Flame: Graphite furnace
Blank: 0.5 M nitric acid

Analysis
Samples: *Standard solution 1*, *Standard solution 2*, and *Sample solution*
Plot the absorbances of the *Sample solution, Standard solution 1*, and *Standard solution 2* versus their concentrations, in ppb, of silver, and draw the straight line best fitting the three plotted points. The intercept on the x-axis of the extended regression line indicates the silver concentration in the *Sample solution*.
Calculate the silver, in ppm, in the portion of Oxaliplatin taken:

$$\text{Result} = (C/W) \times 100$$

C = absolute value of the intercept, in ppb of silver, on the x-axis

In-Process Revision

W = weight of Oxaliplatin taken for the preparation of the *Sample stock solution* (mg)

Acceptance criteria: NMT 5.0 ppm

• **HEAVY METALS**

Standard stock solution: Transfer 1 mL each of 1000-ppm standard solutions of cadmium, chromium, copper, iron, nickel, and lead (commercially available) to a 100-mL volumetric flask. Add 5 mL of nitric acid, and dilute with water to volume.

Internal standard solution: Transfer 1 mL of a 10,000-ppm standard solution of yttrium (commercially available) to a 100-mL volumetric flask, and dilute with 5% nitric acid to volume.

Standard solutions: Transfer 0.2, 2.0, and 20.0 mL of *Standard stock solution* to separate 100-mL volumetric flasks. Add 1.0 mL of *Internal standard solution* and 5.0 mL of nitric acid to each flask, and dilute with water to volume. The concentrations of these solutions are 0.02, 0.20, and 2.00 ppm, respectively.

Blank solution: Transfer 1.0 mL of *Internal standard solution* and 5.0 mL of nitric acid to a 100-mL volumetric flask, and dilute with water to volume.

Sample solution: Weigh 1 g of Oxaliplatin into a 100-mL volumetric flask, and add 80 mL of water. Stir vigorously for several min with a magnetic stirrer until no more sample seems to be dissolving. Add 5 mL of nitric acid, and mix again until the sample is completely dissolved. Remove the stirrer bar from the flask, rinsing it before removal. Add 1.0 mL of the *Internal standard solution,* and dilute with water to volume.

Spectrometric conditions

(See *Plasma Spectrochemistry* ⟨730⟩.)

Measure the responses of the elements cadmium, chromium, copper, iron, nickel, lead, and yttrium (internal standard), using an inductively coupled plasma–atomic optical emission spectrometer (ICP–OES), by measuring the emissions at 226.502, 283.563, 327.395, 259.940, 221.648, 220.353, and 371.029 nm, respectively. Optimize the instrument settings as directed by the manufacturer.

System suitability

Before samples are analyzed, the instrument must pass a suitable performance check. Generate the calibration curve, using the *Blank solution* and the *Standard solutions,* and run these solutions in the following order: the *Blank solution,* then the 0.02-, 0.20-, and 2.00-ppm solutions. The linear regression coefficient is NLT 0.99; the response of the *Blank solution* is between –5.0 and 5.0 ppb for each element; and the responses of yttrium obtained from the *Standard solutions* are drifted by NMT 5.0% of the response obtained from the *Blank solution.* Run the *Standard solution* of 0.20 ppm, and record the responses of each element: the relative standard deviations for replicate runs are NMT 5.0%; and the recovery against the calibration curve is between 95% and 105%. After samples are analyzed, the instrument must pass the same suitable performance check to ensure that the calibration is still valid.

Analysis

Sample: *Sample solution*

Record the responses of each element, and determine the concentration of each element, using the calibration graph. Calculate the content of each element, in ppm, in the portion of Oxaliplatin taken:

$$\text{Result} = (C/W) \times 100$$

C = concentration of each element in the *Sample solution* (ppm)

W = weight of Oxaliplatin taken to prepare the *Sample solution* (g)

Acceptance criteria

Total heavy metals: NMT 20 ppm

Change to read:

Organic Impurities

• **PROCEDURE 1: LIMIT OF OXALIC ACID**

[NOTE—Use vigorous shaking and very brief sonication to dissolve the substance to be examined. Inject the *Sample solution* within 20 min of preparation. Polypropylene HPLC autosampler vials should be used.]

Buffer: Add 1.36 g of potassium dihydrogen phosphate to 10 mL of 10% tetrabutylammonium hydroxide in water, and dilute with water to 1000 mL. Adjust the pH with phosphoric acid to 6.0.

Mobile phase: Acetonitrile and *Buffer* (1:4)

Standard stock solution: 0.06 mg/mL of USP Oxaliplatin Related Compound A RS in water. [NOTE—USP Oxaliplatin Related Compound A RS is available as oxalic acid dihydrate.]

Standard solution: 15 µg/mL of USP Oxaliplatin Related Compound A RS in water, from *Standard stock solution*

System suitability solution: 0.05 mg/mL of sodium nitrate in water. Transfer 2 mL of this solution and 25 mL of the *Standard stock solution* to a 100-mL volumetric flask, and dilute with water to volume

Sensitivity solution: 1.5 µg/mL of USP Oxaliplatin Related Compound A RS ▲in water,▲*USP34* from *Standard solution*

Sample solution: 2 mg/mL of Oxaliplatin in water

Chromatographic system

(See *Chromatography* ⟨621⟩*, System Suitability*.)

Mode: LC

Detector: UV 205 nm

Column: 4.6-mm × 25-cm column; 5-µm packing L1

Flow rate: 2 mL/min

Column temperature: 40°

Injection size: 20 µL

System suitability

Samples: *Standard solution*, *System suitability solution*, and *Sensitivity solution*

[NOTE—The elution order is sodium nitrate, followed by oxalic acid.]

Suitability requirements

Resolution: NLT 2.0 between oxalic acid and sodium nitrate, *System suitability solution*

Relative standard deviation: NMT 3.0%, *Standard solution*

~~**Sensitivity**~~▲**Signal-to-noise ratio:**▲*USP34* ~~The peak at approximately the same retention time as that of the *Standard solution* should be visible~~▲NLT 10,▲*USP34* *Sensitivity solution*

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of oxalic acid in the portion of Oxaliplatin taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

r_U = response of oxalic acid from the *Sample solution*

r_S = response of oxalic acid from the *Standard solution*

C_S = concentration of USP Oxaliplatin Related Compound A RS in the *Standard solution* (mg/mL)

C_U = concentration of Oxaliplatin in the *Sample solution* (mg/mL)

M_{r1} = molecular weight of anhydrous oxalic acid, 90.03

M_{r2} = molecular weight of USP Oxaliplatin Related Compound A RS, 126.07

Acceptance criteria: NMT 0.05%

In-Process Revision

• **PROCEDURE 2: LIMIT OF (*SP*-4-2)-DIAQUA[(1*R*,2*R*)-CYCLOHEXANE-1,2-DIAMINE-*N*,*N*′]PLATINUM, OXALIPLATIN RELATED COMPOUND C, AND UNSPECIFIED IMPURITIES**

[NOTE—Use vigorous shaking and very brief sonication to dissolve the substance to be examined. Inject the *Sample solution* within 20 min of preparation. Polypropylene HPLC autosampler vials should be used.]

Mobile phase, System suitability solution, Oxaliplatin standard stock solution, Oxaliplatin related compound B standard stock solution, and **Oxaliplatin related compound C standard stock solution:** Proceed as directed in the *Assay*.

Standard solution: 0.01 mg/mL of oxaliplatin, 0.01 mg/mL of oxaliplatin related compound B, and 0.004 mg/mL of oxaliplatin related compound C in water, from *Oxaliplatin standard stock solution, Oxaliplatin related compound B standard stock solution,* and *Oxaliplatin related compound C standard stock solution*, respectively

Sample solution: 2 mg/mL of Oxaliplatin in water

Chromatographic system: Prepared as directed in the *Assay*.

Suitability requirements

Resolution: NLT 2.0 between oxaliplatin and oxaliplatin related compound C, *System suitability solution*

Tailing factor: Between 0.8 and 2.0 for oxaliplatin peak, *System suitability solution*

Relative standard deviation: NMT 3.0% for oxaliplatin, oxaliplatin related compound B, and oxaliplatin related compound C peaks, *Standard solution*

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of (*SP*-4-2)-diaqua[(1*R*,2*R*)-cyclohexane-1,2-diamine-*N*,*N*′]platinum in the portion of Oxaliplatin taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

r_U = response of (*SP*-4-2)-diaqua[(1*R*,2*R*)-cyclohexane-1,2-diamine-*N*,*N*′]platinum from the *Sample solution*

r_S = response of (*SP*-4-2)-diaqua[(1*R*,2*R*)-cyclohexane-1,2-diamine-*N*,*N*′]platinum from the *Standard solution*

C_S = concentration of USP Oxaliplatin Related Compound B RS in the *Standard solution* (mg/mL)

C_U = concentration of Oxaliplatin in the *Sample* (mg/mL)

M_{r1} = molecular weight of (*SP*-4-2)-diaqua[(1*R*,2*R*)-cyclohexane-1,2-diamine-*N*,*N*′]platinum, 345.30

M_{r2} = molecular weight of USP Oxaliplatin Related Compound B RS, 433.28

[NOTE—USP Oxaliplatin Related Compound B RS is converted to (*SP*-4-2)-diaqua[(1*R*,2*R*)-cyclohexane-1,2-diamine-*N*,*N*′]platinum in solution preparation.]

Calculate the percentage of oxaliplatin related compound C in the portion of Oxaliplatin taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = response of oxaliplatin related compound C from the *Sample solution*

r_S = response of oxaliplatin related compound C from the *Standard solution*

C_S = concentration of USP Oxaliplatin Related Compound C RS in the *Standard solution* (mg/mL)

C_U = concentration of Oxaliplatin in the *Sample solution* (mg/mL)

Calculate the percentage of the unspecified impurity diaquodiaminocyclohexaneplatinum dimer in the portion of Oxaliplatin taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times (1/F) \times 100$$

r_U = response of diaquodiaminocyclohexaneplatinum dimer from the *Sample solution*

r_S = response of oxaliplatin related compound B from the *Standard solution*

C_S = concentration of USP Oxaliplatin Related Compound B RS in the *Standard solution* (mg/mL)

C_U = concentration of Oxaliplatin in the *Sample solution* (mg/mL)

Total impurities: NMT 0.15%. [NOTE—Total impurities include oxalic acid, (*SP*-4-2)-diaqua[(1*R*,2*R*)-cyclohexane-1,2-diamine-*N*,*N*′]platinum, oxaliplatin related compound C, and the total unspecified impurities.]

• **PROCEDURE 3: LIMIT OF OXALIPLATIN RELATED COMPOUND D**

[NOTE—Use vigorous shaking and very brief sonication to dissolve the substance to be examined. Inject the *Sample solution* within 20 min of preparation. Polypropylene HPLC autosampler vials should be used.]

Mobile phase: Methanol and ethanol (7:3)

Oxaliplatin related compound D standard stock solution: 0.05 mg/mL of USP Oxaliplatin Related Compound D RS in methanol

Oxaliplatin related compound D standard solution: 15 µg/mL of USP Oxaliplatin Related Compound D RS in methanol, from *Oxaliplatin related compound D standard stock solution*

Oxaliplatin standard stock solution: 0.75 mg/mL of USP Oxaliplatin RS in methanol

Oxaliplatin standard solution: 37.5 µg/mL of USP Oxaliplatin RS in methanol, from *Oxaliplatin standard stock solution*

Standard solutions: Transfer 40 mL of *Oxaliplatin standard stock solution* to separate 50-mL volumetric flasks. Add 1.0, 3.0, and 5.0 mL of *Oxaliplatin related compound D standard solution* to each flask, and dilute with methanol to volume. The concentration of oxaliplatin in these solutions is 0.6 mg/mL. The concentration of oxaliplatin related compound D in these solutions is 0.3, 0.9, and 1.5 µg/mL, respectively.

System suitability solution: Transfer 5.0 mL of *Oxaliplatin standard solution* and 4.0 mL of *Oxaliplatin related compound D standard stock solution* to a 50-mL volumetric flask, and dilute with methanol to volume.

Sample solution: 0.6 mg/mL of Oxaliplatin in methanol

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

In-Process Revision

Mode: LC
Detector: UV 254 nm
Column: 4.6-mm × 25-cm column; 5-µm packing L70
Flow rate: 0.3 mL/min
Column temperature: 40°
Injection size: 20 µL
Run time: 30 min

System suitability
Samples: *System suitability solution* and the 0.9 µg/mL *Standard solution*
Suitability requirements
Resolution: NLT 1.5 between oxaliplatin and oxaliplatin related compound D, *System suitability solution*
Relative standard deviation: NMT 3.0% for peak height ratio of oxaliplatin related compound D to the sum of oxaliplatin and oxaliplatin related compound D, the 0.9 µg/mL *Standard solution*

Analysis
Samples: *Standard solutions* and *Sample solution*
Plot a calibration curve for the *Standard solutions* with the peak response ratios of oxaliplatin related compound D to the sum of oxaliplatin and oxaliplatin related compound D on the *y*-axis and the concentrations of oxaliplatin related compound D, in µg/mL, on the *x*-axis. Read the concentration of oxaliplatin related compound D, in µg/mL, in the *Sample solution* from the calibration curve obtained.
Calculate the percentage of oxaliplatin related compound D in the portion of Oxaliplatin taken:

$$\text{Result} = (C/W) \times 5$$

C = concentration of oxaliplatin related compound D in the *Sample solution* (mg/mL)
W = weight of Oxaliplatin taken to prepare the *Sample solution* (mg)

Acceptance criteria: NMT 0.10%

SPECIFIC TESTS

- **ACIDITY**
Sample solution: Dissolve 100 mg in 50 mL of carbon dioxide-free water, and add 0.5 mL of phenolphthalein TS.
Acceptance criteria: The solution is colorless, and NMT 0.6 mL of 0.01 M sodium hydroxide is required to change the color to pink.
- **BACTERIAL ENDOTOXINS TEST ⟨85⟩:** NMT 1.0 USP Endotoxin Unit/mg of Oxaliplatin

Change to read:

- **CONTENT OF PLATINUM**
Sample: Ignite an empty porcelain crucible fitted with a lid in a furnace at 800° for 30 min. Cool in a desiccator, and weigh. Add about 200 mg of the Oxaliplatin, weighed, to the crucible, and ignite in a furnace by stepwise increments as follows: introduce into the furnace; and increase the temperature to 200° within 15 min, then to 400° within 15 min, then to 600° within 15 min, then finally to 800° within 15 min. Allow to remain in the furnace at 800° for 30 min. Remove, cool in a desiccator, and reweigh.
Calculate the percentage of platinum in the portion of Oxaliplatin taken:

~~$\text{Result} = (D/W) \times 100$~~

~~D = difference between the net weights before and after the ignition (mg)~~
~~W = weight of oxaliplatin taken for determination (mg)~~

▲

$$\text{Result} = (W_2/W_1) \times 100$$

W_2 = weight of residue after ignition (mg)
W_1 = weight of oxaliplatin before ignition (mg)

▲*USP34*

Acceptance criteria: 48.1%–50.1% of the oxaliplatin taken, on the dried basis
- **LOSS ON DRYING ⟨731⟩:** Dry about 1 g at 100° to 105° for 2 h: it loses NMT 0.4% of its weight.
- **MICROBIAL ENUMERATION TESTS ⟨61⟩:** The total aerobic microbial count does not exceed 20 cfu/g, and the total combined molds and yeast count does not exceed 5 cfu/g.
- **OPTICAL ROTATION,** *Specific Rotation* **⟨781S⟩:** Between +74.5° and +78.0°, measured at 20°
Sample solution: 5 mg/mL, in water

BRIEFING

Paramethasone Acetate, *USP 32* page 3208;
Paramethasone Acetate Tablets, *USP 32* page 3209. It is proposed to omit these monographs from the *USP* for the following reasons.
1. All drug products containing paramethasone acetate have been discontinued in the United States.
2. The drug is currently not used in veterinary medicine in the United States.
3. USP has not been able to secure a viable source of the RS material.

(MD-PS: L. Santos, M. Waddell.) RTS—C77734

In-Process Revision

• **C. Thin-Layer Chromatography**

Standard solution: 2 mg/mL of USP Paramethasone Acetate RS in chloroform and methanol (1:1)

Sample solution: 2 mg/mL of Paramethasone Acetate in chloroform and methanol (1:1)

Chromatographic system

(See *Chromatography* ⟨621⟩, *Thin-Layer Chromatography*.)

Mode: TLC

Adsorbent: 0.25-mm layer of chromatographic silica gel mixture

Application volume: 10 µL

Developing solvent system: Methylene chloride, nitromethane, and glacial acetic acid (60:40:1)

Analysis

Samples: *Standard solution* and *Sample solution*

Develop the chromatogram until the solvent has moved about three-fourths of the length of the plate. Remove the plate, and air-dry for 15 min. Return the plate to the chamber, and develop again, in the same solvent system, until the solvent front has moved about three-fourths of the length of the plate. Remove the plate, mark the solvent front, and allow the solvent to evaporate. Locate the spots under short-wavelength UV light.

Acceptance criteria: The R_F value of the principal spot from the *Sample solution* corresponds to that from the *Standard solution.*

ASSAY

• **Procedure**

Standard solution: Prepare as directed for *Standard Preparation* under *Single-Steroid Assay* ⟨511⟩, using USP Paramethasone Acetate RS to prepare a solution containing 10 mg/mL.

Sample solution: 10 mg/mL of Paramethasone Acetate, previously dried, in alcohol and chloroform (1:1)

Analysis: Proceed as directed for *Procedure* under *Single-Steroid Assay* ⟨511⟩, applying 10 µL each of the *Sample solution* and the *Standard solution* to the chromatographic plate, and using a solvent system of methylene chloride, nitromethane, and glacial acetic acid (60:40:1). Proceed as directed through the fourth sentence of the second paragraph under *Procedure.* Centrifuge the tubes for 5 min, and determine the absorbances of the supernatants in 1-cm cells, at the wavelength of maximum absorbance at 242 nm, against the blank. Calculate the percentage of $C_{24}H_{31}FO_6$ in the portion of Paramethasone Acetate taken:

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times 100$$

A_U = absorbance of the *Sample solution*

A_S = absorbance of the *Standard solution*

C_S = concentration of USP Paramethasone Acetate RS in the *Standard solution* (mg/mL)

C_U = concentration of Paramethasone Acetate in the *Sample solution* (mg/mL)

Acceptance criteria: 95.0%–101.0% on the dried basis

SPECIFIC TESTS

• **X-Ray Diffraction** ⟨941⟩**:** The X-ray diffraction pattern of Paramethasone Acetate conforms to either one pattern or a mixture of the patterns shown in the accompanying table.

▲Paramethasone Acetate Tablets

DEFINITION

Paramethasone Acetate Tablets contain NLT 85.0% and NMT 115.0% of the labeled amount of $C_{24}H_{31}FO_6$.

IDENTIFICATION

• The IR absorption spectrum of the *Sample solution*, prepared as directed in the *Assay*, exhibits maxima only at the same wavelengths as that of the *Standard solution*, prepared as directed in the *Assay.*

In-Process Revision

~~**ASSAY**~~
~~• **PROCEDURE**~~
~~**Standard solution:** Transfer 6 mg of USP Paramethasone Acetate RS to a separator containing 15 mL of water, and proceed as directed under *Sample solution*, beginning with "Add 3 drops of hydrochloric acid".~~
~~**Sample solution:** Finely powder NLT 20 Tablets. Transfer a portion of the powder, equivalent to 6 mg of paramethasone acetate, to a separator containing 15 mL of water. Add 3 drops of hydrochloric acid, and heat on a steam bath for 5 min, mixing frequently. Cool the separator to room temperature, add 4 drops of sodium hydroxide solution (1 in 2), and immediately extract with four 25-mL portions of chloroform. Filter the extracts through anhydrous sodium sulfate, collecting the extracts in a beaker.~~
~~[**CAUTION—**Do not allow the filter paper to extend above the top of the funnel.]~~
~~Rinse the filter with several small portions of chloroform, add the rinsings to the beaker, and evaporate the chloroform on a steam bath with the aid of a current of air until about 3 mL remains. Transfer the residual liquid, with the aid of several small portions of chloroform, to a glass-stoppered, 10-mL conical flask, and evaporate on a steam bath with the aid of a current of air to dryness. Add 2.0 mL of chloroform to the flask, insert the stopper, and mix to dissolve the residue. Determine the absorbances of the solutions.~~
~~**Spectrometric conditions**~~
~~**Analytical wavelength:** IR 6.04 µm~~
~~**Cell:** 1 mm~~
~~**Blank:** Chloroform~~
~~**Analysis**~~
~~**Samples:** *Standard solution* and *Sample solution*~~
~~Calculate the percentage of $C_{24}H_{31}FO_6$ in the portion of Tablets taken:~~

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times 100$$

~~A_U = absorbance of the *Sample solution*~~
~~A_S = absorbance of the *Standard solution*~~
~~C_S = concentration of USP Paramethasone Acetate RS in the *Standard solution* (mg/mL)~~
~~C_U = nominal concentration of Paramethasone Acetate in the *Sample solution* (mg/mL)~~

~~**PERFORMANCE TESTS**~~
~~• **DISINTEGRATION** ⟨**701**⟩~~
~~[NOTE—The use of disks is being omitted.]~~
~~**Time:** 15 min~~
~~• **UNIFORMITY OF DOSAGE UNITS** ⟨**905**⟩**:** Meet the requirements~~
~~**Procedure for content uniformity**~~
~~**Sample solution:** Transfer 1 finely powdered Tablet to a 50-mL volumetric flask. Add 25 mL of chloroform, and shake by mechanical means for 15 min. Dilute with chloroform to volume and filter, discarding the first 20 mL of the filtrate. Dilute a portion of the subsequent filtrate, if necessary, with chloroform to obtain a solution containing 20 µg/mL of paramethasone acetate.~~
~~**Standard solution:** 20 µg/mL of USP Paramethasone Acetate RS in the same medium. Transfer 10.0 mL each of the *Sample solution* and the *Standard solution* to separate 25-mL volumetric flasks, and transfer 10 mL of chloroform to a third flask to provide the blank. To each flask add 3.0 mL of a 1-in-4000 solution of blue tetrazolium in alcohol and 5.0 mL of a 1-in-20 solution of tetramethylammonium hydroxide TS in alcohol, mixing after each addition. Fifteen min, accurately timed, after the addition of the last reagent, add 1 mL of glacial acetic acid to each flask, and dilute with chloroform to volume. Determine the absorbances of the solutions.~~
~~**Spectrometric conditions**~~
~~**Analytical wavelength:** UV 525 nm~~
~~**Cell:** 1 cm~~
~~**Blank:** Chloroform~~
~~Calculate the percentage of $C_{24}H_{31}FO_6$ in the Tablet taken:~~

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times 100$$

~~A_U = absorbance of the *Sample solution*~~
~~A_S = absorbance of the *Standard solution*~~
~~C_S = concentration of USP Paramethasone Acetate RS in the *Standard solution* (µg/mL)~~
~~C_U = nominal concentration of Paramethasone Acetate in the *Sample solution* (µg/mL)~~

~~**ADDITIONAL REQUIREMENTS**~~
~~• **PACKAGING AND STORAGE:** Preserve in well-closed containers.~~
~~• **USP REFERENCE STANDARDS** ⟨**11**⟩~~

BRIEFING

Pilocarpine Hydrochloride, *USP 32* page 3306 and page 1179 of *PF* 34(5) [Sept.–Oct. 2008]. On the basis of comments received, it is proposed to make the following changes:

1. The *Assay* and *Organic Impurities, Procedure 1* are revised to replace the current methods with a stability-indicating HPLC procedure. The liquid chromatographic procedure in the *Assay* and *Organic Impurities, Procedure 1* were based on analyses performed with the Phenomenex Luna Phenyl Hexyl brand of L11 column. The typical retention time reported for pilocarpine is about 6 min.
2. The *Acceptance criteria* in the *Assay* is revised from 98.5%–101.0% to 98.0%–102.0% to reflect the specification for the marketed, approved product.
3. The test for *Melting Range or Temperature* is deleted. This test was included in the original monograph when there was no selective method to quantify the impurities. The revised monograph contains an HPLC method; therefore, the *Melting Range or Temperature* test contributes no additional value in establishing the quality of the drug substance.
4. The temperature condition is added in *Packaging and Storage* for clarification.

(MD-OOD: F. Mao.) RTS—C73083

Pilocarpine Hydrochloride

$C_{11}H_{16}N_2O_2 \cdot HCl$ 244.72
2(3*H*)-Furanone, 3-ethyldihydro-4-[(1-methyl-1*H*-imidazol-5-yl)methyl]-, monohydrochloride, (3*S*-*cis*)-;
Pilocarpine monohydrochloride [54-71-7].

DEFINITION

Change to read:

Pilocarpine Hydrochloride contains NLT ~~98.5%~~▲98.0%▲*USP34* and NMT ~~101.0%~~▲102.0%▲*USP34* of $C_{11}H_{16}N_2O_2 \cdot HCl$, calculated on the dried basis.

BRIEFING

Quinidine Sulfate Oral Suspension, *USP 32* page 3465. On the basis of comments received, it is proposed to update the formula in the *Assay* to accommodate the dihydroquinidine contained in the Reference Standard.

(CRX: R. Schnatz.) RTS—C71345

Quinidine Sulfate Oral Suspension

DEFINITION

Quinidine Sulfate Oral Suspension contains NLT 90.0% and NMT 110.0% of the labeled amount of quinidine sulfate $[(C_{20}H_{24}N_2O_2)_2 \cdot H_2SO_4 \cdot 2H_2O]$. Prepare Quinidine Sulfate Oral Suspension 10 mg/mL as follows (see *Pharmaceutical Compounding—Nonsterile Preparations* ⟨795⟩).

Quinidine Sulfate	1 g
Vehicle: a mixture of Vehicle for Oral Solution (regular or sugar-free), *NF*, and Vehicle for Oral Suspension, *NF* (1:1)	A sufficient quantity
To make	100 mL

If using Quinidine Sulfate Tablets, place in a suitable mortar, and comminute into a fine powder, or add quinidine sulfate powder to the mortar. Add 15 mL of the Vehicle, and mix to a uniform paste. Add the Vehicle in small portions almost to volume, and mix thoroughly after each addition. Transfer the contents of the mortar to the calibrated bottle. Add sufficient Vehicle to volume, and mix well.

ASSAY

Change to read:

- **PROCEDURE**
  Solution A: Add 35.0 mL of methanesulfonic acid to 20.0 mL of glacial acetic acid, and dilute with water to 500 mL.
  Solution B: Dissolve 10.0 mL of diethylamine in water to obtain 100 mL of solution.
  Mobile phase: Acetonitrile, *Solution A, Solution B*, and water (10:1:1:40
  Standard solution: 100 µg/mL of USP Quinidine Sulfate RS, in *Mobile phase*
  Sample solution: Agitate the container of Oral Suspension for 30 min on a rotating mixer, remove a 5-mL sample, and store in a clear glass vial at –70° until analyzed. At the time of analysis, remove the sample from the freezer, allow it to reach room temperature, and mix on a vortex mixer for 30 s. Pipet 1.0 mL of the *Sample solution* into a 100-mL volumetric flask, and dilute with *Mobile phase* to volume.

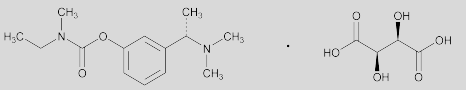
BRIEFING

Rivastigmine Tartrate. Because there is no existing *USP* monograph for this drug substance, a new monograph, based on validated methods of analysis, is being proposed. The liquid chromatographic procedures in the test for *Organic Impurities, Procedure 1* and in the *Assay* are based on analyses performed with the 5-µm Hypersil BDS C8 brand of L7 column. The typical retention times are about 10 min for rivastigmine and about 2 min for the tartrate. The liquid chromatographic procedure in the test for *Enantiomeric Purity* is based on analyses performed with the Chiral AGP brand of L41 column. The typical retention time for the rivastigmine peak is about 8.5 min.

(MD-GRE: E. Gonikberg.) RTS—C54956

Add the following:

▲Rivastigmine Tartrate



$C_{14}H_{22}N_2O_2 \cdot C_4H_6O_6$ 400.42
Ethylmethylcarbamic acid, 3-[(S)-1-(dimethylamino)ethyl]phenyl ester, (2*R*,3*R*)-2,3-dihydroxybutanedioate;
(*S*)-3-[1-(Dimethylamino)ethyl]phenyl ethylmethylcarbamate, hydrogen tartrate [129101-54-8].
Rivastigmine [123441-03-2].
250.34

DEFINITION
Rivastigmine Tartrate contains NLT 98.0% and NMT 102.0% of the labeled amount of $C_{14}H_{22}N_2O_2 \cdot C_4H_6O_6$, calculated on the anhydrous basis.

IDENTIFICATION
• **A. INFRARED ABSORPTION** ⟨**197K**⟩
• **B. IDENTIFICATION TESTS—GENERAL,** *Tartrate* ⟨**191**⟩**:** A solution containing about 4 mg/mL in methanol meets the requirements of the test for *Tartrate.*
• **C.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay.*

ASSAY
• **PROCEDURE**
Buffer: 8.6 mg/mL of monobasic ammonium phosphate. Adjust with ammonia solution to a pH of 7.0.

BRIEFING

Simethicone Emulsion, *USP 32* page 3555 and page 4099 of the *First Supplement*. Difficulties were reported in subtracting the blank toluene spectrum from the spectra for the *Standard solution* and *Sample solution* under *Identification*. On the basis of comments received, it is proposed to replace the current *Infrared Absorption* ⟨197S⟩ method based on the analysis of the toluene solutions with the method employing the attenuated total reflectance technique ⟨197A⟩.

(MD-GRE: E. Gonikberg.) RTS—C78862

Simethicone Emulsion

DEFINITION
Simethicone Emulsion is a water-dispersible form of Simethicone composed of Simethicone, suitable emulsifiers, preservatives, and water. It may contain suitable viscosity-increasing agents. It contains an amount of polydimethylsiloxane ($[-(CH_3)_2SiO-]_n$) that is NLT 85.0% and NMT 110.0% of the labeled amount of simethicone.

IDENTIFICATION

Delete the following:

▲• ~~**INFRARED ABSORPTION** ⟨**197S**⟩~~
~~[NOTE—Use the blank to set the instrument.]~~
~~**Cell:** 0.5 mm~~
~~**Blank:** Prepare as directed in the *Assay*.~~
~~**Standard solution:** Prepare as directed in the *Assay*.~~
~~**Sample:** Equivalent to 50 mg of simethicone from Emulsion~~
~~**Sample solution:** Prepare as directed in the *Assay*.~~
~~**Acceptance criteria:** The IR absorption spectrum exhibits maxima only at the same wavelengths as that of the *Standard solution*. [NOTE—If necessary, the dilute hydrochloric acid may be omitted to improve separation.]~~▲*USP34*

In-Process Revision

Add the following:

▲• **INFRARED ABSORPTION** ⟨197A⟩
[NOTE—Use the *Blank* to set the instrument.]
Blank, Standard solution, and **Sample solution:** Prepare as directed in the *Assay*.
Analysis: Place about 5 drops of the *Sample solution* in the sample trough, and dry it with a stream of nitrogen. Examine the spectrum in the range between 1400 cm^{-1} and 700 cm^{-1}.
Acceptance criteria: It exhibits maxima only at the same wavelengths as a similarly obtained spectrum of the *Standard solution.*▲*USP34*

ASSAY

• **PROCEDURE**
■[NOTE—Use glass apparatus only; avoid use of plasticware. Proper mixing of the Emulsion before sampling and testing is crucial.]■1S *(USP32)*
Standard solution: 2 mg/mL of USP Polydimethylsiloxane RS in toluene. [NOTE—Treat a 25.0-mL aliquot in the same manner as the *Blank*, beginning with "add 50 mL of dilute hydrochloric acid (2 in 5)…".]
Sample: Equivalent to 50 mg of simethicone from Emulsion
Sample solution: To the *Sample* add 25.0 mL of toluene, and treat in the same manner as the *Blank*, beginning with "add 50 mL of dilute hydrochloric acid (2 in 5)…".
Spectrometric conditions
Mode: IR spectrophotometry
Cell: 0.5 mm
Analytical wavelength: Maximum absorbance at about 7.9 µm ■(1259 cm^{-1})■1S *(USP32)*
Blank: To 25.0 mL of toluene add 50 mL of dilute hydrochloric acid (2 in 5), close the bottle securely with a cap having an inert liner, ■vigorously shake by hand for 5 s, and then shake for 5–20 min on a suitable shaker. [NOTE—The following shakers were found suitable: (1) a reciprocating shaker at a rate of about 200 oscillations/min and a stroke of 38 ± 2 mm or (2) a wrist-action shaker with a radius of 13.3 ± 0.4 cm (measured from center of shaft to center of bottle) using an arc of 10° at a frequency of 300 ± 30 strokes/min. The recommended shaking time is about 20 min, which can be adjusted as needed.] Centrifuge the mixture. [NOTE—The following centrifuging conditions were found suitable: at 1500 × g for 30–40 min.] Remove from the centrifuge, and immediately transfer about 5 mL of the upper organic (toluene) layer to a 15-mL screw-capped test tube, containing about 1 g of anhydrous sodium sulfate.■1S *(USP32)* Close the tube with a screw-cap having an inert liner, agitate vigorously, and centrifuge the mixture until a clear supernatant is obtained. ■[NOTE—The following centrifuging conditions were found suitable: at 1500 × g for about 10 min.]■1S *(USP32)*
Analysis
■[NOTE—Wash the cell with copious amounts of toluene, to ensure that there is no carryover or residue.]■1S *(USP32)*
Samples: *Standard solution*, *Sample solution*, and *Blank*
Calculate the percentage of $[–(CH_3)_2SiO–]_n$ in the Emulsion:

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times 100$$

A_U = absorbance of the *Sample solution*
A_S = absorbance of the *Standard solution*
C_S = concentration of USP Polydimethylsiloxane RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of simethicone in the *Sample solution* (mg/mL)

Acceptance criteria: 85.0%–110.0%

IMPURITIES
Inorganic Impurities
• **HEAVY METALS** ⟨231⟩
Standard solution: To 20 mL of chloroform add 1.0 mL of a freshly prepared 0.002% solution of dithizone in chloroform, 0.5 mL of *Standard Lead Solution* (see *Heavy Metals* ⟨231⟩) (containing 10 µg of lead/mL), and 0.5 mL of a mixture of 1 volume of ammonia TS and 9 volumes of a 0.2% solution of hydroxylamine hydrochloride.
Sample solution: 1.0 g of simethicone from Emulsion in 10 mL of chloroform. Dilute with the same solvent to 20 mL. Add 1.0 mL of a freshly prepared 0.002% solution of dithizone in chloroform, 0.5 mL of water, and 0.5 mL of a mixture of 1 volume of ammonia TS and 9 volumes of a 0.2% solution of hydroxylamine hydrochloride.
Analysis: Immediately shake both solutions vigorously for 1 min.
Acceptance criteria: NMT 5 ppm. Any red color in the *Sample solution* is not more intense than that in the *Standard solution*.

SPECIFIC TESTS
• **MICROBIAL ENUMERATION TESTS** ⟨61⟩ and **TESTS FOR SPECIFIED MICROORGANISMS** ⟨62⟩**:** The total aerobic microbial count does not exceed 100 cfu/g.
• **DEFOAMING ACTIVITY**
Foaming solution: 10 mg/mL of octoxynol 9 in water
Sample solution: Transfer a quantity of Emulsion, equivalent to 300 mg of simethicone, to a 60-mL bottle. Dilute with water to 30 g, cap the bottle, and shake vigorously.
Analysis: [NOTE—For each test, use a clean, unused, 250-mL glass jar.] Add, dropwise, 500 µL of the *Sample solution* to a clean, unused, cylindrical 250-mL glass jar, fitted with a 50-mm cap, containing 100 mL of the *Foaming solution*. Cap the jar, and clamp it in an upright position on a wrist-action shaker. Using a radius of 13.3 ± 0.4 cm (measured from the center of the shaft to the center of the bottle), shake for 10 s through an arc of 10° at a frequency of 300 ± 30 strokes/min. Record the time required for the foam to collapse. The time, in s, for foam collapse is determined at the instant the first portion of foam-free liquid surface appears, measured from the end of the shaking period.
Acceptance criteria: The defoaming activity time does not exceed 15 s.

ADDITIONAL REQUIREMENTS
• **PACKAGING AND STORAGE:** Preserve in tight containers.
• **USP REFERENCE STANDARDS** ⟨11⟩
USP Polydimethylsiloxane RS

BRIEFING

Sulfasalazine, *USP 32* page 3632 and page 4100 of the *First Supplement;* **Sulfasalazine Tablets,** *USP 32* page 3632 and page 4100 of the *First Supplement*. As part of monograph modernization, it is proposed to replace dimethylformamide (DMF), a possible carcinogenic solvent used in *Identification* test *B*, with the solvent mixture used for the *Sample solution* in the *Assay*. It is also proposed to use more diluted *Standard* and *Sample solutions* in *Identification* test *B* to minimize potential saturation of the spectra.

ASSAY
• **PROCEDURE**
Sample stock solution: 1.5 mg/mL of Sulfasalazine in 0.1 N sodium hydroxide
Sample solution: Transfer 5.0 mL of the *Sample stock solution* to a 1000-mL volumetric flask containing 750 mL of water, mix, add 20.0 mL of 0.1 N acetic acid, and dilute with water to volume.
Standard solution: 7.5 µg/mL of USP Sulfasalazine RS in the same medium as the *Sample solution*
Spectrometric conditions
(See *Spectrophotometry and Light-Scattering* ⟨851⟩.)
Mode: UV-Vis
Analytical wavelength: Maximum at about 359 nm
Blank: Water
Analysis
Samples: *Standard solution*, *Sample solution*, and *Blank*
Concomitantly determine the absorbances of the *Samples*. Calculate the percentage of $C_{18}H_{14}N_4O_5S$ in the portion of Sulfasalazine taken:

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times 100$$

A_U = absorbance of the *Sample solution*
A_S = absorbance of the *Standard solution*
C_S = concentration of USP Sulfasalazine RS in the *Standard solution* (µg/mL)
C_U = concentration of Sulfasalazine in the *Sample solution* (µg/mL)
Acceptance criteria: 97.0%–101.5% on the dried basis

IMPURITIES
Inorganic Impurities
• **RESIDUE ON IGNITION** ⟨**281**⟩**:** NMT 0.5%
• **CHLORIDE AND SULFATE,** *Chloride* ⟨**221**⟩
Analysis: Digest 2.0 g of Sulfasalazine with 100 mL of water at 70° for 5 min. Cool immediately to room temperature, and filter. Transfer a 25-mL portion of the filtrate to a 50-mL beaker (retain the remainder of this filtrate for the *Sulfate* test). Add 1 mL of nitric acid, mix, and allow to stand for 5 min. Pass through a fine texture, retentive filter paper (Whatman No. 42 or equivalent).
Acceptance criteria: The filtrate shows no more chloride than corresponds to 0.10 mL of 0.020 N hydrochloric acid (0.014%).
• **CHLORIDE AND SULFATE,** *Sulfate* ⟨**221**⟩**:**
Analysis: Transfer a 25-mL portion of the filtrate from the *Chloride* test to a 50-mL beaker. Add 1 mL of 3 N hydrochloric acid, mix, and allow to stand for 5 min. Pass through a fine texture, retentive filter paper (Whatman No. 42 or equivalent).
Acceptance criteria: The filtrate shows no more sulfate than corresponds to 0.20 mL of 0.020 N sulfuric acid (0.04%).
• **HEAVY METALS,** *Method II* ⟨**231**⟩**:** NMT 20 ppm
Organic Impurities
• **PROCEDURE**
Standard stock solution: 10 mg/mL of USP Sulfasalazine RS in a mixture of alcohol and 2 M ammonium hydroxide (4:1)
Standard solutions: Dilute aliquots of the *Standard stock solution* stepwise with the same medium to obtain solutions having concentrations of 200, 150, 100, and 20 µg/mL, corresponding to 2.0%, 1.5%, 1.0%, and 0.2%, respectively (*Standard solutions A, B, C,* and *D*).
Sample solution: 10 mg/mL of Sulfasalazine in a mixture of alcohol and 2 M ammonium hydroxide (4:1)
Chromatographic system
(See *Chromatography* ⟨621⟩*, Thin-Layer Chromatography*.)
Mode: TLC
Adsorbent: 0.25-mm layer of chromatographic silica gel mixture
Application volume: 10 µL
Developing solvent system: Chloroform, acetone, and formic acid (12:6:1)
Analysis
Samples: *Standard stock solution, Standard solutions,* and *Sample solution*
Proceed as directed in the chapter. Allow the spots to dry, and develop the chromatogram in an unequilibrated chamber until the solvent front has moved about three-fourths of the length of the plate. Remove the plate from the chamber, mark the solvent front, dry with the aid of a current of hot air, and examine the plate under short-wavelength UV light.
Acceptance criteria: The R_F value of the principal spot of the *Sample solution* corresponds to that of the *Standard stock solution*. No spots, other than the principal spot, in the chromatogram of the *Sample solution* are larger or more intense than the principal spot of *Standard solution A* (2%), and the sum of the intensities of any secondary spots detected does not exceed 4%.

SPECIFIC TESTS
• **LOSS ON DRYING** ⟨**731**⟩**:** Dry a sample at 105° for 2 h: it loses NMT 1.0% of its weight.

ADDITIONAL REQUIREMENTS
• **PACKAGING AND STORAGE:** Preserve in tight, light-resistant containers.
• **USP REFERENCE STANDARDS** ⟨**11**⟩

USP Sulfasalazine RS

BRIEFING

Terbinafine Hydrochloride, *USP* 32 Page 3677. On the basis of supporting validation data, it is proposed to replace the non-selective titration-based method in the *Assay* with a selective HPLC method. The liquid chromatographic procedures in the *Assay* are based on analyses performed with an Inertsil ODS-2 brand of L1 column. The typical retention time for terbinafine is 15.6 min. It is also proposed to revise the acceptance criteria in the *Assay* to reflect the change in the analytical technique and the revised limit for approved products. In the test for *Organic Impurities* it is proposed to use the USP Reference Standard for the *System suitability solution*. In addition, minor editorial changes consistent with USP monograph redesign format are proposed.

BRIEFING

Venlafaxine Tablets. Because there is no existing *USP* monograph for this drug product, a new monograph, based on validated methods of analyses, is being proposed. The liquid chromatographic procedure in the test for *Organic Impurities* is based on analyses performed with an Inertsil C8-3, brand of L7 column. The typical retention times for venlafaxine related compound A and venlafaxine are 14 and 15 min respectively. The liquid chromatographic procedure for the *Assay* is based on analyses performed with an ACE C18, brand of L1 column. The typical retention time for the venlafaxine peak is 5 min.

(MD-PP: H. Ramanathan, R. Ravichandran. BPC: M. Marques.)
RTS—C55365

Add the following:

▲Venlafaxine Tablets

DEFINITION

Venlafaxine Tablets contain NLT 90.0% and NMT 110.0% of the labeled amount of venlafaxine free base ($C_{17}H_{27}NO_2$).

IDENTIFICATION

• **A. ULTRAVIOLET ABSORPTION** ⟨**197U**⟩
Diluent: Methanol and 0.1 N hydrochloric acid (4:1)
Sample solution: Dissolve a quantity of finely powdered Tablets, equivalent to 75 mg of venlafaxine, with 200 mL of *Diluent*, then sonicate for 30 min. Dilute with *Diluent* to 250 mL. Centrifuge a portion at 4000 rpm for 10 min. Dilute a portion of the filtrate with *Diluent* to make an approximate 1-in-2.5 solution. Pass a portion through a suitable 0.45-µm membrane filter.
Wavelength range: 250–350 nm

• **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the test for *Organic Impurities*.

ASSAY

• **PROCEDURE**
Buffer: 3.4 g of potassium dihydrogen phosphate in 700 mL of water. Add 5 mL of triethylamine, and adjust with phosphoric acid to a pH of 3.0.
Diluent: Methanol and 0.1 N hydrochloric acid (4:1)
Mobile phase: Acetonitrile and *Buffer* (3:7)
Standard solution: 0.34 mg/mL of USP Venlafaxine Hydrochloride RS in *Diluent*
Sample solution: 0.3 mg/mL of venlafaxine in *Diluent* (from NLT 20 finely powdered Tablets). [NOTE—Sonicate for 30 min.] Centrifuge a portion at 4000 rpm for 10 min. Pass a portion of the supernatant through a 0.45-µm membrane filter.
Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: LC
Detector: UV 275 nm
Column: 4.6-mm × 25-cm; 5-µm packing L1
Flow rate: 1.0 mL/min
Injection size: 10 µL
Run time: 5 times the retention time of the venlafaxine peak
System suitability
Sample: *Standard solution*
Suitability requirements
Tailing factor: NMT 2.0
Relative standard deviation: NMT 2.0%
Analysis
Samples: *Standard solution* and *Sample solution*
Calculate the percentage of label claim of $C_{17}H_{27}NO_2$ in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

r_U = peak response of the *Sample solution*
r_S = peak response of the *Standard solution*
C_S = concentration of USP Venlafaxine Hydrochloride RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of venlafaxine in the *Sample solution* (mg/mL)
M_{r1} = molecular weight of venlafaxine, 277.40
M_{r2} = molecular weight of venlafaxine hydrochloride, 313.86
Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS

• **DISSOLUTION** ⟨**711**⟩
Medium: Water; 900 mL, deaerated
Apparatus 2: 50 rpm
Time: 30 min
Standard stock solution: 0.95 mg/mL of USP Venlafaxine Hydrochloride RS in methanol
Standard solution: 28.5 µg/mL of USP Venlafaxine Hydrochloride RS in *Medium* from the *Standard stock solution*
Sample solution: Pass a portion of the solution under test through a suitable 0.45-µm filter.
Detector: UV 275 nm
Path length: 1 cm
Blank: *Medium*
Calculate the percentage of venlafaxine dissolved:

$$\text{Result} = (A_U/A_S) \times (C_S/L) \times V \times (M_{r1}/M_{r2}) \times 100$$

In-Process Revision

A_U = absorbance obtained from the *Sample solution*
A_S = absorbance obtained from the *Standard solution*

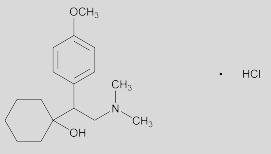
BRIEFING

Venlafaxine Hydrochloride. Because there is no existing *USP* monograph for this drug substance, a new monograph, based on validated methods of analyses is being proposed. The proposed liquid chromatographic procedure in the test for *Organic Impurities* is based on analyses performed with an Inertsil C8, brand of L7 column. The typical retention time for venlafaxine and venlafaxine related compound A is 7.6 and 8.2 min, respectively. The liquid chromatographic procedure for the *Assay* is based on analyses performed with an Kromasil 100 C8, brand of L7 column. The typical retention time under these conditions for venlafaxine is 5.3 min.

(MD-PP: H. Ramanathan, R. Ravichandran.) RTS—C67356

Add the following:

▲Venlafaxine Hydrochloride



$C_{17}H_{27}NO_2 \cdot HCl$ 313.86
Cyclohexanol, 1-[2-(dimethylamino)-1-(4-methoxyphenyl)ethyl]-, hydrochloride;
(±)-1-[α-[(Dimethylamino)methyl]-*p*-methoxybenzyl]cyclohexanol hydrochloride [99300-78-4].

In-Process Revision

DEFINITION

Venlafaxine Hydrochloride contains NLT 98.0% and NMT 102.0% of $C_{17}H_{27}NO_2 \cdot HCl$, calculated on the dried basis.

IDENTIFICATION

- **A. INFRARED ABSORPTION ⟨197K⟩**
- **B.** The retention time of the major peak on the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

In-Process Revision

BRIEFING

Water for Hemodialysis, *USP 32* page 3872. The AAMI guidelines for the quality of water used in hemodialysis operations have been commented by FDA for having high microbial and endotoxin specifications (200 cfu/mL and 2 EU/mL, respectively) that may not adequately protect hemodialysis patients. FDA has suggested the levels of 100 cfu/mL and 1 EU/mL as more appropriate. Though the USP monograph for *Water for Hemodialysis* has always included the tighter 100 cfu/mL microbial specification, it has an AAMI-consistent endotoxin specification. This proposed monograph revision decreases the endotoxin specification to be consistent with FDA opinions, thereby offering safer protection for hemodialysis patients. Because this water could be subject to microbial contamination from objectionable microorganisms that could endanger the health of acutely ill hemodialysis patients, a requirement for the absence of the opportunistic pathogen *Pseudomonas aeruginosa* is an appropriate requirement for this water. The deletion of the *Oxidizable Substances* test, as an alternative to *Total Organic Carbon* ⟨643⟩ testing, is also proposed, consistent with other bulk waters.

(PW: A. Hernandez-Cardoso.) RTS—C79382

Water for Hemodialysis

DEFINITION

Water for Hemodialysis is water that complies with the U.S. Environmental Protection Agency National Primary Drinking Water Regulations and that has been subjected to further treatment, using a suitable process, to reduce chemical and microbiological components. It is produced and used onsite under the direction of qualified personnel. It contains no added antimicrobials and is not intended for injection.

DIETARY SUPPLEMENTS—MONOGRAPHS

BRIEFING

Calcium with Vitamin D Tablets, *USP 32* page 968. In order to clarify an interpretation of acceptance criteria for dissolution testing, it is proposed to eliminate the symbol Q, as the amount of dissolved active ingredient expressed as a percentage of the labeled content of the dosage unit, from the *Tolerances* section. The Q value is applicable for interpretation of the dissolution tests, which are performed as directed under *Dissolution* ⟨711⟩.

(DS-PS: Natalia Davydova.) RTS—C78870

Calcium with Vitamin D Tablets

DEFINITION

Calcium with Vitamin D Tablets contain NLT 90.0% and NMT 125.0% of the labeled amount of calcium (Ca), derived from substances generally recognized as safe, and NLT 90.0% and NMT 165.0% of the labeled amount of Vitamin D, as cholecalciferol ($C_{27}H_{44}O$) or ergocalciferol ($C_{28}H_{44}O$). They contain no other vitamins or minerals for which nutritional value is claimed. They may contain other labeled added substances or additional ingredients in amounts that are unobjectionable.

STRENGTH

- **CALCIUM**

[NOTE—A commercially available atomic absorption standard solution for calcium may be used where preparation of a *Calcium standard stock solution* is described in the following assay. Concentrations of the *Standard solutions* and the *Sample stock solution* may be modified to fit the linear or working range of the instrument.]

Solution A: Dissolve 26.7 g of lanthanum chloride in 0.125 N hydrochloric acid to make 100 mL.

Calcium standard stock solution: Weigh 1.001 g of calcium carbonate, previously dried at 300° for 3 h and cooled in a desiccator for 2 h, and dissolve in 25 mL of 1 N hydrochloric acid. Boil to expel carbon dioxide, and dilute with water to 1000 mL to obtain a solution having a concentration of 400 µg/mL of calcium.

Standard stock solution: 100 µg/mL of calcium from a volume of *Calcium standard stock solution* in 0.125 N hydrochloric acid

Standard solutions: Into separate 100-mL volumetric flasks, separately pipet 1.0, 1.5, 2.0, 2.5, and 3.0 mL of the *Standard stock solution*. To each flask add 1.0 mL of *Solution A*, dilute with water to volume, and obtain *Standard solutions* having concentrations of 1.0, 1.5, 2.0, 2.5, and 3.0 µg/mL, of calcium.

Sample stock solution: Weigh and finely powder NLT 20 Tablets. Transfer the equivalent to 500 mg of calcium, in 25 mL of concentrated hydrochloric acid, and heat for 30 min on a steam bath. Cool, dilute with water to 1000 mL, and filter.

Sample solution: Quantitatively dilute a volume of *Sample stock solution* with 0.125 N hydrochloric acid to obtain a concentration of 100 µg/mL of calcium. Transfer 2.0 mL of this solution to a 100-mL volumetric flask, add 1.0 mL of *Solution A*, and dilute with water to volume.

Spectrometric conditions

(See *Spectrophotometry and Light-scattering* ⟨851⟩.)

Mode: Atomic absorption spectrophotometer
Lamp: Calcium hollow-cathode
Flame: Nitrous oxide–acetylene
Analytical wavelength: Calcium emission line, 422.7 nm
Blank: 0.125 N hydrochloric acid containing 0.1% *Solution A*

Analysis

Samples: *Standard solutions* and *Sample solution*

Determine the absorbances of both the solutions, using the blank. Plot the absorbances of the *Standard solution*s versus concentration, in µg/mL, of calcium, and draw the straight line best fitting the five plotted points. From the graph so obtained, determine the concentration, in µg/mL, of calcium in the *Sample solution*.

Calcium in the portion of Tablets taken:

$$\text{Result} = C \times V \times D \times F_1 \times (100/L)$$

C = concentration of calcium in the *Sample solution* (µg/mL)
V = volume of the *Sample solution*, 1000 mL
D = dilution factor involved in the *Sample solution*
F_1 = conversion factor, 0.001 mg/µg
L = label claim (mg)

Acceptance criteria: 90.0%–125.0%

- **CHOLECALCIFEROL OR ERGOCALCIFEROL (VITAMIN D)**

[NOTE—Use low-actinic glassware throughout this procedure.]

Mobile phase: *n*-Hexane and isopropyl alcohol (99:1)

Standard solution: 2 µg/mL of USP Ergocalciferol RS or USP Cholecalciferol RS in *n*-hexane

System suitability solution: Heat a volume of *Standard solution* at 60° for 1 h to partially isomerize vitamin D (ergocalciferol or cholecalciferol) to its corresponding precursor.

Sample solution: Weigh, and grind NLT 20 Tablets. Transfer the equivalent to 20 µg of cholecalciferol or ergocalciferol to a container having a polytef-lined screw cap. Add 8 mL of dimethyl sulfoxide and 12 mL of *n*-hexane, and shake for 45 min on a wrist-action shaker with tubes in a water bath maintained at 60°. Centrifuge for 10 min, withdraw the hexane layer by means of a pipet, and transfer to an evaporation flask. Add 12 mL of *n*-hexane to the dimethyl sulfoxide layer, mix on a vortex mixer for 5 min, and again withdraw the hexane layer by means of a pipet, and add to the evaporation flask. Repeat this extraction with three additional 12-mL portions of *n*-hexane, adding the hexane extracts to the evaporation flask. Evaporate the combined hexane extracts in vacuum at room temperature to dryness. Dissolve in and dilute the residue in a volume of *n*-hexane to obtain a concentration of 2 µg/mL.

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

Mode: LC
Detector: UV 265 nm
Column: 4.6-mm × 15-cm; 5-µm packing L8
Flow rate: 1 mL/min
Injection size: 100 µL

System suitability

Samples: *Standard solution* and *System suitability solution*

Suitability requirements

Resolution: NLT 10 between the vitamin D form present and its corresponding precursor, *System suitability solution*

Relative standard deviation: NMT 3.0%, *Standard solution*

Analysis

Samples: *Sample solution* and *Standard solution*

Measure the responses for the vitamin D peaks. Calculate the percentage of $C_{27}H_{44}O$ or $C_{28}H_{44}O$ in the Tablets taken:

$$\text{Result} = 1.09 \times (r_U/r_S) \times (C_S/C_U) \times (100)$$

1.09 = correction factor to account for the average amount of previtamin D present in the formulation
r_U = peak heights for cholecalciferol or ergocalciferol from the *Sample solution*

In-Process Revision

r_S = peak heights for cholecalciferol or ergocalciferol from the *Standard solution*
C_S = concentration of USP Ergocalciferol RS or USP Cholecalciferol RS in the *Standard solution* (mg/mL)
C_U = nominal concentration of ergocalciferol or cholecalciferol in the *Sample solution* (mg/mL)

Acceptance criteria: 90.0%–165.0%

PERFORMANCE TESTS

Change to read:

• **DISINTEGRATION AND DISSOLUTION OF DIETARY SUPPLEMENTS** ⟨**2040**⟩**:** Meet the requirements for *Dissolution* with respect to calcium

Medium: 0.1 N hydrochloric acid; 900 mL
Apparatus 2: 75 rpm
Time: 30 min
Analysis: Determine the amount of calcium (Ca) dissolved, using the procedure in the assay for *Calcium*, making any necessary volumetric adjustments.
Tolerances: NLT 75% ~~(Q)~~▲*USP34* of the labeled amount of Ca is dissolved.

• **WEIGHT VARIATION OF DIETARY SUPPLEMENTS** ⟨**2091**⟩**:** Meet the requirements

SPECIFIC TESTS

• **MICROBIAL ENUMERATION TESTS—NUTRITIONAL DIETARY SUPPLEMENTS** ⟨**2021**⟩**:** The total aerobic microbial count does not exceed 3000 cfu/g, and the total combined molds and yeasts count does not exceed 300 cfu/g. Tablets also meet the requirements of the tests for absence of *Salmonella* species and *Escherichia coli*, and for absence of *Staphylococcus aureus*.

ADDITIONAL REQUIREMENTS

• **PACKAGING AND STORAGE:** Preserve in tight, light-resistant containers.
• **LABELING:** The label states that the product is *Calcium with Vitamin D Tablets*. The label states also the quantities of calcium and Vitamin D in terms of metric units/Tablet, and the salt form of calcium and the chemical form of Vitamin D present in the Tablet.
• **USP REFERENCE STANDARDS** ⟨**11**⟩
USP Cholecalciferol RS
USP Ergocalciferol RS

BRIEFING

Excipients, USP and NF Excipients, Listed by Category, *NF 27* page 1143, page 4022 of the *First Supplement*, and page 1197 of *PF* 35(5) [Sept.–Oct. 2009]. It is proposed to add *Butyl Stearate* to the *Emollient* category to complement the proposed new monograph for *Butyl Stearate*, which appears elsewhere in this issue of *PF*.

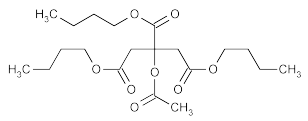
NF MONOGRAPHS

BRIEFING

Acetyltributyl Citrate, *NF 27* page 1153; **Triethyl Citrate,** *NF 27* page 1371. On the basis of comments and data received, it is proposed to revise the methods in the *Assay* sections for Acetyltributyl Citrate and Triethyl Citrate. Reports have indicated that the current method fails to separate the acetyltributyl citrate, tributyl citrate, triethyl citrate, and acetyltriethyl citrate peaks. Also, in the test for *Acidity*, it is proposed to add the preparation for neutralized isopropyl alcohol and to clarify the procedure.

(EM1: R. Lafaver.) RTS—C45943

Acetyltributyl Citrate



$C_{20}H_{34}O_8$ 402.48

DEFINITION
Acetyltributyl Citrate contains NLT 99.0% of $C_{20}H_{34}O_8$, calculated on the anhydrous basis.

IDENTIFICATION
- **A. INFRARED ABSORPTION** ⟨**197F**⟩
- **B.** The retention time of the *Sample solution* corresponds to that of a similar preparation of USP Acetyltriethyl Citrate RS, as obtained in the *Assay*.

• **USP REFERENCE STANDARDS** ⟨**11**⟩
USP Acetyltributyl Citrate RS
USP Tributyl Citrate RS

BRIEFING

Benzalkonium Chloride, *NF 27* page 1173 and page 1012 of *PF* 34(4) [July–Aug. 2008]. On the basis of comments and data received and to align with the newly revised Benzalkonium Chloride monograph in the *European Pharmacopoeia, 6th Edition*, it is proposed to make the following revisions:

1. Add *Identification* test *D* based on peak identification and using USP Benzalkonium Chloride RS in the test for *Ratio of Alkyl Components*.
2. A requirement for column efficiency as part of the system suitability is deleted in the test for *Ratio of Alkyl Components*. An alternative analytical column, Alltech Nucleosil 100CN 4.6-mm × 25-cm, may also be used in this test. Calculation is revised for clarification.
3. The *Assay, Procedure 2: Total Alkylbenzyldimethylammonium Chlorides* is updated by introducing the addition of 0.1 N sodium hydroxide to help further titration, and by replacing chloroform with methylene chloride to improve occupational safety.
4. The test for *Limit of Benzyl Alcohol, Benzaldehyde, and (Chloromethyl)benzene* in *Organic Impurities* is proposed based on analysis performed using a Macherey-Nagel Nucleosil 100-5 C18 column. Benzyl alcohol, benzaldehyde, and (chloromethyl)benzene elute at approximately 10, 13, and 24 min, respectively, on this system.
5. Add USP Benzyl Alcohol RS and USP Benzaldehyde RS in the *USP Reference Standards* section. These reference standards are used in the newly proposed test for *Limit of Benzyl Alcohol, Benzaldehyde, and (Chloromethyl)benzene.*

(EM2: H. Wang.) RTS—C67223

Benzalkonium Chloride

Ammonium, alkyldimethyl(phenylmethyl)-, chloride; Alkylbenzyldimethylammonium chloride [8001-54-5].

DEFINITION
Benzalkonium Chloride is a mixture of alkylbenzyldimethylammonium chlorides of the general formula:

$$[C_6H_5CH_2N(CH_3)_2R]Cl$$

in which R represents a mixture of alkyls, including all or some of the group beginning with *n*-C_8H_{17} and extending through higher homologs, with *n*-$C_{12}H_{25}$, *n*-$C_{14}H_{29}$, and *n*-$C_{16}H_{33}$ composing the major portion. On the anhydrous basis, the content of the *n*-$C_{12}H_{25}$ homolog is NLT 40.0%, and the content of the *n*-$C_{14}H_{29}$ homolog is NLT 20.0% of the total alkylbenzyldimethylammonium chloride content. The amount of the *n*-$C_{12}H_{25}$ and *n*-$C_{14}H_{29}$ homolog components together is NLT 70.0% of the total alkylbenzyldimethylammonium chloride content. The total alkylbenzyldimethylammonium chloride content, calculated on the anhydrous basis, with allowance made for the amount of residue on ignition, is NLT 97.0% and NMT 103.0% of $[C_6H_5CH_2N(CH_3)_2R]Cl$.

IDENTIFICATION

Change to read:

• **A. ■PROCEDURE**
Analysis: To 2 mL of a solution (1 in 100) add 1 mL of 2 N nitric acid.
Acceptance criteria: A white precipitate is formed, and it is dissolved after adding 5 mL of alcohol.■2S (*NF27*)
• **B. PROCEDURE**
Analysis: Dissolve 200 mg in 1 mL of sulfuric acid, add 100 mg of sodium nitrate, and heat on a steam bath for 5 min. Cool, dilute with water to 10 mL, add 500 mg of zinc dust, and warm for 5 min on a steam bath. To 2 mL of the clear supernatant, add 1 mL of sodium nitrite solution (1 in 20), cool in ice water, and then add 3 mL of a solution of 500 mg of 2-naphthol in 10 mL of 6 N ammonium hydroxide.
Acceptance criteria: An orange-red color is produced.
• **C. IDENTIFICATION TESTS—GENERAL,** *Chloride* ⟨**191**⟩**:** The solution in a mixture of equal volumes of water and alcohol meets the requirements of the tests.

Add the following:

▲• **D.** The retention times of the major peaks for benzalkonium chloride in the *Sample solution* correspond to those of the *Standard solution*, as obtained in the test for *Ratio of Alkyl Components.*▲*NF29*

ASSAY

Change to read:

• **PROCEDURE 1: RATIO OF ALKYL COMPONENTS**
Solution A: Adjust a 0.1 M solution of sodium acetate with glacial acetic acid to a pH of 5.0.
Mobile phase: Acetonitrile and *Solution A* (9:11). Acetonitrile and *Solution A* may be adjusted from (2:3) to (3:2) to meet system suitability requirements.
Standard solution: 4 mg/mL of USP Benzalkonium Chloride RS
Sample solution: 4 mg/mL of Benzalkonium Chloride
Chromatographic system
(See *Chromatography* ⟨621⟩*, System Suitability*.)
Mode: LC
Detector: UV 254 nm

~~**Column efficiency:** NLT 1000 theoretical plates from the C_{12} peak~~
▲▲*NF29*

In-Process Revision

Relative standard deviation: NMT 2.0% for the C_{12} peak

Analysis

Samples: *Standard solution* and *Sample solution*

Identify the homolog peaks by comparison of the retention times with those from the *Standard solution*.

~~Calculate the percentage of each quaternary ammonium homolog taken:~~

~~$$\text{Result} = (A/B) \times 100$$~~

~~A = product of the area obtained from the homolog multiplied by its molecular weight~~

~~B = sum of all of these products~~

~~The molecular weights of C_{10}, C_{12}, C_{14}, and C_{16} are 312, 340, 368, and 396, respectively.~~

▲Calculate the percentage of each quaternary ammonium homolog taken:

$$\text{Result} = \frac{r_U \times M_r}{\sum_i (r_U \times M_r)} \times 100$$

r_U = area of the peak due to a given homolog in the chromatogram from the *Sample solution*

M_r = molecular weight of a given homolog. The molecular weights of C_{10}, C_{12}, C_{14}, and C_{16} homologs are 312, 340, 368, and 396, respectively.

▲*NF29*

Acceptance criteria: On the anhydrous basis, the content of the *n*-$C_{12}H_{25}$ homolog is NLT 40.0%, and the content of the *n*-$C_{14}H_{29}$ homolog is NLT 20.0% of the total alkylbenzyldimethylammonium chloride content. The amount of the *n*-$C_{12}H_{25}$ and *n*-$C_{14}H_{29}$ homolog components together is NLT 70.0% of the total alkylbenzyldimethylammonium chloride content.

Change to read:

• **PROCEDURE 2: TOTAL ALKYLBENZYLDIMETHYLAMMONIUM CHLORIDES**

~~**Analysis:** Weigh a quantity of Benzalkonium Chloride equivalent to about 500 mg of anhydrous benzalkonium chloride, and transfer, with the aid of 35 mL of water, to a glass-stoppered, 250-mL conical separator containing 25 mL of chloroform. Add 10.0 mL of freshly prepared potassium iodide solution (1 in 20), insert the stopper in the separator, shake, allow the layers to separate, and discard the chloroform layer. Wash the aqueous layer with three 10-mL portions of chloroform, and discard the washings. Transfer the aqueous layer to a glass-stoppered, 250-mL conical flask, and rinse the separator with three 5-mL portions of water, adding the washings to the flask. Add 40 mL of cold hydrochloric acid to the flask, mix, and titrate the with 0.05 M potassium iodate VS until the solution becomes light brown in color. Add 5 mL of chloroform, insert the stopper into the flask, and shake vigorously. Continue the titration, dropwise, with shaking after each addition, until the chloroform layer becomes colorless and the aqueous layer is clear yellow. Perform a blank determination, using 20 mL of water as the sample. The difference between the two titrations represents the amount of potassium iodate equivalent to the weight of benzalkonium chloride in the sample. Each mL of 0.05 M potassium iodate is equivalent to X/10 mg of benzalkonium chloride, where X represents the average molecular weight of the sample, derived by summing, for all homologs, the products:~~

~~$$\text{Result} = (A/B) \times M_r$$~~

~~A = area of the peak produced by that homolog in the chromatogram from the *Ratio of alkyl components* test~~

~~B = total peak area for all homologs in that chromatogram from the *Ratio of alkyl components* test~~

~~M_r = molecular weight of a given homolog~~

▲**Sample:** Weigh a quantity of Benzalkonium Chloride equivalent to 500 mg of anhydrous benzalkonium chloride.

Analysis: Transfer the *Sample*, with the aid of 35 mL of water, to a glass-stoppered, 250-mL conical separator containing 25 mL of methylene chloride. Add 10 mL of 0.1 N sodium hydroxide, and 10.0 mL of freshly prepared potassium iodide solution (1 in 20), insert the stopper into the separator, shake, allow the layers to separate, and discard the methylene chloride layer. Wash the aqueous layer with three 10-mL portions of methylene chloride, and discard the washings. Transfer the aqueous layer to a glass-stoppered, 250-mL conical flask, and rinse the separator with three 5-mL portions of water, adding the washings to the flask. Add 40 mL of cold hydrochloric acid to the flask, mix, and titrate with 0.05 M potassium iodate VS until the solution becomes light brown in color. Add 5 mL of methylene chloride, insert the stopper into the flask, and shake vigorously. Continue the titration, dropwise, with shaking after each addition, until the methylene chloride layer becomes colorless and the aqueous layer is clear yellow. Record the titrant volume, V_t (mL). Perform a blank determination, using 20 mL of water as the sample, and record the titrant volume, V_b (mL). [NOTE—$V_b > V_t$.] The difference between the two titrations represents the amount of potassium iodate equivalent to the weight of benzalkonium chloride in the sample. Each mL of 0.05 M potassium iodate is equivalent to x/10 mg of benzalkonium chloride, where x represents the average molecular weight of the sample, derived by summing, for all homologs, the products:

$$\text{Result (x)} = \sum_i \left[(r_U / r_T) \times M_r \right]$$

r_U = area of the peak produced by a given homolog in the chromatogram from the *Ratio of Alkyl Components* test

r_T = sum of the peak areas for all homologs in the chromatogram from the *Ratio of Alkyl Components* test

M_r = molecular weight of a given homolog. The molecular weights of the C_{10}, C_{12}, C_{14}, and C_{16} homologs are 312, 340, 368, and 396, respectively.

■• **PROCEDURE 1: LIMIT OF AMINES AND AMINE SALTS**

Sample: 5.0 g of Benzalkonium Chloride

Analysis and **Acceptance criteria:** Dissolve the *Sample* with heating ▲carefully on top of a steam bath with water as the steam source▲*NF29* in 20 mL of a mixture of methanol and 1 N hydrochloric acid VS (97:3). ▲[NOTE—However, the mixed solution must not reach the boiling point.]▲*NF29* Add 100 mL of isopropyl alcohol. Pass a stream of nitrogen slowly through the solution. Gradually add 12.0 mL of 0.1 N tetrabutylammonium hydroxide VS, while recording the potentiometric titration curve. If the curve shows two inflection points, the volume of titrant added between the two points is NMT 5.0 mL, corresponding to NMT 0.1 mmol/g of amines and amine salts. If the curve shows no point of inflection, the substance being examined does not comply with the test. If the curve shows one point of inflection, repeat the test, but add 3.0 mL of a 25.0 mg/mL solution of dimethyldecylamine in isopropyl alcohol before the titration. If after addition of 12.0 mL of the titrant, the titration curve shows only one point of inflection, the substance being examined does not comply with the test.■2S *(NF27)*

▲• **PROCEDURE 2: LIMIT OF BENZYL ALCOHOL, BENZALDEHYDE, AND (CHLOROMETHYL)BENZENE**

[NOTE—Prepare the solutions immediately before use.]

Solution A: Dissolve 1.09 g of sodium 1-hexanesulfonate and 6.9 g of monobasic sodium phosphate in water in a 1000-mL volumetric flask, adjust to pH 3.5 with phosphoric acid, and dilute with water to volume.

Solution B: Methanol

Mobile phase: See the gradient table below.

Time (min)	Solution A (%)	Solution B (%)
0	80	20
10	80	20
14	50	50
35	50	50
36	20	80
55	20	80
56	80	20
65	80	20

Standard solution A: 0.25 mg/mL of USP Benzyl Alcohol RS in methanol

Standard solution B: 0.075 mg/mL of USP Benzaldehyde RS in methanol

Standard solution C: 0.025 mg/mL of USP Benzyl Alcohol RS in methanol, prepared from *Standard solution A* and methanol

Sample solution: 50 mg/mL of Benzalkonium Chloride in methanol

Chromatographic system

(See *Chromatography* ⟨621⟩, *System Suitability*.)

Mode: LC

Detector: UV 210 nm for benzyl alcohol and (chloromethyl)benzene; UV 257 nm for benzaldehyde

Column: 4.6-mm × 15-cm analytical column; 5-µm packing L1

Column temperature: 30°

Flow rate: 1.0 mL/min

Injection size: 20 µL

System suitability

Samples: *Standard solution A*, *Standard solution B*, *Standard solution C*, and *Sample Solution*

[NOTE—See the relative retention times in the table below.]

Component	Relative Retention Time (RRT)
Benzyl alcohol	1.0
Benzaldehyde	1.3
(Chloromethyl)benzene	2.4

Suitability requirements

Relative standard deviation: NMT 5.0% for the benzyl alcohol peak obtained from *Standard solution A*

Signal-to-noise ratio: NLT 10 for the principal peak in the chromatogram from *Standard solution C*

Analysis

Samples: *Standard solution A*, *Standard solution B*, *Standard solution C*, and *Sample solution*

To calculate the content of (chloromethyl)benzene, multiply the peak area of (chloromethyl)benzene by 0.7.

Acceptance criteria

Benzyl alcohol: The response of the benzyl alcohol peak from the *Sample solution* is NMT that of the benzyl alcohol peak from the *Standard solution A*, corresponding to NMT 0.5%.

Benzaldehyde: The response of the benzaldehyde peak from the *Sample solution* is NMT that of the benzaldehyde peak from *Standard solution B*, corresponding to NMT 0.15%.

(Chloromethyl)benzene: The response of the (chloromethyl)benzene peak from the *Sample solution* is NMT 0.1 times that of the principal peak in the chromatogram from *Standard solution A*, corresponding to NMT 0.05%.▲*NF29*

USP Benzaldehyde RS▲*NF29*

In-Process Revision

BRIEFING

Benzalkonium Chloride Solution, *NF 27* page 1174. On the basis of comments and data received and to align with the newly revised Benzalkonium Chloride Solution monograph in the *European Pharmacopoeia, 6th Edition*, it is proposed to make the following revisions:

1. *Identification* test *A* is updated and modified to omit the use of mercuric chloride TS.
2. Add *Identification* test *D* based on peak identification and using USP Benzalkonium Chloride RS in the test for *Ratio of Alkyl Components*.
3. A requirement for column efficiency as part of the system suitability is deleted in the test for *Ratio of Alkyl Components*. An alternative analytical column, Alltech Nucleosil 100CN 4.6-mm × 25-cm, may also be used in this test. Calculation is revised for clarification.
4. The *Assay, Procedure 2: Total Alkylbenzyldimethylammonium Chlorides* is updated by introducing the addition of 0.1 N sodium hydroxide to help further titration, and by replacing chloroform with methylene chloride to improve occupational safety.
5. The test for *Limit of Benzyl Alcohol, Benzaldehyde, and (Chloromethyl)benzene* in *Organic Impurities* is proposed based on the analysis performed using a Macherey-Nagel Nucleosil 100-5 C18 column. Benzyl alcohol, benzaldehyde, and (chloromethyl)benzene elute at approximately 10, 13, and 24 min, respectively, on this system.
6. Add a test for *Acidity or Alkalinity*.
7. Add a test for *Limit of Amines and Amine Salts* to replace the test for odor perception in *Limit of Foreign Amines*.
8. On the basis of the submitted method, the test for *Alcohol Determination* is replaced by a procedure using gas chromatography. This test is based on analyses performed with the J&W Scientific DB-624 brand of G43 column. The typical retention times for alcohol and tertiary butyl alcohol are 4.8 and 7.0 min, respectively.
9. Add a *Labeling* section to indicate the concentration of benzalkonium chloride, and the name and quantity of coloring agent added. The labeling should also indicate the concentration of alcohol.
10. Add USP Alcohol RS, USP Benzyl Alcohol RS, and USP Benzaldehyde RS in the *USP Reference Standards* section. These reference standards are used in the updated test for *Alcohol Content* and in the newly proposed test for *Limit of Benzyl Alcohol, Benzaldehyde, and (Chloromethyl)benzene.*

Other changes are editorial in nature.

(EM2: H. Wang.) RTS—C68683

Benzalkonium Chloride Solution

DEFINITION

Change to read:

Benzalkonium Chloride Solution contains NLT 95.0% and NMT 105.0% of the labeled amount of benzalkonium chloride in ~~concentrations of 1.0% or more~~▲solution that has a concentration of 1.0% or more;▲NF29 and NLT 93.0% and NMT 107.0% of the labeled amount ~~in concentrations of less than 1.0%~~▲in solution that has a concentration of less than 1.0%.▲NF29 It may contain a suitable coloring agent and may contain NMT 10% of alcohol.

[**CAUTION–**Mixing Benzalkonium Chloride Solution with ordinary soaps and with anionic detergents may decrease or destroy the bacteriostatic activity of the Solution.]

IDENTIFICATION

Change to read:

• **A. ▲PROCEDURE▲NF29** ~~Add 2 N nitric acid or mercuric chloride TS to a solution having an equivalent to 10 mg/mL of benzalkonium chloride. A white precipitate is formed, and it is soluble in alcohol.~~

▲Analysis: Add 1 mL of 2 N nitric acid to 2 mL of a solution having an equivalent to 10 mg/mL of benzalkonium chloride.

Acceptance criteria: A white precipitate is formed, and it is dissolved after adding 5 mL of alcohol.▲NF29

• **B. IDENTIFICATION TESTS—GENERAL,** *Chloride* ⟨**191**⟩**:** A solution of it in a mixture of equal volumes of water and alcohol meets the requirements.

• **C. PROCEDURE**

Analysis: Dissolve the residue obtained by evaporating, on a steam bath, a volume of Solution equivalent to 200 mg of benzalkonium chloride in 1 mL of sulfuric acid, add 100 mg of sodium nitrate, and heat on a steam bath for 5 min. Cool, dilute with water to 10 mL, add 500 mg of zinc dust, and warm for 5 min on a steam bath. To 2 mL of the clear supernatant add 1 mL of sodium nitrite solution (1 in 20), cool in ice water, then add 3 mL of a solution of 500 mg of 2-naphthol in 10 mL of 6 N ammonium hydroxide.

Acceptance criteria: An orange-red color is produced.

Add the following:

▲• **D.** The retention times of the major peaks for benzalkonium chloride in the *Sample solution* correspond to those of the *Standard solution*, as obtained in the test for *Ratio of Alkyl Components*.▲NF29

ASSAY

Change to read:

• **PROCEDURE 1: RATIO OF ALKYL COMPONENTS**

Solution A: Adjust a 0.1 M solution of sodium acetate with glacial acetic acid to a pH of 5.0.

Mobile phase: Acetonitrile and *Solution A* (9:11). Acetonitrile and *Solution A* may be adjusted from (2:3) to (3:2) to meet system suitability requirements.

Standard solution: 4 mg/mL of USP Benzalkonium Chloride RS

Sample solution: Transfer a volume of Solution, equivalent to 400 mg of benzalkonium chloride, to a 100-mL volumetric flask, and dilute with water to volume.

Chromatographic system

(See *Chromatography* ⟨621⟩*, System Suitability*.)

Mode: LC

Detector: UV 254 nm

Column: 3.9-mm × 30-cm; packing L10, ▲or 4.6-mm × 25-cm; packing L10▲NF29

Flow rate: 2 mL/min

Injection size: 20 µL

System suitability

Sample: *Standard solution*

▲[NOTE—See the relative retention time table below.]

Component	Relative Retention Time (RRT)
C_{10} homolog	0.9
C_{12} homolog	1.0
C_{14} homolog	1.3
C_{16} homolog	1.7

▲NF29

In-Process Revision

Suitability requirements

Resolution: NLT 1.5 between the C_{12} and C_{14} peaks

~~**Column efficiency:** NLT 1000 theoretical plates from the C_{12} peak~~

▲▲*NF29*

Relative standard deviation: NMT 2.0% for the C_{12} peak

Analysis

Samples: *Standard solution* and *Sample solution*

Identify the homolog peaks by comparison of the retention times with those from the *Standard solution*.

~~Calculate the percentage of each quaternary ammonium homolog taken:~~

$$\text{Result} = (A/B) \times 100$$

~~A = product of the area obtained from the homolog multiplied by its molecular weight~~

~~B = sum of all of these products~~

~~The molecular weights of C_{10}, C_{12}, C_{14}, and C_{16} are 312, 340, 368, and 396, respectively.~~

▲Calculate the percentage of each quaternary ammonium homolog taken:

$$\text{Result} = \frac{r_U \times M_r}{\sum_i (r_U \times M_r)} \times 100$$

r_U = area of the peak due to a given homolog in the chromatogram from the *Sample solution*

M_r = molecular weight of a given homolog. The molecular weights of the C_{10}, C_{12}, C_{14}, and C_{16} homologs are 312, 340, 368, and 396, respectively.

▲*NF29*

Acceptance criteria: On the anhydrous basis, the content of the *n*-$C_{12}H_{25}$ homolog is NLT 40.0%, and the content of the *n*-$C_{14}H_{29}$ homolog is NLT 20.0% of the total alkylbenzyldimethylammonium chloride content. The amount of the *n*-$C_{12}H_{25}$ and *n*-$C_{14}H_{29}$ homolog components together is NLT 70.0% of the total alkylbenzyldimethylammonium chloride content.

Change to read:

- **PROCEDURE 2: TOTAL ALKYLBENZYLDIMETHYLAMMONIUM CHLORIDES**

~~**Sample solution:** Evaporate or dilute with water to 30 mL a volume of Solution, equivalent to 275 mg of benzalkonium chloride. Transfer the solution with the aid of a minimum quantity of water to a glass-stoppered, 250-mL conical separator. Add 25 mL of chloroform. Add 10.0 mL of freshly prepared potassium iodide solution (1 in 20), insert the stopper in the separator, shake, allow the layers to separate, and discard the chloroform layer. Wash the aqueous layer with three 10-mL portions of chloroform, and discard the washings. Transfer the aqueous layer to a glass-stoppered, 250-mL conical flask, and rinse the separator with three 5-mL portions of water, adding the washings to the flask. Add 40 mL of cold hydrochloric acid to the flask.~~

~~**Analysis:** Titrate with 0.05 M potassium iodate VS until the solution becomes light brown in color. Add 5 mL of chloroform, insert the stopper into the flask, and shake vigorously. Continue the titration, dropwise, with shaking after each addition, until the chloroform layer becomes colorless and the aqueous layer is clear yellow. Perform a blank determination, using 20 mL of water as the sample. The difference between the two titrations represents the amount of potassium iodate equivalent to the weight of benzalkonium chloride in the sample. Each mL of 0.05 M potassium iodate is equivalent to x/10 mg of benzalkonium chloride, where x represents the average molecular weight of the sample, derived by summing, for all homologs, the products:~~

~~$\text{Result} = (A/B) \times M_r$~~

~~A = area of the peak produced by that homolog in the chromatogram from the *Ratio of Alkyl Components* test~~

~~B = total peak area for all homologs in that chromatogram~~

~~M_r = molecular weight of a given homolog~~

▲**Sample solution:** Evaporate or dilute with water to 30 mL a volume of Solution, equivalent to 275 mg of benzalkonium chloride.

Analysis: Transfer the *Sample solution* with the aid of a minimum quantity of water to a glass-stoppered, 250-mL conical separator. Transfer 25 mL of methylene chloride. Add 10 mL of 0.1 N sodium hydroxide, and 10.0 mL of freshly prepared potassium iodide solution (1 in 20), insert the stopper in the separator, shake, allow the layers to separate, and discard the methylene chloride layer. Wash the aqueous layer with three 10-mL portions of methylene chloride, and discard the washings. Transfer the aqueous layer to a glass-stoppered, 250-mL conical flask, and rinse the separator with three 5-mL portions of water, adding the washings to the flask. Add 40 mL of cold hydrochloric acid to the flask, mix, and titrate with 0.05 M potassium iodate VS until the solution becomes light brown in color. Add 5 mL of methylene chloride, insert the stopper into the flask, and shake vigorously. Continue the titration, dropwise, with shaking after each addition, until the methylene chloride layer becomes colorless and the aqueous layer is clear yellow. Record the titrant volume, V_t (mL). Perform a blank determination, using 20 mL of water as the sample, and record the titrant volume, V_b (mL). [NOTE—$V_b > V_t$.] The difference between the two titrations represents the amount of potassium iodate equivalent to the weight of benzalkonium chloride in the sample. Each mL of 0.05 M potassium iodate is equivalent to x/10 mg of benzalkonium chloride, where x represents the average molecular weight of the sample, derived by summing, for all homologs, the products:

$$\text{Result (x)} = \sum_i \left[(r_U / r_T) \times M_r \right]$$

r_U = area of the peak produced by a given homolog in the chromatogram from the *Ratio of Alkyl Components* test

r_T = sum of the peak areas for all homologs in the chromatogram from the *Ratio of Alkyl Components* test

M_r = molecular weight of a given homolog. The molecular weights of the C_{10}, C_{12}, C_{14}, and C_{16} homologs are 312, 340, 368, and 396, respectively.

▲*NF29*

Acceptance criteria

For labeled concentrations of NLT 1%: 95.0%–105.0%

For labeled concentrations less than 1%: 93.0%–107.0%

OTHER COMPONENTS

Add the following:

▲• **ALCOHOL CONTENT (IF ADDED)**

Internal standard solution: 0.06 mL/mL of tertiary butyl alcohol in water

Alcohol stock solution: 0.03 mL/mL of C_2H_5OH in water, using USP Alcohol RS

Standard solutions: Introduce 5 mL, 10 mL, and 20 mL, respectively, of *Alcohol stock solution* into three separate identical 50-mL volumetric flasks. To each flask, add a 5-mL portion of the *Internal standard solution*. Dilute with water to volume, and mix thoroughly. *Standard solutions* contain alcohol content of 0.003 mL/mL, 0.006 mL/mL, and 0.012 mL/mL, respectively.

Sample solution: Weigh an appropriate amount of Benzalkonium Chloride Solution into a 50-mL volumetric flask, and pipet 5 mL of *Internal standard solution*. Dilute with water

In-Process Revision

to volume, and mix thoroughly to obtain a solution containing an alcohol content of between 0.003 mL/mL and 0.012 mL/mL.

Chromatographic system
(See *Chromatography* ⟨621⟩, *System Suitability*.)
Mode: GC
Detector: Flame ionization
Column: 0.25-mm × 30-m glass or quartz capillary; 1.4-µm layer of phase G43
Temperature
Detector: 250°
Injection port: 250°
Column: See the temperature program table below.

In-Process Revision

BRIEFING

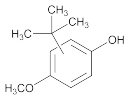
Butylated Hydroxyanisole, *NF 27* page 1178. On the basis of comments received and supporting data, it is proposed in the *Assay* to replace the current GC procedure employing a packed column, which is no longer available, with a validated HPLC method. The HPLC chromatographic procedure in the *Assay* is based on analysis performed with a Waters Symemetry C18 brand of column with 3.5-µm L1 packing. The typical retention times for 3-*tert*-butyl-4-hydroxyanisole and 2-*tert*-butyl-4-hydroxyanisole are about 4.2 and 4.6 min, respectively. Interested parties are encouraged to comment on the proposal.

(EM1: R. Lafaver.) RTS—C59587

Butylated Hydroxyanisole



$C_{11}H_{16}O_2$ 180.24
Phenol, (1,1-dimethylethyl)-4-methoxy-;
tert-Butyl-4-methoxyphenol [25013-16-5].

DEFINITION
Butylated Hydroxyanisole contains NLT 98.5% of $C_{11}H_{16}O_2$.

BRIEFING

Polyoxyl Stearyl Ether, *NF* 27 page 1318. On the basis of comments and data received, it is proposed to make the following revisions. Interested parties are encouraged to comment on the proposal.
1. The chemical formula is provided.
2. Data show that current USP Polyoxyl Stearyl Ether RS cannot be used to identify polyoxyl 2 stearyl ether and polyoxyl 20 stearyl ether in *Identification* test *A, Infrared Absorption*. Therefore, in the section *USP Reference Standards ⟨11⟩*, USP Polyoxyl Stearyl Ether RS is changed to USP Polyoxyl 10 Stearyl Ether RS, and two more Reference Standards are introduced: USP Polyoxyl 2 Stearyl Ether RS and USP Polyoxyl 20 Stearyl Ether RS. Articles with various oxyethylene units can be identified using their corresponding USP Reference Standards.
3. *Identification* test *C*, based on the article's hydroxyl value, is added.
4. A new test chapter, *Ethylene Oxide and Dioxane ⟨228⟩*, was proposed in *PF* 35(4) [July–Aug. 2009], page 917. The detailed procedure in this monograph in *Organic Impurities*, *Limit of Free Ethylene Oxide and Dioxane*, is deleted and now appears in the proposed chapter *⟨228⟩, Method I*. A new subsection is added to the monograph in *Organic Impurities*, in which the *Analysis* refers the reader to the chapter.

Polyoxyl Stearyl Ether

Change to read:

Polyethylene glycol monostearyl ether

▲$CH_3(CH_2)_{17}(OCH_2CH_2)_nOH$, n = 2–20▲*NF29* [9005-00-9].

DEFINITION
Polyoxyl Stearyl Ether is a mixture of the monostearyl ethers of mixed polyethylene glycols, the average polymer length being equivalent to NLT 2 and NMT 20 oxyethylene units (nominal value). It may contain various amounts of free stearyl alcohol and some free polyethylene glycol.

IDENTIFICATION
- **A. INFRARED ABSORPTION ⟨197F⟩:** Use a thin film of melted Polyoxyl Stearyl Ether.
- **B. PROCEDURE**
  Sample: 0.1 g
  Analysis: Dissolve or disperse the *Sample* in alcohol. Add 10 mL of diluted hydrochloric acid, 5 mL of barium chloride TS, and 10 mL of phosphomolybdic acid solution (1 in 10).
  Acceptance criteria: A precipitate is formed.

Add the following:

▲• **C.** It meets the requirements of the test for *Fats and Fixed Oils, Hydroxyl Value ⟨401⟩*.▲*NF29*

~~• **PROCEDURE: LIMIT OF FREE ETHYLENE OXIDE AND DIOXANE**~~

~~[**CAUTION**—Ethylene oxide is toxic and flammable. Prepare these solutions in a well-ventilated fume hood, using great care. Protect both hands and face by wearing polyethylene protective gloves and an appropriate face mask. Store all solutions in hermetic containers, and refrigerate at a temperature between 4° and 8°.]~~

~~[NOTE—Before using the Polyethylene Glycol 200 in this test, remove any volatile components from it by placing 500 mL of Polyethylene Glycol 200 in a 1000-mL round-bottom flask, attaching the flask to a rotary evaporator, and evaporating at a temperature of 60° and under a vacuum of 10–20 mm Hg for 6 h.]~~

~~**Solution A:** 10 µg/mL of acetaldehyde. [NOTE—Prepare *Solution A* fresh just before use.]~~

~~**Ethylene oxide stock solution:** Fill a chilled pressure bottle with liquid ethylene oxide, and store in a freezer when not in use. Use a small piece of polyethylene film to protect the liquid from contact with the rubber gasket. Tare a glass-stoppered conical flask, add about 50 mL of Polyethylene Glycol 200, and reweigh the flask. Transfer about 5 mL of the liquid ethylene oxide to a 100-mL beaker chilled in a mixture of sodium chloride and wet ice (1:3). Using a gas-tight syringe that has been previously cooled to –10°, transfer 300 µL (corresponding to about 250 mg) of liquid ethylene oxide to the Polyethylene Glycol 200, and swirl gently to mix. Replace the stopper, reweigh the flask, and determine the amount of ethylene oxide absorbed by weight difference. Adjust the weight of the mixture with Polyethylene Glycol 200 to 100.0 g, replace the stopper, and swirl gently to mix. [NOTE—This stock solution contains 2.5 mg/g of ethylene oxide. Prepare this stock solution fresh just before use, and store in a refrigerator]~~

~~**Ethylene oxide solution:** Tare a glass-stoppered conical flask, and chill it in a refrigerator. Add 35 mL of Polyethylene Glycol 200, and reweigh the flask. Using a gas-tight gas chromatographic syringe that has been chilled in a refrigerator, transfer 1 g of the chilled *Ethylene oxide stock solution* to the tared, conical flask. Adjust the weight of the solution with Polyethylene Glycol 200 to 50.0 g, replace the stopper, and swirl gently to mix. Transfer about 10 g of this solution to a 50-mL volumetric flask. Add 30 mL of water. Dilute with water to volume to obtain a solution containing 10 µg/mL of ethylene oxide. [NOTE—Prepare this solution fresh just before use, and store in a refrigerator.]~~

~~**Dioxane solution:** 0.5 mg/mL of dioxane~~

~~**Standard solution A:** Transfer 0.1 mL of *Ethylene oxide solution* to a 10-mL pressure headspace vial, add 0.1 mL of *Solution A* and 0.1 mL of *Dioxane solution*, and seal the vial.~~

~~**Standard solution B:** Transfer 1.0 g of the substance under test to another 10-mL pressure headspace vial, add 0.1 mL of *Ethylene oxide solution*, 0.1 mL of *Dioxane solution*, and 1.0 mL of *N,N*-dimethylacetamide, and seal the vial.~~

In-Process Revision

~~**Sample solution:** Transfer 1.0 g to a 10-mL pressure headspace vial, add 1.0 mL of *N,N*-dimethylacetamide and 0.2 mL of water, and seal the vial.~~

~~**Chromatographic system**~~

~~**Split ratio:** 20:1~~

~~**System suitability**~~

~~**Sample:** Gaseous phase of *Standard solution A*~~

~~[NOTE—The relative retention times for acetaldehyde and ethylene oxide are 0.94 and 1.0, respectively.]~~

~~**Suitability requirements**~~

~~**Resolution:** NLT 2.0 between acetaldehyde and ethylene oxide~~

~~**Signal-to-noise ratio:** NLT 5 for dioxane peak~~

~~**Relative standard deviation:** NMT 15%~~

~~**Analysis**~~

~~**Samples:** Gaseous headspace of *Standard solution B* and *Sample solution*~~

~~Using a heated, gas-tight gas chromatographic syringe, separately inject equal volumes of the *Samples*, record the chromatograms, and measure the areas for the major peaks: the mean areas of the ethylene oxide and dioxane peaks of the *Sample solution* are not greater than half the mean areas of the corresponding peaks of *Standard solution B*.~~

~~Calculate the concentration of ethylene oxide, in µg/g, in the portion of the substance under test taken:~~

$$\text{Result} = A r_U / [(r_S W_U) - (r_U W_S)]$$

~~A = quantity of ethylene oxide added to *Standard solution B* (µg)~~

~~r_U = peak response of ethylene oxide from the *Sample solution*~~

~~r_S = peak response of ethylene oxide from *Standard solution B*~~

~~W_U = weights of the substance under test taken to prepare the *Sample solution* (g)~~

~~W_S = weights of the substance to prepare *Standard solution B* (g)~~

~~**Acceptance criteria:** NMT 1 µg/g~~

~~Calculate the concentration of dioxane, in µg per g, in the portion of the substance under test taken:~~

$$\text{Result} = A_D r_U / 5[(r_S W_U) - (r_U W_S)]$$

~~A_D = amount of dioxane added to *Standard solution B* (µg)~~

~~r_U = dioxane peak response from the *Sample solution*~~

~~r_S = dioxane peak response from the *Standard solution B*~~

~~W_U and W_S are as defined above.~~

~~**Acceptance criteria:** NMT 10 µg/g~~

▲• **PROCEDURE: LIMIT OF FREE ETHYLENE OXIDE AND DIOXANE**

Analysis: Proceed as directed in *Ethylene Oxide and Dioxane* ⟨228⟩*, Method I*.

Acceptance criteria

Ethylene oxide: NMT 1 µg/g (ppm)

Dioxane: NMT 10 µg/g (ppm)▲*NF29*

SPECIFIC TESTS

- **FATS AND FIXED OILS,** *Acid Value* ⟨**401**⟩**:** NMT 1.0, determined on 5.0 g
- **FATS AND FIXED OILS,** *Hydroxyl Value* ⟨**401**⟩**:** Within the ranges specified in the table below

Oxyethylene Units/Molecule (Nominal Value)	Hydroxyl Value
2	150–180
10	75–90
20	40–60

- **FATS AND FIXED OILS,** *Iodine Value* ⟨**401**⟩**:** NMT 2.0
- **FATS AND FIXED OILS,** *Saponification Value* ⟨**401**⟩**:** NMT 3.0, determined on 10.0 g
- **ALKALINITY**

  Sample: 2.0 g of Polyoxyl Stearyl Ether

  Analysis: Transfer the *Sample* to a hot mixture of 10 mL of alcohol and 10 mL of water. Add 0.05 mL of bromothymol blue TS. Titrate with 0.1 N hydrochloric acid to a yellow endpoint.

  Acceptance criteria: NMT 0.5 mL of 0.1 N hydrochloric acid
- **WATER DETERMINATION,** *Method I* ⟨**921**⟩**:** NMT 3.0%
- **APPEARANCE OF SOLUTION:** 5.0 g of Polyoxyl Stearyl Ether in 50.0 mL of alcohol. The solution is not more intensely colored than a solution prepared immediately before use by mixing 12.0 mL of ferric chloride CS, 5.0 mL of cobaltous chloride CS, and 2.0 mL of cupric sulfate CS with dilute hydrochloric acid (10 g/L) to make 50.0 mL, and diluting 12.5 mL of this solution with dilute hydrochloric acid (10 g/L) to make 100.0 mL. Make the comparison by viewing the substance and the solution downward in matched color-comparison tubes against a white surface (see *Color and Achromicity* ⟨631⟩).

ADDITIONAL REQUIREMENTS

- **PACKAGING AND STORAGE:** Preserve in tight containers, and store in a cool, dry place.
- **LABELING:** Label it to indicate the average nominal number of oxyethylene units.

GENERAL CHAPTERS

General Tests and Assays

General Requirements for Tests and Assays

BRIEFING

USP Reference Standards ⟨11⟩, *USP 32* page 35, page 3924 of the *First Supplement,* and page 507 of *PF* 31(2) [Mar.–Apr. 2005], page 1680 of *PF* 31(6) [Nov.–Dec. 2005], page 1161 of *PF* 32(4) [July–Aug. 2006], page 95 of *PF* 33(1) [Jan.–Feb. 2007], page 981 of *PF* 33(5) [Sept.–Oct. 2007], page 332 of *PF* 34(2) [Mar.–Apr. 2008], page 680 of *PF* 34(3) [May–June 2008], page 1021 of *PF* 34(4) [July–Aug. 2008], page 1230 of *PF* 34(5) [Sept.–Oct. 2008], page 1531 of *PF* 34(6) [Nov.–Dec. 2008], page 144 of *PF* 35(1) [Jan.–Feb. 2009], page 330 of *PF* 35(2) [Mar–Apr. 2009], page 612 of *PF* 35(3) [May–June 2009], page 913 of *PF* 35(4) [July–Aug. 2009], and page 1217 of *PF* 35(5) [Sept.–Oct. 2009]. With the endorsement of the Reference Standards Expert Committee (RSEC), a subcommittee has revised the general test chapter *USP Reference Standards* ⟨11⟩ to focus the chapter on information related to the use and handling of USP Reference Standards. The proposed chapter focuses on definition, required uses, and information the analyst needs to perform tests and assays in USP's compendia that require the use of USP Reference Standards. All process-oriented information has been removed from the chapter, including the role of the RSEC, internal USP processes for the development of USP Reference Standards, and historical information relating to the Reference Standards program. Current versions of chapter 11 include a listing of all USP Reference Standards and their associated chemical name and molecular weight. These will be moved to the associated monograph and removed from chapter 11 at the time the proposed revision becomes official. This is currently targeted to occur in *USP 34–NF 29*. The most current list of official USP Reference Standards is located on the USP Web site and in the USP Reference Standards Catalog. When final, the chapter will include only required information. This approach is being applied to many of USP's general test chapters [see *Stimuli* article on *General Chapter Management in the 2010–2015 Cycle* appearing in *PF* 35(5)]. As a result of this new alignment of the chapter, the RSEC has recommended the development of an above 1000 general informational chapter to include much of the removed information, with the exception of the list of Reference Standards. This new greater than 1000 chapter may be considered in the 2010–2015 cycle.

(RS: B. Jones) RTS—C74311

Change to read:

⟨11⟩ USP REFERENCE STANDARDS

~~USP Reference Standards are highly characterized specimens of drug substances, excipients, reportable impurities, degradation products, compendial reagents, and performance calibrators.~~

~~They are explicitly required in many Pharmacopeial assays and tests and are provided solely for such use. Assessment of the suitability for use in other application(s) rests with the purchaser.~~

~~AUTHORITY FOR ESTABLISHMENT AND RELEASE~~

~~USP Reference Standards are established and released under the authority of the USPC Board of Trustees upon recommendation of the USP Reference Standards Expert Committee, which approves each lot as being suitable for use in its compendial applications. For some Reference Standards a preliminary review and approval is sought from other Expert Committees of the Council of Experts.~~

~~The distribution of controlled substances is subject to the regulations and licensing provisions of the Drug Enforcement Administration of the Department of Justice.~~

~~Industry Advisory Panels and other expert groups (such as Project Teams) may be assembled to advise USP on various aspects of the Reference Standards Program.~~

~~HISTORY~~

~~Future availability of the first USP Reference Standards was announced in 1926 (*USP X*) "... in order to facilitate the adoption of the biological assay standards of the Pharmacopoeia, and to provide a greater degree of uniformity in their application." The list of USP Reference Standards that in 1936 comprised 6 items has grown to almost 1650 in 2004, and the collection has tracked the progress in pharmaceutical sciences: The first vitamins (Cod Liver Oil) and the first enzyme (Pepsin) in 1936; the first sulfonamide (Sulfanilamide) and the first hormones (Insulin; Posterior Pituitary) in 1942; the first performance standards (Melting Point Standards) in 1947; the first penicillin (Penicillin G Sodium) in 1950; the first recombinant DNA technology protein (Insulin Human) in 1985, etc.~~

~~The continuous increase in the number of USP Reference Standards (over 100 new standards are being developed yearly) reflects not only the increase in the number of monographs and General Chapters, but also the development and extensive use of modern analytical methodology (such as chromatography, spectrophotometry, biological and biochemical assays, etc.) which require measurements relative to a reference standard.~~

In-Process Revision

NOMENCLATURE

Standards designated as USP Reference Standards (USP RS) are, with a few exceptions, required for use in *USP–NF* monographs or General Chapters. The exceptions include current lots of USP and NF Reference Standards for which uses are no longer specified in the current *USP* or *NF* but for which sufficient demand remains (upon depletion of the current lots, future lots will be designated as Authentic Substances), Reference Standards specified in monographs developed by USP that are not intended for publication in the *USP–NF*, Reference Standards specified in the current edition of the *Food Chemicals Codex* (labeled with an additional designation ''FCC''), and Fluoride Dentifrices (evaluated and distributed by agreement with the FDA and the Cosmetics, Toiletries, and Fragrances Association). A USP Reference Standard required in a monograph or General Chapter proposed in *Pharmacopeial Forum* may be released in advance of the official date of the proposed *PF* revision.

Reference Standards currently labeled as ''NF Reference Standards'' will eventually all be designated and labeled as ''USP Reference Standards'' pursuant to the consolidation of *USP* and *NF* within the USPC as of January 2, 1975. Meanwhile, where a USP Reference Standard is called for, the corresponding substance labeled as an ''NF Reference Standard'' may be used.

As a service, the USPC tests and distributes additional Authentic Substances (designated by AS) not currently required for use in a USP monograph or General Chapter. These also are provided under the supervision of the USP Reference Standards Expert Committee. They are highly characterized samples of chemicals, including substances of abuse, which are collaboratively tested and made available as a service primarily to analytical, clinical, pharmaceutical, and research laboratories. Such materials may be used for identification, method development, evaluation of method performance, or other applications as found suitable and validated by the user.

Authentic Visual References

Unlike chemical reference standards, Authentic Visual References (AVRs) are not used in chemical analyses. Instead, the AVRs are visual images used by analysts to compare certain test articles to ensure that they meet compendial requirements and are incorporated by reference into the monograph. Approval of AVRs for use in a monograph is the decision of the Expert Committee that approves the specific monograph.

DIVERSITY AND IMPLICATIONS

The USP Reference Standards collection is very diverse in terms of appearance, chemical structure, composition, and uses. This diversity has significant implications for the way the materials are tested, packaged, stored, and utilized.

The USP Reference Standards may be crystalline or amorphous powders, volatile or viscous liquids, solutions or suspensions, gels or pastes, plastic sheets, etc. In chemical structure they vary from simple inorganic salts to proteins produced by recombinant DNA technology. Some are highly purified single components, while others are complex mixtures (in most cases extracted from plant or animal sources).

USES OF USP REFERENCE STANDARDS

The official and authorized uses of USP Reference Standards are specified in the USP monographs and General Chapters and they include the following:

- quantitative uses in assays for drug substances and formulations, limit tests, or blanks and controls
- qualitative uses, such as identification tests, system suitability tests, chromatographic peak markers, etc.
- performance standards and calibrators, such as dissolution calibrators, melting point standards, the particle count set, etc.

As discussed under *Nomenclature*, USP also establishes and distributes standards not specified for use in a USP monograph or General Chapter.

The most frequent applications of USP Reference Standards (USP RS) are in chromatographic and spectroscopic methodologies. However, they are also widely used in biological and biochemical applications, such as microbial assays for antibiotics, enzymatic reactions, cell culture tests, whole animal tests; in thermal analysis for polymers; and in titration, etc. Some of the most frequently used USP RS are those utilized in General Chapters tests such as *Dissolution* ⟨711⟩, *Bacterial Endotoxins Test* ⟨85⟩, *Total Organic Carbon* ⟨643⟩, and *Particulate Matter in Injections* ⟨788⟩.

STEPS IN ESTABLISHING A USP REFERENCE STANDARD

The establishment of a new USP Reference Standard is triggered by the proposal of a new monograph or of a revision of an existing monograph by the inclusion of a test requiring a new USP RS. The need for a new lot of an existing USP Reference Standard is identified when its inventory reaches a pre-established threshold. The new lot is designated as a ''replacement lot'' if a new bulk material is to be procured or as a ''continuation lot'' if the candidate material is another portion of the bulk used for the existing official lot.

USP scientists generate a set of documents including procurement specifications and a testing protocol. A bulk material is obtained, generally from a major manufacturer of the article. The material is tested and characterized in an inter-laboratory collaborative study organized according to the protocol designed at USP Headquarters. The results are evaluated by USP Staff, additional testing or investigations are performed when necessary, and a report is compiled and presented for review and approval to the USP Reference Standards Expert Committee. After approval the material is subdivided (if not packaged prior to the collaborative study), labeled, quality checks are performed, and the standard is made available for distribution. If a candidate material is found to be unsuitable by USP scientific staff or by the Reference Standards Committee, a new bulk is procured and tested.

COLLABORATIVE STUDY FOR THE EVALUATION OF A USP RS CANDIDATE MATERIAL

The goals of the evaluation study are to confirm the identity and assess the purity of the material, to determine its suitability for use in the official applications, to provide the user with all the necessary information and directions for use, and to acquire time-zero information for future continued suitability for use studies.

USP scientists design a detailed testing protocol that includes the following elements: types of tests, number of tests, number of collaborators, number of replicates, and references to the procedures to be used.

The following factors are considered when designing the study protocol: the compendial status of the standard, its official uses, the history of the standard, its composition and complexity, the characteristics of the methodology, and the availability of material and of competent laboratories.

The testing protocol may comprise visual and microscopic evaluation; identification tests (more elaborate for first-time standards); determination of physical–chemical constants (e.g., melting range, specific rotation, refractive index, specific gravity, etc); chromatographic and electrophoretic purity tests; inorganic contaminants determination; volatile tests (water, solvents); functional group analysis (such as titrations, UV absorptivity, elemental analysis); thermal analysis; and assays against another well-characterized standard (a previous lot,

In-Process Revision

an international standard, etc). Specialized testing is implemented where appropriate, such as for dissolution calibrators and the particle count set, for standards that define an attribute (negative and positive bioreaction, ion exchange capacity, permeability diameter), and for biological standards that define a Unit of activity (heparin, endotoxin, enzymes, complex antibiotics). Vapor sorption analysis may also be performed to assist in determining packaging and storage conditions, and directions for use. For lyophilized single use USP RS, acceptable vial content reproducibility and stability of the lyophilized form are demonstrated.

The number of collaborators is generally not less than three (two outside of USP); but it can increase significantly, especially when the methodology is complex or does not have a high level of precision or when potential users express an interest in participating in the evaluation of the candidate. (Participation in all evaluation studies is open to all competent, interested parties.) Where appropriate, statistical control is exercised in the design of the evaluation study and in the analysis of the results. The USP Reference Standards Laboratory and the FDA laboratories participate in almost all evaluation studies. Other collaborators include Health Canada, the USP Research and Development Laboratory, and industrial and academic laboratories from the United States and from abroad.

BIOLOGICAL REFERENCE STANDARDS

The World Health Organization, an agency of the United Nations, manages a program providing International Standards for biological materials.

USP collaborates closely with the WHO in the harmonization of analytical methodology, in the definition of the units of potency, and in some cases to share in the preparation of a reference standard. In many cases the USP Units and the International Units of potency are identical.

SUITABILITY FOR USE AND PURITY ASSIGNMENT

The data collected in the collaborative evaluation study are analyzed to determine whether the material is suitable for its monograph designated use. Characterization data and results must be considered as a whole when evaluating suitability for intended use, assignment strategy, and assigned value. For Reference Standards used in quantitative applications, this includes the determination of a calculation value to be used in the compendial utilization of the standard.

The method of choice in computing the assigned value is a mass balance analysis using independently determined components such as moisture, solvent residues, inorganic residues, chromatographic impurities, and ion content. The assay results against a previous lot or against another validated standard and the results of the functional group analysis are for confirmatory purposes only. Exceptions to the mass balance approach include many biological Reference Standards, especially those which define the Unit of activity.

The number of significant figures in the labeled calculation value is a function of the use of the standard and the number of significant figures in the acceptance range or limit. Generally, Reference Standards used in assays are labeled with three significant figures and standards used in limit tests with two significant figures. Reference Standards having multiple applications in different methodologies may require separate assay specific assignments.

The assigned value is labeled without any associated uncertainty. However, for calibration standards, the labeled value is a range, determined by a statistical analysis of the results.

Previous approaches used a purity threshold above which the content was no longer labeled, and the analyst was directed to use a default value of 100.0%. This approach is no longer in use, but older lots of standards have not been re-labeled, and users should continue to apply the default 100.0% value for compendial quantitative applications.

For antibiotics, the designation "µg/mg" is sometimes used as a unit of biological activity, and values greater than 1000 µg/mg may be assigned to some of these standards. This can happen when the first standard is assigned a value higher than its actual purity and subsequent standards of higher purity are defined relative to the previous lot. A relatively overstated assigned value can also result when less selective separation techniques are replaced with more selective modern methodologies. As a result, the original content might have been assumed to be higher than the actual level.

No value is assigned to standards having only qualitative applications.

A report compiling the results of the evaluation study and including the proposed label text is submitted for review and approval to the USP Reference Standards Expert Committee.

LABEL TEXT

The label text is designed to provide the user with all the information needed for the correct storage and usage of the Reference Standard in monograph application(s). The label includes directions for use, safety warnings, required information for controlled substances, and a calculation value for standards with quantitative applications. For calibrators, acceptance ranges are provided. Where necessary, USP Reference Standards are accompanied by additional documentation, such as Technical Sheets or Typical Chromatograms. USP generally does not provide Certificates of Analysis because all the information that the user needs for the official or authorized applications of the standard is provided in the label text and, where necessary, in the additional documentation provided.

Directions for use are lot specific, and they take precedence over any other indication in the compendium.

Material Safety Data Sheets are generated for every standard that USP distributes. They are available on the USP website.

USP REFERENCE STANDARDS EXPERT COMMITTEE

The USP Reference Standards Expert Committee comprises professionals from industry, government agencies and academia from the United States and abroad. It is organized in groups and may be assisted in the review of the evaluation studies by an Industry Advisory Panel. The approval of the evaluation report has to be unanimous.

PACKAGING

The USP Reference Standard production process operates under a registered ISO 9001:2000 Quality System and appropriate cGMP principles.

USP Reference Standards are packaged in individual units designed to maintain the integrity of the contained Reference Standard material. The packaging and storage conditions for USP Reference Standards provide protection for all materials even though the material may not need such exceptional protection due to its inherent stability. The most common packaging configurations are vials for solid materials and ampuls for liquids. The packaging environment is determined by the sensitivity of the material to light, oxidation, or atmospheric humidity, and by its toxicity. Where appropriate, containers are filled in a glove box under inert gas and in conditions of controlled low residual humidity. (The need to store such standards under inert gas protection is indicated on the label.) They may also be sealed in a foil bag as an added protective barrier. Ampuls are filled and sealed on an automated device and are typically purged with an inert gas. The most common ampul sizes are 2 mL and 5 mL. Vials may be filled by manual, semi-automated, or fully automated operations. Vials may be of different sizes depending upon the amount of material. The amount of material per individual container depends on the compendial

application of the standard and is generally sufficient for several replicates. Larger amounts are provided when additional experiments are required (such as a titrimetric determination of the water content at the time of use). In general, Reference Standard containers are slightly over filled so that the user can retrieve the labeled, nominal amount of material. Vials are closed with Teflon-lined stoppers and secured with aluminum crimps and a USP logo tamper-evident seal. Lots using prior vial closure configurations may still be in distribution.

Various considerations may determine the need to provide the standard in single-use containers, mainly for materials with significant handling issues or for those that are available only in small amounts. Such single-use containers are generally filled by lyophilization, and their content is labeled in mass or activity Units per container. If so labeled, the content of the container is to be reconstituted in its entirety without any additional weighing. Instructions for reconstitution are given either on the label or in the monographs where the standard is being used.

IMPURITY REFERENCE STANDARDS

The topic of impurities is addressed in several sections of USP, such as *General Notices,* General Chapters such as *Ordinary Impurities* ⟨466⟩, *Impurities in Official Articles* ⟨1086⟩, etc. In addition, most of the monographs for drug substances and many of those for formulations include specific tests for the identification or quantitation of impurities. Such tests generally require an official Reference Standard. The development of these impurity Reference Standards is one of the reasons for the continuous accelerated growth of the USP Reference Standards.

In many cases, the materials for impurity Reference Standards are expensive and difficult to procure. Only a limited amount of material may be available—procurement might require custom synthesis—and it may be of lesser quality than the Reference Standard for the official article, requiring purification. The limited amount of material available can affect the testing protocol and the packaging. Impurity Reference Standards might be available as purified single-component materials, solutions, or solid dispersions, or mixtures of more than one impurity. Other options include samples of the official article with a labeled content of impurity(ies), the in situ generation of the impurity from the official article by a validated specified procedure, the use of relative chromatographic mobilities and relative response factors, or of theoretical values such as UV absorptivities at selective wavelengths.

In earlier editions of the compendium, the impurities were designated by their chemical names. For ease of indexing and searching, these have been gradually replaced with the designation "X Related Compound Y RS," where X is the name of the official article and Y is a sequential alphabetical letter. Reference Standard impurity mixtures might be designated by their use, such as "X System Suitability RS". The conventional names and the chemical names are cross-referenced in the final section of this chapter and in a special section of the Official USP Reference Standards Catalog.

CONTINUED SUITABILITY FOR USE PROGRAM

To ensure that the Reference Standards maintain the properties determined at the initial evaluation, USP maintains a Continued Suitability for Use Program. The retesting intervals and protocols are a function of the uses and properties of the standard and of the information available about its stability. Abbreviated protocols use the stability-indicating methodology employed in the initial characterization of the material to confirm the consistency of attributes such as appearance, chromatographic purity, or volatiles content.

PROPER USE

Neither the Reference Standards nor the Authentic Substances are intended for use as drugs or as medical devices.

USP Reference Standards do not carry an expiration date as long as they are in distribution. A lot of USP RS may be used in its official applications as long as it is listed as "Current Lot" in the current (most recent) Official USP Reference Standards Catalog. Upon depletion, the lot is designated in the catalog as "Previous Lot" and a "Valid Use Date" is assigned. USP publishes the Official Catalog of Reference Standards (which also includes Authentic Substances) bimonthly as a separate brochure*. An updated version of the catalog can be found on the USP website at www.usp.org. It is the responsibility of the user to ascertain that a particular supply of USP Reference Standard has official status either as a "Current Lot" or as a "Previous Lot" within the valid use date.

Many Pharmacopeial tests and assays are based on comparison of a test specimen with a USP Reference Standard. In such cases, measurements are made on preparations of both the test specimen and the Reference Standard. Where it is directed that a Standard solution or a Standard preparation be prepared for a quantitative determination by stepwise dilution or otherwise, it is intended that the Reference Standard substance shall be accurately weighed (see *Weights and Balances* ⟨41⟩ and *Volumetric Apparatus* ⟨31⟩). Due account should also be taken of the relatively large errors associated with weighing small masses (see also *Dilution* under *Tests and Assays* in the *General Notices and Requirements*).

The label text provides the user with directions on the proper use of a Reference Standard. The directions include one of the following options. A Reference Standard may be used as follows:

- As is, i.e., without any prior treatment or correction for volatiles. This is the preferred option, and it is selected whenever validated data show that the volatiles content is constant over time.
- Immediately after a prior drying under stated conditions. Drying should not be performed in the original container. A portion of the material should be transferred to a separate drying vessel.
- With a correction for the water content or the loss on drying determined on a separate portion of material. Where the titrimetric determination of water is required at the time a Reference Standard is to be used, proceed as directed for *Method I* under *Water Determination* ⟨921⟩. Instrumental or microanalytical methods are acceptable for this purpose. When using typical amounts (about 50 mg of the Reference Standard), titrate with a two- to five-fold dilution of the reagent. Where the determination of the loss on drying on a separate portion of USP Reference Standard is required, proceed as directed on the label. Smaller sample sizes than those required in General Chapter *Loss on Drying* ⟨731⟩ may be used for a USP Reference Standard, provided that the user can obtain a sufficiently accurate result.

Whenever the labeled directions for use require a preliminary drying or a correction for volatiles, it should be performed "at the time" of use. Further experimental details should be controlled by the user's Standard Operating Procedures and good laboratory practices.

STORAGE

To serve its intended purpose, each USP Reference Standard must be properly stored, handled, and used. Generally, Reference Standards should be stored in their original stoppered containers away from heat and protected from light. Avoid humid storage areas in particular. Where special storage conditions are necessary, directions are given on the label.

* For nonsubscribers, the most recent Official Catalog is available from: U.S. Pharmacopeial Convention, Inc., Reference Standards Order Department, 12601 Twinbrook Parkway, Rockville, MD 20852. Telephone 1-301-881-0666. FAX 1-301-816-8148. Toll free telephone 1-800-227-USPC or access the Catalog on USP's website www.usp.org/dsd/refstd.

In-Process Revision

~~RELATIONSHIPS WITH OTHER STANDARDS-SETTING ORGANIZATIONS~~

~~USP maintains continuous contact with other organizations that establish Reference Materials for compendial and other purposes, such as the European and the Japanese Pharmacopoeias (through the Pharmacopeial Discussion Group), the World Health Organization, the National Institute for Science and Technology, the Reference Materials Committee of ISO (REMCO), etc.~~

~~The specific nature of pharmacopeial reference substances has been officially recognized by ISO REMCO in the introduction of the ISO Guide 34—General requirements for the competence of reference material producers (Second Edition 2000): "Pharmacopoeial standards and substances are established and distributed by pharmacopoeial authorities following the general principle of this guide. It should be noted, however, that a different approach is used by the pharmacopoeial authorities to give the user the information provided by certificate of analysis and the expiration dates. Also, the uncertainty of their assigned values is not stated since it is negligible in relation to the defined limits of the method-specific assays of the pharmacopoeias for which they are used."~~

~~The *USP Reference standards* section of an individual *USP* or *NF* monograph or general chapter names each USP Reference Standard required for assay and test procedures and refers to this chapter for additional information and instructions. It is especially important to refer to the current Supplement to *USP* and to *NF* for official revisions listed in the following section.~~

~~USP REFERENCE STANDARDS SPECIFIED IN USP AND NF MONOGRAPHS AND GENERAL CHAPTERS~~

~~NOTE—Consult the latest Supplement or *Interim Revision Announcement* pertaining to *USP* and to *NF* for revisions, additions, or deletions.~~

~~Revisions, additions, and deletions of individual USP Reference Standards are listed cumulatively in each Supplement to *USP–NF*. As a consequence, therefore, it is necessary to consult only the current edition of *USP–NF* and the latest Supplement for the complete list of USP Reference Standards currently specified in *USP–NF* monographs and general chapters. The list provides up-to-date and complete names and applicable chemical information for the USP Reference Standards that are in distribution as of the official date of that Supplement.~~

~~Revisions of this chapter are implemented continuously via the *Interim Revision Announcements* that are published in *Pharmacopeial Forum*. Those interim revisions of USP Reference Standards are cumulatively included in the next *USP–NF* Supplement.~~

~~The alphabetical list that follows constitutes an index of all revisions to this chapter. Thus, it is unnecessary to name repetitively the revised Reference Standards in the general index to the Supplement.~~

~~In the list that follows, chemical names are given for many substances (e.g., related compounds) that are not *USP* or *NF* monograph articles. Following the name of such a chemical substance RS, the empirical formula and molecular weight, separated by the ✧ symbol, may be given in parentheses if those data are available.~~

NOTE—For reader's ease of viewing, the pages of the list of crossed off USP Reference Standards are not printed; however, the complete document will be displayed for the online version of *PF*.

▲Reference Standards provided by the United States Pharmacopeial Convention (USP Reference Standards, or RS) are highly characterized specimens reflective of specified drugs and foods (drug substances, biologics, excipients, dietary supplements, food ingredients, impurities, degradation products, reagents, and performance verification standards). When approved as suitable for use as comparison standards for documentary tests or assays (i.e., as a monograph component) in the *United States Pharmacopeia (USP)* or *National Formulary (NF)*, USP RS also assume official status and legal recognition in the United States. Assessment of the suitability for use in other applications rests with the user. Official USP RS are primary standards in jurisdictions that so recognize them as such and, when appropriate, are calibrated relative to international reference materials such as those provided by the World Health Organization. USP RS are never intended for therapeutic use. USP's RS are provided for legal metrology purposes and can help ensure comparability of results and traceability to Systéme International d'Unités (SI) units whether certified or not. USP RS are Reference Materials as defined in the *International Vocabulary of Metrology—Basic and General Concepts and Associated Terms (VIM)*: 3rd Edition 2007.

TYPES OF REFERENCE STANDARDS

Reference Standards for *USP* or *NF* Articles

Reference Standards for official articles in *USP* or *NF* are provided as pure materials or as mixtures of chemicals reflective of the corresponding drug substances or excipients. The use of these materials is specified in the article's monograph, and these materials generally are necessary for use in the *Assay* and/or the *Identification* tests. The suitability of a USP RS for uses outside those specified in a monograph is the responsibility of the user. The property value or calculation value of the Reference Standard is stated on the label and should be included in calculations

used in the monograph and applicable general chapters. For Reference Standards that do not bear a property value or calculation value on the label or in accompanying documentation, assume the Reference Standard is 100.0% pure for compendial quantitative applications.

Impurity Reference Standards

Reference Standards for impurities may include the following:

- Organic impurities that may arise either during the manufacturing process or during the shelf-life storage of an article and may include starting materials, intermediates, by-products, reagents, catalysts, and/or degradation products.
- Inorganic impurities that normally result from a synthesis process and may include reagents, catalysts, heavy metals, or inorganic salts
- Residual solvents that may be either inorganic or organic liquids that are used to prepare solutions or suspensions during the synthesis of an article

Impurity Reference Standards may be presented as purified single-component materials or as mixtures of more than one impurity. Other options for controlling impurities may include presenting the official article with a labeled impurity content; using relative chromatographic retention times and response factors; or providing theoretical values such as UV absorptivities at selected wavelengths.

In earlier editions of the compendium, impurities were designated by their chemical names. For ease of indexing and searching, these have been gradually replaced with the designation ''X-related compound Y RS'' where X is the name of the official article and Y is a sequential alphabetical letter. The assignment of this letter does not necessarily match the naming schemes of other compendia. Reference Standard impurity mixtures may also be designated by their intended use, such as ''X System Suitability RS''. The conventional names and the chemical names are reproduced in the catalog and on the RS product label.

Certified Reference Materials

USP's Certified Reference Materials (CRMs) are Reference Standards that provide certified property values with associated uncertainties and metrological traceability, in accordance with International Organization for Standardization (ISO) Guides 30-35. Correct use of these CRMs support traceability of results to SI units and comparability of procedures.

USP Reference Standards for Biologicals

USP provides RS for biologic drugs and ancillary materials. For historical and other reasons, and as noted in Section 5.50.10 of the *General Notices and Requirements*, USP RS for biologicals may diverge in unitage, by definition, or otherwise from other internationally recognized standards. Unless so noted in the documentary standard, international reference standards generally are not interchangeable and the USP RS is required in the tests and assays of *USP–NF*.

NF Reference Standards

Reference Standards currently labeled as ''NF Reference Standards'' are intended to be designated and labeled as ''USP Reference Standards'' pursuant to the consolidation of *USP* and *NF* within the USP as of January 2, 1975. Where a USP Reference Standard is called for, the corresponding substance labeled as an ''NF Reference Standard'' may be used.

Transition of Authentic Substances to USP Reference Standards

Previously, highly characterized reference materials not required for use in a *USP–NF* monograph or general chapter were developed by USP as a service and were distributed as Authentic Substances (AS). AS typically are highly characterized chemicals that are collaboratively tested and made available as a service primarily to analytical, clinical, pharmaceutical, and research laboratories. Such materials may be used for identification, method development, evaluation of method performance, or other applications as found suitable and validated by the user. USP will no longer introduce materials labeled ''Authentic Substances.'' All reference materials released, whether or not required for use in a *USP–NF* monograph or general chapter, will be ''USP Reference Standards.''

Authentic Visual References

Authentic Visual References are USP Reference Standards, but unlike chemical reference materials, Authentic Visual References (AVR) are not used in chemical analyses. Instead, AVR are visual images used by analysts to compare certain test articles to ensure that they meet compendial requirements. AVR are incorporated by reference into the monograph.

USP Performance Verification Test Standards

These materials are provided to analyze and where appropriate to facilitate adjustment of the operation of an instrument to ensure that the results obtained are accurate and/or precise or otherwise give acceptable results. The use of these Reference Standards is generally described in associated general test chapters and allied information.

APPLICATIONS OF USP REFERENCE STANDARDS

Official applications of USP RS are specified in *USP–NF* monographs and general chapters. They include the following:

- quantitative uses in assays for drug substances and formulations, limit tests, or blanks and controls
- qualitative uses, (e.g., identification tests, system suitability tests, or chromatographic peak markers)
- method-specific uses, (e.g., performance verification standards, AVR, melting point standards, and the particle count set)

As described above, USP also provides Authentic Substances, not specified for use in a *USP* monograph or general chapter, which are used at the user's discretion.

PACKAGING

The amount of material per individual USP RS container depends on the compendial application of the standard and is generally sufficient for several replicates. Some standards (mainly materials with significant handling requirements or materials that are available only in small amounts) are provided in single-use containers. Such single-use products generally are lyophilized, and their content is labeled in mass or activity units per container. If so labeled, the content of the container should be reconstituted in its entirety without any additional weighing. Instructions for reconstitution are given either on the label or in the monographs where the standard is used.

LABELING

The label text provides all the information needed for the correct storage and use of the USP RS in monograph applications. The label includes directions for use, safety warnings, required information for controlled substances, and a property value or calculation value for standards with quantitative applications. For performance verifica-

tion standards, acceptance ranges are provided. Where necessary, USP RS are accompanied by additional documentation such as Technical Data Sheets or Typical Chromatograms.

Unless otherwise directed in the procedure in the individual monograph or in a general chapter, USP RS should be used in accordance with the instructions on the label of the Reference Standard. Material Safety Data Sheets for all USP reference materials are available on the USP Web site.

Although USP RS undergo retesting on a predefined schedule to determine continued suitability for use, USP RS do not carry an expiration date on the label. A lot of USP RS may be used in its official applications as long as it is listed as ''Current Lot'' in the current USP Reference Standards Catalog or has not reached its Valid Use Date. Upon depletion, the lot is designated in the catalog as ''Previous Lot'' and a ''Valid Use Date'' is assigned. USP publishes the Catalog of Reference Standards bimonthly. The most current version of the catalog can be found on the USP Web site at www.usp.org. The user is responsible for ascertaining before use that the USP RS lot of interest currently carries official status, either as a ''Current Lot'' or as a ''Previous Lot'' within the Valid Use Date.

PROPER USE

Many compendial tests and assays are based on comparison of a test specimen with a USP RS. In such cases, measurements are made on preparations of both the test specimen and the Reference Standard. Where it is directed that a Standard solution or a Standard preparation be prepared for a quantitative determination by stepwise dilution or otherwise, it is intended that the Reference Standard substance be accurately weighed (see *Weights and Balances* ⟨41⟩ and *Volumetric Apparatus* ⟨31⟩. Due account should also be taken of the potential errors associated with weighing small masses (see also *Dilution* under *Tests and Assays* in the *General Notices and Requirements*). Reference Standards that are defined on a content-per-container basis are an exception, as noted above.

USP RS instructions for use include the following:

- **As Is**: Use without any prior treatment or correction for volatiles. This is the preferred option, and is selected whenever valid data indicate that the volatiles content is constant over time.
- **Dry Before Use**: Use immediately after drying under stated conditions. Drying should not be performed in the original container. A portion of the material should be transferred to a separate drying vessel.
- **Determine Water Content Titrimetrically At Time of Use**: Use with a correction for the water content or the loss on drying, determined on a separate portion of material. Where the titrimetric determination of water is required at the time a Reference Standard is to be used, proceed as directed for *Method I* under *Water Determination* ⟨921⟩. Instrumental or microanalytical methods are acceptable for this purpose. When using typical amounts (about 50 mg of the Reference Standard), titrate with a 2- to 5-fold dilution of the reagent. Where the determination of the loss on drying on a separate portion of USP RS is required, proceed as directed on the label. Sample sizes smaller than those required in the general test chapter *Loss on Drying* ⟨731⟩ may be used for a USP RS provided that the user can obtain a sufficiently accurate result.

Whenever the labeled directions for use require drying or a correction for volatiles, it should be performed at the time of use. Further experimental details should be controlled by the user's Standard Operating Procedures and good laboratory practices.

STORAGE

USP RS should be stored in the packaging configuration provided by USP (e.g., vials that are packaged in hermetically sealed bags). When special storage conditions are specified, label directions should be followed. Unopened vials should be stored as indicated on the label. The user is responsible for ensuring that the contents of opened vials continue to be suitable for their intended use and that value assignment and uncertainty information are maintained.▲*USP34*

OTHER TESTS AND ASSAYS

BRIEFING

⟨**521**⟩ **Sulfonamides,** *USP 32* page 177. It is proposed to delete this general test chapter from *USP–NF* as it is not referenced in any *USP* monograph.

(MD-AA: B. Davani) RTS—C76341

Delete the following:

▲⟨521⟩ SULFONAMIDES

Identification of Individual Sulfonamides in Mixed Sulfonamides

NOTE—The following instructions for preparations and procedure are applicable to all sulfonamides except sulfadiazine. When testing for sulfadiazine proceed in the same manner, except to use sulfadiazine preparations having one-half the designated concentration, and apply twice the designated volumes of sulfadiazine preparations to the chromatographic plates.

Standard Preparation—Transfer a quantity of the pertinent USP Reference Standard to a suitable glass-stoppered, conical flask, dissolve in methanol to obtain a solution having a concentration of about 2 mg per mL, and mix. A separate *Standard Preparation* is required for each sulfonamide present in mixed sulfonamides.

Test Preparation—Transfer a portion of the thoroughly mixed suspension or finely powdered tablets, equivalent to about 100 mg of each sulfonamide, to a 50-mL volumetric flask containing 10 mL of ammonia TS, and swirl. Add methanol to volume, mix, filter, and use the filtrate in the *Procedure*.

Preparation of Chromatographic Plates—Prepare three identical chromatographic plates according to the following directions. Apply separately, and 2 cm apart along a spotting line 1.5 cm from the bottom of the plate and parallel to it, 2 µL of each *Standard Preparation* and 2 µL of the *Test Preparation* to a suitable thin-layer chromatographic plate (see *Chromatography* ⟨621⟩) coated with a 0.25-mm layer of chromatographic silica gel mixture. On another spot, 2 cm along the spotting line from the application of the *Test Preparation*, apply, successively, 2 µL of each *Standard Preparation* to obtain a mixed standard. Dry the spots immediately with the aid of a stream of nitrogen.

Procedure—Prepare a chromatographic chamber lined with filter paper and containing a solvent system consisting of ethyl acetate, methanol, and a 1 in 4 aqueous solution of ammonium hydroxide (17 : 6 : 5), and allow to equilibrate for 1 hour. Similarly prepare a second chamber to contain a solvent system consisting of solvent hexane, chloroform, and butyl alcohol (1 : 1 : 1), and a third chamber to contain a solvent system consisting of chloroform and methanol (95 : 5). Place one prepared chromatographic plate in each equilibrated chamber, and develop the chromatograms until the solvent front has moved about three-fourths of the length of each plate. Remove each plate from its developing chamber, mark the solvent front, and allow the solvent to evaporate. Locate the spots on the plates by viewing under short-wavelength UV light. Spray the plates with a 1 in 100 solution of *p*-dimethylaminobenzaldehyde in dilute hydrochloric acid (1 in 20), and heat at 110° for 5 minutes or until bright yellow spots become visible. The R_f values of the yellow spots obtained from each *Test Preparation* correspond to those obtained from the mixed *Standard Preparations* on the respective plates. The individual sulfonamides may be identified by comparison of the R_f values of the yellow spots obtained from the *Test Preparations* and individual *Standard Preparations* on the respective plates.

Determination of Individual Sulfonamides in Mixed Sulfonamides

Standard Preparation—A separate *Standard Preparation* is required for each sulfonamide being determined. Transfer about 50 mg, accurately weighed, of the pertinent USP Reference Standard to a 50-mL volumetric flask containing 1.5 mL of ammonium hydroxide, add methanol, dissolve in methanol, dilute with methanol to volume, and mix. Transfer 1.0 mL of this solution to a 100-mL volumetric flask, add dilute hydrochloric acid (1 in 100) to volume, and mix. [NOTE—Retain the methanol solutions for the *Mixed Standard Preparation*. The methanol solutions are stable for at least 1 week, and the acid solutions for at least 1 month.]

Mixed Standard Preparation—Transfer 1.0 mL of each methanol solution, prepared as required for each *Standard Preparation*, to a small glass-stoppered flask, and mix. [NOTE—This Standard is used to identify the components of the *Assay Preparation* on the chromatogram.]

Assay Preparation—Prepare as directed in the individual monograph.

Procedure—Prepare the necessary number of chromatographic sheets (Whatman No. 1 filter paper, or equivalent), about 20 × 20 cm in size, by drawing a pencil line parallel to and 2.5 cm from one edge of the paper. Mark the line at points 2.5 and 5 cm from each edge of the paper. Impregnate the paper by dipping it in the immobile solvent (prepared fresh by dissolving 30 mL of redistilled formamide in 70 mL of acetone) for 30 seconds. Remove the paper, drain for 10 seconds, and blot between filter paper. Place the impregnated paper on dry filter paper, and air-dry for 3 to 5 minutes. With a micropipet, and with repeated applications, streak 100 µL of the *Assay Preparation* along the starting line, applying the volume in five streaks of about 20 µL each and evaporating the solvent with a gentle stream of nitrogen between applications. [NOTE—Make the streak as narrow as possible along the starting line, and keep within the 5-cm border.] Rinse the tip of the pipet with a drop of methanol–ammonia TS mixture (9 : 1), and then streak the rinse along the starting line between the 5- and 2.5-cm points at the right edge. Repeat the rinsing with two additional drops, and then blow out the pipet.

Apply 10 µL of the *Mixed Standard Preparation* at the mark 2.5 cm from the left edge.

In-Process Revision

~~Place 50 mL of methylene chloride (mobile solvent) in a tray in a 23 × 23 × 7.5 cm chromatographic chamber arranged for ascending chromatography (see *Chromatography* ⟨621⟩), and allow the chamber to equilibrate for about 15 minutes. Remove the cover, place from 7 to 10 mL of water in a second tray, and without delay, suspend the prepared chromatographic paper sheet so that it dips into the mobile solvent. Cover and seal the chamber, and allow the chromatogram to develop for 1 hour. Remove the paper from the chamber, and allow to air-dry for 5 minutes. Place the chromatogram on a dry sheet of filter paper, and view it under short-wavelength UV light. [NOTE—Conduct the following identification and marking without delay to avoid excessive exposure of the sulfonamide spots to UV irradiation.] Identify and mark the respective spots by matching R_F values with those of the spots produced by the *Mixed-Standard Preparation*. [NOTE—Sulfadiazine and sulfamerazine are chromatographed with increasing R_F, respectively.]~~

~~Cut the marked zones from the paper, cut each zone into five or six pieces, and place the pieces from each spot in separate, glass-stoppered, 50-mL flasks. Add 20.0 mL of dilute hydrochloric acid (1 in 100) to each flask, and allow to stand for about 30 minutes, swirling each flask at least five times during this period. Filter the solutions through dry glass wool into separate test tubes, discarding the first 5 mL of the filtrate. Transfer 5.0 mL of the subsequent filtrate from each solution into separate 10-mL volumetric flasks. Transfer 3.0 mL of each required *Standard Preparation* into separate, 10-mL volumetric flasks. To each flask, and to a blank flask containing 5 mL of dilute hydrochloric acid (1 in 100), add 1.0 mL of sodium nitrite solution (1 in 1000) and 0.10 mL of hydrochloric acid, and allow to stand for 5 minutes with frequent swirling. To each flask add 1.0 mL of ammonium sulfamate solution (1 in 200), and allow to stand for 5 minutes, swirling frequently. Finally, to each flask add 1.0 mL of freshly prepared *N*-(1-naphthyl)ethylenediamine dihydrochloride solution (1 in 1000), mix, dilute with water to volume, and mix. Allow each solution to stand between 15 and 60 minutes, and then concomitantly determine the absorbances of the solutions, in 1-cm cells, recording the spectra from 440 to 700 nm, with a suitable spectrophotometer, using the blank to set the instrument. Draw a baseline, and determine the corrected absorbance for each solution at the wavelength of maximum absorbance at about 545 nm.~~

~~Calculate the concentration, in mg per mL, of each sulfonamide in the *Assay Preparation* by the formula:~~

$$0.12C(A_U/A_S)$$

~~in which C is the concentration, in µg per mL, of the pertinent USP Reference Standard in the *Standard Preparation*; A_U is the corrected absorbance of the *Assay Preparation*; and A_S is the corrected absorbance of the pertinent *Standard Preparation*. From the concentration of the *Assay Preparation* thus determined, and applying appropriate dilution factors, calculate the percentage of sulfonamide in the specimen taken.~~ ▲*USP34*

Physical Tests and Determinations

BRIEFING

⟨**621**⟩ **Chromatography,** *USP 32* page 227, page 3952 of the *First Supplement*, and page 1238 of *PF* 34(5) [Sept.–Oct. 2008]. The General Chapters Expert Committee proposes a revised version of *Chromatography* ⟨621⟩.

The revision retains in ⟨621⟩ all the required critical information needed in order to perform a monograph procedure (e.g., definitions, calculations, interpretation of chromatograms) and eliminates descriptive or noncritical information (e.g., theory of chromatography). The revision is also harmonized, to the extent possible, with the equivalent chapter in the *European Pharmacopoeia* (*Eur. Ph.*), 2.2.46, *Chromatographic Separation Techniques*.

The primary proposed changes are as follows:

1. A *General Procedures* section is added to describe basic procedures to be used when a monograph requires a chromatographic method.
2. A section titled *Definitions and Interpretation of Chromatograms* is added to define the main chromatographic terms and their application in *USP* monographs. To the extent possible, the symbols of the International Union of Pure and Applied Chemistry (IUPAC) are adopted. In this section, subsection changes are as follows:
   - In *Number of Theoretical Plates*, measuring column efficiency, and the section *Resolution*, calculations based on the tangent method are deleted, and calculations based on the half-height of the peak are provided.
   - In *Peak-to-Valley Ratio*, a definition and the calculation are aligned with *Eur. Ph.*
3. A section titled *Quantitation* is added to describe basic quantitation procedures.
4. In the section *System Suitability,* the revision adopts the procedure from *Eur. Ph.* to calculate repeatability requirements when they are not stated in monographs.

The General Chapters Expert Committee is considering the disposition of the information about different types of chromatography that has been removed from the chapter. This information is neither critical nor intended to be enforceable. The committee requests input from stakeholders regarding whether this noncritical information should be moved to chapters with numbers greater than ⟨1000⟩ to provide background for Chapter ⟨621⟩; or whether, considering the broad nature of the information and the availability of source information outside the compendia, the information should simply be removed from *USP–NF*.

Readers are encouraged to submit their comments and opinions.

NOTE—Because the large number of crossed-off pages would present the reader with the task of searching through them to review the revised text, the printed pages in this *PF* represent only the added proposed revision of ⟨621⟩. The complete text of this proposal is available using the online electronic version of *PF* 35(6).

⟨621⟩ CHROMATOGRAPHY

▲INTRODUCTION

Chromatographic separation techniques are multistage separation methods in which the components of a sample are distributed between two phases, of which one is stationary and the other mobile. The stationary phase may be a solid or a liquid supported on a solid or a gel. The stationary phase may be packed in a column, spread as a layer, distributed as a film, or applied

In-Process Revision

by other techniques. The mobile phase may be gaseous or liquid or supercritical fluid. The separation may be based on adsorption, mass distribution (partition), or ion exchange; or it may be based on differences among the physicochemical properties of the molecules, such as size, mass, and volume. This chapter contains general procedures, definitions, and calculations of common parameters and describes general requirements for system suitability. The types of chromatography useful in qualitative and quantitative analysis employed in *USP* procedures are column, gas, paper, thin-layer (including high-performance thin-layer chromatography), and pressurized liquid chromatography (commonly called high-pressure or high-performance liquid chromatography).

GENERAL PROCEDURES

This section describes the basic procedures used when a chromatographic method is described in a monograph. The following procedures are followed unless otherwise indicated in the individual monograph.

Paper Chromatography

Stationary Phase: The stationary phase is a sheet of paper of suitable texture and thickness. Development may be ascending, in which the solvent is carried up the paper by capillary forces, or descending, in which the solvent flow is also assisted by gravitational force. The orientation of paper grain with respect to solvent flow is to be kept constant in a series of chromatograms. (The machine direction is usually designated by the manufacturer.)

Apparatus: The essential equipment for paper chromatography consists of a vapor-tight chamber with inlets for addition of solvent and a rack of corrosion-resistant material about 5 cm shorter than the inside height of the chamber. The rack serves as a support for solvent troughs and for antisiphon rods that, in turn, hold up the chromatographic sheets. The bottom of the chamber is covered with the prescribed solvent system or mobile phase. Saturation of the chamber with solvent vapor is facilitated by lining the inside walls with paper wetted with the prescribed solvent system.

Spotting: The substance or substances analyzed are dissolved in a suitable solvent. Convenient volumes, delivered from suitable micropipets, of the resulting solution, normally containing 1–20 μg of the compound, are placed in 6- to 10-mm spots not less than 3 cm apart.

Descending Paper Chromatography Procedure

(1) A spotted chromatographic sheet is suspended in the apparatus, using the antisiphon rod to hold the upper end of the sheet in the solvent trough. [NOTE—Ensure that the portion of the sheet hanging below the rods is freely suspended in the chamber without touching the rack, the chamber walls, or the fluid in the chamber.]
(2) The chamber is sealed to allow equilibration (saturation) of the chamber and the paper with the solvent vapor. Any excess pressure is released as necessary.
(3) After equilibration of the chamber, the prepared mobile phase is introduced into the trough through the inlet.
(4) The inlet is closed, and the mobile solvent phase is allowed to travel the desired distance down the paper.
(5) The sheet is removed from the chamber.
(6) The location of the solvent front is quickly marked, and the sheet is dried.
(7) The chromatogram is observed and measured directly or after suitable development to reveal the location of the spots of the isolated drug or drugs.

Ascending Paper Chromatography Procedure

(1) The mobile phase is added to the bottom of the chamber.

(2) The chamber is sealed to allow equilibration (saturation) of the chamber and the paper with the solvent vapor. Any excess pressure is released as necessary.
(3) The lower edge of the stationary phase is dipped into the mobile phase to permit the mobile phase to rise on the chromatographic sheet by capillary action.
(4) When the solvent front has reached the desired height, the chamber is opened, the sheet is removed, the location of the solvent front is quickly marked, and the sheet is dried.
(5) The chromatogram is observed and measured directly or after suitable development to reveal the location of the spots of the isolated drug or drugs.

Thin-Layer Chromatography

Stationary Phase: The stationary phase is a relatively thin, uniform layer of dry, finely powdered material applied to a glass, plastic, or metal sheet or plate (typically called the plate). The stationary phase of TLC plates has an average particle size of 10–15 μm, and that of high-performance TLC (HPTLC) plates has an average particle size of 5 μm. Commercial plates with a preadsorbent zone can be used if they are specified in a monograph. Sample applied to the preabsorbent region develops into sharp, narrow bands at the preabsorbent–sorbent interface. The separations achieved may be based on adsorption, partition, or a combination of both effects, depending on the particular type of stationary phase.

Apparatus: A chromatographic chamber made of inert, transparent material and having the following specifications is used: a flat-bottom or twin trough, a tightly fitted lid, and a size suitable for the plates. The chamber is lined on at least one wall with filter paper. Sufficient mobile phase or developing solvent is added to the chamber that, after impregnation of the filter paper, a depth appropriate to the dimensions of the plate used is available. The chromatographic chamber is closed and allowed to equilibrate. [NOTE—Unless otherwise indicated, the chromatographic separations are performed in a saturated chamber.]

Detection/Visualization: An ultraviolet (UV) light source suitable for observations under short- (254 nm) and long- (365 nm) wavelength UV light and a variety of other spray reagents used to make spots visible are often used.

Spotting: Solutions are spotted on the surface of the stationary phase (plate) at the prescribed volume in sufficiently small portions to obtain circular spots of 2–5 mm in diameter (1–2 mm on HPTLC plates) or bands of 10–20 mm × 1–2 mm (5–10 mm × 0.5–1 mm on HPTLC plates) at an appropriate distance from the lower edge of and sides of the plate. [NOTE—During development, the application position must be at least 5 mm (TLC) or 3 mm (HPTLC) above the level of the mobile phase.] The solutions are applied on a line parallel to the lower edge of the plate with an interval of at least 10 mm (5 mm on HPTLC plates) between the centers of spots, or 4 mm (2 mm on HPTLC plates) between the edges of bands, then allowed to dry.

Procedure

(1) Place the plate in the chamber, ensuring that the spots or bands are above the surface of the mobile phase.
(2) Close the chamber.
(3) Allow the mobile phase to ascend the plate until the solvent front has traveled three-quarters of the length of the plate, or the distance prescribed in the monograph.
(4) Remove the plate, mark the solvent front with a pencil, and allow to dry.
(5) Visualize the chromatograms as prescribed.
(6) Determine the chromatographic retardation factor (R_F) values for the principal spots or zones.

In-Process Revision

(7) Presumptive identification can be made by observation of spots or zones of identical R_F value and about equal magnitude obtained, respectively, with an unknown and a standard chromatographed on the same plate. A visual comparison of the size or intensity of the spots or zones may serve for semiquantitative estimation. Quantitative measurements are possible by means of densitometry (absorbence or fluorescence measurements).

Column Chromatography

Solid Support: Purified siliceous earth is used for normal-phase separation. Silanized chromatographic siliceous earth is used for reverse-phase partition chromatography.

Stationary Phase: The solid support is modified by the addition of a stationary phase specified in the individual monograph. If a mixture of liquids is used as the stationary phase, mix the liquids before the introduction of the solid support.

Mobile Phase: The mobile phase is specified in the individual monograph. If the stationary phase is an aqueous solution, equilibrate with water. If the stationary phase is a polar organic fluid, equilibrate with that fluid.

Apparatus: Unless otherwise specified in the individual monograph, the chromatographic tube is about 22 mm in inside diameter and 200–300 mm long. Attached to it is a delivery tube, without stopcock, about 4 mm in inside diameter and about 50 mm long.

APPARATUS PREPARATION: Pack a pledget of fine glass wool in the base of the tube. Combine the specified volume of stationary phase and the specified amount of solid support to produce a homogeneous, fluffy mixture. Transfer this mixture to the chromatographic tube, and tamp, using gentle pressure, to obtain a uniform mass. If the specified amount of solid support is more than 3 g, transfer the mixture to the column in portions of approximately 2 g, and tamp each portion. If the assay or test requires a multisegment column with a different stationary phase specified for each segment, tamp after the addition of each segment, and add each succeeding segment directly to the previous one. Pack a pledget of fine glass wool above the completed column packing. [NOTE—The mobile phase should flow through a properly packed column as a moderate stream or, if reverse-phase chromatography is applied, as a slow trickle.]

If a solution of the analyte is incorporated into the stationary phase, complete the quantitative transfer to the chromatographic tube by scrubbing the beaker used for the preparation of the test mixture with a mixture of about 1 g of *Solid Support* and several drops of the solvent used to prepare the sample solution before adding the final portion of glass wool.

Procedure

(1) Transfer the mobile phase to the column space above the column packing, and allow it to flow through the column under the influence of gravity.

(2) Rinse the tip of the chromatographic column with about 1 mL of mobile phase before each change in composition of mobile phase and after completion of the elution.

(3) If the analyte is introduced into the column as a solution in the mobile phase, allow it to pass completely into the column packing, then add mobile phase in several small portions, allowing each to drain completely, before adding the bulk of the mobile phase.

(4) Where the procedure indicates the use of multiple chromatographic columns mounted in series and the addition of mobile phase in divided portions is specified, allow each portion to drain completely through each column, and rinse the tip of each with mobile phase before the addition of each succeeding portion.

Gas Chromatography (GC)

Liquid Stationary Phase: This type of phase is available in packed or capillary columns.

Packed Column GC: The liquid stationary phase is deposited on a finely divided, inert solid support, such as diatomaceous earth, porous polymer, or graphitized carbon, which is packed into a column that is typically 2–4 mm in internal diameter and 1–3 m in length.

Capillary Column GC: In capillary columns, which contain no packed solid support, the liquid stationary phase is deposited on the inner surface of the column and may be chemically bonded to it.

Solid Stationary Phase: This type of phase is available only in packed columns. In these columns the solid phase is an active adsorbent, such as alumina, silica, or carbon, packed into a column. Polyaromatic porous resins, which are sometimes used in packed columns, are not coated with a liquid phase. [NOTE—Packed and capillary columns must be conditioned before use until the baseline and other characteristics are stable. The column or packing material supplier provides instructions for the recommended conditioning procedure.]

Apparatus: A gas chromatograph consists of a carrier gas source, injection port, column, detector, and recording device. The injection port, column, and detector are temperature controlled and may be varied as part of the analysis. The typical carrier gas is helium, nitrogen, or hydrogen, depending on the column and detector in use. The type of detector used depends on the nature of the compounds analyzed and is specified in the individual monograph. Detector output is recorded as a function of time, and the instrument response, measured as peak area or peak height, is a function of the amount present.

Temperature Program: The length and quality of a GC separation can be controlled by altering the temperature of the chromatographic column. When a temperature program is necessary, the individual monograph indicates the conditions in table format. The table indicates the initial temperature, rate of temperature change (ramp), final temperature, and hold time at the final temperature.

Procedure

(1) Equilibrate the column, injector, and detector with flowing carrier gas until a constant signal is received.
(2) Inject a sample through the injector septum, or use an autosampler.
(3) Begin the temperature program.
(4) Record the chromatogram.
(5) Analyze as indicated in the monograph.

Liquid Chromatography (LC)

The term *liquid chromatography*, as used in the compendia, is synonymous with high-pressure liquid chromatography and high-performance liquid chromatography. LC is a separation technique based on a solid stationary phase and a liquid mobile phase.

Stationary Phase: Separations are achieved by partition, adsorption, or ion-exchange processes, depending on the type of stationary phase used. The most commonly used stationary phases are modified silica or polymeric beads. The beads are modified by the addition of long-chain hydrocarbons. The specific type of packing needed to complete an analysis is indicated by the ''L'' designation in the individual monograph (see also the section *Chromatographic Columns*, below). The size of the beads is often described in the monograph as well. Changes in the packing type and size are covered in the *System Suitability* section of this chapter.

Chromatographic Column: The term *column* includes stainless steel, lined stainless steel, and polymeric columns, packed with a stationary phase. The length and inner diameter of the column affects the separation, and therefore typical column dimensions are included in the

individual monograph. Changes to column dimensions are discussed in the *System Suitability* section of this chapter. Compendial monographs do not include the name of appropriate columns; this omission avoids the appearance of endorsement of a vendor's product and natural changes in the marketplace. See the section *Chromatographic Columns* for more information.

Mobile Phase: The mobile phase is a solvent or a mixture of solvents, as defined in the individual monograph.

Apparatus: A liquid chromatograph consists of a reservoir containing the mobile phase, a pump to force the mobile phase through the system at high pressure, an injector to introduce the sample into the mobile phase, a chromatographic column, a detector, and a data collection device.

Gradient Elution: The technique of continuously changing the solvent composition during the chromatographic run is called gradient elution or solvent programming. The gradient elution profile is presented in the individual monograph as a gradient table, which lists the time and proportional composition of the mobile phase at the stated time.

Procedure

(1) Equilibrate the column and detector with mobile phase at the specified flow rate until a constant signal is received.
(2) Inject a sample through the injector, or use an autosampler.
(3) Begin the gradient program.
(4) Record the chromatogram.
(5) Analyze as directed in the monograph.

CHROMATOGRAPHIC COLUMNS

A complete list of packings (L), phases (G), and supports (S) used in *USP–NF* tests and assays is located in *USP–NF* and *PF*, *Reagents, Indicators, and Solutions—Chromatographic Columns*. This list is intended to be a convenient reference for the chromatographer in identifying the pertinent chromatographic column specified in the individual monograph.

DEFINITIONS AND INTERPRETATION OF CHROMATOGRAMS

Chromatogram: A chromatogram is a graphical representation of the detector response, concentration of analyte in the effluent, or other quantity used as a measure of effluent concentration versus effluent volume or time. In planar chromatography, *chromatogram* may refer to the paper or layer with the separated zones.

Figure 1 represents a typical chromatographic separation of two substances, 1 and 2. t_{R1} and t_{R2} are the respective retention times; and h is the height, h/2 the half-height, and $W_{h/2}$ the width at half-height, for peak 1. W_1 and W_2 are the respective widths of peaks 1 and 2 at the baseline. Air peaks are a feature of gas chromatograms and correspond to the solvent front in LC. The retention time of these air peaks, or unretained components, is designated as t_M.

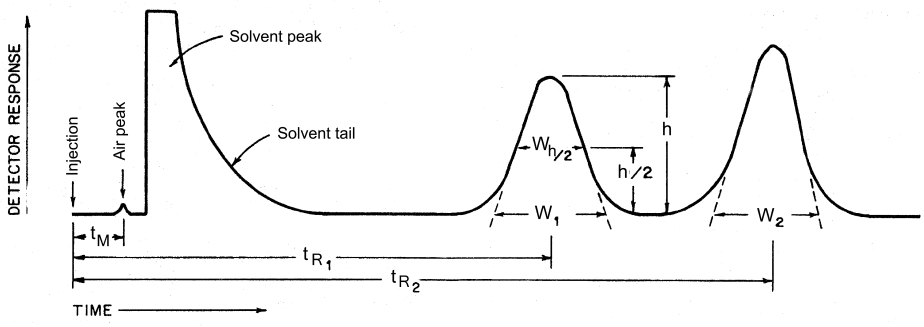

Figure 1. Chromatographic separation of two substances.

Dwell Volume (D): The dwell volume (also known as gradient delay volume) is the volume between the point at which the eluents meet and the top of the column.

Hold-Up Time (t_M): The hold-up time is the time required for elution of an unretained component (see *Figure 1,* shown as an air or unretained solvent peak, with the baseline scale in min).

Hold-Up Volume (V_M): The hold-up volume is the volume of mobile phase required for elution of an unretained component. It may be calculated from the hold-up time and the flow rate F, in mm/min:

$$V_M = t_M \times F$$

In size exclusion chromatography, the symbol V_O is used.

Number of Theoretical Plates (N)*: N is a measure of column efficiency, calculated by:

$$N = 5.54\left(\frac{t_R}{W_{h/2}}\right)^2$$

where t_R is the retention time of the substance, and $W_{h/2}$ is the peak width at half-height. The value of N depends upon the substance being chromatographed as well as the operating conditions, such as the flow rate and temperature of the mobile phase or carrier gas, the quality of the packing, the uniformity of the packing within the column, and, for capillary columns, the thickness of the stationary phase film and the internal diameter and length of the column.

Peak: The peak is the portion of the chromatographic recording of the detector response when a single component is eluted from the column. If separation is incomplete, two or more components may be eluted as one unresolved peak.

Peak-to-Valley Ratio (p/v): The p/v may be employed as a system suitability criterion in a test for related substances when baseline separation between two peaks is not achieved. *Figure 2* represents a partial separation of two substances, where H_p is the height above the extrapolated baseline of the minor peak and H_v is the height above the extrapolated baseline at the lowest point of the curve separating the minor and major peaks:

$$p/v = H_p / H_v$$

* The parameters k, N, r, and r_G were developed for isothermal GC separations and isocratic HPLC separations. Because these terms are thermodynamic parameters, they are valid only for separations made at constant temperature, mobile phase composition, and flow rate. However, for separations made with a temperature program or solvent gradient, these parameters may be used simply as comparative means to ensure that adequate chromatographic conditions exist to perform the methods as intended in the monographs.

In-Process Revision

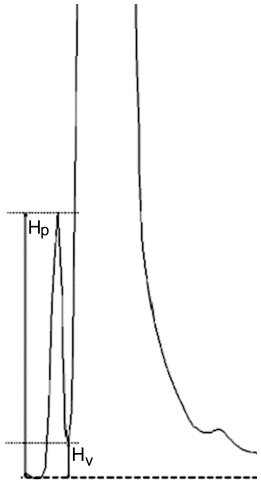

Figure 2. Peak-to-valley ratio determination.

Relative Retardation (R_{ret}) : The relative retardation is the ratio of the distance traveled by the analyte to the distance simultaneously traveled by a reference compound (see *Figure 3*) and is used in planar chromatography.

$$R_{rel} = b / c$$

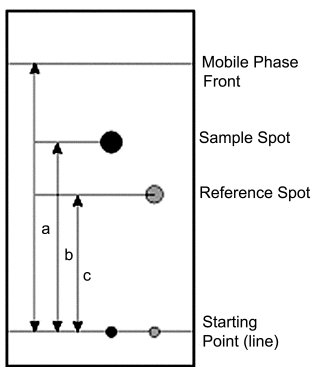

Figure 3. Typical planar chromatography.

Relative Retention (*r*)*: Retention time comparisons are normally made in terms of relative retention times to take into account any difference in experimental conditions within chromatograms:

$$r = t_{R2} - t_M / t_{R1} - t_M$$

where t_{R2} is the retention time measured from the point of injection of the compound of interest; t_{R1} is the retention time measured from the point of injection of the compound used as reference; and t_M is the retention time of a nonretained marker defined in the procedure, all determined under identical experimental conditions on the same column. Because in most procedures there is no need to identify an unretained peak, comparisons are normally made in terms of unadjusted relative retention, r_G:

$$r_G = t_{R2} / r_{R1}$$

Unless otherwise indicated, values for relative retention stated in monographs correspond to unadjusted relative retention.

Relative Standard Deviation in Percentage

$$\%RSD = \frac{100}{\bar{x}} \left(\frac{\sum_{i=1}^{N} \left(x_i - \bar{x} \right)^2}{N-1} \right)^{1/2}$$

Retardation Factor (R_F): The retardation factor is the ratio of the distance traveled by the center of the spot to the distance simultaneously traveled by the mobile phase and is used in planar chromatography. Using the symbols in *Figure 3*:

$$R_F = b / a$$

Retention Factor (k)*: The retention factor is also known as the capacity factor (k′). Defined as:

$$k = \frac{\text{amount of substance in stationary phase}}{\text{amount of substance in mobile phase}}$$

or

$$k = \frac{\text{time spent by substance in stationary phase}}{\text{time spent by substance in mobile phase}}$$

The retention factor of a component may be determined from the chromatogram:

$$k = t_R - t_M / t_M$$

Retention Time (t_R): In liquid chromatography and gas chromatography, the retention time, t_R, is defined as the time elapsed between the injection of the sample and the appearance of the maximum peak response of the eluted sample zone. t_R may be used as a parameter for identification. Chromatographic retention times are characteristic of the compounds they represent but are not unique. Coincidence of retention times of a sample and a reference substance can be used as a partial criterion in construction of an identity profile but may not be sufficient on its own to establish identity. Absolute retention times of a given compound may vary from one chromatogram to the next.

Retention Volume (V_R): The retention volume is the volume of mobile phase required for elution of a component. It may be calculated from the retention time and the flow rate in mL/min:

$$V_R = t_R \times F$$

Resolution (R_S): The resolution is the separation of two components in a mixture, calculated by:

$$R_S = 1.18(t_{R2} - t_{R1}) / (W_{1,h/2} + W_{2,h/2})$$

where t_{R2} and t_{R1} are the retention times of the two components; and $W_{1,h/2}$ and $W_{2,h/2}$ are the corresponding widths at half-height.

Separation Factor (α): The separation factor is the relative retention calculated for two adjacent peaks (by convention, the value of the separation factor is always >1):

$$\alpha = k_2/k_1$$

Symmetry Factor (A_S): The symmetry factor (also known as the tailing factor) of a peak (see *Figure 4*) is calculated by:

$$A_S = W_{0.05} / 2f$$

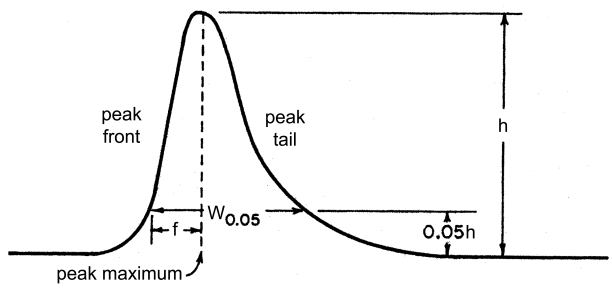

Figure 4. Asymmetrical chromatographic peak.

SYSTEM SUITABILITY

System suitability tests are an integral part of gas and liquid chromatographic methods. These tests are used to verify that the chromatographic system is adequate for the intended analysis.

In-Process Revision

The tests are based on the concept that the equipment, electronics, analytical operations, and samples analyzed constitute an integral system that can be evaluated as such.

Factors that may affect chromatographic behavior include the following:

- Composition, ionic strength, temperature, and apparent pH of the mobile phase
- Flow rate, column dimensions, column temperature, and pressure
- Stationary phase characteristics, including type of chromatographic support (particle-based or monolithic), particle or macropore size, porosity, and specific surface area
- Reverse-phase and other surface modification of the stationary phases, the extent of chemical modification (as expressed by end-capping, carbon loading, etc.)

The resolution, R_S, is a function of the number of theoretical plates, N (also referred to as efficiency), the separation factor, α, and the capacity factor, k. [NOTE—All terms and symbols are defined in the preceding section *Definitions and Interpretation of Chromatograms*.] For a given stationary phase and mobile phase, N may be specified to ensure that closely eluting compounds are resolved from each other, to establish the general resolving power of the system, and to ensure that internal standards are resolved from the drug. This is a less reliable means to ensure resolution than is direct measurement. Column efficiency is, in part, a reflection of peak sharpness, which is important for the detection of trace components.

Replicate injections of a standard preparation or other standard solutions are compared to ascertain whether requirements for precision are met. Unless otherwise specified in the individual monograph, data from five replicate injections of the analyte are used to calculate the relative standard deviation, %RSD, if the requirement is 2.0% or less; data from six replicate injections are used if the relative standard deviation requirement is more than 2.0%.

For the *Assay* in a drug substance monograph, where the value is 100% for the pure substance, and no maximum relative standard deviation is stated, the maximum permitted %RSD is calculated for a series of injections of the reference solution:

$$\%RSD = KB\sqrt{n} / t_{90\%,\, n-1}$$

where K is a constant (0.349), obtained from the expression $K = (0.6/\sqrt{2}) \times (t_{90\%}, 5/\sqrt{6})$, in which $0.6/\sqrt{2}$ represents the required percentage relative standard deviation after six injections for B = 1.0; B is the upper limit given in the definition of the individual monograph minus 100%; n is the number of replicate injections of the reference solution ($3 \leq n \leq 6$); and $t_{90\%,\, n-1}$ is the Student's t at the 90% probability level (double sided) with n – 1 degrees of freedom.

Unless otherwise prescribed, the maximum permitted relative standard deviation does not exceed the appropriate value given in the table of repeatability requirements. This requirement does not apply to tests for related substances.

Repeatability Requirements

	Number of Individual Injections			
	3	4	5	6
B (%)	**Maximum Permitted RSD**			
2.0	0.41	0.59	0.73	0.85

Repeatability Requirements *(Continued)*

	Number of Individual Injections			
2.5	0.52	0.74	0.92	1.06
3.0	0.62	0.89	1.10	1.27

The symmetry factor, A_S, a measure of peak symmetry, is unity for perfectly symmetrical peaks; and its value increases as tailing becomes more pronounced (see *Figure 4*). In some cases, values less than unity may be observed. As peak symmetry moves away from values of 1, integration, and hence precision, become less reliable.

The signal-to-noise ratio (S/N) is a useful system suitability parameter. The S/N is calculated as follows:

$$S/N = 2H/h$$

where H is the height of the peak measured from the peak apex to a baseline extrapolated over a distance $\geq$5 times the peak width at its half-height; and h is the difference between the largest and smallest noise values observed over a distance $\geq$5 times the width at the half-height of the peak and, if possible, situated equally around the peak of interest after the injection or application of a blank (see *Figure 5*).

These tests are performed by collecting data from replicate injections of standard or other solutions as specified in the individual monograph.

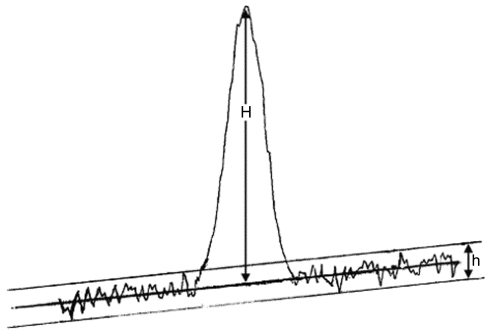

Figure 5. Noise and chromatographic peak, components of the S/N ratio.

The specification of definitive parameters in a monograph does not preclude the use of other suitable operating conditions. Adjustments are permitted only when

- Suitable standards (including Reference Standards) are available for all compounds used in the suitability test; and
- Those standards show that the adjustments improved the quality of the chromatography with respect to the system suitability requirements.

Adjustments to chromatographic systems performed in order to comply with system suitability requirements are not to be made in order to compensate for column failure or system malfunction.

If adjustments of operating conditions are necessary in order to meet system suitability requirements, each of the items in the following list is the maximum variation that can be considered, unless otherwise directed in the monograph; these changes may require additional validation data. To verify the suitability of the method under the new conditions, assess the relevant analytical performance characteristics potentially affected by the change. Multiple adjustments can have a cumulative ef-

fect on the performance of the system and are to be considered carefully before implementation. Adjustments to the composition of the mobile phase in gradient elution are not recommended. If adjustments are necessary, only column changes (same packing material) or dwell volume adjustments are recommended.

pH of Mobile Phase (HPLC): The pH of the aqueous buffer used in the preparation of the mobile phase can be adjusted to within ±0.2 units of the value or range specified.

Concentration of Salts in Buffer (HPLC): The concentration of the salts used in the preparation of the aqueous buffer employed in the mobile phase can be adjusted to within ±10% if the permitted pH variation (see above) is met.

Ratio of Components in Mobile Phase (HPLC): The following adjustment limits apply to minor components of the mobile phase (specified at 50% or less). The amounts of these components can be adjusted by ±30% relative. However, the change in any component cannot exceed ±10% absolute (i.e., in relation to the total mobile phase). Adjustment can be made to one minor component in a ternary mixture. Examples of adjustments for binary and ternary mixtures are given below.

Binary Mixtures

SPECIFIED RATIO OF 50 : 50: 30% of 50 is 15% absolute, but this exceeds the maximum permitted change of ±10% absolute in either component. Therefore, the mobile phase ratio may be adjusted only within the range of 40 : 60 to 60 : 40.

SPECIFIED RATIO OF 2 : 98: 30% of 2 is 0.6% absolute. Therefore the maximum allowed adjustment is within the range of 1.4 : 98.6 to 2.6 : 97.4.

Ternary Mixtures

SPECIFIED RATIO OF 60 : 35 : 5: For the second component, 30% of 35 is 10.5% absolute, which exceeds the maximum permitted change of ±10% absolute in any component. Therefore the second component may be adjusted only within the range of 25% to 45% absolute. For the third component, 30% of 5 is 1.5% absolute. In all cases, a sufficient quantity of the first component is used to give a total of 100%. Therefore, mixture ranges of 50 : 45 : 5 to 70 : 25 : 5 or 58.5 : 35 : 6.5 to 61.5 : 35 : 3.5 would meet the requirement.

Wavelength of UV-Visible Detector (HPLC): Deviations from the wavelengths specified in the procedure are not permitted. The procedure specified by the detector manufacturer, or another validated procedure, is used to verify that error in the detector wavelength is, at most, ±3 nm.

Stationary Phase

COLUMN LENGTH (GC, HPLC): Can be adjusted by as much as ±70%.

COLUMN INNER DIAMETER (HPLC): Can be adjusted if the linear velocity is kept constant. See *Flow Rate (HPLC)* below.

COLUMN INNER DIAMETER (GC)—Can be adjusted by as much as ±50% for GC.

FILM THICKNESS (CAPILLARY CG)—Can be adjusted by as much as –50% to 100%.

Particle Size (HPLC): The particle size can be reduced by as much as 50%, but cannot be increased.

Particle Size (GC): Changing from a larger to a smaller or from a smaller to a larger particle size GC mesh support is acceptable if the chromatography meets the requirements of system suitability and the same particle size range ratio is maintained. The particle size range ratio is defined as the diameter of the largest particle divided by the diameter of the smallest particle.

Flow Rate (GC): The flow rate can be adjusted by as much as ±50%.

Flow Rate (HPLC): When column dimensions have been modified, the flow rate can be adjusted using:

$$F_2 = F_1 \frac{l_2 d_2^2}{l_1 d_1^2}$$

in which F_1 is the flow rate indicated in the monograph, in mL/min; F_2 is the adjusted flow rate, in mL/min; l_1 is the length of the column indicated in the monograph; l_2 is the length of the column used; d_1 is the column inner diameter indicated in the monograph; and d_2 is the internal diameter of the column used. Additionally, the flow rate can be adjusted by $\pm 50\%$.

Injection Volume (HPLC): The injection volume can be reduced as far as is consistent with accepted precision and detection limits; no increase is permitted.

Injection Volume and Split Volume (GC): The injection volume and split volume may be adjusted if detection and repeatability are satisfactory.

Column Temperature (HPLC): The column temperature can be adjusted by as much as $\pm 10^\circ$. Column thermostating is recommended to improve control and reproducibility of retention time.

Oven Temperature (GC): The oven temperature can be adjusted by as much as $\pm 10\%$.

Oven Temperature Program (GC): Adjustment of temperatures is permitted as stated above. When the specified temperature must be maintained or when the temperature must be changed from one value to another, an adjustment of up to $\pm 20\%$ is permitted.

Unless otherwise directed in the monograph, system suitability parameters are determined from the analyte peak.

Measured values of R_r or R_F or t_R for the sample substance do not deviate from the values obtained for the reference compound and mixture by more than the statistically determined reliability estimates from replicate assays of the reference compound. Relative retention times may be provided in monographs for informational purposes only to aid in peak identification. There are no acceptance criteria applied to relative retention times.

Suitability testing is used to ascertain the effectiveness of the final operating system, which should be subjected to this testing. Make injections of the appropriate preparation(s) as required in order to demonstrate adequate system suitability (as described in the *Chromatographic system* section of the method in a monograph) throughout the run.

The preparation can be a standard preparation or a solution containing a known amount of analyte and any additional materials (e.g., excipients or impurities) useful in controlling the analytical system. Whenever there is a significant change in the chromatographic system (equipment, mobile phase component, or other components) or in a critical reagent, system suitability is to be reestablished. No sample analysis is acceptable unless the suitability of the system has been demonstrated.

QUANTITATION

During quantitation, disregard peaks caused by solvents and reagents or arising from the mobile phase or the sample matrix.

In the linear range, peak areas and peak heights are usually proportional to the quantity of compound eluting. The peak areas and peak heights are commonly measured by electronic integrators but may be determined by more classical approaches. Peak areas are generally used but may be less accurate if peak interference occurs. The components measured are separated from any interfering components. Peak tailing and fronting is minimized, and the measurement of peaks on tails of other peaks are avoided when possible.

Although comparison of impurity peaks with those in the chromatogram of a standard at a similar concentration is preferred, impurity tests may be based on the measurement of the peak response due to impurities and expressed as a percentage of the area of the drug peak. The standard may be the drug itself at a level corresponding to, for example, 0.5% impurity, assuming similar peak responses. When impurities must be determined with greater certainty, use a standard of the impurity itself or apply a correction factor based on the response of the impurity relative to that of the main component.

External Standard Method: The concentration of the component(s) quantified is determined by comparing the response(s) obtained with the sample solution to the response(s) obtained with a standard solution.

Internal Standard Method: Equal amounts of the internal standard are introduced into the sample solution and a standard solution. The internal standard is chosen so that it does not react with the test material, is stable, is resolved from the component(s) quantified (analytes), and does not contain impurities with the same retention time as that of the analytes. The concentrations of the analytes are determined by comparing the ratios of their peak areas or peak heights and the internal standard in the sample solution with the ratios of their peak areas or peak heights and the internal standard in the standard solution.

Normalization Procedure: The percentage content of a component of the test material is calculated by determining the area of the corresponding peak as a percentage of the total area of all the peaks, excluding those due to solvents or reagents or arising from the mobile phase or the sample matrix and those at or below the limit at which they can be disregarded.

Calibration Procedure: The relationship between the measured or evaluated signal y and the quantity (e.g., concentration, mass) of substance x is determined, and the calibration function is calculated. The analytical results are calculated from the measured signal or evaluated signal of the analyte and its position on the calibration curve.

In tests for impurities for both the *External Standard Method,* when a dilution of the sample solution is used for comparison, and the *Normalization Procedure,* any correction factors indicated in the monograph are applied (e.g., when the response factor is outside the range 0.8–1.2).

When the impurity test prescribes the total of impurities or there is a quantitative determination of an impurity, choice of an appropriate threshold setting and appropriate conditions for the integration of the peak areas is important. In such tests the limit at or below which a peak is disregarded is generally 0.05%. Thus, the threshold setting of the data collection system corresponds to at least half of this limit. Integrate the peak area of any impurity that is not completely separated from the principal peak, preferably by valley-to-valley extrapolation (tangential skim).▲*USP34*

GENERAL CHAPTERS

General Information

BRIEFING

⟨**1121**⟩ **Nomenclature,** *USP 32* page 632. On the basis of comments received, it is proposed to revise the graphical examples illustrating the definition of the active moiety in the section *Monograph Naming Policy for Salt Drug Substances in Drug Products and Compounded Preparations*.

(NOM: A.Wilk) RTS—C77398

In-Process Revision

Change to read:

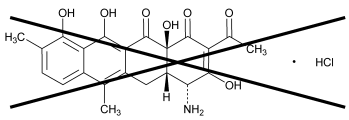
MONOGRAPH NAMING POLICY FOR SALT DRUG SUBSTANCES IN DRUG PRODUCTS AND COMPOUNDED PREPARATIONS

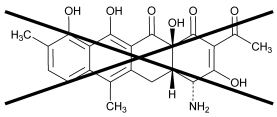
The titles of USP monographs for drug products and compounded preparations formulated with a salt of an acid or base use the name of the active moiety, as defined below. The strength of the product or preparation also is expressed in terms of the active moiety.

An active moiety is the molecule or ion, excluding those appended portions of the molecule that cause the drug to be an ester, salt (including a salt with hydrogen or coordination bonds), or other noncovalent derivative (such as a complex, chelate, or clathrate) of the molecule, responsible for the physiological or pharmacological action of the drug substance, without regard to the actual charged state of the molecule in-vivo.

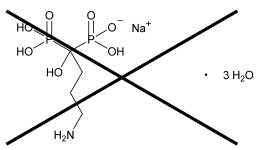
~~For example, the active moiety of a hydrochloride salt of a base will be the free base and not the protonated form of the base. The active moiety of a metal acid salt will be the free acid.~~

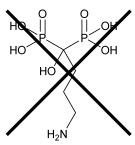
~~i. Example: Chelocardin Hydrochloride active moiety is Chelocardin~~





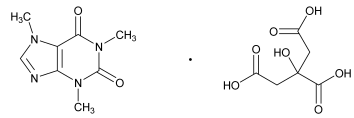
~~ii. Example: Alendronate Sodium active moiety is Alendronic Acid~~

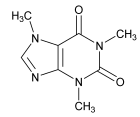




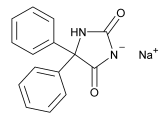
▲For example, the active moiety of a salt of a base will be the free base, and not the protonated form of the base. The active moiety of an acid salt will be the free acid.

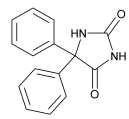
i. Example: Caffeine Citrate active moiety is Caffeine





ii. Example: Phenytoin Sodium active moiety is Phenytoin





▲*USP34*

This Policy is followed by USP in naming drug products and compounded preparations that are newly recognized in the USP. Revising existing monographs to conform to this Policy is not intended, except where the USP Council of Experts determines that, for reasons such as safety, a nomenclature change is warranted.

Related Issues

Labeling—The labeling clearly states the specific salt form of the active moiety that is present in the product/preparation, as this information may be useful to practitioners and patients. The names and strengths of both the active moiety and specific salt form (where applicable) are provided in the labeling.

Exceptions—In those rare cases in which the use of the specific salt form of the active moiety in the title provides vital information from a clinical perspective, an exception to this Policy may be considered. In such cases, where the monograph title contains the specific salt form of the active moiety, the strength of the product or preparation also is expressed in terms of the specific salt form.

Change to read:

~~WATER FOR HEMODIALYSIS~~

▲GENERAL PURIFICATION CONSIDERATIONS▲USP34

Chemical and microbial components that can be found in drinking water meeting U.S. Environmental Protection Agency National Primary Drinking Water Regulations (or equivalent) may have the potential to produce significant negative effects in patients undergoing hemodialysis. It is, therefore, necessary to subject the water to further treatment to reduce these components to acceptable levels. The *Water for Hemodialysis* monograph provides bacterial and chemical tests that are required to ensure patient safety. Additional testing is recommended as follows:

(1) Excess levels of aluminum, fluorides, and ~~chlorides~~

▲chlorine▲USP34
may be found seasonally in drinking water as a result of chemicals used in water treatment. These components should be monitored in Water for Hemodialysis being produced in accordance with established standard operating procedures. The maximum acceptable levels of these

▲and other▲USP34
elements and compounds,

▲as proposed by AAMI (Association for the Advancement of Medical Instrumentation)▲USP34
are listed in *Table 1*.

▲These attributes should be periodically monitored to assure they are being controlled by the routine testing performed in accordance with the *Water for Hemodialysis* monograph.▲USP34

(2) A comprehensive validation testing of the system producing Water for Hemodialysis should be performed ~~, at least annually,~~

▲initially and periodically thereafter▲USP34
to ensure that the water treatment equipment ~~is functioning properly. The maximum acceptable levels of elements and compounds are listed in *Table 1*. Routine testing is performed in accordance with the monograph.~~

▲and system sanitization processes are functioning properly.▲USP34

[2] U.S. Environmental Protection Agency Publication EPA-600-R-94-111, Cincinnati, OH.

▲In addition, the absence of *Pseudomonas aeruginosa* should be routinely determined because this is an opportunistic pathogen hazardous to acutely ill hemodialysis patients. Both the high microbial counts and the presence of *Pseudomonas aeruginosa* can be associated with inadequate water system maintenance and sanitization. Sampling the water should be done at all use points where the water enters the dialysis equipment.▲*USP34* Samples should be assayed within 30 minutes of collection or immediately refrigerated and then assayed within 24 hours of collection. ~~Quantification of bacterial endotoxins is performed using the Limulus Amebocyte Lysate (LAL) clotting method or any other LAL test found in the USP general test chapter *Bacterial Endotoxins Test* ⟨85⟩.~~

▲The microbial enumeration and absence tests are performed using procedures found in the USP general test chapters *Microbial Enumeration Tests* ⟨61⟩ and *Tests for Specified Microorganisms* ⟨62⟩. Quantification of bacterial endotoxins is performed using procedures found in the USP general test chapter *Bacterial Endotoxins Test* ⟨85⟩.▲*USP34*

Because of the incubation time required to obtain definitive microbiological results, water systems should be microbiologically monitored to confirm that they continue to produce water of acceptable quality. ''Alert'' and ''Action Levels'' are therefore necessary for the monitoring and control of the system. An Alert Level constitutes a warning and does not require a corrective action. An Action Level indicates a drift from normal operating conditions and requires that corrective action be taken to bring the process back into the normal operating range. Exceeding an Alert or Action Level does not imply that water quality has been compromised. ~~The recommended Action Level for a total viable microbial count in the product water is 50 cfu per mL, and the recommended Alert Level for bacterial endotoxins is 0.5 USP Endotoxin Unit per mL~~

▲The maximum recommended Action Level for a total viable microbial count in the product water should be no greater than 25 cfu/mL, and the maximum recommended Action Level for bacterial endotoxins should be no greater than 0.25 USP Endotoxin Unit/mL. As with all process control values, Action and Alert Levels should be established from normal system monitoring trends and process capabilities in a fashion that allow remedial actions to occur in response to process control level excursions well before specifications are exceeded▲*USP34* (also see *Microbial Considerations* under *Water for Pharmaceutical Purposes* ⟨1231⟩).

In-Process Revision

BRIEFING

⟨1788⟩ Methods for the Determination of Particulate Matter in Parenteral Injections and Ophthalmic Products. The Parenteral Products—Industrial Expert Committee proposed the general information chapter, ⟨1788⟩ *Particulate Matter Determination in Parenteral Ophthalmic Products* in *PF* 34(2) [Mar.–Apr. 2008], which reintroduced text that appeared in *Particulate Matter in Injections* ⟨788⟩, but was deleted when the chapter was harmonized. The Expert Committee thought that the deleted text was valuable information for end users in setting up equipment and measuring particulate matter. The Parenteral Products—Industrial Expert Committee is now resubmitting this new general information chapter in response to industry comments received from the *PF* 34(2) proposal and to include additions and edits that reflect current industry practice; therefore, the *PF* 32(4) text was cancelled.

(PPI: D. Hunt) RTS—C65454

Add the following:

▲⟨1788⟩ METHODS FOR THE DETERMINATION OF PARTICULATE MATTER IN PARENTERAL INJECTIONS AND OPHTHALMIC SOLUTIONS

INTRODUCTION

Methodology for the determination of particulate matter content in solution products is contained in this chapter. Also included are solutions constituted from sterile solids intended for parenteral use. Determination of the particulate matter content is an essential means to control the level contained in the final product and thus reduce risk to the recipient. *Injections* ⟨1⟩ specifies that these solutions are expected to be essentially free from particulate matter that can be observed on visual inspection. *Particulate Matter in Injections* ⟨788⟩ specifies limits for the particulate matter content in the product solutions in two subvisible size thresholds. Likewise, *Particulate Matter in Ophthalmic Solutions* ⟨789⟩ establishes these particle content expectations for ophthalmic solutions. The tests described herein are physical limits tests performed for the purpose of enumerating subvisible particles (particulate matter) within specific size ranges for both injections and ophthalmic solutions.

Particulate matter consists of mobile undissolved particles, other than gas bubbles, unintentionally present in the test solutions. Using the test methods, any semisolid to solid material (and even immiscible liquids) that trigger detector response above a selected size threshold will be tabulated.

Two general categories of particulate matter sources will be detected: extrinsic and intrinsic. Extrinsic material is additive and foreign, and not part of the formulation, package, or assembly process. Intrinsic material is that which is associated with the package, formulation ingredients and process, or assembly process.

Examples of extrinsic material are fibers, cellulosic matter, vegetative matter, corrosion products, paint/coatings, and building materials (gypsum, concrete, metal, plastic, etc.). Extrinsic particles are additive and generally nonchanging over the life of the product, unless by fragmentation, swelling (hydration), or degradation. Fragments of rubber, plastic, and metal are examples of extrinsic particulate matter deposited in the product during assembly or not removed in the container preparation process.

Intrinsic sources are inherent to the product and process—formulation, package, and commercial assembly steps. Intrinsic sources represent a variety of phenomena yielding unwanted substances, such as extraction, leaching, degradation of ingredient (active or excipient), change of ingredient by precipitation/salt form/crystalline form, change of package physical integrity, change of impurity level, change of micellar association, oligamerization, and package and process-related materials not removed during product assembly. Combinations of all of the above and physical phenomena such as aggregation, sedimentation, and coalescence by matrix (oils, semisolids) may bring smaller particles (<10 μm)

into the detection zone of the test method (≥10 μm). Intrinsic sources of detectable particulate matter are of great concern, because the substance may be present, but not evident until particles form over time, even long after lot release.

Regardless of material character or source, the simple intent of the determination is to quantitate the level of all detectable particulate matter. Two quite different methods are provided herein for the determination of particulate matter: light obscuration and membrane microscope, in a two-stage test approach. If possible, the product solution is first tested by the light obscuration (LO) procedure (stage 1). If it fails to meet the test limits, the product should then be tested by the membrane microscope (MM) procedure (stage 2) with its own set of test limits. These methods are for solution products; however, certain solution formulations may not be easily analyzed by LO. Any product that does not have a clarity and a viscosity approximating those of water may provide erroneous data when analyzed by the light obscuration counting method. Also, formulation characteristics such as color, viscosity, or inherent solution properties (shear-induced changes) may provide erroneous LO data. Similarly, products that produce air or gas bubbles when drawn into the LO sensor, such as bicarbonate-buffered formulations may provide erroneous data. For these product solutions, membrane microscope testing should be used exclusively. Documentation demonstrating that the light obscuration procedure is incapable of testing the test article or produces invalid results is required in each case. It is expected that most test articles will meet the requirements on the basis of the light obscuration test alone; however, it may be necessary to assay some test articles by the light obscuration method followed by the membrane microscope method in order to reach a conclusion. Refer to the specific monographs when a question of test applicability occurs. Higher limits may be appropriate for certain products and should be specified in the individual monograph.

Certain products may not be amenable to direct or simple analysis due to volumes of 1 mL or less or delivery characteristics. Examples include low-volume parenteral and ophthalmic products and those in novel packages intended for specific uses. The expectation is compliance for these products; however, the methods of the manufacturer may need to be validated to demonstrate conformance with the test limits. Special low-volume 'sippers' for LO sampling and the pooling of multiple containers may be necessary for these package presentations. Consider this example: a low-volume (100 μL) product is packaged in a prefilled sterile syringe. The nature of the package allows simple delivery of the solution product and may be used for direct sampling, but the 100-μL volume precludes the pooling of the larger volumes (~25 mL) for the LO method. Direct sampling to a small membrane for microscopical counting and evaluating single and pooled package particle content may be the optimal means to collect data. Also in this example, careful statistical evaluation of the batch population using small sample volumes (but not doses) will be necessary to validate product acceptability.

In some instances, the viscosity of a product may be sufficiently high so as to preclude its analysis by either test method. In this event, a quantitative dilution with an appropriate diluent may be made to decrease viscosity, as necessary, to allow the analysis to be performed.

In the tests described below for all product forms, the results obtained in examining a discrete unit or group of units for particulate matter cannot be extrapolated with certainty to other units that remain untested. Thus, statistically sound sampling plans based on known operational factors should be developed if valid inferences are to be drawn from observed data to characterize the level of particulate matter in a large group of units. Sam-

pling plans should be based on consideration of product volume, dose evaluated, numbers of particles historically found to be present in comparison to limits, particle size distribution of particles present, and variability of particle counts between units.

LIGHT OBSCURATION PARTICLE COUNT TEST

USP Reference Standards ⟨11⟩—USP Particle Count RS for system suitability testing.

The test applies to large-volume injections (LVI) labeled as containing more than 100 mL, unless otherwise specified in the individual monograph. This test applies also to single-dose or multiple-dose, small-volume injections (SVI) labeled as containing 100 mL or less that are either in solution or in solution constituted from sterile solids, in which a test for particulate matter is specified in the individual monograph. The test applies to ophthalmic solutions.

Test Apparatus

The apparatus is a liquid-borne particle counting system that uses a light-obscuration sensor with a suitable sample-feeding device to deliver controlled aliquots of sample for analysis. Suspended particles in the sample fluid flowing between a light source and sensor produce changes in signal that are correlated to particle dimension. Due to the nature of the detection and counting system, air bubbles and immiscible liquids may block sufficient light from being recorded along with the target suspended particles. Air bubbles must be diminished through proper preparation techniques. Immiscible liquids may be inherent to the package, such as lubrication oils. Solutions with excessive immiscible liquids may not be amenable to light obscuration analysis. Improper handling of certain samples, such as protein formulations, may form shear-induced semisolids due to mixing effects and the resultant semisolids counted as ''particles''. Adequate training should be provided for those responsible for the technical performance of the test.

For the light obscuration method, the ideal sample consists of a clear, water-like fluid with individual, free particles of moderate buoyancy and high contrast (opacity, color, refractive index) such that each particle passing between the illuminator and sensor effectively blocks the illumination. It is the responsibility of those performing the test to ensure that the operating parameters of the instrumentation are appropriate to the required accuracy and precision of the test result and that the artifacts and interferences inherent in certain products and with certain methods of preparation are eliminated or accommodated. An example is a protein formulation that may form shear-induced semisolids due to mixing and counted as ''particles''. Adequate training should be provided for those responsible for the technical performance of the test.

It is important to note that for Pharmacopeial applications the ultimate goal is that the particle counter reproducibly size and count particles present in the material under investigation. The instruments available range from systems in which calibration and other components of standardization are carried out using manual procedures to sophisticated systems incorporating hardware- or software-based functions for the standardization procedures. Thus, it is not possible to specify exact methods to be followed for standardization of the instrument, and it is necessary to emphasize the required end result of a standardization procedure rather than a specific method for obtaining this result. This section is intended to emphasize the criteria that must be met by a system rather than specific methods to be used in their determination. It is the responsibility of the user to apply the various

methods of standardization applicable to a specific instrument. Critical operational criteria consist of the following.

SENSOR CONCENTRATION LIMITS

Use an instrument that has a concentration limit (the maximum number of particles per mL) identified by the manufacturer that is greater than the concentration of particles in the test specimen to be counted. The vendor-certified concentration limit for a sensor is specified as that count level at which coincidence counts due to simultaneous presence of two or more particles in the sensor view volume comprise less than 10% of the counts collected for 10-μm particles.

SENSOR DYNAMIC RANGE

The dynamic range of the instrument used (range of sizes of particles that can be accurately sized and counted) should include the smallest particle size to be enumerated in the products.

Instrument Standardization Tests

The following discussion of instrument standardization emphasizes performance criteria rather than specific methods for calibrating or standardizing a given instrument system. This approach is particularly evident in the description of calibration, in which allowance must be made for manual methods as well as those based on hardware, software, or the use of electronic testing instruments. Appropriate instrument qualification is essential to performance of the test according to requirements. Because different brands of instruments may be used in the test, the user is responsible for ensuring that the counter used is operated according to the manufacturer's specific instructions. The principles that should be followed to ensure that instruments operate within acceptable ranges are defined below. The following information for instrument standardization helps ensure that the sample volume accuracy, sample flow rate, particle size response curve, sensor resolution, and count accuracy are appropriate to performance of the test. Procedures should be conducted at intervals of not more than 6 months.

SAMPLE VOLUME ACCURACY

Because the particle count from a sample aliquot varies directly with the volume of fluid sampled, it is important that the sampling accuracy is known to be within a certain range. For a sample volume determination, determine the dead (tare) volume in the sample feeder with particle-free water.[1] Transfer a volume of particle-free water that is greater than the sample volume to a container, and weigh. Using the sample feeding device, withdraw a volume that is appropriate for the specific sampler, and again weigh the container. Determine the sample volume by subtracting the tare volume from the combined sample plus tare volumes. Verify that the value obtained is within 5% of the appropriate sample volume for the test. Alternatively, the sample volume may be determined using a suitable Class A graduated cylinder (see *Volumetric Apparatus* ⟨31⟩). [NOTE—Instruments of this type require a variable tare volume. This is the amount of sample withdrawn prior to counting. This volume may be determined for syringe-operated samplers by setting the sample volume to zero and initiating sampling, so that the only volume of solution drawn is the tare. Subtract the tare volume from the total volume of solution drawn in the sampling cycle to determine the sample volume.]

[1] The particle-free water should be passed through a filter having a nominal pore size of 1.2 μm or finer.

SAMPLE FLOW RATE

Verify that the flow rate is within the manufacturer's specifications for the sensor used. This may be accomplished by using a calibrated stopwatch to measure the time required for the instrument to withdraw and count a specific sample volume (i.e., the time between beginning and ending of the count cycle as denoted by instrument indicator lights or other means). Sensors may be operated accurately over a range of flow rates. Perform the *Test Procedure* at the same flow rate as that selected for calibration of the instrument.

CALIBRATION

Use one of the following methods:

Manual Method—Calibrate the instrument with a minimum of three calibrators, each consisting of near-monosize polystyrene spheres having diameters of about 10, 15, and 25 μm, in an aqueous vehicle. The calibrator spheres should have a mean diameter of within 5% of the 10-, 15-, and 25-μm nominal diameters and be standardized against materials traceable to NIST standard reference materials.[2] The total number of spheres counted should be within the sensor's concentration limit. Prepare suspensions of the calibrator spheres in water at a concentration of 1000–5000 particles per mL, and determine the channel setting that corresponds to the highest count setting for the sphere distribution. This is determined by using the highest count threshold setting to split the distribution into two bins containing equal numbers of counts, with the instrument set in the differential count mode (moving window half-count method). Use only the central portion of the distribution in this calculation to avoid including asymmetrical portions of the peak. The portion of the distribution, which is divided equally, is the count window. The window is bounded by threshold settings that will define a threshold voltage window of $\pm$20% around the mean diameter of the test spheres. The window is intended to include all single spheres, taking into account the standard deviation of the spheres and the sensor resolution, while excluding noise and aggregates of spheres. The value of 20% was chosen based on the worst-case sensor resolution of 10% and the worst-case standard deviation of the spheres of 10%. Because the thresholds are proportional to the cross-sectional area of the spheres (and all particles) rather than the diameter, the lower and upper voltage settings are determined by the equations:

$$V_L = 0.64V_S$$

in which V_L is the lower voltage setting and V_S is the voltage at the peak center, and

$$V_U = 1.44V_S$$

in which V_U is the upper voltage setting. Once the center peak thresholds are determined, use these thresholds for the standards to create a regression of log voltage versus log particle size, from which the instrument settings for the 10- and 25-μm sizes can be determined.

Automated Method—The calibration (size response) curve may be determined for the instrument-sensor system by the use of validated software routines offered by instrument vendors; these may be included as part of the instrument software or used in conjunction with a microcomputer interfaced to the counter. The use of these automated methods is appropriate if the vendor supplies written certification that the software provides a response curve equivalent to that attained by the manual method and if the automated calibration is validated as necessary by the user.

Electronic Method—Using a multichannel peak height analyzer, determine the center channel of the particle counter pulse response for each standard suspen-

[2] ASTM standard F658-87 provides useful discussions pertaining to calibration procedures applying near-monosize latex spheres.

sion. This peak voltage setting becomes the threshold used for calculation of the voltage response curve for the instrument. The standard suspensions used for the calibration are run in order, and median pulse voltages for each are determined. These thresholds are then used to generate the size response curve manually or via software routines. The thresholds determined from the multichannel analyzer data are then transferred to the counter to complete the calibration.

SENSOR RESOLUTION

The particle size resolution of the instrumental particle counter is dependent upon the sensor used and may vary with individual sensors of the same model. Determine the resolution of the particle counter for 10-μm particles using the 10-μm calibrator spheres. The relative standard deviation of the size distribution of the standard particles used is not more than 5%. Acceptable methods of determining particle size resolution are manual determination of the amount of peak broadening due to instrument response; using an electronic method of measuring and sorting particle sensor voltage output with a multichannel analyzer; and automated methods.

Manual Method—Adjust the particle counter to operate in the cumulative mode or total count mode. Refer to the calibration curve obtained earlier, and determine the threshold voltage for the 10-μm spheres. Adjust 3 channels of the counter to be used in the calibration procedure as follows:

Channel 1 is set for 90% of the threshold voltage.

Channel 2 is set for the threshold voltage.

Channel 3 is set for 110% of the threshold voltage.

Draw a sample through the sensor, observing the count in *Channel 2*. When the particle count in that channel has reached approximately 1000, stop counting, and observe the counts in *Channels 1* and *3*. Check to see if the *Channel 1* and *3* counts are 1.68 ±10% and 0.32 ±10%, respectively, of the count in *Channel 2*. If not, adjust the *Channel 1* and *3* thresholds to meet these criteria. When these criteria have been satisfied, draw a sample of suspension through the counter until the counts in *Channel 2* have reached approximately 10,000, or until an appropriate volume (e.g., 10 mL) of the sphere suspension has been counted. Verify that the *Channel 1* and *3* counts are 1.68 ±3% and 0.32 ±3%, respectively, of the count in *Channel 2*. Record the particle size for the thresholds just determined for *Channels 1, 2,* and *3*. Subtract the particle size for *Channel 2* from the size for *Channel 3*. Subtract the particle size for *Channel 1* from the size for *Channel 2*. The values so determined are the observed standard deviations on the positive and negative side of the mean count for the 10-μm standard. Calculate the percentage of resolution of the sensor by the formula:

$$100\left(\sqrt{S_O^2 - S_S^2/D}\right)$$

in which S_O is the highest observed standard deviation determined for the sphere; S_S is the supplier's reported standard deviation for the spheres; and D is the diameter, in μm, of the spheres as specified by the supplier. The resolution is not more than 10%.

Automated Method—Software that allows for the automated determination of sensor resolution is available for some counters. This software may be included in the instrument or used in conjunction with a microcomputer interfaced to the counter. The use of these automated methods is appropriate if the vendor supplies written certification that the software provides a resolution determination equivalent to the manual method and if the automated resolution determination is validated as necessary by the user.

In-Process Revision

Electronic Method—Record the voltage output distribution of the particle sensor, using a multichannel analyzer while sampling a suspension of the 10-μm particle size standard. To determine resolution, move the cursor of the multichannel analyzer up and down the electric potential scale from the median pulse voltage to identify a channel on each side of the 10-μm peak that has approximately 61% of the counts observed in the center channel. Use of the counter size response curve to convert the mV values of these two channels to particle sizes provides the particle size at within one standard deviation of the 10-μm standard. Use these values to calculate the resolution as described under *Manual Method*.

PARTICLE COUNTING ACCURACY—SYSTEM SUITABILITY

Determine the particle counting accuracy of the instrument, using *Method 1* (for sensors requiring the moving window half-count (MWHC) method for calibration), *Method 2* (for multichannel sensors), or *Method 3* for any instrument (manual comparison to membrane microscope method).

Method 1 (MWHC Instruments)—

Procedure—Prepare the suspension and blank using the USP Particle Count RS. With the instrument set to count in the cumulative (total) mode, collect counts at settings of ≥10 μm and ≥15 μm. Prepare the blank and suspension sample in the same manner. Degas the mixture by one of three means: sonication (at 80–120 watts) for about 30 seconds, or by allowing to stand, or by vacuum. Gently stir the contents by hand-swirling or by mechanical means, taking care not to introduce air bubbles or contamination. Stir continuously throughout the analysis. Withdraw directly from the container three consecutive volumes of NLT 5 mL each, obtain the particle counts, and discard the data from the first portion. [NOTE—Complete the procedure within 5 minutes.] Repeat the procedure, using the suspension in place of the blank. From the averages of the counts resulting from the analysis of the two portions of the suspension at ≥10 μm and from the analysis of the two portions of the blank at ≥10 μm, calculate the number of particles in each mL by the formula:

$$(P_S - P_B)/V$$

in which P_S is the average particle count obtained from the suspension; P_B is the average particle count obtained from the blank; and V is the average volume, in mL, of the four portions tested. Repeat the calculations, using the results obtained at the setting of NLT 15 μm.

Interpretation—The MWHC instrument meets the requirements for *Particle Counting Accuracy* if the count obtained at ≥10 μm and the ratio of the counts obtained at ≥10 μm to those obtained at ≥15 μm conform to the values that accompany the USP Particle Count RS. If the instrument does not meet the requirements for *Particle Counting Accuracy*, and adequate test volumes remain, repeat the procedure with them. Prepare new suspension and blank if insufficient volumes remain and then repeat the procedure. If the results of the second test are within the limits given above, the instrument meets the requirements of the test for *Particle Counting Accuracy*. If on the second attempt the system does not meet the requirements of the test, determine and correct the source of the failures, and retest the instrument.

Method 2 (Multichannel Instruments)—

Procedure—Use either (a) a dilution of the USP Particle Count RS; or (b) a commercial preparation of standard calibrator spheres of nominal diameter 15–30 μm in a suspension containing between 50 and 200 particles per mL, certified by the manufacturer; or (c) a laboratory-prepared suspension of standard calibrator spheres having a nominal diameter of 15–30 μm, containing between 50 and 200 particles per mL. Use of non-USP stan-

dards ''b'' and ''c'' is acceptable when they are compliant with USP standardization criteria: five successive counts are NMT ±10% of stated size.

Degas the suspension by one of three means: sonication (at 80–120 watts) for about 30 seconds, or by allowing to stand, or by vacuum. Gently stir the contents by hand-swirling or by mechanical means, taking care not to introduce air bubbles or contamination. Stir continuously throughout the analysis and perform five counts on 5-mL volumes of the suspension, using the particle counter 10-μm size threshold. Obtain the mean cumulative particle count per mL.

Interpretation—The instrument meets the requirements for *Particle Counting Accuracy* if the count obtained at ≥10 μm conforms to the values that accompany the USP Particle Count RS. If the instrument does not meet the requirements for *Particle Counting Accuracy*, repeat the procedure. If the results of the second test are within the limits given above, the instrument meets the requirements of the test for *Particle Counting Accuracy*. If on the second attempt the system does not meet the requirements of the test, determine and correct the source of the failures, and retest the instrument.

Method 3 (Alternate Manual Method)—

Procedure—Prepare a suspension of standard calibrator spheres having a nominal diameter of 15–30 μm, containing between 50 and 200 particles per mL. Degas the suspension by one of three means: sonication (at 80–120 watts) for about 30 seconds, or by allowing to stand, or by vacuum. Gently stir the contents by hand-swirling or by mechanical means, taking care not to introduce air bubbles or contamination. Stir continuously throughout the analysis and perform five counts on 5-mL volumes of the suspension, using the particle counter 10-μm size threshold. Obtain the mean cumulative particle count per mL. Pipet a volume of this suspension containing 250–500 particles into a filter funnel prepared as described for *Filtration Apparatus* under *Membrane Microscope Particle Count Test*. After drying the membrane, count the total number of standard spheres collected on the membrane filter. This count should be within 20% of the mean instrumental count per mL for the suspension.

Test Environment

Perform the test in an environment that does not contribute any significant amount of particulate matter. Specimens should be cleaned to the extent that any level of extraneous particles added has a negligible effect on the outcome of the test. Preferably, the test specimen, glassware, closures, and other required equipment are prepared in an environment protected by high-efficiency particulate air (HEPA) filters, and nonshedding garments and powder-free gloves are worn throughout the preparation of samples.

Cleanse glassware, closures, and other required equipment, preferably by immersing and cleaning the items using warm, nonionic detergent solution. Rinse in flowing tap water, and then rinse again in flowing filtered water. Organic solvents may also be used to facilitate cleaning. [NOTE—These steps describe one way to clean equipment; alternatively, particulate-free equipment may be obtained from a suitable vendor.] Just before use, rinse the equipment in filtered water, using a hand-held pressure nozzle with final filter or other appropriate filtered water source. To collect blank counts, use a cleaned vessel of the type and volume representative of that to be used in the test. Place a 50-mL or more volume of filtered water in the vessel, and agitate the water sample in the cleaned glassware by inversion or swirling. [NOTE—A smaller volume, consistent with the article to be counted, can be used.] Degas by one of three means: sonication (at 80–120 watts) for about 30 seconds, or by vacuum, or by allowing to stand. Swirl the vessel containing the water sample by hand or agitate by mechanical

means to suspend particles. Determine the particulate matter in five samples of filtered water, each of 5 mL. If the number of particles of 10 μm or greater size exceeds 25 for the combined 25 mL (NMT 1/mL), the precautions taken for the test are not sufficient: the filtered water or glassware have not been properly prepared or the counter is generating spurious counts. In this case, repeat the preparatory steps until conditions of analysis are suitable for the test. It is recommended that when utilizing the test for the *Particulate Matter in Ophthalmic Solutions* ⟨789⟩ method, the blank test should be considered failed, if in addition, the number of particles of 25 μm or greater in size exceeds 3.

Test Procedure

TEST PREPARATION

Prepare the test specimens in the following sequence. Outside of the unidirectional airflow cabinet to be used for the test, remove outer closures, sealing bands, and remove or tape over labels. Rinse the exteriors of the containers with filtered water as directed under *Test Environment*. Protect the containers from environmental contamination until analyzed. Open and withdraw, pour, or otherwise sample the contents of the containers under test in a manner least likely to generate particles that could enter the test specimen. Contents of containers with removable stoppers may be withdrawn directly by removing the closures. Sampling devices having a needle to penetrate the unit closure may also be employed. Products packaged in flexible plastic containers may be sampled by cutting the medication or administration port tube or a corner from the unit with a suitably cleaned razor blade or scissors. Dry or lyophilized products may be constituted using their internal diluent, by removing the closure to add supplied product diluent or by injecting filtered water via hypodermic syringe. If test specimens are to be pooled, remove the closure and empty the contents into a clean container.

NUMBER OF TEST SPECIMENS

The number of test specimens should be adequate to provide a statistically sound assessment of whether a batch or other large group of units is adequately represented. At minimum, if the volume in the container is less than 25 mL, test a solution pool of 10 or more units to provide at least 25 mL. Small-volume parenteral injection product or ophthalmic product units may be tested individually if the unit volume is 25 mL or more. For large-volume injections, individual units are tested.

For all products, regardless of volume, comprehensive experience regarding the integrity and consistency of the batch is gained throughout development, allowing the proper sampling plans to be applied in commercial production that ensure sample selection is representative of batch quality. All batches should have sampling plans that accommodate desired statistical measures of batch quality and facilitate process control.

PRODUCT DETERMINATION

Depending upon the dosage form being tested, proceed as directed under the appropriate category below.

Liquid Preparations—

Volume in Container Less Than 25 mL—Prepare the containers as directed under *Test Preparation*. Mix and suspend the particulate matter in each unit by inverting the unit 20 times. [NOTE—Because of the small volume of some products, it may be necessary to agitate the solution more vigorously to suspend the particles properly.] Open and combine the contents of 10 or more units in a cleaned container, to obtain a volume of NLT 25 mL. De-

gas the pooled solution by one of three means: sonication for about 30 seconds, or by vacuum, or by allowing the solution to stand.

Gently stir the contents of the container by hand-swirling or by mechanical means, taking care not to introduce air bubbles or contamination. Remove four portions, each of NLT 5 mL, and count the number of particles ≥10 μm and 25 μm. Disregard the result obtained for the first portion. [NOTE—For low-volume products, a pool of 15 or more units may be necessary to achieve a pool volume sufficient for four 5-mL sample aliquots. Smaller sample aliquots (i.e., less than 5 mL) can be used if the assay result obtained with the smaller aliquots is validated to give an assessment of batch suitability equivalent to that obtained with the 5-mL aliquots specified above.]

Volume in Container 25 mL or More—Prepare the containers as directed under *Test Preparation*. Mix and suspend the particulate matter in each unit by inverting the unit 20 times prior to opening the container for degassing. Degas the solution by one of three means: by sonication for about 30 seconds, or by vacuum, or by allowing the solution to stand. When sampling, ensure that the counter probe can be inserted into the middle of the solution. Gently stir the contents of the unit by hand-swirling or by mechanical means. Remove four portions, each of NLT 5 mL, and count the number of particles ≥10 μm and 25 μm. Disregard the result obtained for the first portion.

Dry or Lyophilized Preparations—Prepare the containers as directed under *Test Preparation*. Open each container, taking care not to contaminate the opening or cover. Constitute as directed under *Test Preparation*, using the specified volume of enclosed filtered water or an appropriate laboratory-filtered diluent if suitable. Replace the closure, and manually agitate the container sufficiently to dissolve the drug. [NOTE—For some dry or lyophilized products, it may be necessary to let the containers stand for a suitable interval, and then agitate again to dissolve.] After the drug in the constituted sample is completely dissolved, degas the solution by sonication for about 30 seconds, or by exposing to vacuum, or by allowing the solution to stand. When sampling, ensure that the counter probe can be inserted into the middle of the solution. Gently stir the contents of the unit by hand-swirling or by mechanical means to mix and suspend any particulate matter. Proceed as directed for the appropriate unit volume under *Liquid Preparations*, and analyze by withdrawing a minimum of four portions, each of NLT 5 mL, and count the number of particles ≥10 and 25 μm. Disregard the result obtained for the first portion.

Products Packaged with Dual Compartments Constructed to Hold the Drug Product and a Solvent in Separate Compartments—Prepare the units to be tested as directed under *Test Preparation* and according to product insert directions. Mix each unit as directed in the labeling, activating and agitating so as to ensure thorough mixing of the separate components and drug dissolution. Open and degas the units or pooled specimen to be tested by one of three means: sonication, or by vacuum, or by allowing the solution to stand. Proceed as directed for the appropriate unit volume under *Liquid Preparations*, mix and suspend the particulate matter present in each unit by inversion or swirling or by mechanical means and analyze by withdrawing a minimum of four portions, each of NLT 5 mL, and count the number of particles ≥10 and 25 μm. Disregard the result obtained for the first portion.

Products Labeled ''Pharmacy Bulk Package Not for Direct Infusion''—Proceed as directed for *Liquid Preparations* when the volume is 25 mL or more. Calculate the test result on a portion that is equivalent to the maximum dose given in the labeling. For example, if the total bulk package volume is 100 mL and the maximum dose volume is 10 mL, then the average light obscuration

particle count per mL would be multiplied by 10 to obtain the test result based on the 10-mL maximum dose. [NOTE—For the calculations of test results, consider this maximum dose portion to be the equivalent of the contents of one full container.]

LO Calculations

Note that the particle limits should be reported as all particles ≥10 μm and all particles ≥25 μm. If the instrument has been configured to count in differential bins, such as ≥10–25 μm, ≥25–50 μm, ≥50 μm, etc., all bins ≥10 μm are added to yield total ≥10 μm count; all bins ≥25 μm need to be added to yield total count ≥25 μm.

For example, the analyst has counted the test samples in eight bins: a) ≥10–15 μm, b) ≥15–25 μm, c) ≥25–40 μm, d) ≥40–75 μm, e) ≥75–100 μm, and f) ≥100 μm. $P_{\Sigma\geq 10}$ would then be calculated as:

$$P_{\Sigma\geq 10} = P_{\geq 10\text{–}15\ \mu m} + P_{\geq 15\text{–}25\ \mu m} + P_{\geq 25\text{–}40\ \mu m} + P_{\geq 40\text{–}75\ \mu m} + P_{\geq 75\text{–}100\ \mu m} + P_{\geq 100\ \mu m}$$

POOLED SAMPLES

Average the counts from the two or more aliquot portions analyzed. Calculate the number of particles in each container by the formulae:

$$P_{\Sigma 10} V_T / V_A n$$

$$P_{\Sigma 25} V_T / V_A n$$

in which $P_{\Sigma 10}$ is the average particle count per threshold obtained from all portions analyzed and $P_{\Sigma 25}$ is the average particle count per threshold obtained from all portions ≥25 μm analyzed. V_T is the volume, in mL, of pooled sample; V_A is the volume, in mL, of each portion analyzed; and n is the number of containers pooled.

INDIVIDUAL SAMPLES

Average the counts obtained for the 5-mL or greater aliquot portions from each separate unit analyzed, and calculate the number of particles in each container by the formulae:

$$P_{\Sigma 10} V / V_A$$

$$P_{\Sigma 25} V / V_A$$

in which $P_{\Sigma 10}$ is the average particle count obtained from all portions analyzed and $P_{\Sigma 25}$ is the average particle count obtained from all portions portions ≥25 μm analyzed. V is the volume, in mL, of the tested unit; and V_A is the volume, in mL, of each portion analyzed.

INDIVIDUAL UNIT SAMPLES

Average the counts obtained for the two or more 5-mL aliquot portions taken from the solution unit. Calculate the number of particles in each mL of product solution taken by the formulae:

$$P_{\Sigma 10} / V$$

$$P_{\Sigma 25} / V$$

in which $P_{\Sigma 10}$ is the average particle count per threshold obtained from all portions analyzed and $P_{\Sigma 25}$ is the average particle count per threshold obtained from all portions ≥25 μm analyzed. V is the volume, in mL, of the portion taken.

For all types of product, if the tested material has been diluted to decrease the viscosity, the dilution factor must be accounted for in the calculation of the final test result. For all test results, the particle count $\geq$10 μm represents all threshold bin counts.

MEMBRANE MICROSCOPE PARTICLE COUNT TEST

The microscope particulate matter test may be applied to all product types: both large-volume and small-volume parenteral injections and ophthalmic solution products. This test enumerates any material retained on the isolation membrane[3] $\geq$10 μm after rinsing and drying the membrane. Because a wide range of test aliquots may be utilized, particle counts may be determined on a per volume or per container basis without dilution or extrapolation. The MM method is often used in conjunction with LO methodology, providing isolated particles for further study. In some cases test articles cannot be tested meaningfully by stage 1 light obscuration, and so the MM assay is the sole method for particle enumeration.

In the performance of the MM assay, estimate the size of retained solids viewed at 100× magnification, tabulating them into specific size categories. In this process, materials may be encountered on the membrane surface that do not appear solid or substantial, showing little or no surface relief such as a ''stain'' or discontinuity on the membrane. For the purpose of this assay, do not attempt to size or enumerate such semisolid particles. However, from a formulation robustness aspect, consistent evidence of such materials may be indication that further development research is warranted to understand their content. The nature of these materials and subsequent decision to count or investigate must be based on product formulation experience. Interpretation of microscopical enumeration may be aided by testing a sample of the solution by the light obscuration particle count or a validated, alternate method.

Test Apparatus

MICROSCOPE

Use a compound binocular microscope that corrects for changes in interpupillary distance by maintaining a constant tube length. The objective and eyepiece combination of lenses should give a magnification of 100 ± 10×. The objective should be of 10× nominal magnification, a planar achromat or better in quality, with a minimum numerical aperture of 0.25. In addition, the objectives should be compatible with an episcopic illuminator attachment. The eyepieces should be matched. In addition, one eyepiece should be designed to accept and focus an eyepiece graticule. The microscope should have a mechanical stage capable of holding and traversing the entire filtration area of a 25- or 47-mm membrane filter.

ILLUMINATORS

Two illuminators are required. One is an external, focusable illuminator that can be adjusted to give incident oblique illumination at an angle of 10° to 20°. The other is an episcopic brightfield illuminator internal to the microscope. Both illuminators should be of sufficient output to provide a bright and even source of illumination and may be equipped with blue daylight filters to decrease operator fatigue during use.

[3] Soft particles and semisolid substances may also be retained.

CIRCULAR DIAMETER GRATICULE

Use a circular diameter graticule (see *Figure 1*) matched to the microscope model objective and eyepiece such that the sizing circles are within 2% of the stated size at the plane of the stage.

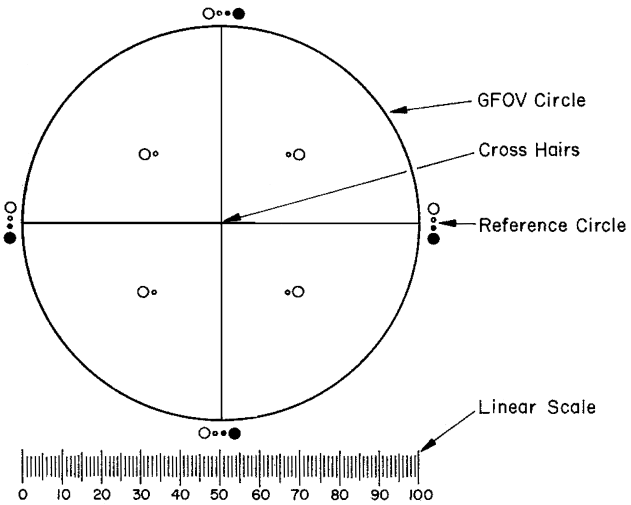

Figure 1. Circular diameter graticule. The large circle divided by crosshairs into quadrants is designated the graticule field of view (GFOV). Transparent and black circles having 10- and 25-μm diameters at 100 × are provided as comparison scales for particle sizing.

STAGE MICROMETER

A commercial stage micrometer, such as 1 mm in 10-μm increments, is quite useful for day-of-use verification of 100 × set-up. The USP graticule will not change; however, optical elements of the microscope may have been altered, or the improper objective may been selected for the count—verification of the USP graticule linear scale with the stage micrometer linear scale is a simple and unequivocal verification of proper magnification.

FILTRATION APPARATUS

Use a filter funnel suitable for the volume to be tested, generally having an inner diameter of about 20 mm for 25 mm membranes or about 38 mm for 47 mm membranes. The funnel is made of plastic, glass, or stainless steel. Use a filter support made of stainless steel screen or sintered glass as the filtration diffuser. The filtration apparatus is equipped with a vacuum source, a solvent dispenser capable of delivering solvents filtered through a membrane filter at a range of pressures from 10–80 psi, and membrane filters (25- or 47-mm nongridded or gridded, black or dark gray (of a suitable material that is compatible with the product), with a nominal pore size of 1.0 μm or finer). The use of finer pore-size membranes for counting may be preferable because the membrane surface is much smoother and yields improved contrast for particle margin recognition. However, finer pore size selections may impede more viscous sample fluid during the assay. Finally, always use nonserrated forceps to handle membrane filters.

Test Environment

It is ideal to use two unidirectional airflow hoods (UAFH) or other unidirectional airflow enclosures, one for ''wet'' sample preparations, and the other an enclosure for the microscope counting phase. The UAFH has a capacity sufficient to envelop the area in which the analysis is prepared. The UAFH provides HEPA-filtered air, which typically contains NMT 100 particles (0.5 μm or larger) per cubic meter. A blank determination is necessary at the beginning of each test sequence to verify minimal contribution from the background, equipment, and personnel operations. To determine the blank count, assemble a clean filtration apparatus with a fresh membrane, rinse the interior with filtered water to drain, then deliver a 50-mL or more volume of filtered water to the filtration funnel while applying vacuum, and draw

the entire volume of water through the membrane filter. Remove the membrane from the filter funnel base, and place onto a holding device that will be used for test specimens, typically atop a strip of double-sided tape on a microscope slide or in a commercial membrane holder or Petri dish. After allowing the membrane to dry, examine the entire filtration area microscopically at a magnification of 100 ×. If NMT 20 particles ≥10 μm and NMT 5 particles ≥25 μm or larger are present within the filtration area, the background particle level is sufficiently low for performance of the microscope assay for *Particulate Matter in Injections* ⟨788⟩. If the particle load exceeds these limits, repeat the procedure.

There is value in further limiting the background for both injections and ophthalmic solutions testing in regard to good laboratory practice, and more specifically in regard to the *Particulate Matter in Ophthalmic Solutions* ⟨789⟩ ≥25 μm and ≥50 μm limits, which may be considered more restrictive than injectable limits in consideration of total particle content allowed for the (usually) small-unit volumes. Compare total particle load for a lower volume SVI and lower volume LVI with a 5-mL ophthalmic product in the following table.

Comparison of Total At-limit Load for Selected Products

Size Limit	Blank Count	SVI, 5 mL	LVI, 125 mL	Ophthalmic Product, 5 mL
≥10 μm	20	3000 particles	1500 particles	250 particles
≥25 μm	5	300 particles	250 particles	25 particles
≥50 μm	Not defined	N/A	N/A	10 particles

Therefore, for the smaller volume ophthalmic products and for a low-particle count injectable product, it may be beneficial for the laboratory to strive for consistent and low blank counts such as NMT 5 ≥10 μm, NMT 1 ≥25 μm and none ≥50 μm per blank.

Throughout this procedure, it is preferable to use powder-free gloves and thoroughly clean glassware and equipment. Prior to conducting the test, clean the work surfaces of the unidirectional flow enclosure with an appropriate filtered solvent. Glassware and equipment should be rinsed successively with a warm, residue-free solution of detergent, hot water, filtered distilled or deionized water, and isopropyl alcohol. [NOTE—Prior to use, pass the distilled or deionized water and the isopropyl alcohol through membrane filters having a nominal pore size of 0.2-μm or finer.] Perform the rinsing in the unidirectional airflow enclosure. Allow the glassware and filtration apparatus to dry in the unidirectional airflow enclosure, upstream of all other operations. Preferably, the enclosure is located in a separate room that is supplied with filtered air-conditioned air and maintained under positive pressure with respect to the surrounding areas.

MICROSCOPE PREPARATION

Two illuminators are necessary. First, select a filter membrane containing particles, and position it for counting on the microscope stage, for viewing at 100 ×. Next, using an auxiliary illuminator, bring the illumination close to the microscope stage to give a concentrated area of illumination on the filter membrane, and adjust the illuminator height so that the angle of incidence of the light is 10–20 with the horizontal, providing a full and even illumination when viewing the membrane at 100 ×. Next, using an internal episcopic brightfield illuminator, fully open the field and aperture diaphragms. Center the lamp filament, and focus the microscope on

the above membrane. Adjust the intensity of reflected illumination until particles are clearly visible and show pronounced shadows. This is often done by adjusting the intensity of episcopic illumination to the lowest setting, then increasing the intensity until shadows cast by particles show the least perceptible decrease in contrast.

USING THE CIRCULAR DIAMETER GRATICULE

The USP graticule is specifically fabricated for each microscope. The relative error of the graticule used is ±2% and is initially measured with a NIST-certified stage micrometer. To accomplish this, align the graticule micrometer scale with the stage micrometer so that they are parallel. (Compare the scales, using as large a number of graduations on each as possible.) Read the number of graticule scale divisions, GSD, compared to stage micrometer divisions, SMD. Calculate the relative error by the formula:

$$100[(GSD - SMD)/SMD]$$

A relative error of ±2% is acceptable and verifies good alignment, focus, and proper magnification. Thereafter, a day-of-use verification by the microscope operator with the NIST stage micrometer or commercial stage micrometer is sufficient to demonstrate proper setup.

The basic technique of measurement applied with the use of the circular diameter graticule is to count all particles 10 μm and larger, further categorizing into ≥10-μm and ≥25-μm particles. The circular zone or graticule field of view is a useful zone for active sizing and counting. Particles are compared to the linear scale and/or circles to determine their size in equivalent circular diameter. This is conducted by transforming mentally the image of each particle into a circle and then comparing to the 10- and 25-μm graticule reference circles. The sizing process is carried out without superimposing the particle on the reference circles; particles are not moved from their locations within the graticule field of view (the large circle) for comparison to the reference circles. Compare the area of the particle being sized to that of the black or transparent circles. Use the area of the clear graticule reference circles to size white or transparent particles. Use the area of the black reference circles to size dark particles. The intent of comparing particles to an equivalent circular diameter is correlation to the light obscuration particle sizing methodology, for which many manufacturers have extensive databases. In practice, particles with nearly circular areas will correlate well with the graticule circle diameters. For particles with one long axis, such as rods and needles, the conversion to circular area will produce more significant bias to smaller estimated sizes. It may be simpler, and most conservative, to count particles in the longest chord. To use an extreme example, the total count of mono-dispersions of fine needle crystals would vary greatly depending on the size determination utilized.

In order to properly focus the ocular lenses and attain balanced single-field view, each operator must bring the USP graticule lines into sharp focus by adjusting the eyepiece diopter ring (it helps to have an ''infinite'' view, or out-of-focus specimen). Next, focus the microscope on a specimen, through this same eyepiece, and then looking only through the other eyepiece, adjust its diopter ring to bring the specimen into sharp focus. The USP graticule and specimen particles are now in focus on a well-balanced illumination field.

PREPARATION OF FILTRATION APPARATUS

Preferably, wash the filtration funnel, base, and diffuser in a solution of liquid detergent and hot water. Rinse with hot water. Following the hot water rinse, apply a second rinse with filtered water, using a pressurized jet of water over the entire exterior and interior surfaces of the filtra-

tion apparatus. Repeat the pressurized rinse procedure using filtered isopropyl alcohol. Finally, using the pressurized system, rinse the apparatus with filtered water.

Remove a membrane filter from its container, using ultra-cleaned nonserrated forceps. Use a low pressurized stream of filtered purified water to wash both sides of the filter thoroughly by starting at the top and sweeping back and forth to the bottom. Assemble the cleaned filtration apparatus with the diffuser on top of the filtration base, placing the clean membrane filter on top of the diffuser. Place the funnel assembly on top of the filtration base, and lock it into place.

Test Procedure

TEST PREPARATIONS

Prepare the test specimens in the following sequence. Outside of the unidirectional airflow cabinet used for the test, remove outer closures, sealing bands, and remove or tape over labels. Rinse the exteriors of the containers with filtered water as directed under *Test Environment*. Protect the containers from environmental contamination until analyzed. Open and withdraw, pour, or otherwise sample the contents of the containers under test in a manner least likely to generate particles that could enter the test specimen. Contents of containers with removable stoppers may be withdrawn directly by removing the closures. Sampling devices having a needle to penetrate the unit closure may also be employed. Products packaged in flexible plastic containers may be sampled by cutting the medication or administration port tube or a corner from the unit with a suitably cleaned razor blade or scissors. Dry or lyophilized products may be constituted using their internal diluent, by removing the closure to add supplied product diluent or by injecting filtered water via hypodermic syringe. If test specimens are to be pooled, remove the closure and empty the contents into a clean container.

NUMBER OF TEST SPECIMENS

The number of test specimens should be adequate to provide a statistically sound assessment of whether a batch or other large group of units is adequately represented. At minimum, if the volume in the container is less than 25 mL, test a solution pool of 10 or more units to provide at least 25 mL. Small-volume parenteral injection product or ophthalmic product units may be tested individually if the unit volume is 25 mL or more. For LVI, individual units are tested.

For all products, regardless of volume, comprehensive experience regarding the integrity and consistency of the batch is gained throughout development, allowing the proper sampling plans to be applied in commercial production that ensure sample selection is representative of batch quality. All batches should have sampling plans that accommodate desired statistical measures of batch quality and facilitate process control.

PRODUCT PARTICLE COUNT DETERMINATION

Depending upon the dosage form being tested, proceed as directed under the appropriate category below.

Liquid Preparations—Thoroughly mix the units to be tested by inverting 20 times. Open the units in a manner consistent with the generation of the lowest possible numbers of background particles. For products <25 mL in volume, one may open them and drain to the filtration barrel individually, or combine the contents of 10 or more units in a cleaned container. [NOTE—When pooling containers, these are included in the blank determination step.] Filter LVI units individually. SVI units that have a volume of 25 mL or more may be filtered individually.

Transfer to the filtration funnel the total volume of a solution pool or of a single unit, and apply vacuum. If the volume of solution to be filtered exceeds the volume of the filtration funnel, add, stepwise, a portion of the solution until the entire volume is filtered. It is prudent to maintain the liquid volume in the filtration funnel above one-half of the funnel volume between refills, especially if the partial count procedure is to be used (see *Partial Count Procedure* under *Enumeration of Particles*). [NOTE—This is necessary to ensure even distribution of particles on the analytical membrane.] After the last addition of solution, begin rinsing the walls of the funnel by directing a low-pressure stream of filtered water in a circular pattern along the walls of the funnel, and stop rinsing the funnel before the volume falls below about one-fourth of the fill level. Maintain the vacuum until all the liquid in the funnel is gone.

Remove the filtration funnel from the filtration base while maintaining vacuum, then turn the vacuum off, and remove the filter membrane with nonserrated forceps. Place the filter in the prepared holder and label with sample identification. Allow the filter to air-dry in the unidirectional airflow enclosure with the cover ajar.

Dry or Lyophilized Preparations—To test a dry powder vial or similar container of drug powder, constitute the material with an appropriate diluent, using the method least likely to introduce extraneous contamination, as directed for *Test Preparation* under *Light Obscuration Particle Count Test.* Using a solution pool of 10 or more units, or the desired number of individual units, proceed as directed for *Liquid Preparations.*

Products Packaged with Dual Compartments Constructed to Hold the Drug Product and a Solvent in Separate Compartments—Activate each unit as directed in the labeling, agitating the contents sufficiently to ensure thorough mixing of the separate components, and then proceed as directed for *Liquid Preparations.*

Pharmacy Bulk Packages or Multiple-Dose Containers—For *Products Labeled ''Pharmacy Bulk Package—Not for Direct Infusion''* or for multiple-dose containers, proceed as directed for *Liquid Preparations*, filtering the total unit volume.

Calculate the test result on a portion that is equal to the maximum dose given in the labeling. Consider this portion to be the equivalent of the contents of one full container. For example, if the total bulk package volume is 100 mL and the maximum dose listed is 10 mL, the microscopic total unit volume count test result would be multiplied by 0.1 to obtain the test result for the 10-mL dose volume. [NOTE—For calculation of the test result, consider this portion to be the equivalent of the contents of one full container.]

Enumeration of Particles

The microscope test described in this section is flexible in that typical artifacts such as air and immiscible liquids do not interfere with the final count. The method has a broad size detection and counting range, if applying the partial count procedure. This method may be used when all particles on an analysis membrane surface are counted or when only those particles on some fractional area of a membrane surface are counted.

TOTAL COUNT PROCEDURE

Note that the particle limits should be reported as all particles $\geq$10 μm and all particles $\geq$25 μm. If the lab method has been configured to tally the particle count in differential bins, such as $\geq$10–25 μm, $\geq$25–50 μm, $\geq$50 μm, etc., all tallies $\geq$10 μm are added to yield total $\geq$10 μm count; all bins $\geq$25 μm need to be added to yield total count $\geq$25 μm. Using a number of narrow size bins may be beneficial in product improvement efforts to separate particle groups.

In performance of a total count, the graticule field of view (GFOV) is defined by the large circle of the graticule and the vertical crosshair is used as a counting target. Scan the membrane in paths that cover the effective filtration area (EFA), adjoining but not overlapping previous scan paths. Repeat this procedure, tabulating particle counts minimally in the ≥10–25 μm and ≥25 μm thresholds, moving across the membrane until all particles on the membrane within the EFA are counted. More and narrower size range tallies may be deemed useful by the production team. Record the total number of particles that are ≥10–25 μm and the number that are ≥25 μm or larger.

For large-volume products, calculate the particle count, in particles per mL, for each unit tested by the formulae:

$$P_{\Sigma\geq 10}/V$$

$$P_{\Sigma\geq 25}/V$$

in which $P_{\Sigma\geq 10}$ is the total particle count obtained from all portions analyzed and $P_{\Sigma\geq 25}$ is the total particle count obtained from all portions ≥25 μm analyzed. V is the volume, in mL, of the solution tested.

For example, the analyst has counted the test samples in four tallies: a) ≥10–25 μm, b) ≥25 μm–50 μm, c) ≥50–100 μm, and d) ≥100 μm. $P_{\Sigma\geq 10}$ would then be calculated as:

$$P_{\Sigma\geq 10} = P_{\geq 10\text{–}25\ \mu m} + P_{\geq 25\text{–}50\ \mu m} + P_{\geq 50\text{–}100\ \mu m} + P_{\geq 100\ \mu m}$$

For small-volume injections, calculate the particle count, in particles per container, by the formulae:

$$P_{\Sigma\geq 10}/n$$

$$P_{\Sigma\geq 25}/n$$

in which $P_{\Sigma\geq 10}$ is the total particle count obtained from all portions analyzed and $P_{\Sigma\geq 25}$ is the total particle count obtained from all portions ≥25 μm analyzed. n is the number of units pooled (one in the case of an individual unit).

PARTIAL COUNT PROCEDURE

Note that the particle limits should be reported as all particles ≥10 μm and all particles ≥25 μm. When partial counting of particles on a membrane is performed, the analyst should first ensure that an even distribution of particles is present on the membrane. This is assessed by rapid scanning of the prepared membrane in order to detect clumps of particles. Significant clumping should not be present. Count the 10-μm or larger particles in one GFOV at the edge of the filtration area as well as those in the center of the membrane. The number of 10-μm or larger particles in the GFOV with the highest total particle count is NMT twice that of the GFOV with the lowest particle count. Reject a filter failing these criteria, and prepare another if a partial count procedure is used, or, alternatively, analyze this membrane by the total count method.

The normal number of GFOV counted for a partial count is 20. If a smaller confidence interval about the result is desired, a larger number of fields and particles may be counted. Count all particles that have a circular area diameter of 10 μm or larger and 25 μm or larger within the GFOV and those that are in contact with the right side of the GFOV circle. Do not count particles outside of the GFOV. Ignore those that touch the left side of the GFOV circle. The dividing line between right and left sides of the GFOV circle is the vertical cross hair. [NOTE—Make the best possible judgment on particle size without changing the microscope magnification or illumination.]

To perform a partial count of the particles on a membrane, start at the right center edge of the filtration area and begin counting adjacent GFOVs. When the left edge of the filtration area is reached, move one GFOV toward the top of the filter, and continue counting GFOVs by moving in the opposite direction. Moving from one GFOV to the next can be accomplished by one of two methods. One method is to define a landmark (particle or surface irregularity in the filter) and move over one GFOV in relation to the landmark. A second method is to use the vernier scale on the microscope stage to move 1 mm between GFOVs. To facilitate the latter, adjust the microscope x- and y-stage positioning controls to a whole number at the starting position at the center right edge of the filtration area, then each GFOV will be one whole division of movement of the x-stage positioning control. If the top of the filtration area is reached before the desired number of GFOVs is reached, begin again at the right center edge of the filtration area one GFOV lower than the first time. This time move downward on the membrane when the end of a row of GFOVs is reached. Continue as before until the number of GFOVs is complete.

For large-volume products, extrapolate the total count of particles per mL by the formulae:

$$P_{\Sigma 10}A_T/A_PV$$

$$P_{\Sigma 25}A_T/A_PV$$

in which $P_{\Sigma 10}$ is the total particle count obtained from all fields of view and all size thresholds and $P_{\Sigma 25}$ is the total particle count obtained from all fields of view and all size thresholds $\geq$25 μm; A_T is the filtration area, in mm², of the membrane (inner filtration barrel diameter); A_P is the partial area counted, in mm², based on the number of graticule fields counted (GFOV area × number GFOV counted); and V is the volume, in mL, of solution filtered.

For a solution pool (for small-volume product units containing less than 25 mL) or for a single unit of a small-volume product, extrapolate the total count of particles per unit by the formulae:

$$P_{\Sigma 10}A_T/A_Pn$$

$$P_{\Sigma 25}A_T/A_Pn$$

in which $P_{\Sigma 10}$ is the total particle count obtained from all fields of view and all size thresholds and $P_{\Sigma 25}$ is the total particle count obtained from all fields of view and all size thresholds $\geq$25 μm; n is the number of units counted (one in the case of an individual unit). For all types of product, if the tested material has been diluted to decrease viscosity, the dilution factor must be accounted for in the calculation of the final test result.▲*USP34*

DIETARY SUPPLEMENT CHAPTERS

BRIEFING

〈**2030**〉 **Supplemental Information for Articles of Botanical Origin,** *USP 32* page 777. The Dietary Supplements—General Chapters Expert Committee recommends to include an additional article, Elm, in this general chapter and to make editorial changes in the existing articles to maintain consistency throughout the chapter.

SUPPLEMENTAL INFORMATION AND GENERAL GUIDANCE PROTOCOLS

Black Cohosh *Actaea racemosa* L. [*Cimicifuga racemosa* (L.) Nutt.] (Fam. Ranunculaceae)

Botanical Identification—*Actaea racemosa* L. Herbaceous perennial from rhizome.

Stem: Erect, solitary, to 2.5 m tall, glabrous.

Leaves: Basal and cauline, alternate, 2–4-ternately compound, petioles 15 to 60 cm long, bases clasping stem; leaflets 20 to 70; terminal leaflet of central division 3-lobed, 6 to 15 cm long, 6 to 16.5 cm wide, with 3 prominent veins arising from base; subterminal leaflets with blades ovate-lanceolate to obovate, 4 to 12 cm long and 3 to 8 cm wide; margins toothed to deeply incised; green above, paler below; glabrous or rarely pubescent along veins of undersurface.

Inflorescence: Terminal panicle of 4 to 9 slender branches, each 7 to 60 cm long, pubescent; 1 bract subtending each pedicel.

Flowers: Perfect, radially symmetric; sepals 4, greenish-white, caducous; petals 0; staminodes (1–) 4 (–8), petaloid, cream-colored, 2 to 3 mm long, clawed, apex bifid; stamens 55 to 110; pistils 1 (–3), glabrous to pubescent, ovary superior, style short, stigma 0.5 mm wide.

Fruit: Many-seeded follicle, 5 to 10 mm long, ovoid, laterally compressed with curved, stout beak (peristent style), pubescent; seeds hemispheric, brown, scales lacking. Chromosome number: n = 8.

There are currently two varieties of *A. racemosa* recognized based on differences in leaf morphology: var. *racemosa* and var. *dissecta*. The former variety has triternate-pinnate leaves with serrate margins, while the latter has quadriternate-pinnate leaves that are deeply incised with serrate lobes. Variety *dissecta* is only known from very few herbarium specimens, all of which were collected well over 100 years ago, making this taxon of uncertain taxonomic significance.

Compendial History—Black cohosh appeared on the secondary list of substances in the first *United States Pharmacopoeia (USP)* of 1820, where it was listed as an anti-inflammatory and antispasmodic. It soon rose to the primary list in 1830, a position it held until the 10th decennial revision of 1920. Black cohosh appeared in the first edition of the *United States Dispensatory (USD)* in 1833 and remained through 1955 for a total of 122 years. Carrying forward the traditional Native American use of black cohosh for women's ailments and Barton's use for throat complaints, current therapeutics finds the plant used in a number of preparations for coughs and for gynecological disorders. In 2001, both the rhizome and the dry rhizome extract of black cohosh were proposed once again for inclusion in the *United States Pharmacopeia–National Formulary (USP–NF).* (See revised proposal on page 1455 of *PF* 28(5) [Sept.–Oct. 2002].) The monograph became official in the *Second Supplement* to *USP 30–NF 25*.

Constituents—Major constituents of black cohosh are triterpene glycosides principally as beta-xylopyranosides and alpha-arabinopyranosides. The aglycones are mostly derived from acteol and cimigenol. The nomenclature of these compounds is quite confusing in the literature with different names often given to the same compounds. A cyclopropane ring is a common feature of these compounds, which are structurally related to cycloartenol. The isoflavone formononetin has been reported in some publications, however recent evidence indicates its absence in the roots and rhizomes of *Actaea racemosa.* Other constituents include tannins, resin, fatty acids, starch, sugars, and aromatic acids including ferulic acid, isoferulic acid, caffeic acid, and salicylic acid.

Sources

▲and Distribution—

Sources—▲*USP34*

Black cohosh can be found in moist deciduous forests, ravines, moist meadows, creek margins, and mountainous terrain. Black cohosh flowers from June to September and is native to eastern North America from Ontario south to Georgia and west to Missouri. The entire supply of Black Cohosh comes from the United States. The major producers of black cohosh are Kentucky and Tennessee, with additional supplies coming from Georgia, Ohio, North Carolina, Michigan, South Carolina, Virginia, West Virginia, and Wisconsin. Although there are reports of black cohosh being grown in China and India for export, the true identity of the cultivated material has not been verified and may well be an Asian species of *Actaea* such as *A. cimicifuga* (syn. *Cimicifuga foetida*). The vast majority of the commercial black cohosh is wild harvested. Concern over the conservation of black cohosh due to increasing demand makes this species a good candidate for cultivation.

▲*Distribution*—North America (Ontario, Kentucky, Tennessee, Georgia, Ohio, Missouri, North Carolina, Michigan, South Carolina, Virginia, West Virginia, and Wisconsin), China, and India.▲*USP34*

Collection and Cultivation—

Collection (Conservation and Ecology)—Traditionally, black cohosh has been harvested after plants become reproductive, which occurs anywhere from 2 to 8 years of age in cultivated plants depending on growing techniques (see *Cultivation*). A portion of the rhizome with a visible bud on it should be left in the ground to resprout the following year. There is no published information on the relationship between the constituent profile of the rhizome and its age, growing conditions, or place of origin, although such studies are underway. The impact of harvest on wild populations of black cohosh is currently unknown and sources differ in their opinion about it. While some maintain that current levels of harvest threaten the viability of wild populations, others feel that sustainable harvesting is possible at current levels of demand. A study of sustainable harvest limits is currently underway. The regulatory status regarding the trade of black cohosh is under review by the CITES. Refraining from harvesting plants until after they have set seed and leaving a portion of the rhizome in the ground to resprout are key components to sustainable harvesting.

Cultivation Practices—Black cohosh is grown from rhizome cuttings or seeds and requires some shading, depending on altitude and other environmental conditions. If grown from rhizome cuttings, a plant takes 2 to 3 years to become reproductive; grown from seed sown in the greenhouse and then planted, takes 4 to 6 years; direct-seeded may take from 6 to 8 years. Preliminary work indicates that black cohosh can be propagated successfully using in vitro techniques.

In-Process Revision

Optimal Times for Harvest—Rhizomes and roots should be harvested in autumn when the plant is dormant. At that time the underground portions of the plant have lower moisture content than in other seasons. Fall harvesting also allows plants to produce mature seeds before being uprooted.

~~**Drying, Storage, and Shipping**~~

▲Post-Harvest Handling—▲*USP34*

Optimal Handling and Processing Practices—Rhizomes with roots may be processed fresh or dried. They should be thoroughly washed directly after harvest and then laid out to dry. Freshly harvested roots should be solid but not woody.

Drying—Rhizomes with roots are cut and air-dried at 35° to 45°. They are fully dried when they are brittle and snap easily and when no moisture is evident in cross section, either visibly or to the touch.

Storage—Follow general guidelines for storage by packing in airtight containers protected from light, heat, moisture, and insect infestation.

Adulterants

▲and Contaminants—▲*USP34*

Other species of *Actaea,* especially yellow cohosh (*A. podocarpa* syn. *Cimicifuga americana*), have commonly been mixed with *A. racemosa* due to the similarity in above-ground appearance and common growing habitat between species. The two species can be distinguished by differences in their freshly harvested underground parts: the fresh rhizome of *A. podocarpa* has a distinct yellowish hue, whereas that of *A. racemosa* is black. The rhizomes of both species are far more difficult to tell apart when dry because *A. podocarpa* darkens upon drying. The underground portions of baneberry *(Actaea pachypoda* and *A. rubra)* occur as occasional adulterants of black cohosh supplies. Fruiting plants of baneberry may be distinguished from black cohosh by their fleshy white or red poisonous berries, which contrast with the dry follicles of black cohosh. No information was available on how to distinguish the underground portions of black cohosh and baneberry from each other. According to one herb dealer, the roots of baneberry are smaller than those of black cohosh, and therefore are not often harvested by wildcrafters. In the Pacific Northwest, *Actaea elata* (syn. *Cimicifuga elata*) is collected for medicinal use.

Ginger *Zingiber officinale* Roscoe (Fam. Zingiberaceae)

Botanical Identification—*Zingiber officinale* Roscoe. Herbaceous perennial from tuberous rhizome, aromatic due to the presence of volatile oils.

Stem: Erect, unbranched pseudostem formed by the tight overlap of sheathing leaf bases; 9 to 15 dm tall.

Leaf: Simple, alternate and two-ranked, sessile or petioles short with bases sheathing the stem and a ligule where the leaf base meets the stem; blade linear to narrowly lanceolate, 15 to 25 cm long, 1.5 to 3 cm wide; margin entire; glabrous to pubescent.

Inflorescence: Terminal spike, 3.5 to 8 cm long, 1.5 to 2 cm wide, with conspicuous spirally arranged primary bracts; usually borne on specialized leafless stems.

Flower: Perfect, bilaterally symmetric; calyx tubular with 3 lobes; corolla tube 2 to 2.5 cm long with lanceolate apical lobes, 1.5 to 2 cm long, 2 to 3.5 mm wide, greenish yellow; stamen 1, anther cream-colored with dark purple, elongated connective grasping upper part of style; staminodes 4, petaloid, 2 fused into an erect, ovate-oblong lip which is dull purple with cream mottling; ovary inferior; style 1, slender, exerted beyond connective.

Fruit: Loculicidal capsule; seeds shiny black with a white aril. Chromosome number: n = 11.

There are several different varieties and forms of *Zingiber.* The varying morphological characteristics of these are displayed in *Table 1*.

Table 1. Morphological and Key Characteristics of Ginger from Different Areas of Production

Source	Form	Aroma	Color (External)
Africa	Flat surfaces, mostly peeled, starchy and fibrous; 9 cm long, 1.5 cm wide	Poor quality is recognized by its camphoraceous aroma	Uncut surface dark grayish-brown; cut surface brownish-black
Australia		Citrus-like	Buff
Bengal	Flat surfaces, scraped		Gray-brown
China	Short stumpy lobes, unscraped, mostly sliced	Strong, floral to citrus	Pale brown
Cochin	Lateral surfaces lacking cork	Strong, floral to citrus	Cream color with numerous black resin dots
Jamaica (unbleached)	Up to 12 cm long, 1 cm wide; surfaces completely peeled; starchy and fibrous thin cortex	Delicate, citrus-like	All surfaces yellow-brown
Japan	Up to 7 cm long, 12 mm wide; flat surfaces usually completely peeled; starchy and fibrous thick cortex	Bergamot-like	Externally gray-white to light grayish-brown, often with white powder from being coated with lime
Malabar (Cochin and Calcutta)	Cork layer completely removed, mostly treated with chalk	Citrus-like	Almost white
Nigeria	Smaller in size than other varieties, rather less deeply scraped	Delicate	Somewhat darker than other varieties

Compendial History—Ginger was official in the *United States Pharmacopoeia* from the first edition of 1820 through the fourteenth revision of 1950, often appearing in multiple preparations. It also appeared in all editions of the *United States Dispensatory* from 1833 through the final edition of 1973 where it was described as ''a stimulant and carminative that has been used for treatment of dispepsia and flatulent colic''.

Constituents—The essential oils and the pungent principles make up some of the major components of the rhizome of ginger: 4.0% to 10.0% of the rhizome consists of an oleoresin composed of nonvolatile, pungent principles (phenols such as gingerols and their related dehydration products, shogaols); nonpungent fats and their waxes. The essential oil (1% to 3%) contains sesquiterpenes and monoterpenes, mainly geranial and nerals. Generally, but not always sesquiterpenes predominate (30% to 70%) such as zingiberene, sesquiphellandrene and beta-bisabolene, which decompose on drying and storage. The nonvolatile pungent principles include the phenylalkanones, gingerols, and the phenylalkanonols, shogaols with varying chain lengths.

Sources

▲and Distribution—

Sources—▲*USP34*

Zingiber is cultivated in most tropical and subtropical countries to greater or lesser degrees. The world production is estimated to be 100,000 tons. China and India are reported to be the primary areas of production. Approximately 5000 tons of *Zingiber* are imported into the United States. An estimated 80% of this comes from China. In China, Sichuan and Guizhou provinces reportedly produce the largest quantities and highest quality. It is also produced in Zhejian, Shandong, Hubei, Guangdong, and Shanxi provinces. Most of the dried ginger from China available in the United States has had the cortex scraped or rubbed off before it is dried. This gives it a whitish appearance. The freshly dug root is soaked overnight in water, scraped with a knife to remove the outer cortex, and then sun-dried. It has been reported that high arsenic levels in the soil of Changning County of Hunan Province, China has negatively effected *Zingiber* yields.

In India, *Zingiber* is grown on a large scale in the warm, moist regions of Madras and Cochin, and to a lesser extent in Bengal and the Punjab. Varieties grown in Bengal are reportedly the highest quality material in India. Other areas of production include Africa (Nigeria and Sierra Leone), Australia, Fiji, East Indies, Jamaica, and Hawaii. The morphological characteristics of *Zingiber* cultivated in these different areas are outlined in *Table 1*.

In older literature, Jamaican *Zingiber* is reported to be the highest quality and the most aromatic, though supplies are limited.

▲*Distribution*—Most tropical and subtropical countries, such as Australia, China (Sichuan, Guizhou, Zhejian, Shandong, Hubei, Guangdong, and Shanxi provinces), India (Cochin, Malabar, Bengal), Jamaica, Japan, Nigeria, Sierra Leon, Fiji, East Indies. Hawaii in the United States.▲*USP34*

Collection and Cultivation—

Collection (Conservation and Ecology)—When the stems wither and are white, the rhizomes are ready for collection. Usually ginger is harvested after 6 months of growth at the earliest, and sometimes not until as late as 20 months, or to obtain larger roots it is harvested in January or February of the second year of growth. In tropical and subtropical areas, roots are harvested as early as 4 months of growth as they tend to become fibrous and tough as they get older. As *Zingiber* matures it becomes more fibrous and stronger in flavor. Ginger harvest can be described in three stages:

1. Ginger that has been harvested early is known as green ginger and is traded as fresh ginger. It is succulent and tender, mellow, and mildly aromatic with a floral or lemony aroma and mild flavor.
2. Ginger harvested a few months later is more fibrous and drier and is collected for drying and may be sold as a full-flavored, pungent dried whole ginger.
3. The last harvest is usually around 9 months and yields the strongest ginger, which is quite dry and also richest in pungent components. This ginger is dried and then ground into powder.

Cultivation Practices—Ginger is a perennial herb that grows well at subtropical temperatures where the rainfall is at least 1.98 meters per year. The plant is sterile and is grown by vegetative means. Selected pieces of rhizome (''seed pieces'' or ''setts''), each bearing a bud, are planted in holes or trenches. Ideally the soil should be well-drained, rich clay loam. The growing conditions resemble those of potato cultivation. Mulching or manuring is necessary because the plant rapidly exhausts the soil of nutrients.

Ginger is susceptible to water logging and root rot. Preventive methods include using only the cleanest ginger for planting and washing it with fungicide before planting. A study growing *Zingiber* hydroponically yielded up to 125 tons per hectare in 6 to 7 months compared to 35 tons per hectare when grown in soil.

Optimal Times for Harvest—Typically in December or January.

~~*Optimal Handling and Processing Practices*—After harvesting, the rhizome is cleaned and stripped of its stems and roots. Each area processes its *Zingiber* differently after harvest. This results in the different quality and commercial grades available on the market. Green *Zingiber* consists of the rhizomes sent to market without drying. Unscraped or partially scraped varieties are traded as coated or black ginger. These roots have been scalded with boiling water and dried quickly. When dry, black *Zingiber* breaks with a horny, blackish, somewhat diaphanous fracture, due to the pasty condition of the starch. White *Zingiber* is bleached usually by rubbing with chalk or lime to lighten its color and to prevent insect infestation. Preserved ginger consists of soft, yellowish brown pieces obtained by steeping the fresh *Zingiber* in hot syrup and carefully bottling. It is soft, brown yellow and translucent. When baked, *Zingiber* loses its pungency and acquires a bitter taste.~~

▲▲*USP34*

~~**Drying, Storage, and Shipping**~~

▲Post-Harvest Handling—

When dry, black *Zingiber* breaks with a horny, blackish, somewhat diaphanous fracture, due to the pasty condition of the starch.

In-Process Revision

White *Zingiber* is bleached usually by rubbing with chalk or lime to lighten its color and to prevent insect infestation. Preserved ginger consists of soft, yellowish-brown pieces obtained by steeping the fresh *Zingiber* in hot syrup and carefully bottling. It is soft, brown-yellow and translucent. When baked, *Zingiber* loses its pungency and acquires a bitter taste.▲*USP34*

Drying—In general, after harvest, the fresh roots are washed and the whole dark outer skin, consisting of cork and a little underlying parenchyma, is scraped away. Scraping speeds up the drying time of the crude drug. However, excessive scraping can result in lower concentrations of essential oil that is lost with the discarded epidermal tissue. After scraping, the rhizomes are then laid out on clean floors and dried in the sun for 7 to 10 days. During this time they are occasionally turned and are piled up every night. If the fresh rhizomes are too fleshy or moist, drying will take longer and the product will end up looking shriveled. To obtain a whiter product, the ginger is moistened after 5 or 6 days and dried for another 2 days at which time it is ready for export. Dried ginger is more pungent and stronger in taste than fresh ginger.

Storage—Store in a tightly closed container, protected from light and moisture, in a cool area. A study was done on ginger harvested after 8, 9.5, 11, or 12 months. Samples were stored at 10° to 15° and 45% to 55% relative humidity or 25° to 30° and 75% relative humidity for 0, 4, or 8 weeks. Oil and oleoresin yields increased with the age of the ginger. Room temperature storage had adverse effects but refrigerated storage for up to 4 weeks had no affect on quality. When stored for extended periods of time, ground ginger loses its pungency.

Adulterants—Because *Zingiber* is so characteristic, unintentional adulterants are rare. However, in East Asia sometimes the much larger *Zedoary cassumer* and *Zedoary zerumbet* along with *Alpinia allughas* are used and found in European commerce. They are easy to distinguish due to their characteristic aromas. Occasionally, Chinese sugar-candied "ginger" is prepared from *Alpinia galangal*.

In older literature, other herbs have reportedly been used as adulterants. These include various species of *Curcuma, Capsicum,* and Grains of Paradise *(Amomum melegueta)* added to exhausted material in order to enhance the color and pungency.

Zingiber powder is sometimes adulterated with plant starches such as those from wheat middlings, potatoes, corn, barley, rice, legumes, acorns, flaxseed meal, mannihot, oil cakes from linseed, raps, mustard, almond meal, palm kernal or olives, hazelnut shells, and mineral additives. These may be easily identified microscopically. The extent of this type of adulteration in trade is unknown.

Exhausted material should be considered an adulterant.

Valerian *Valeriana officinalis* L. (Fam. Valerianaceae)

Botanical Identification—*Valeriana officinalis* L. Herbacious perennial, rhizomatous.

Stem: Solitary, hollow, 15 to 150 cm.

Leaf: Basal and cauline, opposite, oddly once pinnately lobed, lobes 11 to 21 lanceolate, entire or dentate, basal leaves petiolate, cauline leaves subsessile to clasping.

Inflorescence: Compound cyme, terminal or axillary, many pale pink to white, strongly scented flowers.

Flower: Calyx 5-lobed, lobes inconspicuous in flower, becoming elongate and pappus-like in fruit, corolla funnel-form, slightly saccate at the base, 5-lobed, tube 4 mm, lobes 1 mm, stamens 3, filaments attached to corolla tube alternate to corolla lobes, ovary inferior, tri-loculate, uni-ovulate, only 1 locule fertile, stigma tripartite.

Fruit: Achene crowned by persistent calyx, lanceolate-oblong, 4.5 to 5 mm, hairy or glabrous. Populations of *V. officinalis* range in ploidy level from diploid to tetraploid or octaploid. British *V. officinalis* is usually octaploid, and central European supplies are tetraploid.

There are three subspecies of *V. officinalis*: ssp. *officinalis,* ssp. *collina* (Wallr.) Nyman, and ssp. *sambucifolia* (Mikan fil.) Celak. All three of these subspecies, as well as the other European species of valerian, *V. repens* Host, have been considered acceptable source material for medicinal preparations.

Macroscopic Identification—Various chemotypes will have slightly different characteristics. When dried, the whole rhizome is up to 50 mm long and up to 30 mm in diameter, obconical to cylindrical, with an elongated or compressed base. It has a yellowish-brown to dark brown exterior with a circular stem and leaf scars. The rhizome contains numerous thick, light to dark brown rootlets that are located around a thin ligneous cord. The root is longitudinally wrinkled and approximately 100 mm long and 1 to 3 mm in diameter, almost cylindrical and almost the same color as the rhizome. In longitudinal section, the pith exhibits a central cavity transversed by septa. The stolons are 20 to 50 mm long, pale yellowish grey with prominent nodes separated by longitudinally striated internodes. It is commonly sliced in half for ease of cleaning. The rootlets, which contain the majority of the essential oil, are brittle and break in short, horny fractures and are whitish or yellowish internally. Aroma: when dried properly, *V. officinalis* L., s.l. has only a very faint characteristic, valeric acid-like aroma that becomes stronger as it ages. Improperly dried or old material possesses a strong and characteristic odor due to the enzymatic hydrolysis of esters of the valepotriates (isovaleric acid and hydroxyvaleric acid). Taste: mildly sweet and camphoraceous with a slightly bitter and spicy aftertaste.

Compendial History—Valerian was official in the *United States Pharmacopoeia* from the first edition of 1820 through the eleventh revision of 1930, often appearing in multiple preparations. At its peak from 1850 through 1880 it appeared six to seven times in different preparations. Valerian is among the top 30 most listed botanicals in the history of the *USP.* The root of valerian has been used as a sedative and spasmolytic in Europe since the 16th century.

Constituents—Major constituents of valerian have been identified as sesquiterpenes of volatile oils and iridoids (epoxy-triesters) known as valepotriates. The total content of volatile oil varies widely within a single species and between different species. European *Valeriana officinalis* L. usually contains 0.1% to 2.8% volatile oil. The oil consists of mixtures of monoterpene and sesquiterpene derivatives. The amount of valepotriates present also varies widely between species and genera and even within a species, generally ranging from 0.5% to 1.2%. Valepotriates are particularly unstable; they decompose easily under the effect of moisture, temperatures above 40° (104°F), or acidity (pH < 3).

Valerian also contains small amounts of aliphatic acids, alkaloids, amino acids, phenolic acids, flavonoids, free fatty acids, sugars, and salts. Valerian constituents that have possible sedative effects include acetoxyvalerenic acid, 1-acevaltrate, baldrinal, didrovaltrate, hydroxyvalerenic acid, kessane derivatives, valeranone, valerenal, valerenic acid, and valtrate.

Sources

▲and Distribution—

Sources—▲*USP34*

Valerian is found in damp or dry meadows, scrub, or woods in most of Europe, but rare in the south, and is cultivated and naturalized in North America. Valerian is cultivated in Britain, Belgium, Eastern Europe, France, Germany, ~~Holland,~~

▲▲*USP34*

Japan, the Netherlands, North America, and Russia. The majority of standardized extract products and crude cut and sifted material on the domestic market are prepared from European supplies. A large number of liquid extracts are prepared from domestically cultivated material. Many species other than *V. officinalis* are reported to be traded as medicinal valerian. These

include *V. edulis* Nutt. ex Torr. & A. Gray, *V. corneana* Briq. k, *V. stubendorfi* Kreyer ex Kom., *V. amurensis* P. Smirn. ex Kom., *V. hardwickii* Wall., *V. exaltata* Mikan, and *V. wallichi* DC. syn. *V. jatamansi* Jones.* The most frequently used North American species include *V. sitchensis* Bong and *V. edulis* Nutt.* = *V. edulis* Nutt. ex Torr. & Gray ssp. *procera.* Other species reported to be used locally include *V. arizonica* Gray, *V. capitata* Pall ex Link., *V. diocia* L., and *V. scouleri* Rydb. Detailed chemical analyses of most American species are lacking. A limited number of assays of material cultivated in the Pacific Northwest show varying levels of essential oil ranging from 0.4% to 1.3%. Valerenic acid and valepotriates have been found to be present in fresh and dry samples of *V. sitchensis* Bong. *V. sitchensis* Bong exhibits a strong pungency when fresh. High quality material is reported to contain from 1.0% to 1.5% essential oil, ≥30% extractable matter, and ≥0.5% valerenic acid.

▲*Distribution*—North America, Europe (Britain, Belgium, Eastern Europe, France, Germany, the Netherlands), Russia, and Japan.▲*USP34*

Collection and Cultivation—

Collection (Conservation and Ecology)—The majority of valerian in trade comes from cultivated material. Harvest times will vary geographically. The composition of the essential oil varies greatly among different populations of the same subspecies and even between the same population of plants from year to year. Essential oil content also varies with genotypes, harvest times, growing conditions, age of root, drying techniques, and method of analysis. It has been reported that valerian harvested in higher elevations, grown in dryer regions, or cultivated in phosphate-rich soil yields relatively high levels of essential oil.

Older literature reports that valerian should be harvested in the fall, between August and September, preferably in the second year of growth. Analyses of material cultivated in the Netherlands report that the majority of constituents, including the essential oil and valerenic acid, were highest in roots harvested in the first year of growth with essential oil being highest in September and November (1.2% to 2.1%). The next highest level of essential oil was reported for material harvested in March (0.9% to 1.6%). Valerenic acid and its derivatives were found to be highest in February and March (0.7% to 0.9%) followed by material harvested in September (0.5 to 0.7%) and then in January (0.3% to 0.4%). From a commercial standpoint, it is more cost effective to harvest the roots in the same year the plants are sown than in the second year.

Cultivation Practices—Sowing seeds has been reported to be preferred over planting of seedlings. Best results were achieved by flat field planting at row spacings of 50 cm and a seed rate of 3 kg per hectare. Cutting off the flowering tops before the plant has set seed causes the rhizome to develop more fully.

Optimal Times for Harvest—Wagner reports that harvest should take place in the morning during relatively cool weather, a general recommendation for roots rich in essential oils.

~~*Optimal Handling and Processing Practices*—The essential oil is located in the hypodermis of the rhizome in large thin walled cells. Therefore, care must be taken not to damage these cells during handling. Excess washing of the roots can result in a significant reduction of extractive matter. Because of the sensitivity of volatile oils to heat, it is necessary to minimize the amount of time generated in the grinding or powdering process by doing small lots at a time, with frequent interruptions in run times, or by utilizing a cryogenic grinder.~~

▲▲*USP34*

~~**Drying, Storage, and Shipping**~~

▲Post-Harvest Handling—

Optimal Handling and Processing Practices—The essential oil is located in the hypodermis of the rhizome in large thin-walled cells. Therefore, care must be taken not to damage these cells during handling. Excess washing of the roots can result in a significant reduction of extractive matter. Because of the sensitivity of volatile oils to heat, it is necessary to minimize the amount of time generated in the grinding or powdering process by doing small lots at a time, with frequent interruptions in run times, or by utilizing a cryogenic grinder.▲*USP34*

Drying—For maximum preservation of the essential oils, valerian should be dried at 40° with a flow rate of 0.05 kg per sec per m^2. Alternatively, drying at 20° for approximately 10 days, shade drying at approximately 45°, low temperature vacuum-drying, and freeze-drying are also reported to be appropriate drying techniques.

Careless or prolonged drying produces a darker color in the roots and results in the hydrolysis of the isovalerianic esters and the liberation of isovaleric and hydroxyisovaleric acid. This produces the characteristic valerianic aroma. Properly dried valerian will produce this same aroma over time.

Storage—Store in closed containers protected from light, air, and moisture. Hydroxyvalerenic acid, a decomposition product of acetoxyvalerenic acid, is formed when the herb is stored at too high humidity.

Improper storage conditions can cause significant deterioration of the material. Although the essential oil is relatively stable, it can evaporate with excessive exposure to air. The essential oil can degrade quickly in powdered material. In powdered root, the essential oil content can decrease by 50% within 6 months.

Valepotriates are sensitive to humidity, temperatures above 40°, and acid media (pH <3) and are generally not detected in commercial products after 60 days.

Adulterants—Other species of valerian: An unidentified *Apiaceae* species may be found in valerian trade. Adulteration of valerian in the American market is not common. Many species other than *V. officinalis* are reported to be traded as medicinal valerian. These include *V. edulis* Nutt. ex Torr. & A. Gray, *V. coreana* Briq.k, *V. stubendorfi* Kreyer ex Kom., *V. amurensis* P. Smirn. ex Kom., *V. hardwickii* Wall, *V. exaltata* Mikan, and *V. wallichi* DC. syn. *V. jatamansi* Jones.

▲Elm *Ulmus rubra* Muhlenberg [*Ulmus fulva* Michaux] (Fam. Ulmaceae)

Botanical Identification—*Ulmus rubra* Muhlenberg; Tree to 35 m high, with spreading branches and open flat crown; preparations derived from inner bark. *U. rubra* appears to be more closely related to the introduced

* *V. wallichi* DC. and *V. edulis* Nutt. reportedly are lacking in valerenic acid and its derivatives.

In-Process Revision

Asian species *U. pumila* L. than to other native American species of *Ulmus*; where the two co-occur, interbreeding is common.

Trunk: 18 to 35 m high, to 1 m in diameter, the trunk rises free of branches until about 5 to 6 m.

Branches: Erect, spreading; young twigs are scabrous-pubescent.

Bark: Dark brown to reddish-brown, deeply furrowed. Inner bark is whitish (outer surface yellow-orange; inner surface pale yellow), fragrant (upon powdering a distinctive fenugreek-like odor) and very mucilaginous upon chewing or moistening.

Leaves: Alternate; simple; petiolate with petiole (3–)5–7(–9) mm long; 7–18(–23) cm long, 5–10(–15) cm broad; elliptical to ovate, oblong, or obovate with oblique base and acuminate apex; margins serrate towards base, elsewhere doubly serrate; upper surface scabrous, rough; lower surface tomentose; secondary veins parallel, slightly curved, running to tips of marginal teeth.

Inflorescence: Axillary fascicles, roughly hemispherical, to 1.5(–2.5) cm in diameter.

Flowers: Small, perfect; pedicels 1–2(–3) mm long; calyx campanulate, 5–9-lobed at apex, ca. 2.6–3.5 mm in diameter, reddish-pubescent; petals absent; stamens 5–9, exserted at flowering; styles 2. Flowers occur before the leaves from March through early May.

Fruit: Winged samara, yellowish, irregularly suborbicular or occasionally broadly elliptical or obovate, 10–20 mm in diameter, reddish-pubescent over seed; wing papery-textured.

Compendial History—Slippery elm (Ulmus) inner bark appeared in the list of materia medica in the first *United States Pharmacopoeia (USP)* of 1820 and remained official until it was removed from the *USP XI* (1936). The *USP 1820* included instructions for the preparation of *Infusion of Slippery Elm: ''Take of Slippery elm, sliced, one ounce. Boiling water, one pint. Infuse for twelve hours in a covered vessel, near the fire with frequent agitation, and strain.''* Immediately following its removal from the *USP XI* (official: June 1, 1936), slippery elm bark became an official monograph in the sixth edition of the *National Formulary* (*NF*; official: June 1, 1936) until its elimination from the 11th edition (official: October 1, 1961). It became official again, as *Elm,* on November 15, 1995 in the USP section of the *Third Supplement* of the *United States Pharmacopeia–National Formulary* (*USP 23–NF 18*). A revision was published in the *Seventh Supplement* on November 15, 1997.

In 1982, Elm bark appeared in the Food and Drug Administration (FDA) Advance Notice of Proposed Rulemaking (ANPR) for the establishment of a therapeutic monograph for oral health care drug products for over-the-counter (OTC) human use. In the ANPR (1982) as well as in the subsequent tentative final monograph of 1988 and in the amendment to the monograph of 1991, Elm bark was classified as a Category I (Generally Recognized as Safe and Effective (GRASE)) OTC oral demulcent active ingredient and appropriate standards were urged to be developed in the official compendia.

Aside from *USP–NF*, the monograph of Elm had already appeared in the second edition of *The Dispensatory of the United States of America* (1834) and its last appearance was in the 25th edition of 1960.

Constituents—Constituents of relevance for conformance to *Identification A* under *Elm* are mucilaginous substances. Elm inner bark mucilage is readily extractable by water and consists principally of a polysaccharide which on hydrolysis yields D-galactose, D-methyl galactose, L-rhamnose, and glucose. Borohydride reduction of the periodate-oxidized polysaccharide affords, on partial hydrolysis with hot acid, three oligosaccharides: *O*-(3-*O*-methyl-β-D-galactopyranosyl)-(1→4)-*O*-(3-*O*-methyl-β-D-galactopyranosyl)-(1→4)-L-rhamnose, *O*-(3-*O*-meth-

yl-β-D-galactopyranosyl)-(1→4)-L-rhamnose, and *O*-(3-*O*-methyl-β-D-galactopyranosyl)-(1→4)-3-*O*-methyl-D-galactose.

Other Elm constituents include traces of tannins including proanthocyanidins, some starch, traces of oxalate salts, beta-sitosterol, and minerals.

Sources and Distribution—

Sources—Slippery elm bark is harvested from wild populations in eastern Canada and the United States, from southern Quebec west to North Dakota, south to south-central Texas, and Florida. It is common throughout eastern, southern, and midwestern U.S., and grows in more than 25 states. An increasing amount of the commercial supply is being collected according to sustainable wild resource management plans as a condition of organic certification for wild crops. Conversely, Dutch elm disease has had a significant negative impact on elm populations, from 1930 when it was first found in the United States affecting over 50% of elm trees in the northern states.

Distribution—Canada (New Brunswick, Ontario, Quebec), the United States (Alabama, Arkansas, Connecticut, Delaware, the District of Columbia, Florida, Georgia, Iowa, Illinois, Indiana, Kansas, Kentucky, Louisiana, Massachusetts, Maryland, Maine, Michigan, Minnesota, Missouri, Mississippi, North Carolina, North Dakota, New Hampshire, New Jersey, New York, Ohio, Oklahoma, Pennsylvania, Rhode Island, South Carolina, South Dakota, Tennessee, Texas, Virginia, Vermont, Wisconsin, West Virginia).

Collection and Cultivation—

Collection (Conservation and Ecology)—''Natural'' (both inner and outer bark) and ''rossed'' (inner bark only) are harvested but only the rossed bark will conform to the standards of the *USP* monograph. Harvesting should occur on dry, preferably warm days with no chance of precipitation and it usually commences late morning after the morning dew and humidity pass. This is because post-harvest processing (rossing) generally takes place at the collection site outdoors and humidity can damage the quality of the inner bark. Because the inner bark contains polysaccharide mucilage, when it comes in contact with moisture it begins to gel.

The minimum 10-year-old bark (some harvesters recommend selecting at least 12- to 15-year-old trees) is obtained mainly by pruning or trimming the lower limbs and branches, but can also be obtained from the bole (trunk) and, very rarely, even from the roots in cases where the entire tree is felled. While the inner bark of the root reportedly contains more mucilage than that of the trunk or branches, sustainable wild resource management dictates harvesting only the branches of mature trees. In practice, commercial bark collectors are more likely to select branches from trees that are at least 30 to 50 years old in order to obtain a high enough yield. After pruning, the tree will heal over where harvested and continue to grow, but the trunk and/or branches should never be girdled as this will kill the tree. Girdling is the stripping away of bark from the trunk or a branch all the way around. In practice, the most sustainable method of harvest from mature healthy trees is to prune off entire lower branches in a way that will not harm the tree. If sawn properly so that rain water will not drop directly into the exposed cut area, the tree will grow over the cut area within a couple of years. The proper cut is made just outside the ''branch collar'' and the ''branch bark ridge'' and does the least amount of damage to the trees.

While elm bark should not be gathered from already dead trees, selective collection from dying trees, for example those affected with Dutch elm disease, is feasible. The fungus that causes Dutch elm disease, *Ophiostoma ulmi* and *Ophiostoma novo-ulmi* (syn: *Graphium ulmi* or *Ceratocystis ulmi*) is carried from tree to tree by the European elm bark beetle (*Scolytus multistriatus*), which arrived in North America on a boat of logs from Europe

around 1930, and to a much lesser extent by the native elm bark beetle (*Hylurgopinus rufipes*). Elms appear to succumb to the disease at about 10 years of age and then die off in a two-year period. Once a tree is diagnosed with Dutch elm disease, healthy bark can still be harvested for about two years, up until the tree is near death. To monitor how long harvesting can continue, one can use a drawknife to take samples. Once the inner bark is showing increasingly noticeable black streaking, and as more and more limbs die and debarking is evident, the tree is near death. The near dead tree can be dropped and the remaining healthy bark can be stripped from the entire tree. Discolored (black-streaked) inner bark should be separated out and discarded. Pruning lower limbs from healthy trees and/or selectively harvesting entire older trees that are near death can both be acceptable methods as part of a sustainable resource management plan for a specific area of forest under organic supervision.

Following organic production system rules (e.g., for harvest site selection, absence of prohibited substances, testing of soil and water, disallowed inputs, periodic residue testing, documentation control, independent inspection, etc.) will more likely result in botanical raw material that meets the general requirements for pesticide residue and heavy metals limits, among other potential contaminants. Certified organic production of wild elm bark requires producers to promote ecological balance and conserve biodiversity. Wild collected elm bark that is to be certified organic must be harvested from a designated area that has had no prohibited substance applied to it for a period of 3 years immediately preceding the harvest, and must be harvested in a manner that ensures that such harvesting or gathering will not be destructive to the environment and will sustain the growth and production of the wild crop. Wild crop producers must comply with the same organic system plan requirements and conditions, as applicable to their operation, as their counterparts who produce cultivated crops. The producer of organic wild harvested elm bark must initiate practices to support biodiversity and avoid, to the extent practicable, any activities that would diminish it. Production practices must maintain or improve the natural resources of the operation, including soil, water, wetlands, woodlands and wildlife. This is accomplished, in part, by developing and executing a resource management plan that requires wild harvest from stable populations, minimizing disruption of priority species/sensitive habitats, avoiding erosion, allowing re-establishment, and monitoring wild crop sustainability.

Cultivation Practices—Even though the commercial supply is harvested from wild populations, slippery elm trees can be propagated by cuttings or by seed. For propagation by seed, the ripe seeds are collected from April to June from healthy and successful (dominant) trees from an area similar to the proposed planting site. A ripeness indicator is when the samaras (fruits) are green. It is best to collect seed from trees within 160 km north or south of the planting site, as potential for success is optimal within this range from the parents. Twenty-five seeds per square foot can be scattered, 0.6 cm deep. Slippery elm may be sown as in its normal cycle in the spring in a raised peat moss soil and sand bed. The seedbeds may need a wire top to protect young seedlings. Germination rate is 10 to 25% with light germination in summer and increased germination the following spring. The young trees can be transplanted into tree tubes within the first month of germination and field planted after one or two years depending on the size of the tree tube. The tree saplings must be watered during times of drought as well as routine checking for insect predation and indications of fertilization needs.

Optimal Times for Harvest—Harvest should preferably occur in the spring (March to May), but can also take place in the autumn. In the spring, bark is harvested from mature trees (minimum 10 years) when the sap begins to rise.

Post-Harvest Handling—

Optimal Handling and Processing Practices—To produce pharmacopoeial quality elm inner bark, the outer corky layer of bark must be removed, exposing the inner bark. If post-harvest processing occurs at the wild collection site, the pruned limbs and branches should be placed onto clean tarps and not directly on the ground. The very small branches with leaves are stripped off of the pruned limbs by hand and discarded. To optimize conformance to standards for composition, identity, purity, and quality (e.g., NMT 2% of adhering outer bark, NMT 2% foreign organic matter, NMT 10% total ash, and NMT 0.65% acid-insoluble ash), a clean bark rosser (hand tool with handle and knife blade) should be used to shave off the outer bark. The rough, scaly matter on the surface of the bark is called ''ross'' and to ross bark is to scrape or shave the outer bark from the limb. An experienced rosser can visually discern that at least 98% of the outer bark has been shaved off. The inner bark is white in color (in the spring; reddish later in season) in obvious visible contrast to the brown outer bark layer. After rossing most of the outer bark off, greater care must be exercised to very carefully slice off the remaining thin layer of outer bark so as not to waste any of the inner bark in the process. After removal of the outer bark, the inner bark can then be removed in strips, squares, or chips. An incision is made with a clean knife down the center of the limb. Then a clean crow bar is slipped underneath the incision in order to lift and peel the inner bark off from the cambium. The strips of inner bark are stacked on a clean tarp and later bundled for transport to the drying facility.

Drying—Elm USP requires a loss on drying limit of NMT 12%. So long as rain is not expected, fresh elm inner bark can be sun-cured within a temperature range of 32° to 60°. Drying can also be carried out in a warm room with airflow or in a greenhouse. Greenhouse drying takes about 3 to 4 days. Drying indoors can take 5 to 7 days depending on the heat source. Drying at commercial scale, however, is done typically in enclosed drying chambers wherein time and temperature can be better controlled. The strips of elm bark are placed onto a clean screen floor and dried over about 2 days time at about 50° with fan forced heat through the floor. Due to additional phytosanitary requirements for export of tree barks to Europe, higher heat exposure is necessary, usually at least 65° but up to 93° for up to two days. Post-drying, the strips of inner bark can be cut or sawn into pieces of equal length and bound into bundles with wire. The bundles usually consist of flat, oblong pieces, about 30 cm in length and from 10 to 15 cm in width. The bark strips can be stored this way until further processing (e.g., cutting or powdering) is scheduled.

Storage—To maintain pharmacopoeial purity and quality (e.g., to prevent accumulation of excess moisture), dried elm inner bark should be preserved in well-closed containers, and stored in a cool, dry place.

Adulterants and Contaminants—Common contaminants that could cause a material not to conform with the *Elm USP* identification tests would include other plant parts, for example greater than 2% outer bark which lacks mucilage. Insufficient shaving or rossing of outer bark could cause the material to exceed the monograph limit of NMT 2% of adhering outer bark. Other possible contaminants would include visible discolored inner bark, although no maximum limit has been established (for example, inner bark with visible black streaking obtained from a diseased tree). Powdered bark can also be adulterated with corn meal, rice flour, starch, or other starchy substances. Consequences of contamination with outer bark or adulteration with flour or starch are lower mucilage content, lower swelling index value, and correspondingly less of a therapeutic demulcent effect that is mucilage-dependent. Excess outer bark could also cause the material to fail the quantitative standard of NMT 10% total ash. Methods to determine presence of adulterants include microscopic examination in order to

determine the presence of excess outer bark or any other adulterant, and the concentration of mucilage cells. The Elm mucilage test (*Identification* test *A*) as well as a modified swelling volume test (based on the Psyllium Husk USP monograph) may also be useful to investigate if adulteration is suspected.▲*USP34*

BRIEFING

⟨2040⟩ Disintegration and Dissolution of Dietary Supplements, *USP 32* page 782, page 4007 of the *First Supplement,* a *Revision Bulletin* posted on USP's website on May 1, 2009, and page 984 of *PF* 35(4) [July–Aug. 2009]. In order to clarify acceptance criteria for *Dissolution* testing of *Botanical Dosage Forms*, the following revision is proposed: the existing *Interpretation* section is being deleted and replaced with *Tolerances* where dissolution requirements for botanical dosage forms are defined.

(DS-PS: Natalia Davydova) RTS—C78869

Change to read:

DISINTEGRATION

This test is provided to determine whether dietary supplement tablets or capsules disintegrate within the prescribed time when placed in a liquid medium at the experimental conditions presented below. Compliance with the limits on *Disintegration* stated in the individual monographs for dietary supplements is required except where the label states that the products are intended for use as troches, are to be chewed, or are designed as extended-release dosage forms. Dietary supplements claiming to be extended-release dosage forms must comply with standards other than disintegration to verify that the release of the dietary ingredients from the dosage form is for a defined period of time. Dietary supplements claiming to be extended-release dosage forms shall not be labeled as in compliance with USP unless a USP monograph exists for such product. Determine the type of units under test from the labeling and from observation, and apply the appropriate procedure to 6 or more units.

For purposes of this test, disintegration does not imply complete solution of the unit or even of its active constituent. Complete disintegration is defined as that state in which any residue of the unit, except fragments of insoluble coating or capsule shell, remaining on the screen of the test apparatus or adhering to the lower surface of the disk, if used, is a soft mass having no palpably firm core.

Apparatus

Apparatus A—Use the *Apparatus* described under *Disintegration* ⟨701⟩ for tablets or capsules that are not greater than 18 mm long. For larger tablets or capsules, use *Apparatus B.*

Apparatus B—The apparatus[1] consists of a basket-rack assembly, a 1000-mL low-form beaker for the immersion fluid, a thermostatic arrangement for heating the fluid between 35° and 39°, and a device for raising and lowering the basket in the immersion fluid at a constant frequency rate between 29 and 32 cycles per minute through a distance of not less than 53 mm and not more than 57 mm. The volume of the fluid in the vessel is such that at the highest point of the upward stroke the wire mesh remains at least 15 mm below the surface of the fluid and descends to not less than 25 mm from the bottom of the vessel on the downward stroke. At no time should the top of the basket-rack assembly become submerged. The time required for the upward stroke is equal to the time required for the downward stroke, and the change in stroke direction is a smooth transition rather than an abrupt reversal of motion. The basket-rack assembly moves vertically along its axis. There is no appreciable horizontal motion or movement of the axis from the vertical.

Basket-Rack Assembly—The basket-rack assembly

■(*Figure 1*)■2S *(USP33)* consists of three open-ended transparent tubes, each 77.5 ± 2.5 mm long and having an inside diameter of 32.0 to 34.6 mm and a wall 2.0 to 3.0 mm thick; the tubes are held in a vertical position by two plastic plates, each ~~about~~

■■2S *(USP33)* 97

■ ± 2■2S *(USP33)* mm in diameter and 7.5 to 10.5 mm in thickness, with three holes, ~~each about 33 to 34~~

■36.0 to 40.6■2S *(USP33)* mm in diameter, equidistant from the center of the plate and equally spaced from one another. Attached to the undersurface of the lower plate is 10-mesh No. 23 (0.025-inch) W. and M. gauge woven stainless-steel wire cloth having a plain square weave. The parts of the apparatus are assembled and rigidly held by means of three bolts passing through the two plastic plates. A suitable means is provided to suspend the basket-rack assembly from the raising and lowering device, using a point on its axis.

The design of the basket-rack assembly may be varied somewhat, provided that the specifications for the glass tubes and the screen mesh size are maintained.

[1] An apparatus and disks meeting these specifications are available from Varian Inc., 13000 Weston Parkway, Cary, NC 27513, or from laboratory supply houses.

■

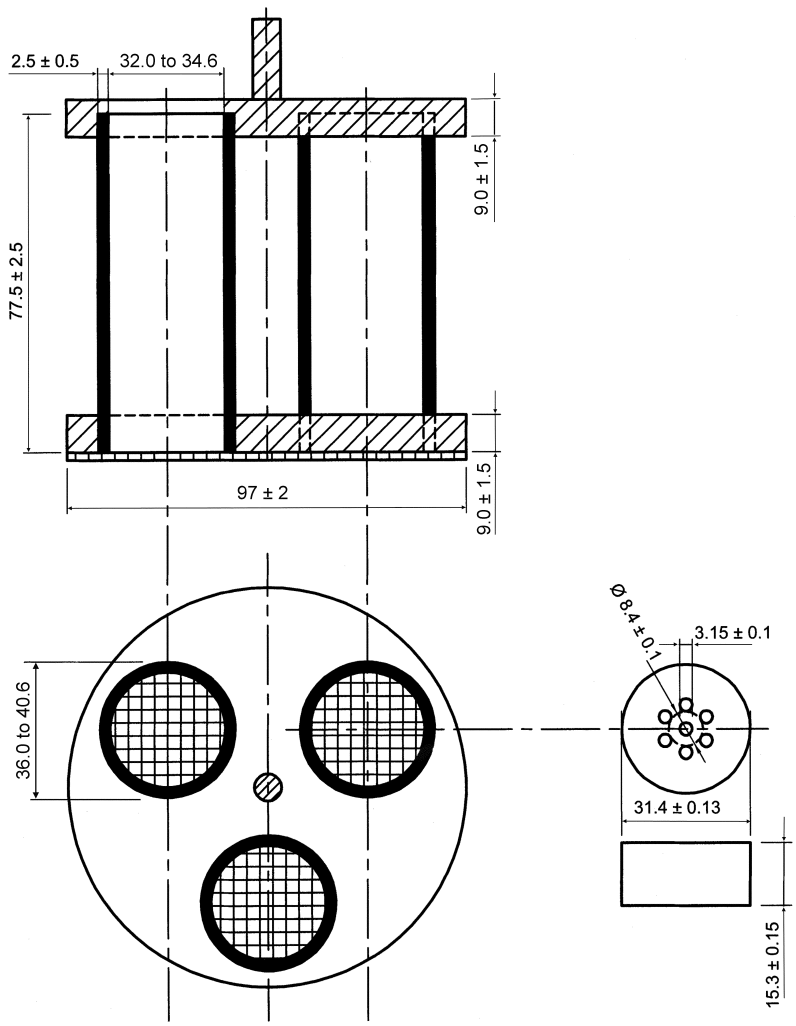

Figure 1. Basket-rack assembly, *Disintegration, Apparatus B* (dimensions in mm).

Beaker—Low form, 1000 mL; the difference between the diameter of the plastic plates, which hold the tubes in a vertical position, and the inside diameter of the beaker should not be more than 6 mm.[2] ■2S (*USP33*)

Disks—Each tube is provided with a perforated cylindrical disk 15.3 ± 0.15 mm thick and 31.4 ± 0.13 mm in diameter. The disk is made of a suitable, transparent plastic material having a specific gravity of between 1.18 and 1.20. Seven 3.15 ± 0.1-mm holes extend between the ends of the cylinder, one of the holes being through the cylinder axis and the others parallel with it and equally spaced on a 4.2 ± 0.1-mm radius from it. All surfaces of the disk are smooth.[3]

Procedure

Uncoated Tablets—Place 1 tablet in each of the tubes of the basket and, if prescribed, add a disk to each tube. Operate the apparatus, using water or the specified medium as the immersion fluid, maintained at 37 ± 2°. At the end of 30 minutes, lift the basket from the fluid, and observe the tablets: all of the tablets disintegrate completely. If 1 or 2 tablets fail to disintegrate completely, repeat the test on 12 additional tablets. The requirement is met if not fewer than 16 of the total of 18 tablets tested disintegrate completely.

Plain Coated Tablets—Place 1 tablet in each of the tubes of the basket and, if the tablet has a soluble external sugar coating, immerse the basket in water at room temperature for 5 minutes. Then, if prescribed, add a disk to each tube, and operate the apparatus, using water or the specified medium as the immersion fluid, maintained at 37 ± 2°. At the end of 30 minutes, lift the basket from the fluid, and observe the tablets: all of the tablets disintegrate completely. If 1 or 2 tablets fail to disintegrate completely, repeat the test on 12 additional tablets. The requirement is met if not fewer than 16 of the total of 18 tablets tested disintegrate completely.

■[2] 1000-mL low-form beakers, designed in compliance with the current ASTM E 960 Type I or Type II or ISO 3819 specifications, are suitable.■2S (USP33)

[3] The use of automatic detection employing modified disks is permitted where the use of disks is specified or allowed. Such disks must comply with the requirements for density and dimensions given in this chapter.

In-Process Revision

Delayed-Release (Enteric-Coated) Tablets—Place 1 tablet in each of the six tubes of the basket, and if the tablet has a soluble external sugar coating, immerse the basket in water at room temperature for 5 minutes. Then operate the apparatus using simulated gastric fluid TS maintained at 37 ± 2° as the immersion fluid. After 1 hour of operation in simulated gastric fluid TS, lift the basket from the fluid, and observe the tablets: the tablets show no evidence of disintegration, cracking, or softening. Operate the apparatus, using simulated intestinal fluid TS, maintained at 37 ± 2°, as the immersion fluid for the time specified in the monograph. Lift the basket from the fluid, and observe the tablets: all of the tablets disintegrate completely. If 1 or 2 tablets fail to disintegrate completely, repeat the test on 12 additional tablets: not fewer than 16 of the total of 18 tablets tested disintegrate completely.

▪Delayed-Release (Enteric-Coated) Soft Shell Capsules—Place 1 softgel capsule in each of the six tubes of the basket. Use two baskets for a total of six tubes for *Apparatus B*. Omit the use of a disk. Operate the apparatus using simulated gastric fluid TS maintained at 37 ± 2° as the immersion fluid. After 1 hour of operation in simulated gastric fluid TS, lift the basket from the fluid and observe the softgels: the softgels show no evidence of disintegration or rupture permitting the escape of the contents. Operate the apparatus with disks, using simulated intestinal fluid TS, maintained at 37 ± 2°, as the immersion fluid. Lift the basket from the fluid, and observe the capsules. All the capsules disintegrate completely within 60 minutes. If 1 or 2 capsules fail to disintegrate completely, repeat the test on 12 additional capsules: not fewer than 16 of a total of 18 capsules tested disintegrate completely.▪2S (*USP33*)

Buccal Tablets—Apply the test for *Uncoated Tablets*. After 4 hours, lift the basket from the fluid, and observe the tablets: all of the tablets disintegrate completely. If 1 or 2 tablets fail to disintegrate completely, repeat the test on 12 additional tablets: not fewer than 16 of the total of 18 tablets tested disintegrate completely.

Sublingual Tablets—Apply the test for *Uncoated Tablets*. At the end of the time limit specified in the individual monograph, all the tablets disintegrate completely. If 1 or 2 tablets fail to disintegrate completely, repeat the test on 12 additional tablets: not fewer than 16 of the total of 18 tablets tested disintegrate completely.

Hard Shell Capsules—Apply the test for *Uncoated Tablets,* using as the immersion fluid, maintained at 37 ± 2°, a 0.05 M acetate buffer prepared by mixing 2.99 g of sodium acetate trihydrate and 1.66 mL of glacial acetic acid with water to obtain a 1000-mL solution having a pH of 4.50 ± 0.05. Attach a removable wire cloth, as described under *Basket-Rack Assembly,* to the surface of the upper plate of the basket-rack assembly. At the end of 30 minutes, lift the basket from the fluid, and observe the capsules: all of the capsules disintegrate except for fragments from the capsule shell. If 1 or 2 capsules fail to disintegrate completely, repeat the test on 12 additional capsules: not fewer than 16 of the total of 18 capsules tested disintegrate completely.

Soft Shell Capsules—Proceed as directed under *Rupture Test for Soft Shell Capsules.*

Use of Disks—

VITAMIN–MINERAL DOSAGE FORMS—Add a disk to each tube unless otherwise specified in the individual monograph.

BOTANICAL DOSAGE FORMS—Omit the use of disks unless otherwise specified in the individual monograph.

DIETARY SUPPLEMENTS OTHER THAN VITAMIN–MINERAL AND BOTANICAL DOSAGE FORMS—Omit the use of disks unless otherwise specified in the individual monograph.

NOTE—The use of disks for enteric-coated tablets is not permitted.

Change to read:

DISSOLUTION

This test is provided to determine compliance with the *Dissolution* requirements where stated in the individual monograph for dietary supplements, except where the label states that tablets are to be chewed.

See *Dissolution* ⟨711⟩ for a description of the apparatus used, the *Apparatus Suitability Test,* and other related information.

•Soft gelatin capsule preparations of dietary supplements meet the requirements for *Disintegration.*

Official until May 1, 2010• (RB 1-May-2009)

▪*Figure 2* shows the schematic view of a flow-through cell specifically intended for lipid-filled soft gelatin capsules. It consists of three transparent parts that fit into each other (USP *Apparatus 4*). The lower part (1) is made up of two adjacent chambers connected to an overflow device. The dissolution medium passes through chamber A and is subjected to an upward flow. The flow in chamber B is directed downward to a small-size bore exit that leads upward to a filter assembly. The middle part (2) of the cell has a cavity designed to collect lipophilic excipients that float on the dissolution medium. A metal grid serves as a rough filter. The upper part (3) holds a filter unit for paper, glass fiber, or cellulose filters.▪2S (*USP33*)

Of the types of apparatus described in ⟨711⟩, use the one specified in the individual monograph.

■

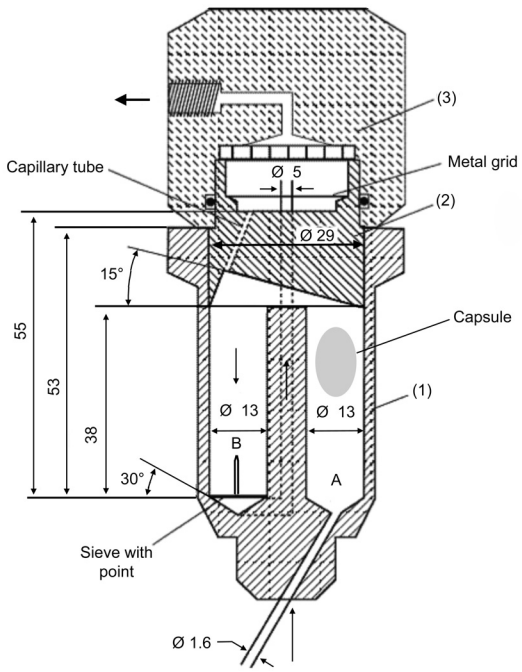

Figure 2. Flow-through cell designed for lipid-filled soft gelatin capsules (dimensions in mm).■2S (*USP33*)

For hard or soft gelatin capsules and gelatin-coated tablets that do not conform to the dissolution specification, repeat the test as follows. Where water or a medium with a pH of less than 6.8 is specified as the *Medium* in the individual monograph, the same *Medium* specified may be used with the addition of purified pepsin that results in an activity of 750,000 Units or less per 1000 mL. For media with a pH of 6.8 or greater, pancreatin can be added to produce not more than 1750 USP Units of protease activity per 1000 mL.

This nonspecific dissolution is intended to be diagnostic of known technological problems that may arise as a result of coatings, lubricants, disintegrants, and other substances inherent in the manufacturing process. For dosage forms containing botanical extracts, this dissolution measurement allows an assessment of the extent of decomposition of the extract to polymeric or other nondissoluble compounds that may have been produced by excessive drying or other manipulations involved in the manufacture of botanical extracts. The operative assumption inherent in this procedure is that if the index or marker compound(s) or the extract is demonstrated to have dissolved within the time frame and under the conditions specified, the dosage form does not suffer from any of the above formulation or manufacturing related problems.

Vitamin–Mineral Dosage Forms

All dietary supplements belonging to USP *Classes II* to *VI,* prepared as tablets or capsules, are subject to the dissolution test and criteria described in this chapter for folic acid (if present) and for index vitamins and index minerals. This test is required because of the importance of the relationship between folate deficiency and the risk of neural tube defects. The accompanying table lists the dissolution requirements for the individual USP classes of dietary supplements. *Class I* dietary supplements are combinations of oil-soluble vitamins for which dissolution standards are not established; hence, dissolution requirements do not apply to the oil-soluble vitamins contained in formulations belonging to *Class IV* or *Class V.* Vitamin–mineral combinations that may not be strictly covered by USP *Class I* to *Class VI* are subject to the dissolution test and criteria specified in the individual monographs.

Dietary Supplements—Vitamin–Mineral Dosage Forms

USP Class	Combination of Vitamins or Minerals Present	Dissolution Requirement
I	Oil-Soluble Vitamins	not applicable
II	Water-Soluble Vitamins	one index vitamin; folic acid (if present)
III	Water-Soluble Vitamins with Minerals	one index vitamin and one index element; folic acid (if present)
IV	Oil- and Water-Soluble Vitamins	one index water-soluble vitamin; folic acid (if present)
V	Oil- and Water-Soluble Vitamins with Minerals	one index water-soluble vitamin and one index element; folic acid (if present)
VI	Minerals	one index element

Unless otherwise stated in the individual monograph, test six dosage units for dissolution as directed under *Dissolution* ⟨711⟩.

DISSOLUTION CONDITIONS FOR FOLIC ACID

NOTE—Perform this test under light conditions that minimize photodegradation.

Medium: water; 900 mL. If the units tested do not meet the requirements for dissolution in water, test six additional dosage units for dissolution in a medium of 900 mL of 0.05 M pH 6.0 citrate buffer solution, prepared by mixing 9.5 mL of 0.1 M citric acid monohydrate and 40.5 mL of 0.1 M sodium citrate dihydrate in a 100-mL volumetric flask, diluting with water to volume, mixing, and adjusting to a pH of 6.0 by using either 0.1 M hydrochloric acid or 0.1 M sodium hydroxide solution.

Apparatus 1: 100 rpm, for capsules.

Apparatus 2: 75 rpm, for tablets.

Time: 1 hour.

NOTE—Compliance with the dissolution requirements for folic acid does not exempt the product from dissolution testing of the pertinent index vitamin or the corresponding index mineral.

In-Process Revision

DISSOLUTION CONDITIONS FOR INDEX VITAMINS AND INDEX MINERALS

Medium: 0.1 N hydrochloric acid; 900 mL.

Apparatus 1: 100 rpm, for capsules.

Apparatus 2: 75 rpm, for tablets.

Time: 1 hour.

For formulations containing 25 mg or more of the index vitamin, riboflavin, use the following conditions:

Medium: 0.1 N hydrochloric acid; 1800 mL.

Apparatus 1: 100 rpm, for capsules.

Apparatus 2: 75 rpm, for tablets.

Time: 1 hour.

NOTE—Compliance with dissolution requirements for the pertinent index vitamin or index mineral does not exempt the product from dissolution testing of folic acid, if present.

SELECTION OF INDEX VITAMINS AND INDEX ELEMENTS

Compliance with the dissolution requirements for dietary supplements representing combinations of water-soluble vitamins (*Water-Soluble Vitamins Capsules* and *Water-Soluble Vitamins Tablets*) and combinations of oil- and water-soluble vitamins (*Oil- and Water-Soluble Vitamins Capsules* and *Oil- and Water-Soluble Vitamins Tablets*) is determined by measuring the dissolution of a single index vitamin from the water-soluble vitamins present. Riboflavin is the index vitamin when present in the formulation. For formulations that do not contain riboflavin, pyridoxine is the index vitamin. If neither riboflavin nor pyridoxine is present in the formulation, the index vitamin is niacinamide (or niacin), and in the absence of niacinamide (or niacin), the index vitamin is thiamine. If none of the above four water-soluble vitamins is present in the formulation, the index vitamin is ascorbic acid.

Compliance with the dissolution requirements for dietary supplements representing combinations of minerals (*Minerals Capsules* and *Minerals Tablets*) is determined by measuring the dissolution of only one index element. Iron is the index element when present in the formulation. For formulations that do not contain iron, the index element is calcium. If neither iron nor calcium is present, the index element is zinc, and in the absence of all three of these elements, magnesium is the index element.

Compliance with dissolution requirements for dietary supplements representing combinations of water-soluble vitamins and minerals (*Water-Soluble Vitamins with Minerals Capsules* and *Water-Soluble Vitamins with Minerals Tablets*) and combinations of oil- and water-soluble vitamins and minerals (*Oil- and Water-Soluble Vitamins with Minerals Capsules* and *Oil- and Water-Soluble Vitamins with Minerals Tablets*) is determined by measuring the dissolution of one index water-soluble vitamin and one index element, designated according to the respective hierarchies described above.

PROCEDURES

In the following procedures, combine equal volumes of the filtered solutions of the six individual specimens withdrawn, and determine the amount of folic acid or the index vitamin or element dissolved, based on the average of six units tested. Make any necessary modifications, including concentration of the analyte in the volume of test solution taken. Use the *Medium* for preparation of the Standard solution and dilution, if necessary, of the test solution.

Folic Acid—Determine the amount of $C_{19}H_{19}N_7O_6$ dissolved by employing the procedure set forth in the *Assay for folic acid* under *Oil- and Water-Soluble Vitamins with Minerals Tablets*, in comparison with a Standard solution having a known concentration of USP Folic Acid RS in the same *Medium*.

Niacin or Niacinamide, Pyridoxine, Riboflavin, and Thiamine—Determine the amount of the designated index vitamin dissolved by employing the procedure set forth in the *Assay for niacin or niacinamide, pyridoxine, riboflavin, and thiamine* under *Water-Soluble Vitamins Tablets.*

Ascorbic Acid—Determine the amount of $C_6H_8O_6$ dissolved by adding 10 mL of 1.0 N sulfuric acid and 3 mL of starch TS to 100.0 mL of test solution, and titrating immediately with 0.01 N iodine VS. Perform a blank determination, and make any necessary correction.

Iron, Calcium, Magnesium, and Zinc—Determine the amount of the designated index element dissolved by employing the procedure set forth in the appropriate *Assay* under *Minerals Capsules*.

TOLERANCES

The requirements are met if not less than 75% of the labeled content of folic acid and not less than 75% of the labeled content of the index vitamin or the index element from the units tested is dissolved in 1 hour.

Botanical Dosage Forms

Compliance with dissolution requirements necessitates the testing of six dosage units individually, or testing two or more dosage units in each of the six vessels of the dissolution apparatus, and measuring the dissolution of one or more index/marker compound(s) or the extract specified in the individual monograph.

PROCEDURES

Combine equal volumes of the filtered solutions of the six or more individual specimens withdrawn, and use the pooled sample as the test solution. Determine the average amount of index or marker compound(s) or the extract dissolved in the pooled sample by the *Procedure* specified in the individual monograph. Make any necessary modifications, including concentration of the analyte in the volume of the test solution taken. Use the *Medium* for preparation of the Standard solution and dilution, if necessary, of the test solution.

~~INTERPRETATION~~

~~*Pooled Sample*—Unless otherwise specified in the individual monograph, the requirements are met if the quantities of the index or marker compound(s) or the extract dissolved from the pooled sample conform to the accompanying acceptance table. The quantity, *Q*, is the amount of dissolved index or marker compound(s) or the extract specified in the individual monograph, expressed as a percentage of the labeled content. The 5%, 15%, and 25% values in the acceptance table are percentages of the labeled content so that these values and *Q* are in the same terms.~~

~~**Acceptance Table for a Pooled Sample**~~

~~Stage~~	~~Number Tested~~	~~Acceptance Criteria~~
~~S_1~~	~~6~~	~~Average amount dissolved is not less than Q + 10%~~
~~S_2~~	~~6~~	~~Average amount dissolved (S_1 + S_2) is equal to or greater than Q + 5%~~
~~S_3~~	~~12~~	~~Average amount dissolved (S_1 + S_2 + S_3) is equal to or greater than Q~~

▲TOLERANCES

Unless otherwise specified in the individual monograph, the requirements are met if not less than 75% of the labeled content of the index or marker compound(s) or the extract from the units tested is dissolved in 1 hour.▲*USP34*

Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms

Unless otherwise stated in the individual monographs for dietary supplement dosage forms in this category, compliance requires the testing of six individual units, measuring the dissolution of the dietary ingredient as the average of the six units tested.

PROCEDURES

Combine equal volumes of the filtered solutions of the six specimens withdrawn, and use the pooled sample as the test solution. Determine the average amount of dietary ingredient dissolved in the pooled sample by the *Procedure* specified in the individual monograph. Make any necessary modifications, including concentration of the analyte in the volume of the test solution taken. Use the *Medium* for preparation of the Standard solution and for dilution, if necessary, of the test solution.

TOLERANCES

Because of the diversity of chemical characteristics and solubilities of dietary ingredients pertaining to this category, general tolerances cannot be established. See individual monographs for *Tolerances*.

In-Process Revision

REAGENTS, INDICATORS, AND SOLUTIONS

Reagent Specifications

BRIEFING

Ammonium Bicarbonate. It is proposed to add this new reagent used in *Identification* test *B* in the monograph for *Glucagon*.

(HDQ: M. Marques.) RTS—C54723

Add the following:

▲**Ammonium Bicarbonate** *(Ammonium Hydrogen Carbonate)*, NH_4HCO_3—**79.06** [*1066-33-7*]—Use a suitable grade with a content of NLT 99.0%.▲*USP34*

BRIEFING

2-Chloroethanol. It is proposed to add this new reagent used in the *Limit of 2-Chloroethanol* test in the monograph for *Carmustine*.

(HDQ: M. Marques) RTS—C52248

Add the following:

▲**2-Chloroethanol** *(Ethylene Chlorohydrin)*, C_2H_5ClO—**80.51** [*107-07-3*]—Use a suitable grade with a content of NLT 99%.▲*USP34*

BRIEFING

Alpha-Chymotrypsin. It is proposed to add this new reagent used in *Identification* test *B* in the monograph for *Glucagon*.

(HDQ: M. Marques) RTS—C54723

Add the following:

▲**Alpha-Chymotrypsin—25 kDa** [*9004-07-3*]—Use a suitable salt-free grade for protein sequencing.

NOTE— A suitable grade is available as catalog number 4423 from www.sigma-aldrich.com.▲*USP34*

BRIEFING

Glycolic Acid, *USP 32* page 826. It is proposed to include the sample silanization procedure.

(HDQ: M. Marques) RTS—C78511

Change to read:

Glycolic Acid, $C_2H_4O_3$—**76.05** [*79-14-1*]—White crystalline powder or chunks.

~~*Assay*—Inject an appropriate volume (silanized) into a gas chromatograph (see *Chromatography* ⟨621⟩) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm × 30-m capillary column coated with a 1-µm layer of phase G2. The injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; the column temperature is maintained at 100° and programmed to rise 10° per minute to 250°. The area of the $C_2H_4O_3$ peak is not less than 98.5% of the total peak area.~~

▲*Assay*—

SILYLATING REAGENT: Pyridine, hexamethyldisilazane, chlorotrimethylsilane (9 : 3 : 1)

SAMPLE PREPARATION: Weigh approximately 25 mg (about 3 drops) of the sample into a test tube. Add 2 mL of the *Silylating reagent* and cap the test tube. Mix well and allow to incubate at room temperature for a minimum of 2 h. A white precipitate of ammonium chloride will form. Centrifuge and use the clear supernatant for injection.

PROCEDURE: Inject an appropriate volume of the *Sample preparation* into a gas chromatograph (see *Chromatography* ⟨621⟩) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm × 30-m capillary column coated with a 1-µm layer of phase G2. The injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; the column temperature is maintained at 100° and programmed to rise 10° per min to 250°. The area of the peak corresponding to $C_2H_4O_3$ is NLT 98.5% of the total peak area.▲*USP34*

BRIEFING

Lead Acetate Cotton. It is proposed to add this new reagent used in the *Limit of Arsenic* test in the monograph for *Aluminum Oxide*, which appears elsewhere in this issue of *PF*.

(HDQ: M. Marques.) RTS—C77141

Add the following:

▲**Lead Acetate Cotton**—Immerse absorbent cotton in a mixture of 1 volume of dilute acetic acid and 10 volumes of lead acetate TS. Drain off the excess of liquid, without squeezing the cotton, by placing it on several layers of filter paper. Allow to dry in air. Store in airtight containers.▲*USP34*

BRIEFING

Mercuric Bromide Test Paper, *USP 32* page 861. It is proposed to add more information on how to prepare this test paper.

(HDQ: M. Marques) RTS—C78623

Mercuric Bromide Test Paper ~~Use alcoholic mercuric bromide TS. Store protected from light.~~

▲Place a 50 mg/mL solution of mercuric bromide in dehydrated alcohol in a dish, and immerse in it pieces of white filter paper weighing 80 g/m^2 (speed of filtration = filtration time expressed in s for 100 mL of water at 20° with a filter surface of 10 cm^2 and a constant pressure of 6.7 kPa; 40–60 s), each measuring 1.5 cm by 20 cm and folded in the middle. Allow the excess of liquid to drain, and allow the paper to dry, protected from light, suspended over a nonmetallic thread. Discard 1 cm from each end of each strip, and cut the remainder into 1.5-cm squares or discs of 1.5-cm diameter. Store in a glass-stoppered container wrapped with black paper.▲*USP34*

BRIEFING

Potassium Arsenate Monobasic. It is proposed to add this new reagent used to evaluate the pullulanase enzyme used in the monograph for *Pullulan*.

(HDQ: M. Marques) RTS—C54621

Add the following:

▲**Potassium Arsenate Monobasic,** KH_2AsO_4—**180.03** [*7784-41-0*]—Use a suitable grade with a content of NLT 98%.▲*USP34*

BRIEFING

Zinc, Activated. It is proposed to add this new reagent used in *Limit of Arsenic* test in the monograph for *Aluminum Oxide*.

(HDQ: M. Marques.) RTS—C77141

Add the following:

▲**Zinc, Activated**—Place zinc pellets in a conical flask and add a sufficient quantity of a 50-ppm solution of chloroplatinic acid to cover all pellets. Allow the metal to remain in contact with the solution for 10 min, drain, wash, and dry immediately.

Assay—To 5 g of activated zinc add 15 mL of hydrochloric acid, 25 mL of water, 0.1 mL of stannous chloride solution (235 mg/mL in hydrochloric acid) and 5 mL of potassium iodide solution (166 mg/mL in water). No stain is produced when in contact with mercurc bromide paper. Repeat the test for arsenic using the same reagents and adding a solution containing 1 μg of arsenic. An appreciable stain appears when in contact with mercuric bromide paper.▲*USP34*

REFERENCE TABLES

BRIEFING

Container Specifications for Capsules and Tablets, *USP 32* page 881, page 4014 of the *First Supplement*, and page 1341 of *PF* 35(5) [Sept.–Oct. 2009].

(HDQ) RTS—C55635; C67684; C77735

The following table is provided as a reminder for the pharmacist engaged in the typical dispensing situation who already is acquainted with the *Packaging and Storage* requirements set forth in the individual monographs. It lists the capsules and tablets that are official in the *United States Pharmacopeia* and indicates the relevant tight (T), well-closed (W), and light-resistant (LR) specifications applicable to containers in which the drug that is repackaged should be dispensed.

This table is not intended to replace, nor should it be interpreted as replacing, the definitive requirements stated in the individual monographs.

Container Specifications for Capsules and Tablets

BRIEFING

Description and Relative Solubility of USP and NF Articles, *USP 32* page 890, page 4014 of the *First Supplement*, page 817 of *PF* 34(3) [May–June 2008], page 1322 of *PF* 34(5) [Sept.–Oct. 2008], page 1565 of *PF* 34(6) [Nov.–Dec. 2008], page 188 of *PF* 35(1) [Jan.–Feb. 2009], page 464 of *PF* 35(2) [Mar.–Apr. 2009], page 651 of *PF* 35(3) [May–June 2009], page 993 of *PF* 35(4) [July–Aug. 2009], and page 1343 of *PF* 35(5) [Sept.–Oct. 2009].

(HDQ) RTS—C49074; C54956; C63974; C67356; C70759; C74528; C77133; C77734; C77792; C78462

Add the following:

▲**Butyl Stearate:** Butyl Stearate occurs as a colorless, waxy solid at temperatures below approximately 25° or as a clear liquid at temperatures above approximately 25°. Soluble in alcohol, most fixed oils; insoluble or practically insoluble in propylene glycol and water. *NF category:* Emollient.▲*NF29*

Change to read:

Cefoperazone Sodium: White to pale buff crystalline powder. Freely soluble in water; ~~and in methanol;~~

▲soluble in methanol;▲*USP34*
slightly soluble in dehydrated alcohol; insoluble in acetone, in ethyl acetate, and in ether.

Change to read:

Doxycycline: Yellow, crystalline powder. Very slightly soluble in water; freely soluble in dilute acid and in alkali hydroxide solutions; ~~sparingly soluble in alcohol;~~

▲very slightly soluble in alcohol;▲*USP34*
practically insoluble in chloroform and in ether.

Change to read:

Ferric Sulfate: Grayish-white or yellowish powder or fawn-colored pearls. Hygroscopic. ~~Rapidly soluble in the presence of a trace of ferrous sulfate; slowly soluble in water; sparingly soluble in alcohol; practically insoluble in acetone and in ethyl acetate.~~

▲Slightly soluble in water and in ethanol (96%). Practically insoluble in acetone and in ethyl acetate.▲*USP34*
Hydrolyzes slowly in aqueous solution.

In-Process Revision

Add the following:

▲**Halobetasol Propionate:** White to off-white powder. Freely soluble in dichloromethane and acetone; practically insoluble in water.▲*USP34*

Add the following:

▲**Levofloxacin:** Light yellowish-white to yellow-white crystals or crystalline powder. Soluble in dimethylsulfoxide and in acetic acid; sparingly soluble in water, in acetone, and in methanol; practically insoluble in glyerin and in *n*-octanol.▲*USP34*

Delete the following:

~~▲Paramethasone Acetate: Fluffy, white to creamy white, odorless, crystalline powder. Melts at about 240°, with decomposition. Insoluble in water; soluble in chloroform, in ether, and in methanol.~~▲*USP34*

Change to read:

Pravastatin Sodium: White to yellowish white, hygroscopic powder. Freely soluble in water and in methanol; soluble in

▲dehydrated▲*USP34*
alcohol; ~~very slightly soluble in acetonitrile;~~

▲▲*USP34*
practically insoluble ~~in ether, in ethyl acetate,~~

▲in acetonitrile▲*USP34*
and in chloroform.

Add the following:

▲**Rivastigmine Tartrate:** White to off-white powder. Very soluble in water and in methanol; very slightly soluble in ethyl acetate.▲*USP34*

Add the following:

▲**Venlafaxine Hydrochloride:** Off-white to white crystalline powder. Soluble in methanol and in water.▲*USP34*

In-Process Revision

Pending Proposals

(Items from earlier numbers of *PF* that have not yet been adopted and become official)

In order for an item to be adopted into the *USP–NF* and become officially binding, it must first be proposed and published in the *Pharmacopeial Forum (PF)* to allow the public an opportunity to review and comment upon it. When an item is adopted, it is published in the *USP–NF,* its *Supplements,* an *IRA* , or a *Revision Bulletin.* Those items that have not yet been adopted are marked as *Pending Proposals.*

The *Pending Proposals* list contains these items separated into the following categories: General Notices and Requirements; *USP* monographs; Dietary Supplements Monographs; General Chapters; Reagents; Indicators; and Solutions; Reference Tables; Excipients; and *NF* Monographs. Each entry in the *Pending Proposals* list contains the monograph title and the citation of the most recent publication of the monograph. Reprints of *PF* proposals may be purchased from USP by sending a written request for information to custsvc@usp.org.

To check the status of a *Pending Proposal,* please contact USP as directed below.

- The briefing accompanying the monograph or general chapter lists the names of the Scientific Liaisons responsible for the proposed revisions. The contact information (phone number and email) for the Scientific Liaison is available in the *Staff Directory* section of *How to Use PF.* For *USP–NF Online* subscribers, the name and contact information for the assigned Scientific Liaison is available in the *Auxiliary Information* portion of each monograph.
- Call USP at 301-816-8344 and ask to speak with the Scientific Liaison assigned to the monograph or general chapter of interest.
- Submit questions by email to stdsmonographs@usp.org. Please indicate the name of the monograph or general chapter in the subject line of the email.

Following these lists the reader will find the *Canceled Proposals* list. These are items that were published in *PF* and were pending, but have since been canceled. This list contains cumulative entries for the six issues per volume of *PF* [i.e., 35(1) through 35(6)]. Note that canceled proposals may be republished in *PF* to be considered for future adoption into the *USP–NF.*

Title and Proposal	***PF Volume, Issue, and Page Numbers of Pending Proposals***		
	Vol.	***No.***	***Page(s)***
General Notices (entire *General Notices and Requirements* revised)	34	1	40
USP Monographs			
Acetaminophen—*Readily carbonizable substances*	34	5	1136
Acetaminophen and Tramadol Hydrochloride Tablets (new)	35	1	56
Acetylcysteine—*USP Reference standards, Assay*	31	3	726
Acitretin—*Assay, Heavy Metals*	35	5	1102
Acitretin Capsules—*Assay*	35	5	1095
Medical Air—*Identification* (add); *Assay; Inorganic Impurities—Carbon Dioxide, Carbon Monoxide, Sulfur Dioxide, Limit of Nitric Acid and Nitrogen Dioxide; Packaging and Storage; Labeling*	35	4	828
Albumin Human—*Definition, Packaging and storage, Expiration date, Labeling, USP Reference standards* (add), *Identification A, B* (add), *Bacterial endotoxins* (add), *Safety* (add), *Sterility* (add), *pH* (add), *Molecular size distribution* (add), *Heat stability* (add), *Incubation* (add) *Prekallikrein activator* (add), *Protein content* (add), *Heme content* (add), *Potassium content* (add), *Sodium content* (add)	31	5	1338
Albuterol Tablets—*Assay*	31	3	726
Alendronate Sodium Tablets—*Dissolution*	35	1	59
Alprazolam Tablets—*Assay*	33	1	41
Alumina, Magnesia, and Calcium Carbonate Chewable Tablets (new)	29	6	1836
Amifostine—*X-ray diffraction* (delete)	34	5	1136
Amiodarone Hydrochloride (new)	34	6	1429
Amlodipine Besylate—*Chemical information, Definition, Labeling* (add), *Water*	34	5	1136
Amlodipine Besylate Tablets (new)	35	1	62
Amphetamine Sulfate—*USP Reference standards, Identification, Chromatographic purity* (delete), *Related compounds* (add), *Organic volatile impurities* (delete), *Assay*	34	4	902
Amphetamine Sulfate Tablets—*Identification, Assay*	34	4	904

Pending Proposals (*continued*)

(Items from earlier numbers of *PF* that have not yet been adopted and become official)

Title and Proposal	PF Volume, Issue, and Page Numbers of Pending Proposals Vol.	No.	Page(s)
Ampicillin—*Definition, USP Reference standards, Related compounds* (add), *Assay*	34	5	1140
Ampicillin Sodium—*Dimethylaniline*	35	1	65
Aprotinin (new)	31	3	732
Aprotinin Injection (new)	31	3	736
Articaine Hydrochloride (new)	35	3	544
Aspirin—*Readily carbonizable substances*	34	5	1143
Atenolol—*Identification B*	35	3	545
Atenolol Tablets—*Dissolution*	35	1	66
Atorvastatin Calcium (new)	35	1	66
Atovaquone Oral Suspension—*Assay*	34	2	247
Atracurium Besylate Injection—*Related compounds*	34	4	905
Atropine Sulfate—*Identification C* (add); *Organic Impurities—Other Alkaloids* (delete), *Procedure* (add); *Melting Range or Temperature* (delete); *Optical Rotation* (delete); *Optical Rotation* (add); *Acidity* (delete); *Packaging and Storage; USP Reference Standards*	35	4	829
Aurothioglucose Injectable Suspension—*Bacterial endotoxins* (add), *Sterility* (add)	34	4	906
Azithromycin—*USP Reference standards, Limit of related substances* (delete), *Related compounds* (add)	34	3	559
Azithromycin for Injection (new)	34	3	562
Azithromycin Tablets (new)	34	5	1143
Aztreonam—*Definition, Assay, Organic Impurities* (add), *Limit of Alcohol* (add), *USP Reference Standards*	35	5	1103
Aztreonam for Injection—*Assay*	34	4	906
Soluble Bacitracin Methylene Disalicylate—*Title change, Definition*	35	5	1105
Bacitracin Methylene Disalicylate Soluble Powder—*Title change, Definition*	35	5	1106
Balsalazide Disodium (new)	35	4	830
Balsalazide Disodium Capsules (new)	35	4	832
Bendroflumethiazide Tablets—*Dissolution*	35	5	1106
Benzethonium Chloride—*Identification B, C* (delete), *Identification B* (add), *USP Reference Standards* (add)	35	4	833
Benzocaine—*Readily carbonizable substances*	34	5	1147
Benzoic Acid—*Readily carbonizable substances*	34	5	1147
Benzoin—*Botanic characteristics, Identification*	35	1	70
Bicalutamide—*Organic Impurities*	35	5	1107
Bicalutamide Tablets—*Labeling, Dissolution*	34	5	1147
Biperiden Hydrochloride Tablets—*Dissolution*	35	5	1108
Bisoctrizole (new)	32	2	309
Bleomycin for Injection—*Identification A, B* (add), *Other requirements*	34	5	1150
Budesonide—*Related compounds*	35	3	539
Bupropion Hydrochloride Extended-Release Tablets—*Dissolution*	35	5	1109
Buspirone Hydrochloride—*Content of chloride*	31	3	742
Caffeine—*Identification B, Melting range* (delete), *Readily carbonizable substances* (delete), *Other alkaloids* (delete)	34	5	1150
Camphor—*Water*	31	3	742
Capecitabine—*Assay, Organic Impurities*	35	4	834
Capecitabine Tablets—*Assay, Dissolution, Organic Impurities*	35	5	1113
Carbidopa—*Specific rotation*	35	1	73
Carbidopa and Levodopa Extended-Release Tablets (new)	34	6	1433
Carmustine (new)	35	3	546
Carmustine for Injection (new)	35	3	548
Cefazolin Sodium—*Chemical information, Related compounds* (add)	34	6	1438
Cefdinir Capsules—*Organic Impurities*	35	5	1115
Cefdinir for Oral Suspension—*Organic Impurities*	35	5	1118
Cefotetan for Injection—*Identification A* (add), *B* (add), *Other Requirements*	35	5	1122
Cefixime for Oral Suspension—*Water* (delete)	34	6	1441
Ceftazidime Injection—*USP Reference standards, Pyrogen* (delete), *Bacterial endotoxins* (add)	34	4	907
Ceftiofur Hydrochloride (new)	34	4	908
Ceftiofur Sodium (new)	34	4	912
Cefuroxime Axetil for Oral Suspension—*pH*	35	5	1123
Chloral Hydrate—*Readily carbonizable substances*	34	5	1150
Ciprofloxacin—*Identification B*	35	4	837
Ciprofloxacin Hydrochloride—*Identification B*	35	4	839

Pending Proposals (*continued*)

(Items from earlier numbers of *PF* that have not yet been adopted and become official)

Title and Proposal	PF Volume, Issue, and Page Numbers of Pending Proposals Vol.	No.	Page(s)
Ciprofloxacin Injection—*Identification A*	35	4	840
Ciprofloxacin Ophthalmic Solution—*Identification A*	35	4	842
Ciprofloxacin Tablets—*Identification A, B* (delete)	35	4	843
Citalopram Hydrobromide—*Identification, Related compounds*	34	4	917
Citalopram Tablets—*Identification A, Uniformity of Dosage Units, Organic Impurities*	35	4	844
Anhydrous Citric Acid *(Harmonization)—Sulfate*	31	3	749
Anhydrous Citric Acid—*Readily carbonizable substances*	34	5	1150
Citric Acid Monohydrate *(Harmonization)—Sulfate*	31	3	750
Citric Acid Monohydrate—*Readily carbonizable substances*	34	5	1151
Citric Acid, Magnesium Oxide, and Sodium Carbonate Irrigation—*USP Reference standards, Assay for citric acid (delayed implementation to January 1, 2009)*	31	2	394
Cladribine—*Specific rotation, Related compounds*	33	1	49
Clarithromycin Tablets—*Dissolution*	35	5	1124
Clavulanate Potassium—*Limit of aliphatic amines, Limit of 2-ethylhexanoic acid*	34	6	1441
Clenbuterol Hydrochloride (new)	35	5	1125
Clindamycin Palmitate Hydrochloride—*Chemical information, Assay*	34	6	1442
Clobetasol Propionate—*Residue on Ignition, Heavy Metals*	35	5	1125
Clopidogrel Tablets—*Related compounds*	33	1	50
Cloprostenol Injection (new)	34	4	918
Cloprostenol Sodium (new)	34	4	920
Cocaine—*Readily carbonizable substances*	34	5	1151
Cocaine Hydrochloride—*Readily carbonizable substances*	34	5	1151
Codeine—*Readily carbonizable substances*	34	5	1151
Codeine Sulfate—*Readily carbonizable substances*	34	5	1151
Cyclophosphamide—*Identification B, Assay, Organic Impurities—Procedure 1 and Procedure 2* (add), *Limit of Chloride* (add), *Limit of Phosphate* (add), *Bacterial Endotoxins Test* (add), *Sterility Tests* (add), *Labeling* (add), *USP Reference Standards*	35	5	1126
Dalteparin Sodium (new)	30	5	1598
Dantrolene Sodium Capsules—*Packaging and storage*	34	5	1151
Dapsone—*Assay*	31	3	750
Deferoxamine Mesylate—*Definition, Identification* (delete), *A* (add), *B* (add), *Assay, Organic Impurities* (add), *Packaging and Storage*	35	4	847
Human Acellular Dermal Matrix (new)	35	3	558
Microsized Human Acellular Dermal Matrix (new)	35	3	561
Desmopressin Nasal Spray Solution (new)	31	4	1059
Dextroamphetamine Sulfate—*Definition, USP Reference standards, Identification, Chromatographic purity* (delete), *Related compounds* (add), *Organic volatile impurities* (delete), *Assay*	34	4	921
Dextrose—*Harmonization*	34	6	1585
Diazepam Extended-Release Capsules—*USP Reference standards, Assay*	32	2	330
Diclazuril (new)	35	1	73
Diclofenac Sodium Delayed-Release Tablets—*Dissolution*	35	5	1129
Diclofenac Sodium Extended-Release Tablets—*Assay, Dissolution, Organic Impurities*	35	5	1130
Dicyclomine Hydrochloride—*Readily carbonizable substances*	34	5	1152
Didanosine for Oral Solution—*Assay*	34	6	1443
Dihydroxyaluminum Sodium Carbonate Chewable Tablets (new)	29	6	1873
Dinoprostone—*Organic Impurities*	35	5	1132
Disulfiram—*Assay, Inorganic Impurities—Selenium*	35	4	848
Docetaxel (new)	35	5	1133
Docusate Sodium—*Residue on Ignition*	35	5	1095
Dofetilide (new)	35	5	1135
Dolasetron Mesylate—*Impurities*	35	2	272
Dopamine Hydrochloride—*Readily carbonizable substances*	34	5	1152
Doxazosin Mesylate—*Assay*	34	5	1152
Dronabinol Capsules—*Definition, Assay, USP Reference Standards*	35	3	549
Ecamsule Solution (new)	34	5	1153
Egg Phospholipids (new)	31	3	757
Endotoxin Indicator for Depyrogenation (new)	34	6	1444
Enrofloxacin (new)	34	4	924
Ensulizole—*USP Reference Standards*	35	4	849
Epirubicin Hydrochloride (new)	35	2	273

Octisalate—*Assay*	34	4	970
Ofloxacin—*Chromatographic purity* (delete), *Related compounds* (add)	30	4	1274
Ofloxacin Tablets—*Uniformity of dosage units*	34	6	1467
Olanzapine Tablets (new)	35	2	282
Olopatadine Hydrochloride (new)	35	3	567
Olopatadine Hydrochloride Ophthalmic Solution (new)	35	3	568
Ondansetron Hydrochloride—*Limit of ondansetron related compound D, Assay*	32	1	126
Ondansetron Tablets (new)	34	4	971
Ondansetron Orally Disintegrating Tablets—*Labeling* (add), *Disintegration, Dissolution, Water* (delete)	34	6	1467
Orlistat (new)	35	5	1166
Orlistat Capsules (new)	35	5	1169
Oseltamivir Phosphate (new)	34	6	1468
Oseltamivir Phosphate Capsules (new)	34	6	1471
Oxaliplatin (new)	34	4	973
Oxaliplatin Injection (new)	35	2	284
Oxaliplatin for Injection (new)	34	6	1473
Oxazepam Capsules—*Assay, Dissolution, Organic Impurities* (add)	35	5	1170
Oxcarbazepine (new)	34	5	1177
Oxcarbazepine Tablets (new)	34	6	1478
Oxybutynin Chloride Tablets—*Dissolution*	35	1	93
Oxycodone Hydrochloride—*USP Reference standards, Limit of oxycodone related compound A (14-hydroxycodeinone) and oxycodone related compound C (codeinone)* (add), *Chromatographic purity*	34	6	1480
Oxygen—*Identification—Procedure, B* (delete); *Assay; Inorganic Impurities—Carbon Dioxide, Carbon Monoxide; Packaging and Storage; Labeling*	35	4	861
Oxygen 93 Percent—*Identification A, B* (delete); *Assay; Inorganic Impurities—Carbon Dioxide, Carbon Monoxide; Packaging and Storage; Labeling*	35	4	862
Pamidronate Disodium—*Alcohol content* (delete)	34	5	1179
Pamidronate Disodium for Injection—*Definition*	33	1	81
Pancuronium Bromide Injection (new)	32	4	1097
Pantoprazole Oral Suspension (new)	35	4	863
Paricalcitol—*Identification, Assay*	33	2	252
Pectin—*Chemical information; Definition; Identification—A, B, C, D* (delete), *Procedure* (add); *Assay—Methoxy Groups* (name change), *Galacturonic Acid, Methoxy Groups* (add); *Impurities—Lead, Procedure 1, Procedure 2* (add), *Procedure 3* (add); *Microbial Enumeration Tests; Packaging and Storage; Labeling; USP Reference Standards* (add)	35	2	287
Penicillamine Capsules—*Dissolution*	31	2	436
Pentamidine Isethionate (new)	35	3	570
Pentobarbital—*Identification B* (delete), *C, Assay, Organic Impurities, Melting Range or Temperature* (delete)	35	4	864
Pentobarbital Sodium—*Labeling* (add), *USP Reference standards, Other requirements* (add)	31	1	73
Petrolatum (new)—*Stage 4 Harmonization*	35	5	1363
White Petrolatum (new)—*Stage 4 Harmonization*	35	5	1364
Liquefied Phenol—*Identification* (add), *Other requirements*	35	1	93
Phenytoin Chewable Tablets (new)	29	6	1965
Physostigmine—*Readily carbonizable substances*	34	5	1179
Physostigmine Salicylate—*Readily carbonizable substances*	34	5	1179
Physostigmine Sulfate—*Readily carbonizable substances*	34	5	1179
Pilocarpine Hydrochloride—*Readily carbonizable substances*	34	5	1179
Pilocarpine Nitrate—*Readily carbonizable substances*	34	5	1179
Piperacillin and Tazobactam for Injection (new)	34	4	980

Pending Proposals (*continued*)

(Items from earlier numbers of *PF* that have not yet been adopted and become official)

Title and Proposal	PF Volume, Issue, and Page Numbers of Pending Proposals Vol.	No.	Page(s)
Potassium and Sodium Bicarbonates and Citric Acid Effervescent Tablets for Oral Solution—*USP Reference standards* (add), *Assay for anhydrous citric acid (delayed implementation to January 1, 2009)*	31	2	440
Potassium Bitartrate—*Heavy metals*	34	5	1180
Potassium Citrate Extended-Release Tablets—*USP Reference standards* (add), *Assay (delayed implementation to January 1, 2009)*	31	2	443
Potassium Citrate and Citric Acid Oral Solution—*USP Reference standards* (add), *Assay for citrate (delayed implementation to January 1, 2009)*	31	2	444
Potassium Iodide Delayed-Release Tablets—*Identification* (add), *Other requirements*	34	6	1481
Potassium Iodide Oral Solution—*Definition*	31	3	786
Potassium Sodium Tartrate—*Limit of ammonia*	31	3	787
Pralidoxime Chloride for Injection—*Identification A, B, C* (add), *Other requirements*	34	5	1180
Pravastatin Sodium Tablets—*USP Reference standards, Related compounds*	34	5	1180
Praziquantel Tablets—*Dissolution*	35	2	291
Primidone—*Identification B, C* (delete), *Assay, Organic Impurities, Melting Range or Temperature* (delete), *USP Reference Standards*	35	3	571
Primidone Tablets—*Assay, Organic Impurities* (add), *USP Reference Standards*	35	3	573
Promethazine Hydrochloride and Codeine Phosphate Oral Solution (new)	35	2	292
Promethazine Hydrochloride and Dextromethorphan Hydrobromide Oral Solution (new)	35	2	295
Promethazine and Phenylephrine Hydrochloride Oral Solution (new)	35	2	298
Promethazine and Phenylephrine Hydrochloride and Codeine Phosphate Oral Solution (new)	35	2	301
Propafenone Hydrochloride—*USP Reference standards, Chromatographic purity* (delete), *Related compounds* (add)	35	1	94
Propranolol Hydrochloride Extended-Release Capsules—*Dissolution*	35	5	1096
Propoxyphene Hydrochloride—*Definition, Assay, Organic Impurities, Melting Range or Temperature* (delete)	35	4	865
Propoxyphene Hydrochloride Capsules—*Identification B* (delete), *Identification C*	35	3	574
Psyllium Husk—*Impurities—Heavy Metals* (add), *Procedure 3* (add)	35	2	304
Pyrantel Pamoate—*USP Reference standards, Related compounds*	34	6	1482
Quinapril Tablets—*Related compounds*	34	5	1182
Ractopamine Hydrochloride Suspension (new)	35	5	1171
Ramipril—*Definition, Assay*	31	3	787
Ramipril Capsules (new)	35	4	867
Oral Rehydration Salts—*USP Reference standards* (add), *Assay for citrate (delayed implementation to January 1, 2009)*	31	5	1399
Repaglinide Tablets—*Loss on Drying* (delete)	35	2	306
Ribavirin Capsules (new)	35	3	576
Riluzole (new)	35	5	1173
Riluzole Tablets (new)	35	5	1174
Risedronate Sodium (new)	34	5	1183
Risedronate Sodium Tablets (new)	34	5	1186
Risperidone Oral Solution (new)	35	4	870
Ritonavir—*Identification*	35	1	95
Salmeterol Xinafoate (new)	35	2	307
Salsalate Tablets—*Assay*	33	6	1211
Secobarbital Sodium—*Chemical structure, Definition, Identification, Related compounds* (add), *Isomer content* (delete), *Assay*	34	4	984
Sennosides—*Content of Sennosides A and B* (add), *USP Reference Standards* (add)	35	2	308
Sertraline Hydrochloride (new)	34	5	1189
Sibutramine Hydrochloride (new)	34	4	986
Sodium Chloride—*Identification, Loss on drying, Limit of potassium (postponed indefinitely)*	32	2	264
Sodium Fluoride Gel (new)	35	5	1175
Sodium Sulfate—*Assay*	34	5	1192

Soybean Oil—*CAS number* (add), *Labeling, Identification* (add), *Specific gravity* (delete), *Refractive index* (delete), *Heavy metals, Free fatty acids* (delete), *Acid value* (add), *Fatty acid composition, Iodine value* (delete), *Saponification value* (delete), *Cottonseed oil* (delete), *Peroxide value, Water* (add), *Alkaline impurities* (add), *Sterol composition* (add), *Other requirements* (add)	34	4	989
Spectinomycin for Injectable Suspension—*Identification* (add), *Other requirements*	34	5	1193
Streptomycin Injection—*Identification* (add), *Other requirements*	34	5	1193
Sucralfate—*Identification*	33	2	254
Sulfadiazine Tablets—*Dissolution*	35	3	577
Sulfadoxine—*Identification, Assay*	34	2	300
Sulfamethazine Granulated—*Assay*	31	3	797
Sulfinpyrazone—*Identification A, B* (add), *Melting Range or Temperature* (delete), *Solubility in acetone* (delete), *Solubility in 0.50 N sodium hydroxide* (delete)	35	3	577
Sumatriptan Tablets (new)	35	4	871
Tacrolimus (new)	35	2	310
Tacrolimus Capsules (new)	35	2	312
Tamsulosin Hydrochloride (new)	35	3	578
Tamsulosin Hydrochloride Capsules (new)	34	5	1193
Telmisartan (new)	35	3	580
Telmisartan Tablets (new)	35	3	581
Terazosin Capsules (new)	35	4	872
Terazosin Tablets (new)	35	4	874
Terbinafine Oral Suspension (new)	35	1	96
Terbutaline Oral Suspension (new)	35	1	97
Terbutaline Sulfate Inhalation Aerosol—*USP Reference standards, Assay*	31	2	450
Terconazole (new)	34	4	991
Thiabendazole Chewable Tablets (new)	29	6	1991
Thimerosal—*Readily carbonizable substances*	34	5	1197
Thioguanine—*USP Reference standards, Identification, Limit of guanine*	34	2	305
Thioridazine Hydrochloride—*Identification*	31	3	798
Tiagabine Hydrochloride Oral Suspension (new)	35	1	98
Ticlopidine Hydrochloride (new)	35	3	582
Ticlopidine Hydrochloride Tablets (new)	35	3	584
Tilmicosin—*Definition, Related compounds, Assay*	31	3	798
Tioconazole—*Assay*	35	4	875
Tizanidine Tablets—*Dissolution*	35	3	585
Topiramate Tablets (new)	34	5	1197
Tramadol Hydrochloride (new)	34	5	1200
Tramadol Hydrochloride Tablets (new)	31	2	462
Tranexamic Acid (new)	34	6	1484
Tranylcypromine Sulfate (new)	35	2	314
Tranylcypromine Tablets (new)	35	3	587
Trenbolone Acetate—*Definition, USP Reference standards, Identification, Chromatographic purity* (delete), *Limit of trenbolone acetate 17α-isomer* (delete), *Related compounds* (add), *Assay*	35	1	100
Tretinoin Gel—*Identification, Assay*	34	6	1485
Triamcinolone Acetonide—*USP Reference standards, Assay*	31	3	800
Tricitrates Oral Solution—*USP Reference standards* (add), *Assay for citrate (delayed implementation to January 1, 2009)*	31	2	465
Tromethamine—*Melting Range or Temperature*	35	2	316
Tryptophan—*Chromatographic purity* (add), *Limit of tryptophan related compound A* (add)	33	6	1214
Tylosin Injection (new)	34	5	1205
Ursodiol Capsules—*Dissolution*	31	3	800
Ursodiol Tablets—*Identification, Assay*	35	4	876
Valacyclovir Hydrochloride (new)	35	3	589
Valacyclovir Tablets (new)	35	4	878
Valganciclovir Tablets (new)	33	1	89
Valproic Acid Capsules—*Disintegration* (delete)	35	3	591
Valrubicin—*Definition, USP Reference standards, Identification, Loss on drying* (delete), *Water* (add), *Limit of residual solvents* (delete), *Related compounds, Assay*	35	1	103
Valrubicin Intravesical Solution—*USP Reference standards, Related compounds*	34	6	1486

STAGE 4 HARMONIZATION

This section contains monographs or chapters undergoing harmonization by the Pharmacopeial Discussion Group (PDG). The PDG consists of the United States Pharmacopeia (USP), the European Pharmacopoeia (EP), and the Japanese Pharmacopoeia (JP). The process of harmonization consists of several steps (Stages 1 through 7, as defined below). Stage 4 drafts are available for comments. Below are descriptions of the developmental Stages as defined by the United States Pharmacopeia, the European Pharmacopoeia, and the Japanese Pharmacopoeia.

Stage 1: Identification The PDG identifies items to be harmonized and designates a coordinating pharmacopeia for each item. The PDG distributes the work by consensus among the three participating pharmacopeias. Harmonization may be carried out retrospectively for existing monographs or chapters, or prospectively for new monographs or chapters.

Stage 2: Investigation The investigation process conducted by the coordinating pharmacopeia results in the preparation of a Stage 3 draft monograph or chapter accompanied by a report giving the rationale for the proposal and including validation data where appropriate. This report is based on input that comes from users, authorities, producers, associations, literature, experts, and staff.

Stage 3: Proposal The Stage 3 draft is reviewed and commented on by the other two pharmacopeias. The coordinating pharmacopeia reviews those comments, prepares a harmonized Stage 4 draft, and sends it to the other two participating pharmacopeias.

Stage 4: Official Inquiry The Stage 4 draft is published in the Forum of each pharmacopeia. In *PF,* this stage appears as OFFICIAL INQUIRY STAGE 4 in the *Harmonization* section. Each pharmacopeia analyzes the comments it receives and submits the consolidated comments to the coordinating pharmacopeia, which then reviews those comments, prepares a harmonized Stage 5A draft, and sends it to the other two participating pharmacopeias.

Stage 5: Consensus

A. Provisional

The Stage 5A draft is reviewed and commented on by the other two pharmacopeias. When consensus is reached, a CONSENSUS STAGE 5B document is prepared by the coordinating pharmacopeia.

B. Final

The Stage 5B draft (consensus document) is sent by the coordinating pharmacopeia to the other two participating pharmacopeias for final approval.

Stage 6: Adoption Each pharmacopeia incorporates the harmonized Stage 5B draft according to its own procedure. Adopted items are published by the three pharmacopeias in their Supplements or, where applicable, in a new edition of their Pharmacopeias.

Stage 7: Date of Implementation The pharmacopeias inform each other of the date of implementation in the particular region.

STAGE 6 HARMONIZATION

This section contains monographs or chapters undergoing harmonization by the Pharmacopeial Discussion Group (PDG). The PDG consists of the United States Pharmacopeia (USP), the European Pharmacopoeia (EP), and the Japanese Pharmacopoeia (JP). The process of harmonization consists of several steps (Stages 1 through 7, as defined below). This section includes Stage 6 adopted text which is provided for information. USP cannot incorporate public comments at Stage 6 without consulting PDG partners. Below are descriptions of the developmental Stages as defined by the United States Pharmacopeia, the European Pharmacopoeia, and the Japanese Pharmacopoeia.

Stage 1: Identification The PDG identifies items to be harmonized and designates a coordinating pharmacopeia for each item. The PDG distributes the work by consensus among the three participating pharmacopeias. Harmonization may be carried out retrospectively for existing monographs or chapters, or prospectively for new monographs or chapters.

Stage 2: Investigation The investigation process conducted by the coordinating pharmacopeia results in the preparation of a Stage 3 draft monograph or chapter accompanied by a report giving the rationale for the proposal and including validation data where appropriate. This report is based on input that comes from users, authorities, producers, associations, literature, experts, and staff.

Stage 3: Proposal The Stage 3 draft is reviewed and commented on by the other two pharmacopeias. The coordinating pharmacopeia reviews those comments, prepares a harmonized Stage 4 draft, and sends it to the other two participating pharmacopeias.

Stage 4: Official Inquiry The Stage 4 draft is published in the Forum of each pharmacopeia. In *PF*, this stage appears as OFFICIAL INQUIRY STAGE 4 in the *Harmonization* section. Each pharmacopeia analyzes the comments it receives and submits the consolidated comments to the coordinating pharmacopeia, which then reviews those comments, prepares a harmonized Stage 5A draft, and sends it to the other two participating pharmacopeias.

Stage 5: Consensus

A. Provisional

The Stage 5A draft is reviewed and commented on by the other two pharmacopeias. When consensus is reached, a CONSENSUS STAGE 5B document is prepared by the coordinating pharmacopeia.

B. Final

The Stage 5B draft (consensus document) is sent by the coordinating pharmacopeia to the other two participating pharmacopeias for final approval.

Stage 6: Adoption Each pharmacopeia incorporates the harmonized Stage 5B draft according to its own procedure. Adopted items are published by the three pharmacopeias in their Supplements or, where applicable, in a new edition of their Pharmacopeias.

Stage 7: Date of Implementation The pharmacopeias inform each other of the date of implementation in the particular region.

STIMULI TO THE REVISION PROCESS

This section may contain the following:

- reports or statements of Expert Committees
- original research reports
- evaluations of new and existing pharmacopeial methods
- commentaries
- articles relevant to compendial issues.

These items are published to stimulate discussion and continual review of Pharmacopeial standards. Generally, if an Expert Committee publishes an article on which they are specifically seeking comment, this will be clearly stated in the article. Readers may submit comments on issues raised in this section, but comment is not as critical as that for the *In-Process Revision* section. Readers interested in submitting comments should see *Instructions to Authors.*

INSTRUCTIONS TO AUTHORS

Contributions in the form of original research reports, evaluations of new and existing compendial methods, and other commentaries and articles relevant to drug standards or to *USP–NF* revision will be considered for publication in *Pharmacopeial Forum* under the section *Stimuli to the Revision Process*. Manuscripts are received with the explicit understanding that they have not been published previously in any language or medium and that they are not simultaneously under consideration by any other publication.

All manuscripts are subject to review by USP headquarters staff, Committee members, or qualified outside referees, and if accepted for publication they will be subject to editing by USP staff. Accepted manuscripts become the property of the USP Convention (USPC) and may not be subsequently published elsewhere without written permission from the USPC. Authors are also responsible for obtaining permission for reprinting any illustrations that have been published elsewhere.

Abstract—Include an abstract of not more than 250 words stating the purpose and the results or conclusions of the article.

Style and Usage—*Stimuli* articles generally follow the current *Chicago Manual of Style* except in scientific usage (numbers, abbreviations, etc.). For the latter, authors should use the current *AMA Manual of Style* or the current *ACS Style Guide*. Authors may usefully consult a current copy of *Pharmacopeial Forum*.

References—Consult the current *AMA Manual of Style*, which is generally consistent with the National Library of Medicine's *Recommended Formats for Bibliographic Citation*. A current copy of *Pharmacopeial Forum* will offer examples of reference formats.

Copyright—Copyright transfer documents will be sent to authors after manuscripts have been accepted for publication.

Contact Person—USP will designate a Scientific Liaison in the Documentary Standards Division as the corresponding author. This ensures that USP receives all comments generated by the *Stimuli* article. Authors should contact the Scientific Liaison if they would like to receive copies of comments generated by their *Stimuli* articles.

Submission Instructions—Manuscripts must be submitted both as an electronic file and as a printed copy of the electronic file. Submit the text in Microsoft® Word or another current word-processing application. The preferred format for graphics submitted electronically is tagged image file format (TIFF). Photocopies are not acceptable. Manuscripts submitted for publication should be addressed to:

Pharmacopeial Standards for the Subdivision Characteristics of Scored Tablets

Geoff Green, Carolyn Berg, Accu-Break Pharmaceuticals Inc.; James E. Polli, University of Maryland School of Pharmacy; Dirk M. Barends, RIVM—National Institute for Public Health and the Environment, Bilthoven, The Netherlands[a]

ABSTRACT The practice of tablet splitting as a way to reduce prescription medication costs has become increasingly prevalent. The United States Pharmacopeial Convention (USPC) has no standards for the subdivision characteristics of scored tablets. Literature results show that many tablets on the US market exhibit unacceptable subdivision characteristics. The *European Pharmacopoeia* (*EP*) provides requirements for subdivision accuracy of scored tablets, if subdivision is indicated in order to comply with the product label. This *Stimuli* article provides a rationale for why standards should be included in *USP* to address the accuracy of subdivision, as well as to account for loss of mass upon subdivision. We propose that for accuracy of subdivision current *EP* standards be adopted, applicable only to any tablet that bears a score mark. For loss of mass, we propose an average of $\leq$ 3% of the intact tablet mass. From data reported in the literature we estimate that as many as half of the scored tablets on the US market would be in compliance with these standards. Generally, we do not advocate such standards be tested on a batch-to-batch basis but rather that the testing should be conducted as part of the development process before marketing approval. We also discuss a third, related, quality attribute: ease of subdivision. Although future research and discussion in this area are warranted, we believe that not only should scored tablets break into accurate partial doses with minimal loss of mass, but also that the tablets should be breakable by a representative sample of the population, including the elderly.

INTRODUCTION

Tablets intended for oral administration are the most common pharmaceutical dosage form in the US, and many tablets bear score mark(s) (*1*). The presence of a score mark implies that the tablet can be subdivided into smaller doses. Patients split tablets for a variety of reasons, including to adjust the dose, to ease swallowing, and to save money. As healthcare costs rise, tablet splitting to save money has become more prevalent in the US. Because some manufacturers have established the same or similar prices for different strengths of tablets of the same medication, consumers can purchase double the strength needed and divide the tablets in half for twice the number of doses (*2*). This has led many healthcare plans to establish mandatory tablet splitting policies as a means to reduce costs, a practice that has drawn opposition from several organizations, including the American Society of Consultant Pharmacists, the American Medical Association, and the American Pharmacists Association. The opposition stems from concerns about the potential for unpredictable dosing, particularly for the elderly (*3–5*).

The most important advantage of score lines, however, is dose flexibility—the ability to adjust a dose up or down in response to medication effects or to comply with the labeled dosage and administration instructions (posology). Dose flexibility can be especially important for medications that typically are titrated to achieve a therapeutic goal or for those that have a narrow therapeutic index, such as warfarin or levothyroxine.

Therefore, scored tablets play an important role in providing dose flexibility, among other benefits. Many studies have shown that scored tablets can be difficult—or even impossible—to break and often display large variations in the mass of the subdivided parts (*6–8*). A research group of the Dutch National Institute for Public Health and the Environment (RIVM) conducted a comprehensive literature review of articles that investigated the subdivision performance of scored tablets and identified several studies that reported unacceptable subdivision characteristics (*9*). Problems included large variations in the mass of the subdivided parts when split by hand, tablet splitter, or other means (*9*). A later study published by the same research group investigated patients' experiences and perceptions with breaking scored tablets. This study reported that 39% of patients were in some way dissatisfied with the subdivision characteristics of their scored tablets and that poorly functioning score lines were perceived as a quality defect. The authors concluded that the subdivision performance of scored tablets cannot be interpreted as a purely technical quality attribute and that badly performing score lines may lead to reduced patient compliance with medication.

Based on available literature, this *Stimuli* article examines: a) the ease or lack thereof in splitting scored tablets, b) the accuracy of the splitting process, and c) the loss of mass of split scored tablets sold in the US. The *Stimuli* article then proposes *USP* standards for the subdivision of scored tablets.

SUBDIVISION PERFORMANCE OF SCORED TABLETS ON THE US MARKET

The RIVM research group concluded that the performance of score lines should be defined by the following three quality attributes: accuracy of subdivision (i.e., uniformity of the mass of the subdivided tablets), ease of breaking, and loss of mass resulting from subdivision (*9*). We follow the same classification to explore the subdivision performance of scored tablets on the US market.

We reviewed published studies that were selected according to the following criteria: (a) the research was conducted in US laboratories or institutions, which presumably supported the assumption of probability that the tablets studied were approved by FDA and marketed in the US, and (b) the research included reports about the measuring subdivision accuracy for scored tablets. Eight studies (''US studies'') satisfied both requirements (*10–17*). In six of the eight US studies, the tablets were obtained from commercial suppliers. One of the studies used tablets donated by the manufacturer (*15*), and one study used professional samples (*16*).

Accuracy of Subdivision

Each of the US studies focused on assessing subdivision accuracy by measuring the whole tablet and the subsequent subdivided tablets' mass as a surrogate for estimating the content uniformity of a split tablet (see General Chapter *Uniformity of Dosage Units* ⟨905⟩ for information about relying on mass as a surrogate for content). Four of the US studies tested the accuracy of subdivision of scored tablets from manual splitting (*Table 1*), and six tested tablet splitting accuracy using a tablet-splitting device (*Table 2*). Of the six studies involving a tablet splitter, four cited cost containment as the rationale for testing the accuracy of tablet splitters; one study reported concern about obtaining accurate pediatric doses; and one study involved obtaining nonmarketed doses of a popular anti-hypertensive drug. In the absence of FDA and/or *USP* standards for uniformity of mass of the subdivided parts, seven of eight (88%) US studies adapted and applied the *USP 24* criteria for the uniformity of dosage units (*11*). The term *uniformity of dosage unit* is defined as the degree of uniformity in the amount of the drug substance among dosage units. This *USP* criterion states all units tested must be within 85.0% to 115.0% of label claim and no units outside the range of 75.0% to 125.0% of label claim with a maximum batch standard deviation (SD) no greater than 6%.

Results of the US studies are comparable to those previously summarized and reported in the RIVM review (*9*). A comparison of *Tables 1* and *2* shows that a tablet-splitting device may improve the accuracy of subdivision—but not in all cases—and accuracy varies with different devices, users, and tablet shapes. In general, oblong-shaped tablets performed slightly better, but this also depended on the user and device.

With respect to the subdivision accuracy of scored tablets putatively on the US market, we conclude: (a) the situation is comparable to that reported in other parts of the world; (b) for many tablets on the US market, significant variation can occur in the mass of subdivided tablet parts, regardless of the splitting method or person; (c) although tablet splitters somewhat improve subdivision accuracy, this accuracy is still unacceptable for scored tablets, and the results can vary widely depending on the device and the user; and (d) the presence of a score mark on a tablet does not necessarily imply that the tablet can be split into accurate partial doses.

Loss of Mass

Four of the eight US studies reported data on the loss of tablet mass upon subdivision (*Table 3*). Of the scored tablets tested, the largest mean percent loss of mass occurred when users split glyburide tablets with a razor blade. In this case the loss was 2.6%, which was approximately 6.5 times higher than the loss of glyburide tablet mass after manual splitting (*14*). McDevitt et al. reported a maximum loss of mass from manually splitting hydrochlorothiazide tablets (nearly 20%, with an average of 1.06%) (*13*). Sertraline tablets split manually and with a tablet splitter showed comparable loss of mass (0.08% using a tablet splitter compared to 0.06% when split manually) (*16*). Although there are limited data available for US-marketed products, the results of these US studies are consistent with those reported by the RIVM review, in which the authors concluded that most tablets, on average, lost less than 1% of the intact tablet mass upon subdivision (*9*).

Ease of Subdivision

Another quality attribute that researchers should consider when assessing the efficacy of a score mark is ease of subdivision (*9*), that is, individuals' ability to subdivide tablets regardless of accuracy or loss of mass. Although this attribute has been studied in some detail by the RIVM research group, including the development of an in vivo test, only two of the eight US studies included this attribute in their splitting accuracy studies (*10*, *14*). Wilson et al. asked elderly diabetic patients to manually subdivide micronized glyburide tablets and to rate the degree of splitting difficulty using a visual analog scale. On average, the rating was 7.7 on a scale of 1 to 10 where 10 was considered the most difficult (*10*). Teng et al. reported that because of their hardness 50-mg hydrochlorothiazide tablets were''difficult to split by hand'' (*14*).

PHARMACOPEIAL STANDARDS FOR THE SUBDIVISON PERFORMANCE OF SCORED TABLETS

In 2002, *EP* presented pharmacopeial standards for the subdivision performance of scored tablets (*12*). This marked the first time a pharmacopeial requirement for the functioning of a score mark was established. Since that date, several proposals for revision to that standard have been published (*6*, *13–18*). Some of these proposals were adopted in subsequent revisions, e.g., in *EP 5.0* (*19*) and in *Supplement EP 5.5* (*20*). The text of *EP 5.5* remained unchanged until *EP 6.4*, which is now cur-

rent (*21*). A historical overview of proposed standards and enforced *EP* standards relative to scored dosage forms is depicted in *Table 4*. With the exception of the proposed revisions in December 2006, which called for the adoption of additional tests and standards for ease of breaking and loss of mass, accuracy of subdivision was the only quality attribute addressed. In other words, *EP*currently presents standards for accuracy of subdivision of scored tablets but has not yet adopted standards for ease of subdivision nor for loss of mass upon subdivision.

PROPOSED STANDARD FOR ACCURACY OF SUBDIVISION FOR SCORED TABLETS

Among the two quality attributes for which standards are being proposed, we view splitting accuracy as primary in importance. If sufficient accuracy is not achievable even under ideal conditions, other aspects become less important because splitting is no longer a viable option for dose adjustment. With respect to accuracy of subdivision, several questions arise:

(a) Which standards should be set?
(b) Which test methods should be used?
(c) Should all scored tablets be forced to comply with these standards?

Answering question (a) suggests two very different approaches that can be taken. The first is that the subdivided tablet parts should conform to uniformity of mass or weight variation standards. In this respect, the ⟨905⟩ standards currently in place for whole dosage forms could be adapted and applied to subdivided tablet parts. Many of the researchers of the US studies adapted a variation of these standards to the studies in *Tables 1* and *2*. Or one could adopt the current enforced *EP* standard for uniformity of mass of subdivided parts of scored tablets. The advantage of adopting the *EP* standard is the ability to leverage the considerable work, research, debate, and discussion that have already taken place.

A second approach to answering question (a) would be to apply the uniformity of content standards where the amount of drug substance within the subdivided tablet parts is assayed. Interestingly, both approaches were adopted in the first *EP* standard, which stated that subdivided tablet parts should comply with ''... either Uniformity of Mass (2.9.5) or Uniformity of Content (2.9.6), as appropriate,'' leaving it up to regulatory authorities to decide which test to apply (*12*). This first *EP* standard for scored tablets proved to be insufficient because it raised a number of questions such as whether or not chemical analyses were necessary for uniformity of mass studies, whether the uniformity of content standards could be used with the uniformity of mass test, and how the tablets should be subdivided (i.e., manually or by a tablet cutter).

Gradually, the standard for uniformity of content variability was dropped by *EP*, perhaps because very few scored tablets could comply with that standard, and the requirement of mass determinations replaced the requirement of chemical analyses. Later, *EP* introduced a provision stating that only one part from every subdivided tablet should be allowed in the final test.

The current *EP* requirement for subdivision accuracy (6.4) has been unchanged for a number of years and appears to work well in practice. This requirement specifies subdivision by hand, using only one part of each subdivided tablet, and limits deviations to ± 15% of the average mass of the subdivided parts. Thus, questions (a) and (b) are answered by the current *EP* standard.

We recognize that the present *EP* standards for accuracy of subdivision evolved from a long process and seem to reflect both the interest of the patient in receiving the correct dose while taking into account current technological/manufacturing capabilities. Also, from the point of view of pharmacopeial harmonization, it is sensible to adopt the present *EP* standards for accuracy of subdivision.

With respect to question (c), Should all scored tablets be forced to comply with these standards? We do not support the restricted applicability of the current *EP* standards that require that only tablets with break marks need to comply with labeling (posology) and should be tested for uniformity of mass. To ''comply with posology'' means that the tablet must be subdivided to arrive at a dose stated in the Product Information Leaflet (PIL), or Package Insert (PI) as it is referred to in the US, for some indications, conditions, and/or patients. We do not support this restricted applicability of the *EP* standard in scored tablets for the reasons outlined below.

First, the presence of a score line in a tablet implies the tablet is meant to be subdivided. Thus, no matter what the reason for subdividing, the score line should perform well. Patients perceive badly functioning score lines as a quality defect, regardless of the reason for the subdivision (*7*). Second, from a practical point of view it is unusual and cumbersome to make the applicability of pharmacopeial standards depend on dosage schemes in the PI. In such a situation, any decision to declare an article either in compliance or out of compliance can be made only in combination with an interpretation of the current PI of that particular drug. Third, the criterion of tablets that ''may be subdivided in parts to comply with posology'' appears not to be entirely objective (*6*). Fourth, off-label use of drug products is common, particularly for pediatric and geriatric patients. Hence, the PI of those medications may not reflect dosing instructions for those patient groups and, therefore, those tablets will not be subject to the compendial subdivision requirements and thus will not be tested for compliance. In practice, standards are needed most for these particular medications because doses for pediatric and geriatric patients are frequently adjusted, and a lack of standards could potentially compromise patients who receive an incorrect dose based on the characteristics of tablet subdivision.

In summary, we recommend that USP adopt the present *EP* standards for accuracy of subdivision but enforce these standards for all scored tablets. *Table 5* depicts our proposals for *USP* standards.

PROPOSED STANDARD FOR LOSS OF MASS FOR SCORED TABLETS

No pharmacopeial standard exists today for loss of mass upon tablet subdivision. A standard of $\leq$ 1% average loss of mass compared to the mass of the intact tablet was proposed in December of 2006, although this standard has not been adopted at the time of this writing (*6*). This proposed standard was tested by the RIVM research group for 29 scored tablets on the European market, and 25 products (86%) were in compliance. Products that exceeded the 1% threshold had a loss of mass of 1.10%, 1.14%, 1.21%, and 2.68%, and all were round, single scored, and between 5.9 and 9.0 mm in diameter. Based on the data from the US studies in *Table 3* and the European data, we propose a limit of $\leq$ 3%. The proposed standard and test method can be found in *Table 5*. The test method mandates subdivision by hand and calculating the loss of mass for each of the subdivided tablets. As in the case for the accuracy of subdivision standard, the loss of mass standard should apply to all scored tablets.

ATTAINABILITY OF THESE STANDARDS

Because the eight US studies were conducted using a variety of methodologies and criteria, one finds it difficult to make any conclusions how many products on the US market would be in compliance if the proposed standards for accuracy of subdivision were adopted. However, in 2006, the RIVM research group conducted a market surveillance study applying the enforced *EP* standards at the time to tablets available in the European market. They concluded that 7 of the 29 (24%) products tested complied with the proposed standards of accuracy of subdivision. Four of the seven products were oblong, and three were round (*6*). For the proposed *USP* loss of mass standard ($\leq$ 3%), all 29 products tested in the RIVM research study complied.

It seems reasonable to assume that the attainability rate for scored tablets on the US market would be comparable to that observed in RIVM research study.

FREQUENCY OF TESTING OF PROPOSED PHARMACOPEIAL STANDARDS

A related question is ''Under what situations should the two standards be tested?'' We advocate that all scored tablets be characterized in terms of accuracy and loss of mass during registrations in a New Drug Application (NDA) or Abbreviated New Drug Application (ANDA). Further, both accuracy and loss of mass should be pharmacopeial standards that are tested during registration and under scale-up and post-approval change (SUPAC) situations when such changes may influence splitting performance. We recognize that not all SUPAC situations would trigger the need for accuracy and loss of mass testing, but it currently may not be easy to discern when testing is needed and when testing is not needed. We suspect that tests for accuracy and loss of mass need not be performed for each batch, although we are not aware of batch-to-batch data that suggests otherwise.

Pharmacopeial standards are not necessarily batch-to-batch tests. Until May 2009, *USP*'s General Notices stated that

> every compendial article in commerce shall be so constituted that when examined ... it meets all the requirements in the monograph defining it. However, it is not to be inferred that the application of every analytical procedure in the monograph to samples from every production batch is necessarily a prerequisite for ensuring compliance with pharmacopeial standards before the batch is released for distribution. Data derived from manufacturing *process validation* studies and from *in-process controls* may provide greater assurance that a batch meets a particular monograph requirement than analytical data derived from an examination of finished units drawn from that batch. On the basis of such assurances, the analytical procedures in the monograph may be omitted by the manufacturer in judging compliance of the batch with the Pharmacopeial standards (*22*).

Thus, the standards proposed in *Table 5* can be enforced as pharmacopeial without necessarily implying the need for batch-to-batch testing. However, even in the absence of batch-to-batch testing, each batch should be compliant.

IN VIVO TEST PROCEDURES FOR EASE OF SUBDIVISION

We do not propose a standard at this time for the ease of subdivision but do advocate further research on this topic. To date, pharmacopeial standards for ease of subdivision have not been adopted in any country/region. However, in view of the unsatisfactory performance of scored tablets previously presented in The Netherlands by the RIVM research group with respect to ease of subdivision (*6*, *8*, *9*) and the data available in the US studies (*10*, *14*), we believe USP should consider adopting a standard for this attribute. As stated previously, patients perceive poorly breaking tablets to have a quality defect, which may lead to reduced patient compliance (*7*). Thus, we hold the view that USP could and should take the lead in enforcing standards for this attribute.

Until recently, very few tests to evaluate the ease of breaking of scored tablets have been proposed. The RIVM published an in vivo test using a panel of elderly volunteers who manually split scored tablets (*8*). This ease of breaking test subsequently was applied in the 2006 market surveillance study in The Netherlands, and it concluded that the proposed test procedure for ease of subdivision was workable (*6*).

Depending on the statistical power required, between 39% and 52% of the tested tablets were in compliance. Of note, 100% of all oblong tablets were considered to be in compliance based on the proposed criteria (*6*). The published test procedure proposed that no less than 80% of the elderly panelists be able to break the tablet, with a minimum confidence level of 90%, one sided (*8*). The authors also concluded that large panels are sometimes needed to meet the minimum statistical power.

It is uncommon to define the statistical power of a pharmacopeial test, but it is not uncommon to define the sample size. Consequently, we reworked this test into a more common two-tier test (*Table 6*). In the first tier, 10 elderly panelists break one tablet each. In order to comply, all 10 tablets must be deemed breakable by hand. At a 90% confidence level, this requirement corresponds to at least 79% of the elderly population being able to break that tablet. If the tablets do not comply with the first-tier test, the elderly panel is expanded from 10 to 30 for the second tier. When a total of 30 tablets have been tested, at least 27 tablets (78%) must be deemed breakable by hand. With a 90% confidence level this corresponds to a minimum of 81% of the elderly population being able to break the tablet.

Although we believe that for the time being, a testing method for the ease of breaking of scored tablets requires additional study, the RIVM research group in The Netherlands has proposed this quality attribute be considered for inclusion within the *EP* standards. In the US, 51.6% of the population > 65 years takes three or more prescription drugs, and by the year 2020 the age group will consume 40% of all prescription drugs. The number of persons 75 years and older will increase from 18.1 million in 2005 to 33.5 million in the year 2030. Thus, a criterion of a mean age $\geq$ 75 years and none < 65 years is representative of the US population that consumes the largest portion of pharmaceutical tablets (*23*). Other procedures, such as panel participants breaking the tablets by hand without having a tryout of the tablet to be tested, stem from real-world experiences. Patients would rarely be able to practice breaking tablets and discarding those that do not break well without jeopardizing the duration of their prescription. Also, breaking by hand is the most common situation. The test anticipates that 20% of the elderly panel will be incapable of subdividing the tablet by hand, so for this subset, use of a tablet splitter may be indicated.

In summary, the standard and criteria proposed by the RIVM research group for ease of subdivision appears to be workable but will need to be validated in future US studies. Although we do not study it in this *Stimuli* article, the authors suggest that any future ease of subdivision testing by the panel of elderly would be unworkable for batch-to-batch testing. The RIVM research group already concluded that this test typically should be performed only once, i.e., during the development phase of a tablet (*8*).

CONCLUSIONS AND RECOMMENDATIONS

In ⟨905⟩, *USP* provides content uniformity requirements for drug products where applicable to ensure that patients receive an accurate dose with minimal variability. However, no such standards or tests are mandated for the subdivided parts of tablets that bear score marks. Upon subdivision, such tablets have shown significant variability in the mass of the subdivided parts. By inference, this should be interpreted as variability in dose, a result contrary to the intent of the whole dosage form standards developed by USP. In an increasingly cost-conscious environment when patients are frequently subdividing dosage forms, we see considerable risk related to unpredictable dosing resulting from inaccurate splitting and the loss of mass. Therefore, we propose that USP should adopt the current EP standards, but USP should make the standards applicable to all scored tablets. The purpose of this proposal would be to ensure adequate content uniformity for divided tablets with a score. For loss of mass, we propose a limit of $\leq$ 3% of the intact tablet mass. We do not believe such standards generally should be tested on a batch-to-batch basis but rather should be determined as part of the development and registration processes. These proposed standards for accuracy of subdivision and loss of mass are attainable both from a pharmaceutical and a technological point of view. We advocate future investigation of the ability of representative populations to demonstrate ease of splitting scored tablets.

ACKNOWLEDGEMENTS

The authors acknowledge Koos Van der Steen and Kik Groot of RIVM for critically reading the manuscript.

Table 4. History of EP Standards Proposed and Enforced for the Subdivision Characteristics of Scored Tablets

Date Published	Period Enforced	Action	Test and Standard(s)	Reference
October 2001	April 1, 2002 – June 30, 2002	First implementation of tablet subdivision accuracy standards.	For tablets for which subdivision is authorized, it is demonstrated to the satisfaction of the competent authority that the subdivided parts comply with either Test A for *Uniformity of content of single-dose preparations (2.9.6)* or with the test for *Uniformity of mass (2.9.5)*, as appropriate. **Uniformity of Content:** Subdivide 10 tablets and randomly select 10 parts from 10 subdivided tablets and, using a suitable analytical method, determine the content of active substance(s) in each individual part. The preparation complies with the test if each individual content is between 85% and 115% of the average content. The preparation fails to comply with the test if more than one individual content is outside these limits or if one individual content is outside the limits of 75% to 125% of the average content. If one individual content is outside the limits of 85% to 115% but within the limits of 75% to 125%, determine the individual contents of another 20 units (subdivided tablet parts) taken at random. The preparation complies with the test if not more than one of the individual contents of the 30 units is outside 85% to 115% of the average content and none is outside the limits of 75% to 125% of the average content. **Uniformity of Mass:** Subdivide 20 tablets and weigh individually 20 parts selected randomly and determine the average mass. The preparation complies with the test if not more than 2 of the individual masses deviate from the average mass by more than the following percentage deviations *and* no individual mass deviates by more than twice that percentage: 10% for tablets < 80 mg; 7.5% for tablets between 81 and 249 mg; 5% for tablets > 250 mg.	Monograph 0478. *Ph. Eur. Suppl. 4.1*; 2002:2433–2436.

Table 4. History of EP Standards Proposed and Enforced for the Subdivision Characteristics of Scored Tablets *(continued)*

Date Published	Period Enforced	Action	Test and Standard(s)	Reference
April 2002	NA	Proposed Revision to Monograph 0478 (*Ph. Eur. 4.1*): Clarify breaking method.	Tablet should be ''broken by hand.''	*Pharmeuropa* 2002 Apr; 14(2):302–304.
October 2002	NA	Proposed revision to Monograph 0478 (*Ph. Eur. 4.1*): Clarify prevailing test method.	**Content of Uniformity** test can be replaced by Uniformity of Mass test for tablets containing 25 mg or greater of an active substance that comprises 25% or more (by weight) of one tablet.	*Pharmeuropa* 2002 Oct; 14(4):725–728.
April 2003	NA	Proposed revision to Monograph 0478 (*Ph. Eur. 4.1*): Clarify prevailing test method and sampling procedure.	If the subdivided parts of the tablet contain < 2 mg of active substance or the content of the active ingredient in the subdivided parts is < 2 % of the total mass of the subdivided tablet, the test of **Uniformity of Content** prevails. Two halves of the same tablet should be included in the test.	*Pharmeuropa* 2003 Apr; 15(2):322–324.
January 2004	NA	Proposed revision to Monograph 0478 (*Ph. Eur. 4.1*): Clarify prevailing test method and sampling procedure.	Two halves of the same tablet should be included in the test. Subdivided tablets should comply with test 2.9.6A (**Uniformity of Content**) irrespective of their content of active ingredient.	*Pharmeuropa* 2004 Jan; 16(1):51–55.
April 2004	NA	Proposed revision to Monograph 0478 (*Ph. Eur. 4.1*): Elimination of **Uniformity of Content** requirement and propose new **Uniformity of Mass** test.	Take 30 tablets at random. Take 10 tablets from among these and break them in parts by hand, mix the parts. Take 10 parts at random and determine the average mass. Weigh each part individually. The tablets comply with the test if the mass of each part is between 85% and 115% of the average mass. The tablets fail to comply with the test if more than one individual mass is outside these limits, or if one individual mass is outside the limits of 75% to 125% of the average mass. If one individual mass is outside the limits of 85% to 115% of the averagemass but within the limits of 75% to 125%, determine the individual massof another 20 parts taken at random from the remaining 20 tablets. The tablets comply with the test if not more than one of the individual masses of the 30 parts is outside 85% to 115% of the average mass and none is outside the limits of 75% to 125%.	*Pharmeuropa* 2004 Apr; 16(2):250–252.

[a] No change in *Ph. Eur. Supplements 5.6, 5.7, 5.8, 6.0, 6.1,* and *6.2 5* to current *Ph. Eur. 6.4*.

Table 4. History of EP Standards Proposed and Enforced for the Subdivision Characteristics of Scored Tablets *(continued)*

Date Published	Period Enforced	Action	Test and Standard(s)	Reference
June 2004	January 1, 2005 to March 31, 2005	Revised Monograph 0478: Revised guidance on prevailing test method and revision to the test and standards for **Uniformity of Content**.	**Uniformity of Content** test prevails if tablets with a content of active substance of tablet less than 2 mg or less than 2% of the total mass. If the preparation has more than one active substance, the requirement applies only to those substances that correspond to the conditions above. *Pharmeuropa* 16(2) proposed testing method and standard adopted for assessing **Uniformity of Content** for subdivided tablets. **Uniformity of Mass** test prevails in all other instances. Original *Ph. Eur.* 4.1 test method and standard remains in place.	Monograph 0478. *Ph. Eur. 5.0.*; 2005: 626–628.
October 2005	NA	Proposed revision to Monograph 0478 (*Ph. Eur. 5.0*): Clarification on timing of testing efficacy of break mark(s) and proposal to eliminate **Uniformity of Content** standards.	In order to ensure that the patient will receive the intended dose, the efficacy of break-mark(s) must be assessed during the development of the product, in respect to uniformity of mass of the subdivided parts. Each authorized dose must be tested using the following test: **Uniformity of Mass**: Take 30 tablets at random, break them by hand and, from all the parts obtained from one tablet, take one part for the test and reject the other part(s). Weigh each of the 30 parts individually and calculate the average mass. The tablets comply with the test if not more than one individual mass is between 85% and 115% of the average mass. The tablets fail to comply with the test if more than one individual mass is outside these limits, or if one individual mass is outside the limits of 75% to 125% of the average mass.	*Pharmeuropa* 2005 Oct; 17(4):512–514.
December 2005	July 1, 2006 to December 31, 2006	Revised Monograph 0478 (*Ph. Eur. 5.0*): Clarification of which tablets are subject to the subdivision standards' elimination of **Uniformity of Content** tests and standards, and revision to **Uniformity of Mass** test.	Only tablets for which the break mark is needed to comply with the posology should be tested. **Uniformity of Mass**: Testing and standards proposed in *Pharmeuropa* 17(4) are adopted and enforced. **Uniformity of Content** requirement is eliminated.	Monograph 0478. *Ph. Eur. Suppl.* 5.5; 2006: 4166–4168.

Table 4. History of EP Standards Proposed and Enforced for the Subdivision Characteristics of Scored Tablets *(continued)*

Date Published	Period Enforced	Action	Test and Standard(s)	Reference
December 2006	NA	Proposed revision to Monograph 0478 (*Ph. Eur. 5.5*): Clarification of which tablets are subject to subdivision standards and tests, instructions for handling broken/crumbled tablets, and proposal of additional standards.	Remove restriction of *Ph. Eur. 5.5*. which states that only tablets for which break marks needed to comply with posology should be tested for **Uniformity of Mass**. **Uniformity of Mass**: instructions should be given about how to handle tablets that cannot be broken or that crumble upon subdivision for their inclusion in the calculation of Uniformity of Mass. Proposed additional testing and standards for efficacy of score marks including **Ease of Subdivision and Loss of Mass upon subdivision.**	*Pharmeuropa Scientific Notes*. 2006(2): 1–7.
June 2008[a]	January 1, 2009 to March 31, 2009[a]	Monograph 0478 unchanged from previous published standards (*Ph. Eur. 5.5*).	Tablets may bear a break-mark or break-marks and may be subdivided in parts, either to ease the intake of the medicinal product or to comply with the posology. In the latter case, subdivision must be assessed and authorized by the competent authority. In order to ensure that the patient will receive the intended dose, the efficacy of the break-mark(s) must be assessed during the development of the product, in respect of uniformity of mass of the subdivided parts. Each authorized dose must be tested using the following test. Take 30 tablets at random and, from all the parts obtained from 1 tablet, take 1 part for the test and reject the other part(s). Weigh each of the 30 parts individually and calculate the average mass. The tablets comply with the test if not more than 1 individual mass is outside the limits of 85% to 115% of the average mass. The tablets fail to comply with the test if more than 1 individual mass is outside these limits, or if 1 individual mass is outside the limits of 75% to 125% of the average mass.	Monograph 0478. *Ph. Eur. Suppl. 6.4*; 2008.

[a] No change in *Ph. Eur. Supplements 5.6, 5.7, 5.8, 6.0, 6.1,* and *6.2 5* to current *Ph. Eur. 6.4*.

Table 5. Standards Proposed to *USP* for the Subdivision Characteristics of Scored Tablets

Loss of Mass	Take 30 tablets at random. Weigh each tablet. Break each tablet by hand, and weigh each of the subdivided parts. Calculate the loss of mass for that tablet. Repeat the procedure for the other 29 tablets, and calculate the mean loss of mass. **Criterion for Loss of Mass**: The tablets comply with the test if the mean loss of mass is not more than 3.0%.
Accuracy of Subdivision	Take 30 tablets at random and break them by hand. From all the parts obtained from one tablet, select one part and reject the other part(s). Weigh each of the 30 parts individually and calculate the average mass. **Criterion for Accuracy of Subdivision**: The tablets comply with the test if not more than 1 individual mass is outside the limits of 85% to 115% of the average mass. The tablets fail to comply with the test if more than 1 individual mass is outside these limits or if 1 individual mass is outside the limits of 75% to 125% of the average mass.

Table 6. Test and Criteria for Ease of Subdivision of Scored Tablets

Ease of subdivision
Panel: Select a panel of 10 healthy elderly volunteers with mean age $\geq$ 75 y and none < 65 y. There are no restrictions on male/female ratio, and previous membership on a breaking panel is not an exclusion criterion, but impaired use of hand and/or fingers is an exclusion criterion.
Procedure: Each panelist is instructed to break by hand one tablet in a way he/she would do if he/she were a patient, without having a ''tryout'' of the tablet to be tested.
The investigator scores every tablet given to the panelist either ''breakable'' or ''not breakable.''
Criterion for Ease of Subdivision: Each of the 10 panelists should be able to subdivide the tablet. If the tablets do not comply with this test, the elderly panel is expanded from 10 to 30 using the same inclusion criteria and procedure. When a total of 30 tablets have been tested, at least 27 tablets (78%) must be deemed ''breakable'' by hand.
Notes: • Each panelist should not break more than 10 tablets during one session. • During the test, panelists must not know the results from other panelists. • Care should be taken that the panelist does not swallow the tablet before or after breaking. • Care should be taken that the panelist washes his/her hands after the session is completed.

A Recombinant Factor C Procedure for the Detection of Gram-negative Bacterial Endotoxin

Bruce Loverock, Barry Simon, Allen Burgenson, and Alan Baines, *Lonza Walkersville, Inc.*[a]

ABSTRACT This *Stimuli* article addresses a modified photometric procedure for the detection of gram-negative bacterial endotoxin (lipopolysaccharide). This procedure is based on the activation of recombinant Factor C (rFC), the endotoxin-sensitive protease that initiates the traditional *Limulus* Amebocyte Lysate (LAL) cascade. The rFC procedure described in this *Stimuli* article is a single-step, quantitative endpoint procedure that measures the enzyme-mediated cleavage of a fluorogenic substrate. This study shows that the rFC procedure is equivalent to LAL in its ability to measure endotoxin and has a quantitation range comparable to that of quantitative photometric LAL procedures. However, unlike LAL, which uses an extract from the blood cells of the horseshoe crab *Limulus polyphemus* that contains Factor C, the rFC procedure uses an rFC cloned from the horseshoe crab, *Carcinoscorpius rotundicauda*, thereby reducing the number of false-positive results involving glucans.

RATIONALE

The majority of parenteral drugs and implantable medical devices are tested for gram-negative bacterial endotoxin using reagents prepared from circulating amebocytes found in the blood of the American horseshoe crab, *Limulus polyphemus*. Variations of this procedure are described in *US Pharmacopeia* (*USP*) General Chapter *Bacterial Endotoxins Test* ⟨85⟩ (*1*). This chapter describes the gel-clot *Limulus* Amebocyte Lysate (LAL) procedure and the various kinetic and endpoint photometric LAL procedures. A comparison of a kinetic turbidimetric LAL, kinetic chromogenic LAL, and the proposed recombinant quantitative photometric procedure that is not subject to false-positive reactions involving glucans, is the subject of this *Stimuli* article. This alternative procedure has been successfully validated according to the requirements described in *USP* General Information Chapter *Validation of Compendial Procedures* ⟨1225⟩ (*2*).

Mechanism of Reaction

The protease cascade and rationale of traditional LAL procedures have been extensively investigated (*3–7*). Factor C (FC), the first component in the LAL cascade, is a protease zymogen that is activated by endotoxin binding (*5, 6, 8*). Following a series of cascading events, a dose-dependent response is seen in the presence of endotoxin (*Figure 1a*, LAL–Endotoxin). In the kinetic turbidimetric variation of the LAL procedure, in the presence of endotoxin the protein coagulogen is converted to coagulin, resulting in a dose-dependent increase in turbidity. In the kinetic chromogenic version of the LAL procedure, a synthetic chromogenic substrate is cleaved to produce a yellow color. An alternative LAL-based pathway triggered by glucans can also invoke a similar response, thus causing a false-positive result (*Figure 1*, LAL–Glucan).

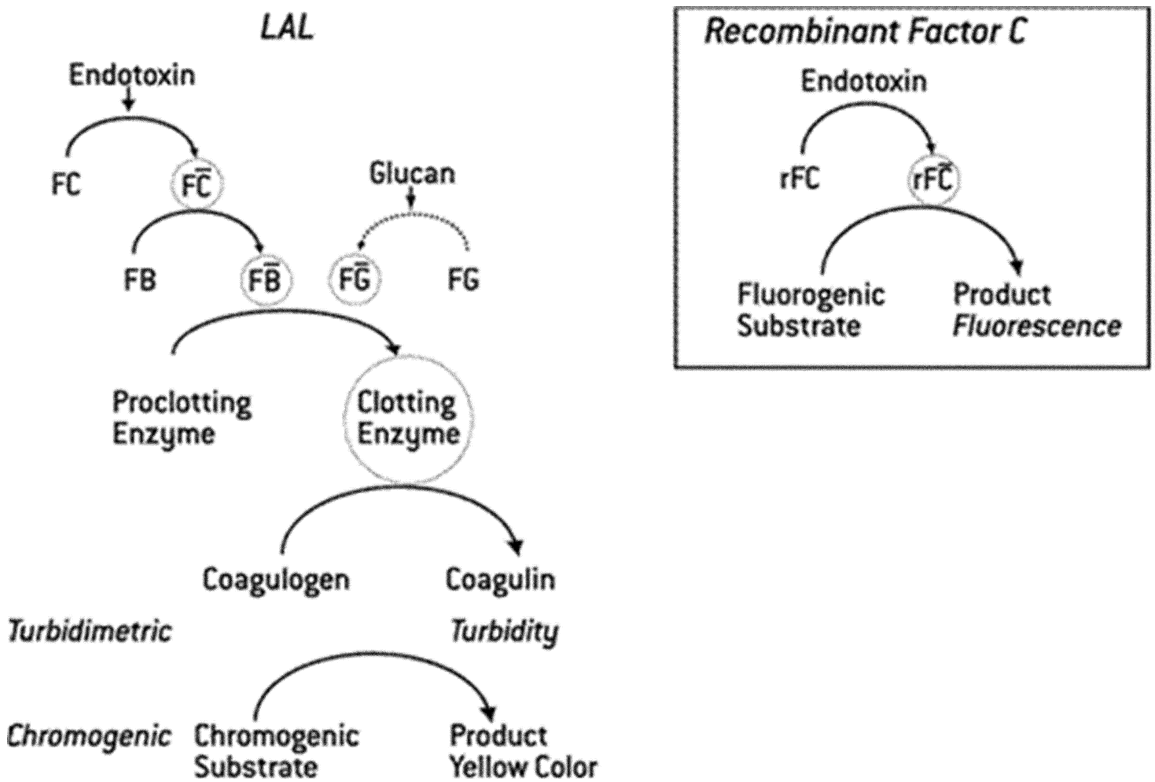

Figure 1a. LAL procedure. Figure 1b. (insert) rFC procedure.

The rFC procedure (*Figure 1b*) utilizes a single protein as its active ingredient, rFC, cloned from the horseshoe crab *Carcinoscorpius rotundicauda* (*8–9*). In the rFC procedure endotoxin binding activates rFC. This activated molecule then acts to cleave a fluorogenic substrate, resulting in the generation of a fluorogenic compound. The rFC endotoxin detection reaction is not subject to false-positive reactions involving glucans (*Figure 1b*, Recombinant Factor C). The rFC protein derived from *C. rotundicauda* shares a 90.5% identical amino acid sequence with the native Factor C protein derived from *L. polyphemus* (unpublished data).

ANALYTICAL PROCEDURE

Precaution: All materials used in this procedure must be endotoxin free.

Recombinant FC is used in a single-step, fluorogenic endpoint procedure to measure endotoxin. One hundred microliters of water blank, standard, and sample are added to a microplate. The microplate is then preincubated in a fluorescent microplate reader at 37° ± 1 °C for 10 min, followed by addition of 100 µL rFC/substrate working reagent to each well. A time zero reading is taken (excitation/emission wavelengths 380/440 nm). The microplate is further incubated at 37° ± 1 °C for 60 min in the fluorescent microplate reader. At elapsed incubation time of 60 min, the microplate is read a second time (excitation/emission wavelengths 380/440 nm). Corrected fluorescence (fluorescence reading at 60 min minus fluorescence reading at time zero) of endotoxin standards and samples are then normalized by the corrected fluorescence of the water blank. The log of the normalized fluorescence of the endotoxin standards is plotted vs the log of endotoxin concentration. Generation of the standard curve is performed using linear regression (least squares). The log increase in fluorescence (net change in relative fluorescence units) vs the log endotoxin concentration is linear over the 0.01 to 10 EU/mL range (EU = endotoxin unit). Endotoxin in samples is predicted using the endotoxin standard curve.

DATA ELEMENTS

Specificity

As defined in ⟨1225⟩, specificity is the ''ability to assess unequivocally the analyte in the presence of components that may be expected to be present, such as impurities, degradation products, and matrix components.'' In the case of analytical procedures for impurities, specificity may be established ''by spiking the drug substance or product with appropriate levels of impurities.''

A multicenter study (6 centers, 3 analysts/center) was initiated to test 10 pharmaceutical or related products using both the rFC and the kinetic chromogenic LAL procedures. Products were tested at maximum valid dilution (MVD), MVD/2, and MVD/10 (see ⟨85⟩ for further details), except for Water for Injection, which was tested undiluted. Parallel samples were tested with endotoxin spiked to a final concentration of 0.1 EU/mL. One hun-

dred sixty-eight measurements were made with the unspiked samples across the 6 study sites for each procedure. For both the rFC and kinetic chromogenic procedures, no detectable endotoxin was observed in any of the unspiked samples (data not shown). This was expected because all test samples were pharmaceuticals released to the marketplace (except for hemodialysate). For measurements of samples spiked to a nominal value of 0.1 EU/mL, spike recoveries in the range of 0.05 to 0.20 EU/mL (50%–200%) are considered acceptable, or "passing" according to requirements in ⟨85⟩. Except for the Human Albumin (HA) samples, all of the measurements made with each procedure were within the acceptable range of 0.05 to 0.20 EU/mL (*Figure 2*).

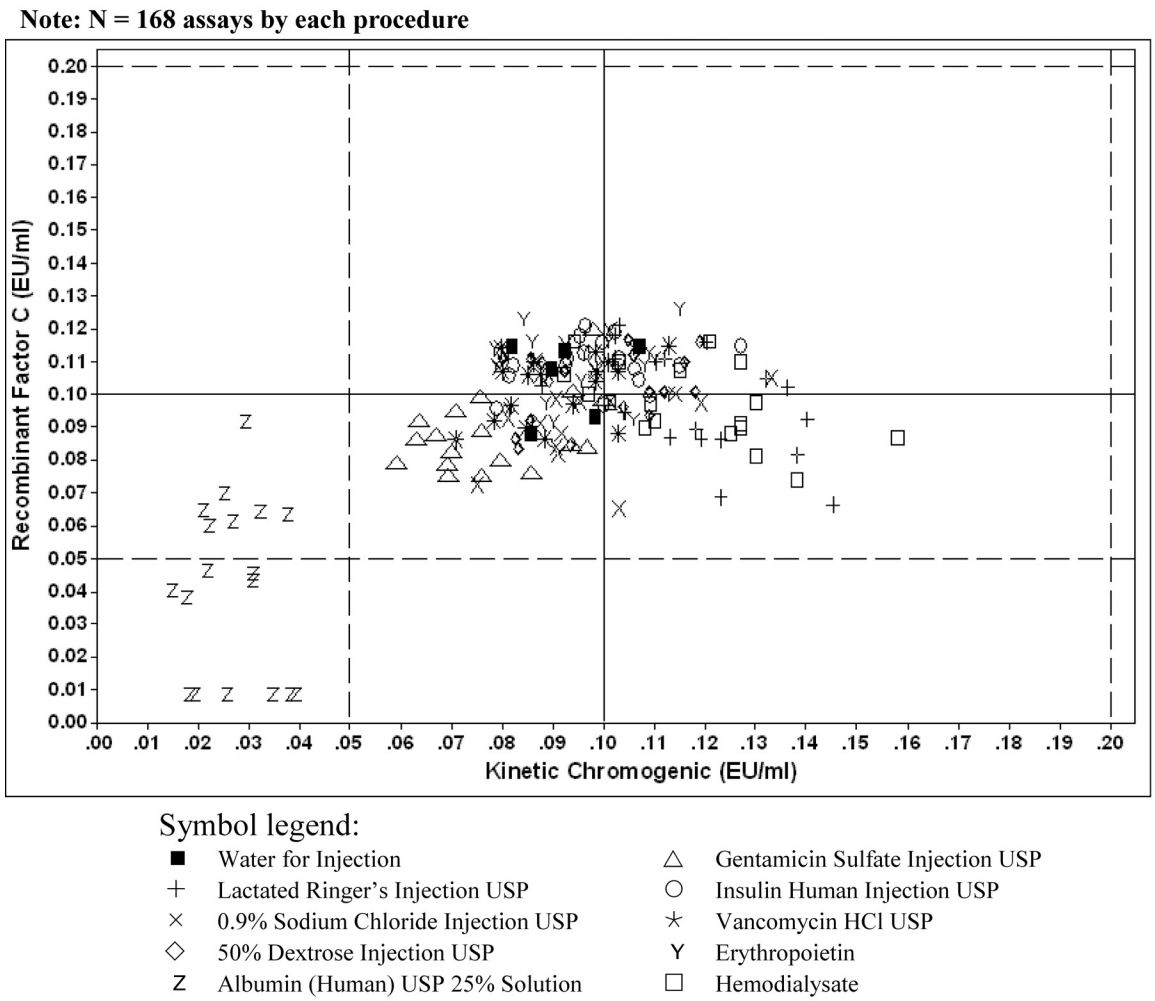

Figure 2. rFC vs kinetic chromogenic LAL: comparison of results for 10 products spiked to 0.1 EU/mL.

With the kinetic chromogenic procedure, all 18 measurements on the HA sample were outside the acceptable range and below 0.05 EU/mL. With the rFC procedure, 7 of the HA measurements were within the acceptable range, and 11 were outside and below 0.05 EU/mL. HA is known to be inhibitory in the LAL-endotoxin reaction due to proteinacious components in the preparation. Other means of circumventing this inhibitory property of HA were not included as part of this study, offering a more direct examination of any inhibitory/enhancement effects across the two analytical procedures.

The two procedures were further compared by determining for each procedure the percent of assay results that were within ± 25% of the nominal 0.1 EU/mL spike. *Table 1* shows that a significantly ($P < 0.01$) greater proportion of the rFC results (85.7%) were within ± 25% of the target concentration than were the proportion of chromogenic results (75.0%).

Table 1. rFC and Chromogenic Assay Results within ± 25% of Spike Value

Note: N = 168 assay results by each procedure		
	Number and % of Results within ± 25% of 0.1 EU/mL Spike	**Number and % of Results beyond ± 25% of 0.1 EU/mL Spike**
rFC	144 85.7%	24 14.3%
Chromogenic	126 75.0%	42 25.0%

The proportion of results within ± 25% of 0.1 EU/mL is greater for the rFC procedure than for chromogenic results; $P < 0.01$, 1-tailed Fisher's Exact Test.

LAL-reactive Material

LAL-reactive Material (LRM) consists of cellulosic material derived from sources such as Cuprophan hemodialysis filters (CF Capillary Flow Dialyzer, Model CF23, Baxter, Deerfield, IL). LRM contains glucans of various linkages, and the β-1,3 linkage is a significant contributor to the LRM false-positive responses in LAL-based procedures (*10*). With an LRM preparation prepared according to the procedure described by Pearson et al. (*11*), the rFC assay has been previously shown to have no significant response to LRM when compared to an LAL-based kinetic chromogenic procedure (*12*).

Response to Different Endotoxin Sources

A comparison was made regarding the response of rFC, kinetic chromogenic LAL, and turbidimetric LAL photometric procedures to different sources of purified endotoxin. Sources tested were: EC-6 (the internationally recognized Reference Standard Endotoxin which is distributed by USP and is derived from *Escherichia coli* stain O113:H10:K(-), *E. coli* O55:B5, *Pseudomonas aeruginosa* F-D Type 1, and *Salmonella minnesota* R595 (Re). Three assays were performed for each endotoxin–procedure combination. The results are summarized in *Figure 3* and *Table 2*.

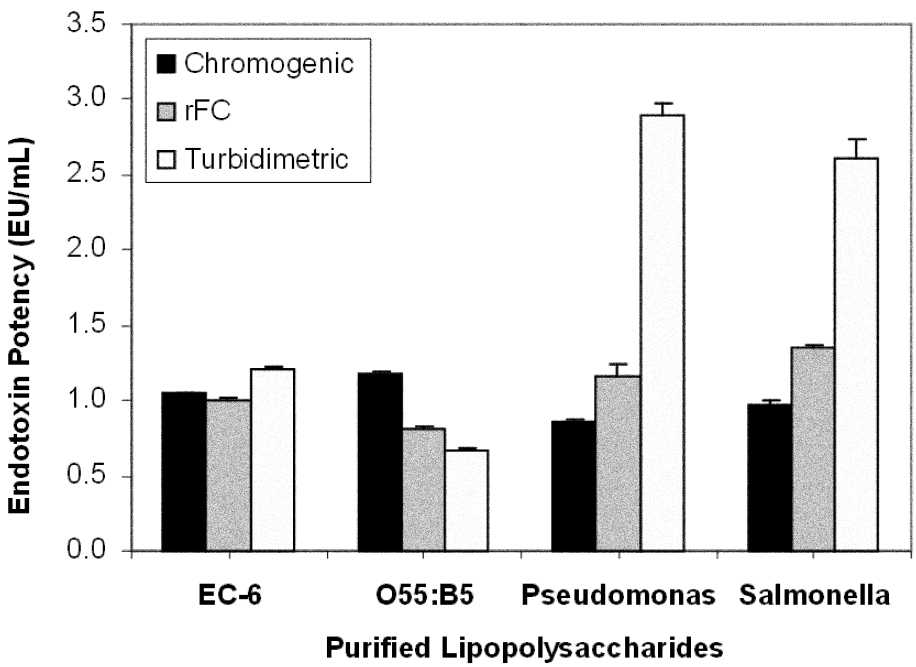

Figure 3. Endotoxin response to different source materials.

Table 2. Results for Different Endotoxin Source Materials

Endotoxin Source	Procedure	Mean[a] (EU/mL)	Standard Error (EU/mL)	Mean Comparisons[b]
EC-6	Chromogenic	1.04	0.012	Turbidimetric Mean > Chromogenic and rFCMean ($P < 0.05$)
	rFC	1.00	0.017	
	Turbidimetric	1.20	0.015	
O55:B5	Chromogenic	1.18	0.023	Chromogenic Mean > rFC Mean > Turbidimetric Mean ($P < 0.05$)
	rFC	0.81	0.021	
	Turbidimetric	0.67	0.007	
Pseudomonas	Chromogenic	0.86	0.014	Turbidimetric Mean > rFC Mean > Chromogenic Mean ($P < 0.05$)
	rFC	1.16	0.071	
	Turbidimetric	2.90	0.081	
Salmonella	Chromogenic	0.98	0.029	Turbidimetric Mean > rFC Mean > Chromogenic Mean ($P < 0.05$)
	rFC	1.36	0.015	
	Turbidimetric	2.61	0.131	

[a] N = 3 assays for each endotoxin–procedure combination.
[b] Multiple comparisons among each pair using Student's *t*-statistic.

The two LAL-based procedures gave statistically significant different mean responses for all four endotoxin sources. The turbidimetric response was greater than the chromogenic response for all sources except O55:B5, where the chromogenic response was greater.

For the O55:B5, *Pseudomonas*, and *Salmonella* sources the rFC mean response was significantly different from the two LAL-based procedures but fell between the two. With EC-6 there was not a significant difference between the rFC and chromogenic procedures, but both of these were significantly less than the turbidimetric results although the magnitude of the difference was small.

Recombinant FC recognizes endotoxin from different source materials as do other photometric procedures, demonstrating equivalency to the LAL-based procedures.

Precision

As defined in ⟨1225⟩, the precision of an analytical procedure ''is the degree of agreement among individual test results when the method is applied repeatedly to multiple samplings of a homogeneous sample. The precision of an analytical method is usually expressed as the standard deviation or relative standard deviation (coefficient of variation) of a series of measurements.''

Comparative precision testing was performed with the rFC and kinetic chromogenic procedures at three test centers, by three analysts at each test center. Each analyst measured endotoxin samples from the three regions of the 0.01 to 10 EU standard curve (low = 0.0316 EU/mL, medium = 0.316 EU/mL, and high = 3.16 EU/mL) over the course of three different days.

Table 3 summarizes the precision study results. Note that total variation [measured standard deviation or percent coefficient of variation (%CV)] from this study is the sum of the variation among replicates within assay, variation among days, variation among analysts, and variation among locations. For the rFC procedure, observed total CV was 20% for the low concentration, 18% for the medium concentration, and 11% for the high concentration. Each of these is less than the corresponding CVs obtained with the kinetic chromogenic procedure. A significant difference between procedures was not detected for the low and medium concentrations, but at the high concentration rFC total variation was significantly less than chromogenic total variation ($P < 0.02$).

Table 3. Precision Study Analysis Summary

rFC		Low Sample 0.0316 EU/mL			Medium Sample 0.316 EU/mL			High Sample 3.16 EU/mL		
Location	N	Mean (EU/mL)	Standard (EU/mL)	%CV[a]	Mean (EU/mL)	Standard (EU/mL)	%CV	Mean (EU/mL)	Standard (EU/mL)	%CV
1	18	0.0291	0.0045	14	0.403	0.049	16	3.52	0.32	10
2	18	0.0276	0.0050	16	0.365	0.052	16	3.45	0.34	11
3	18	0.0365	0.0056	18	0.410	0.058	18	3.65	0.40	13
Over Locations	54	0.0311	0.0051[b]	16	0.392	0.053	17	3.54	0.35	11
			0.0063[c]	20		0.056	18		0.36[d]	11
Chromogenic		**Low Sample 0.0316 EU/mL**			**Medium Sample 0.316 EU/mL**			**High Sample 3.16 EU/mL**		
Location	N	Mean (EU/mL)	Standard (EU/mL)	%CV[a]	Mean (EU/mL)	Standard (EU/mL)	%CV	Mean (EU/mL)	Standard (EU/mL)	%CV
1	18	0.0350	0.0033	10	0.446	0.060	19	3.22	0.54	17
2	18	0.0327	0.0069	22	0.403	0.066	21	3.02	0.42	13
3	18	0.0420	0.0067	21	0.416	0.064	20	3.41	0.49	16
Over Locations	54	0.0366	0.0059[b]	19	0.421	0.063	20	3.22	0.49	16
			0.0070[c]	22		0.065	21		0.50[d]	16

[a] All %CVs were calculated using the known concentrations of the samples rather than the measured mean responses.
[b] Pooled within location standard deviation.
[c] Total standard deviation over locations.
[d] For the High sample, rFC total variation is significantly less than chromogenic total variation ($P < 0.02$). There is not a significant difference in total variation for the Low and Medium samples.

Accuracy of Individual Results

As defined in ⟨1225⟩, the accuracy of an analytical procedure ''is the closeness of test results obtained by that procedure to the true value. The accuracy of an analytical procedure should be established across its range.''

Accuracy of individual assay results was assessed using the data from the precision study, which used three known concentrations of EC-6 (the current Reference Standard Endotoxin) as an endotoxin source. The three samples tested had concentrations of 0.0316 EU/mL, 0.316 EU/mL, and 3.16 EU/mL and were tested at three locations, by a total of nine different analysts, and over three different days by each analyst.

As a measure of ''closeness'' of individual assay results to the known concentration, each assay result was classified as either within ± 25% of the known sample concentration (i.e., ''close'') or beyond ± 25%. *Table 4* shows that at each of the three sample concentrations, the rFC procedure had a greater proportion of assay results within ± 25% of the known concentration than did the chromogenic procedure. The difference, however, was not statistically significant.

Table 4. Accuracy Relative to Known Concentration[a]

		rFC	Chromogenic
0.0316 EU/mL Sample	**Mean standard deviation**	0.0311 EU/mL 0.0063 EU/mL	0.0366 EU/mL 0.0070 EU/mL
	% of results within ± 25% of known concentration[b]	81.5%	74.1%
0.316 EU/mL Sample	**Mean standard deviation**	0.392 EU/mL 0.056 EU/mL	0.421 EU/mL 0.065 EU/mL
	% of results within ± 25% of known concentration[b]	44.4%	29.6%
3.16 EU/mL Sample	**Mean standard deviation**	3.54 EU/mL 0.36 EU/mL	3.22 EU/mL 0.50 EU/mL
	% of results within ± 25% of known concentration[b]	92.6%	87.0%

[a] Results were obtained from the precision study (see *Table 3*) and are based on N = 54 assays of each sample, by each procedure.
[b] The differences between procedures are not significant based on Fisher's Exact Test.

Linearity

As defined in ⟨1225⟩, the linearity of an analytical procedure "is its ability to elicit results that are directly, or by a well-defined mathematical transformation, proportional to the concentration of analyte in samples within a given range."

A series of 18 rFC standard curves were generated as part of the 6-site multicenter study. Each curve included four standards (0.01, 0.1, 1.0, and 10 EU/mL) in replicates of three. The log net change in RFU (difference of the 60-min time point minus the zero time point corrected for the blank) was plotted against log endotoxin concentration to generate a standard curve. *Table 5* summarizes the linear regression statistics from the 18 curves.

Table 5. rFC Linear Regression Summary Statistics[a]

Standard Curve Characteristic	Mean	CV%	Range	
			Minimum	Maximum
Correlation	0.996	0.1%	0.995	0.998
Slope	0.865	1.9%	0.831	0.901
Y-intercept	3.398	1.1%	3.307	3.450

[a] Based on 18 standard curves, by six analysts at six sites.

The correlation coefficient was greater than 0.995 for all 18 standard curves, meeting FDA requirement ($\geq$ |0.980|) for LAL-based procedures (*13*). Standard curve slopes and *y*-intercepts were also highly consistent among the 18 standard curves, with CVs of 1.9% and 1.1% respectively.

Range

As defined in ⟨1225⟩, the range of a procedure ''is validated by verifying that the analytical procedure provides acceptable precision, accuracy, and linearity when applied to samples containing analyte at the extremes of the range as well as within the range.'' Data obtained from the precision study (*Table 3*) show similar variation between the rFC and kinetic chromogenic procedures. The total variation of the rFC procedure was either the same as or lower than the kinetic chromogenic procedure for the three regions (low, middle, and high) of the standard curve. For the three regions the accuracy of the rFC procedure was equivalent to that of the kinetic chromogenic procedure (*Table 4*).

Quantitation Limit

According to ⟨1225⟩, the quantitation limit is the ''lowest amount of analyte in a sample that can be determined with acceptable precision and accuracy under the stated experimental conditions. The quantitation limit is expressed as the concentration of analyte in the sample.''

We evaluated three distinct lots of rFC enzyme to determine the quantitation limit of the rFC procedure. Reference Standard Endotoxin EC-6 was used to prepare the endotoxin standard curve (0.01 to 10 EU/mL). Three separate assays were performed, each with one of the three rFC enzyme lots. Five separate samples of both LAL Reagent Water (control blank) and 0.01 EU/mL EC-6 endotoxin were tested as unknowns in replicates of three with each of the three enzyme lots.

Table 6 contains a summary of the results. The assay results on the 0.01 EU/mL sample show acceptable precision and accuracy, demonstrating that the quantitation limit is at least 0.01 EU/mL. Furthermore, the 99% tolerance intervals for assays on the water blank and 0.01 EU/mL-samples do not overlap, indicating that assays on a sample with 0.01 EU/mL are clearly distinct from assays on a blank sample.

Table 6. rFC Quantitation Limit Summary Statistics

	Number of Assay Results	Mean (EU/mL)	Standard Deviation (EU/mL)	%CV	99% Tolerance Interval (95% Confidence)
0.01 EU/mL sample	15	0.009	0.0007	7.8%	0.006–0.012 EU/mL
Blank water sample	15	0.002	0.0008	n/a[a]	0–0.005 EU/mL

[a] n/a = not applicable

CONCLUSION

The rFC procedure for the detection of gram-negative bacterial endotoxin has been shown to be equivalent to LAL in its ability to quantifiably measure endotoxin and has a quantitative range comparable to that of quantitative photometric LAL procedures. However, unlike the LAL endotoxin procedure that uses Factor C derived from horseshoe crabs, the rFC procedure uses a recombinant form of Factor C. It provides another means of detecting endotoxin by other than traditional LAL procedures. The rFC does not contain the glucan-sensitive Factor G, and therefore the rFC-based procedure is not subject to false positives that can be caused by β-1,3-glucans (*12*). It utilizes material of nonanimal origin as its active ingredient. The requirements for validation of Compendial Methods as specified in ⟨1225⟩ for specificity, precision, accuracy, linearity, range, and quantitation limit have been met for the rFC procedure and are equivalent to current *USP* procedures for endotoxin measurement.

Transfer of HPLC Procedures to Suitable Columns of Reduced Dimensions and Particle Sizes

Uwe D. Neue,[a] Doug McCabe,[a] Vijaya Ramesh,[b] Horacio Pappa,[d] Jim DeMuth[c]

ABSTRACT This *Stimuli* article contains proposals to help the analyst adjust HPLC column length and particle size to achieve separation power at least equivalent to that used in the original procedure, markedly increasing the range of options currently allowed in *Chromatography* ⟨621⟩. The article presents the scientific rationale for application of these proposals to isocratic procedures and follows with gradient procedures.

INTRODUCTION

Users of compendial chromatographic procedures increasingly need to develop analytically equivalent procedures that decrease analysis time and solvent consumption. In this process they face limitations because USP does not provide the necessary flexibility to change the chromatographic column without revalidation of the method. The *United States Pharmacopeia* (*USP*) General Chapter *Chromatography* ⟨621⟩ describes in detail the range of adjustments allowed in the system when the suitability test failed. These adjustments in the operating conditions, when needed, are the maximum variations that can be made without the need for validation rather than verification of method performance under the new conditions. Included, among others, are changes in column length (± 70%), changes in column diameter (± 25%), particle size (can be reduced by as much as 50%), and flow rate (± 50%). Additional changes are being implemented (*1*): The column diameter can be changed freely provided that the linear velocity is kept constant, following the formula: where *F*, *l*, and *d* are the flow rates, the column lengths, and the column diameters, respectively, before the change (subscript 1) and after the change (subscript 2). An adjustment of the flow rate by ± 50% is also allowed.

$$F_2 = F_1 \cdot \frac{l_2 \cdot d_2^2}{l_1 \cdot d_1^2} \qquad (1)$$

Except for this flexibility, ⟨621⟩ is silent on changes allowed to the column specified in the monograph. In some cases *USP* chromatographic procedures prescribe the use of a column that is no longer available and needs to be replaced with another of the same stationary phase but different dimensions. In others cases, switching to a column with different particle size and dimensions may provide a more rapid separation with equivalent chromatographic performance. Both these situations currently require revalidation. This article proposes allowing the flexibility to change column dimensions or particle size as long as equivalent or better column performance is maintained, and it provides guidance to ensure that this is achieved in a scientifically rigorous manner.

PROPOSED CHANGES TO THE *SYSTEM SUITABILITY* SECTION OF ⟨621⟩ WITH RESPECT TO PARTICLE SIZE AND COLUMN LENGTH

This *Stimuli* article proposes a new approach that will both preserve the quality of the separation as well as expand the changes in particle size beyond the current twofold decrease. The intent of this proposal is to allow the chromatographer a reduction in analysis time without sacrificing column performance or impairing the separation capability for a procedure.

Chromatography defines the relationships by which particle size, column length, and flow rate can be changed without affecting the quality of the separation (*2–8*). The column plate count *N* is determined as follows:

$$N = (l / H) = l / (d_p \cdot h) \qquad (2)$$

where *l* is the column length, *H* is the theoretical plate height, d_p is the particle diameter, and *h* is the reduced plate height. The quality of the separation is determined primarily by the plate count, which is why most *USP* chromatographic procedures require a minimum plate count. The plate count remains constant if the ratio of column length to particle diameter remains constant, provided that the reduced plate height remains the same (see equation 2).

The reduced plate height *h* depends exclusively on the reduced velocity υ, which in turn is a function of the particle diameter and the flow rate.

$$h = H / d_p \qquad (3)$$

$$\upsilon = u d_p / D_M \qquad (4)$$

where u is the average linear velocity and D_M is the solute diffusion coefficient. To the practicing chromatographer, this means that the flow rate needs to increase in inverse proportion to the change in particle size in order to maintain the same reduced plate height h:

$$h_2 = h_1 \text{ if } \upsilon_2 = \upsilon_1 \qquad (5a)$$

and therefore

$$F_2 \cdot d_{p,2} = F_1 \cdot d_{p,1} \qquad (5b)$$

and

$$F_2 = F_1 \, (d_{p,1} / d_{p,2}) \qquad (5c)$$

As an example, if the particle size is reduced from 5 μm to 3.5 μm, the flow rate will need to be increased by slightly more than 40%. The combination of the shorter column (equation 2) and the increased flow rate (equation 5c) results in a reduction in analysis time while preserving the performance of the separation.

Analysis time decreases with both the shorter column length l and the higher flow rate F, as the square of the reduction in particle diameter: In addition, because the column length is reduced at the same time as the particle size is decreased, the quantity of solvent per analysis is reduced with the shorter column.

$$t_{a,2} = t_{a,1} \cdot \frac{l_2 \cdot F_1}{l_1 \cdot F_2} = \frac{d_{p,2}^2}{d_{p,1}^2} \qquad (6)$$

Table 1 contains sets of conditions required to maintain the quality of the separation (the same plate count), when users change the particle size.

Table 1. Change in Conditions for Achieving the Same Plate Count

4-mm columns:				
Particle Size (μm)	Column Length (cm)	Flow Rate (mL/min)	Reduction in Analysis Time	Reduction in Solvent Use
5	15	1	1×	1×
3.5	10	1.5	2×	1.5×
2.5	7.5	2	4×	2×
1.7	5	3	9×	3×
2.1-mm columns:				
Particle Size (μm)	Column Length (cm)	Flow Rate (mL/min)	Reduction in Analysis Time	Reduction in Solvent Use
5	15	0.2	1×	1×
3.5	10	0.3	2×	1.5×
2.5	7.5	0.5	4×	2×
1.7	5	0.6	9×	3×

As noted, an increase in flow rate is associated with a reduction in analysis time, and a reduction in the column length is associated with a reduction in solvent consumption. *Figure 1* provides examples from the implementation of this procedure.

From *Figure 1* it can be seen that the separation is quantitatively maintained with each change, in excellent agreement with the theoretical predictions. The good agreement between theory and practice supports allowing this degree of flexibility in the pharmacopeia.

The following rule for conversion between different particle sizes may be used to ensure the plate count remains approximately the same:

> The column length and the particle diameter should be changed approximately in proportion to each other. The flow rate should be increased or decreased in inverse proportion to the change in particle size.

This last change will be beneficial to analysts because current rules for changing the particle diameter do not provide any guidance about how to maintain the quality of the separation.

In some cases, a perfect match of column length and particle size may not be possible. For example, the change in particle size from a 10-μm packing in a 25-cm column to a 5-μm packing would require a 12.5-cm column, which is not commonly available. For such a case, some flexibility can be provided by the following rule:

> If an exact match is not readily available, the ratio of column length to particle size can be changed by ± 25%.

Additional changes in flow rate of ± 50% are already permitted by ⟨621⟩.

As the column volume is reduced, the injection volume should be reduced proportionally. This is consistent with the existing ⟨621⟩ statement that ''the injection volume can be reduced as far as is consistent with accepted precision and detection limits.'' Because scaling to a large diameter and a larger column volume is also possible, we propose changing the statement in ⟨621⟩ as follows:

> *Injection Volume (GC, HPLC)*: Can be adjusted as far as is consistent with accepted precision and detection limits.

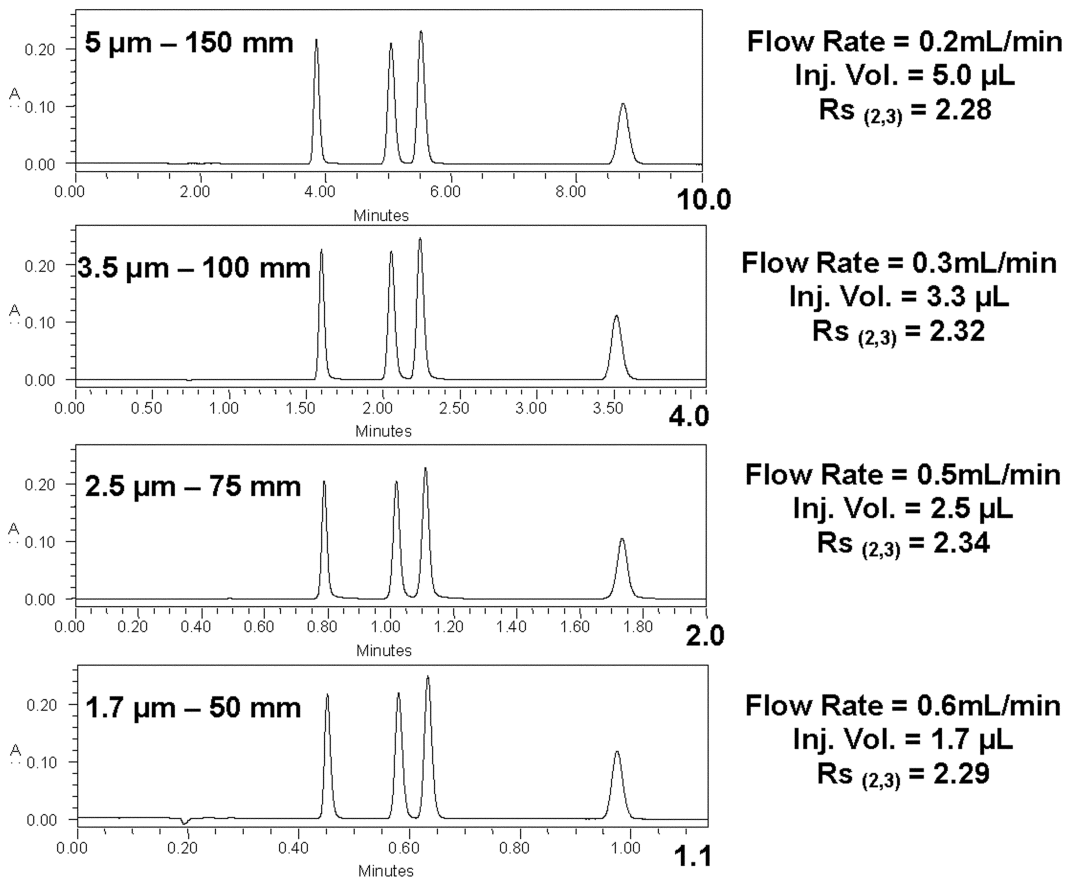

Figure 1. Scaling of a separation at a fixed ratio of column length and particle size using columns with a 2.1-mm internal diameter (reproduced with permission from Reference 7).

As a guide for accomplishing this change, chromatographers may scale the injection volume V_i relative to the column volume V_c, as shown below: The requirements to this point cover the scaling of isocratic methods, which encompass most *USP* methods. However, modern methods are increasingly gradient methods, so we propose the extension of these concepts to this area. In general, all rules written to this point for isocratic methods also apply to gradient methods. In addition, a gradient method is scaled properly if all segments of the gradient $V_{g,s}$ are scaled in proportion to the column volume V_c: Flow rates and injection volumes are scaled as in the isocratic method (see equation 5c—a faster flow rate is used and the particle diameter is reduced). The gradient segment volume $V_{g,s}$ is defined as the time programmed for the gradient segment $t_{g,s}$ multiplied by the flow rate F. This leads to the following formula for the scaling of the time for each gradient segment:

$$t_{g,s,2} = t_{g,s,1}\,[(V_{g,s,2} / F_2) / (V_{g,s,1} / F_1)] \qquad (9)$$

As was true for the isocratic method, this results in a 4-fold reduction in every gradient segment, and thus in the analysis time, for every 2-fold change in particle diameter (and column length).

$$V_{i,2} = V_{i,1} \cdot \frac{V_{c,2}}{V_{c,1}} = V_{i,1} \cdot \frac{l_2 \cdot d_2^2}{l_1 \cdot d_1^2} \qquad (7)$$

$$V_{g,s,2} = V_{g,s,1} \cdot \frac{V_{c,2}}{V_{c,1}} = V_{g,s,1} \cdot \frac{l_2 \cdot d_2^2}{l_1 \cdot d_1^2} \qquad (8)$$

Thus, we propose the following requirement for changing a gradient:

> Gradients are adjusted to the column volume by changing the gradient volume in proportion to the column volume. This applies also to every gradient segment volume.

This simple procedure may be complicated by instrument-dependent gradient delay volumes. The gradient delay volume results in an isocratic section before the beginning of the gradient proper. For a well-functioning instrument and a well-designed gradient, the gradient delay volume is small relative to the column volume, and the analysis is not affected. Alternatively, modern instruments allow for delayed injection to adjust the gradient delay volume to the column volume. An example of a well-scaled gradient method is shown in *Figure 2*. In this case, the method was scaled from a 4.6-mm × 150-mm column packed with 5-μm particles to a 2.1-mm × 50-mm column packed with 1.7-μm particles. Of course, the separation chemistry of both packings was held constant. Following the rules outlined above, the user adjusted the flow rate for both the column diameter and the particle diameter. The gradient times were adjusted to maintain a constant ratio of the gradient segment volumes to the column volumes. As a consequence, the elution pattern and the resolution remain constant, and the analysis time decreased by a factor of 8 with the shorter column.

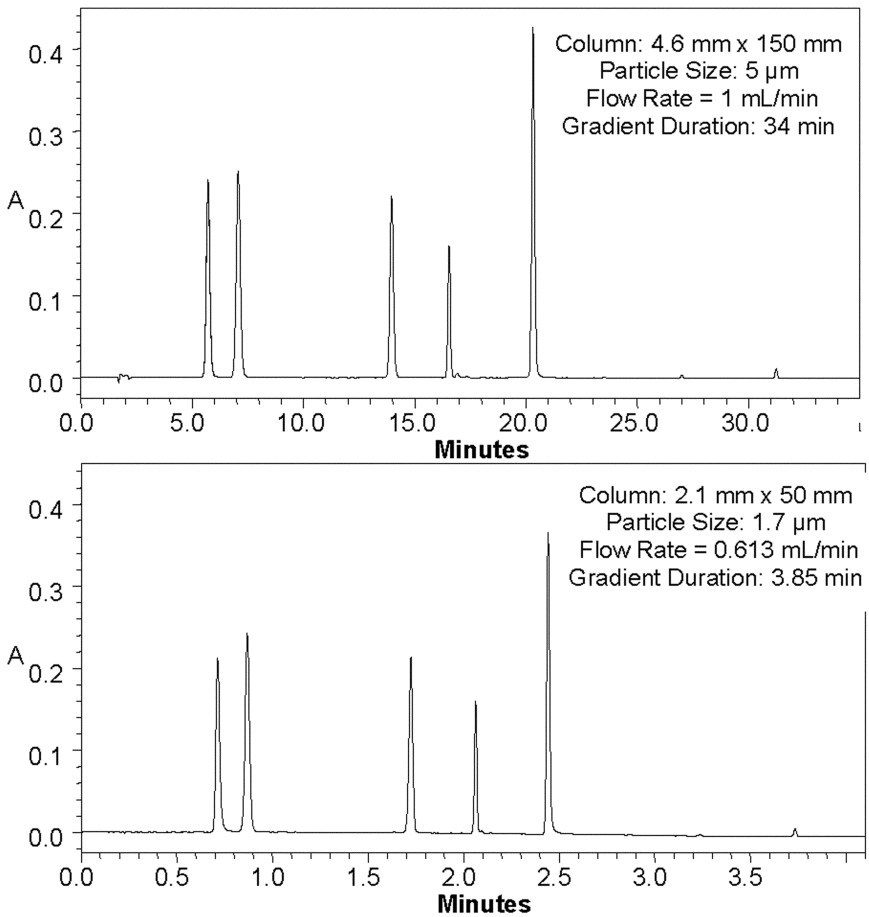

Figure 2. Comparison of two gradient chromatograms scaled by column dimension and particle diameter according to the rules described herein (reproduced with permission from Reference 9).

SUMMARY

The proposed changes to ⟨621⟩ will expand the analyst's ability to reduce solvent consumption and decrease analysis time while maintaining the quality of a chromatographic separation. By adhering to the proposed requirements, analysts can maintain the quality of the separation for the entire range of possible particle diameters, extending and improving on the rule that limits the particle diameter change to – 50% and the change in column length to ± 70%.

NOMENCLATURE

This section includes supplements to the latest edition of the *USP Dictionary of USAN and International Drug Names* that incorporate new United States Adopted Names (USAN) and revisions to existing Dictionary names. Also listed are Proposed and Recommended International Nonproprietary Names (INN) when they have been announced by the World Health Organization.

Possible names suggested for use as USAN and INN are listed for public review and comment along with information on how nonproprietary names are devised. In addition, readers may find articles relevant to current compendial nomenclature issues that also occasionally report on related matters pertaining to USAN and INN.

Nomenclature

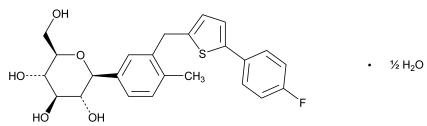
USP Dictionary of USAN and International Drug Names
2009 USP DICTIONARY SUPPLEMENT 4

IMPORTANT—Save this Supplement. This and all supplements appearing in *PF* are needed to keep the 2009 edition of the USP Dictionary (USPD) up-to-date. The cumulative contents of the supplements to the current (2009) edition will be included in the next complete edition of the Dictionary.

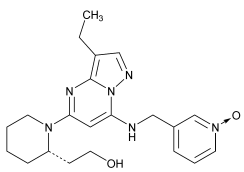
Newly Approved United States Adopted Names (USAN), Released for Publication

The following are newly established United States Adopted Names (USAN). These names will not be listed cumulatively; see preceding and succeeding numbers of *PF* for other new USAN to supplement the Dictionary main volume.

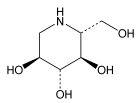
Canagliflozin [*2009*] (kan′′ a gli floe′ zin). $C_{24}H_{25}FO_5S.H_2O$. 453.53. (1) D-Glucitol, 1,5-anhydro-1-C-[3-[[5-(4-fluorophenyl)-2-thienyl]methyl]-4-methylphenyl]-, hydrate (2:1), (1*S*)-; (2) (1*S*)-1,5-Anhydro-1-C-(3-{[5-(4-fluorophenyl)thiophen-2-yl]methyl}-4-methylphenyl)-D-glucitol hemihydrate; (3) (1*S*)-1,5-Anhydro-1-[3-[[5-(4-fluorophenyl)-2-thienyl]methyl]-4-methylphenyl]-D-glucitol hemihydrate. *CAS-928672-86-0*. *Antidiabetic.* ✧*JNJ-28431754; JNJ-28431754-AAA; JNJ-24831754-ZAE; TA-7284*



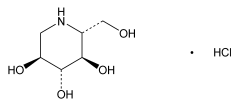
Dinaciclib [*2009*] (din′′ a sye′ klib). $C_{21}H_{28}N_6O_2$. 396.50. (1) 2-Piperidineethanol, 1-[3-ethyl-7-[[(1-oxido-3-pyridinyl)methyl]amino]pyrazolo[1,5-*a*]pyrimidin-5-yl]-, (2*S*)-; (2) 3-[[[3-Ethyl-5-[(2*S*)-2-(2-hydroxyethyl)piperidin-1-yl]pyrazolo[1,5-*a*]pyrimidin-7-yl]amino]methyl]pyridine 1-oxide. *CAS-779353-01-4*. *Treatment of cancer.* ✧*SCH 727965*



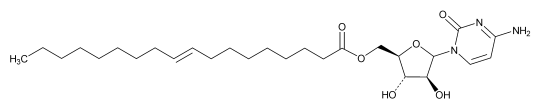
Duvoglustat [*2009*] (doo′′ voe gloo′ stat). $C_6H_{13}NO_4$. 163.20. (1) 3,4,5-Piperidinetriol, 2-(hydroxymethyl)-, (2*R*,3*R*,4*R*,5*S*)-; (2) (2*R*,3*R*,4*R*,5*S*)-2-(Hydroxymethyl)piperidine-3,4,5-triol. *CAS-19130-96-2*. *Treatment of Pompe disease.*



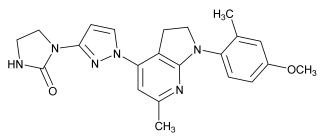
Duvoglustat Hydrochloride[*2009*] (doo′′ voe gloo′ stat hye′′ droe klor′ ide). $C_6H_{13}NO_4.HCl$. 199.60. (1) 3,4,5-Piperidinetriol, 2-(hydroxymethyl)-, hydrochloride (1:1), (2*R*,3*R*,4*R*,5*S*)-; (2) (2*R*,3*R*,4*R*,5*S*)-2-(Hydroxymethyl)piperidine-3,4,5-triol hydrochloride. *CAS-73285-50-4*. *Treatment of Pompe disease.* ✧*AT2220*



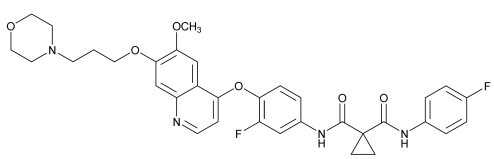
Elacytarabine [*2009*] (el′′ a sye tar′ a been). $C_{27}H_{45}N_3O_6$. 507.66. (1) 2(1*H*)-Pyrimidinone, 4-amino-1-[5-*O*-[(9*E*)-1-oxo-9-octadecenyl]-β-D-arabinofuranosyl]-; (2) 4-Amino-1-[5-*O*-[(9*E*)-octadec-9-enoyl]-β-D-arabinofuranosyl]pyrimidin-2(1*H*)-one. *CAS-188181-42-2*. INN. *Treatment of cancer.* ✧*CP-4055*



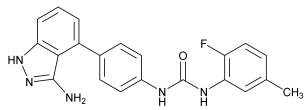
Emicerfont [*2009*] (em′′ i ser′ font). $C_{22}H_{24}N_6O_2$. 404.50. (1) 2-Imidazolidinone, 1-[1-[2,3-dihydro-1-(4-methoxy-2-methylphenyl)-6-methyl-1*H*-pyrrolo[2,3-*b*]pyridin-4-yl]-1*H*-pyrazol-3-yl]-; (2) 1-{1-[1-(4-Methoxy-2-methylphenyl)-6-methyl-2,3-dihydro-1*H*-pyrrolo[2,3-*b*]pyridin-4-yl]-1*H*-pyrazol-3-yl}imidazolidin-2-one. *CAS-786701-13-1*. *Treatment of anxiety disorders, depression, and IBS.* ✧*GW876008X*



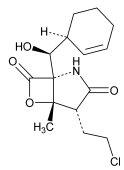
Foretinib [*2009*] (for e′ ti nib). $C_{34}H_{34}F_2N_4O_6$. 632.70. (1) 1,1-Cyclopropanedicarboxamide, *N*-[3-fluoro-4-[[6-methoxy-7-[3-(4-morpholinyl)propoxy]-4-quinolinyl]oxy]phenyl]-*N*′-(4-fluorophenyl)-; (2) *N*-[3-Fluoro-4-({6-methoxy-7-[3-(morpholin-4-yl)propoxy]quinolin-4-yl}oxy)phenyl]-*N*′-(4-fluorophenyl)cyclopropane-1,1-dicarboxamide. *CAS-849217-64-7*. *Antineoplastic.* ✧*GSK1363089G*



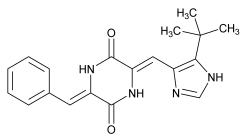
Linifanib [*2009*] (lin if′ a nib). $C_{21}H_{18}FN_5O$. 375.40. (1) Urea, *N*-[4-(3-amino-1*H*-indazol-4-yl)phenyl]-*N*′-(2-fluoro-5-methylphenyl)-; (2)1-[4-(3-Amino-1*H*-indazol-4-yl)phenyl]-3-(2-fluoro-5-methylphenyl)urea. *CAS-796967-16-3*. *Antineoplastic.* ✧*ABT-869*



Marizomib [*2009*] (mar iz′ oh mib). $C_{15}H_{20}ClNO_4$. 313.80. (1) 6-Oxa-2-azabicyclo[3.2.0]heptane-3,7-dione, 4-(2-chloroethyl)-1-[(*S*)-(1*S*)-2-cyclohexen-1-ylhydroxymethyl]-5-methyl-, (1*R*,4*R*,5*S*)-; (2) (1*R*,4*R*,5*S*)-4-(2-Chloroethyl)-1-{(*S*)-[(1*S*)-cyclohex-2-en-1-yl]hydroxymethyl}-5-methyl-6-oxa-2-azabicyclo[3.2.0]heptane-3,7-dione.*CAS-437742-34-2*. *Antineoplastic.* ✧*NPI-0052*



Plinabulin [*2009*] (plin′′ a bue′ lin). $C_{19}H_{20}N_4O_2$. 336.40. (1) 2,5-Piperazinedione, 3-[[5-(1,1-dimethylethyl)-1*H*-imidazol-4-yl]methylene]-6-(phenylmethylene)-, (3*Z*,6*Z*)-; (2) (3*Z*,6*Z*)-6-Benzylidene-3-{[5-(1,1-dimethylethyl)-1*H*-imidazol-4-yl]methylidene}piperazine-2,5-dione. *CAS-714272-27-2*. *Antineoplastic.* ✧*NPI-2358*

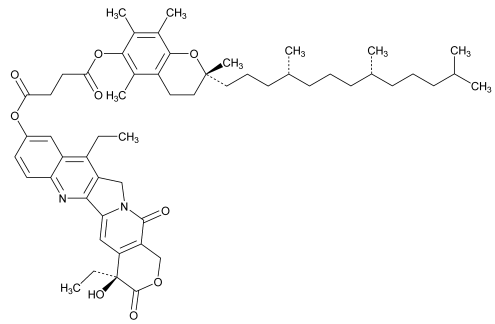


Potassium Sulfate [*2009*] (poe tas′ ee um sul′ fate). K_2SO_4. 174.26. (1) Sulfuric acid potassium salt (1 : 2); (2) Potassium sulfate. *CAS-7778-80-5*. JAN. *Oral bowel cleansing solution.*

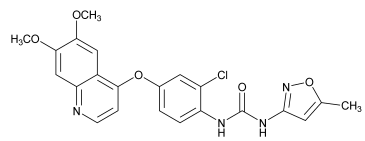
Rintatolimod [*2009*] (rin′′ ta tol′ i mod). $[[C_{10}H_{11}N_4O_7P]_{13}]_n$. $[[C_9H_{12}N_3O_7P]_{12}[C_9H_{11}N_2O_8P]]_n$. (1) 5′-Inosinic acid, homopolymer, complex with 5′-cytidylic acid polymer with 5′-uridylic acid (1 : 1); (2) Poly[5′)-inosinyl-(3′→] duplex with poly[dodecakis[3′)-cytidylyl-(5′→]3′)-uridylyl-(5′→]. The molecular mass ranges from 400,000 to 1,750,000 daltons. *CAS-38640-92-5*. *Treatment of chronic fatigue syndrome; antiviral.* Ampligen (Hemispherx Biopharma).

Taspoglutide [*2008*] (tas′′ poe gloo′ tide). $C_{152}H_{232}N_{40}O_{45}$. 3339.71. (1) 7-36-Glucagon-like peptide I (human), 8-(2-methylalanine)-35-(2-methylalanine)-36-L-argininamide-; (2) [8-(2-Amino-2-methylpropanoic acid),35-(2-amino-2-methylpropanoic acid)]human glucagon-like peptide 1 (GLP-1)-(7-36)-peptidamide. *CAS-275371-94-3*. INN. *Treatment of type 2 diabetes.* ✧*RO5073031*

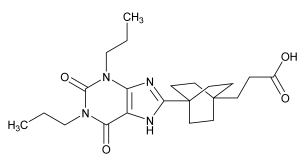
Tenifatecan [*2009*] (ten if′′ a tee′ kan). $C_{55}H_{72}N_2O_9$. 905.20. (1) Butanedioic acid, (4*S*)-4,11-diethyl-3,4,12,14-tetrahydro-4-hydroxy-3,14-dioxo-1*H*-pyrano[3′,4′:6,7]indolizino[1,2-*b*]quinolin-9-yl (2*R*)-3,4-dihydro-2,5,7,8-tetramethyl-2-[(4*R*,8*R*)-4,8,12-trimethyltridecyl]-2*H*-1-benzopyran-6-yl ester; (2) (4*S*)-4,11-Diethyl-4-hydroxy-3,14-dioxo-3,4,12,14-tetrahydro-1*H*-pyrano[3′,4′:6,7]indolizino[1,2-*b*]quinolin-9-yl (2*R*)-2,5,7,8-tetramethyl-2-[(4*R*,8*R*)-4,8,12-trimethyltridecyl]-3,4-dihydro-2*H*-1-benzopyran-6-yl butanedioate. *CAS-850728-18-6*. *Antineoplastic.* ✧*SN2310*



Tivozanib [*2009*] (tye voe′ za nib). $C_{22}H_{19}ClN_4O_5$. 454.90. (1) Urea, *N*-[2-chloro-4-[(6,7-dimethoxy-4-quinolinyl)oxy]-phenyl]-*N*′-(5-methyl-3-isoxazolyl)-; (2) *N*-{2-Chloro-4-[(6,7-dimethoxyquinolin-4-yl)oxy]phenyl}-*N*′-(5-methylisoxazol-3-yl)urea. *CAS-475108-18-0*. *Antineoplastic.* ✧*AV-951*

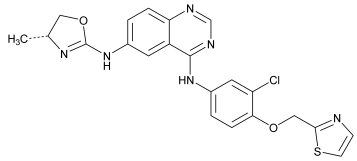


Tonapofylline [*2009*] (toe′′ na pof′ i lin). $C_{22}H_{32}N_4O_4$. 416.50. (1) Bicyclo[2.2.2]octane-1-propanoic acid, 4-(2,3,6,7-tetrahydro-2,6-dioxo-1,3-dipropyl-1*H*-purin-8-yl)-; (2) 3-[4-(2,6-Dioxo-1,3-dipropyl-2,3,6,7-tetrahydro-1*H*-purin-8-yl)bicyclo[2.2.2]oct-1-yl]propanoic acid. *CAS-340021-17-2*. *Treatment of heart failure.* ✧*BG9928*

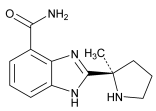


Nomenclature

Varlitinib [*2009*] (var li′ ti nib). $C_{22}H_{19}ClN_6O_2S$. 466.90. (1) 4,6-Quinazolinediamine, *N*⁴-[3-chloro-4-(2-thiazolylmethoxy)-phenyl]-*N*⁶-[(4*R*)-4,5-dihydro-4-methyl-2-oxazolyl]-; (2) *N*⁴-[3-Chloro-4-(thiazol-2-ylmethoxy)phenyl]-*N*⁶-[(4*R*)-4-methyl-4,5-dihydrooxazol-2-yl]quinazoline-4,6-diamine. *CAS-845272-21-1*. *Antineoplastic.* ✧*ARRY-334543*



Veliparib [*2009*] (ve lip′ a rib). $C_{13}H_{16}N_4O$. 244.30. (1) 1*H*-Benzimidazole-7-carboxamide, 2-[(2*R*)-2-methyl-2-pyrrolidinyl]-; (2) 2-[(2*R*)-2-Methylpyrrolidin-2-yl]-1*H*-benzimidazole-4-carboxamide. *CAS-912444-00-9*. *Antineoplastic enhancing agent.* ✧*ABT-888*



Yttrium Y 90 Clivatuzumab Tetraxetan [*2009*] (i′ tree um klye′′ va tooz′ oo mab te trax′ e tan). $C_{6496}H_{9952}N_{1716}O_{2014}S_{44}$. $(C_{16}H_{23}N_4O_7{}^{90}Y)_n$. 145.7 kilodaltons (antibody). (1) Immunoglobulin G1, anti-(human mucin MUC1) (human–mouse monoclonal hPAM4 heavy chain), disulfide with human–mouse monoclonal hPAM4 κ-chain, dimer, 1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid conjugate, yttrium-⁹⁰Y chelate; (2) Immunoglobulin G1, anti-(mucin-1 (MUC-1, PEMT, episialin, tumor-associated mucin, EMA, H23AG, PUM or CD227)); humanized mouse monoclonal hPAM4 γ1 heavy chain (222-215′)-disulfide with humanized mouse monoclonal hPAM4 κ light chain, dimer (228-228′′:231-231′′)-bisdisulfide, substituted (average of 2 to 5 substitutions) on *N*⁶ of lysyl residus by (4,7,10-tris(carboxymethyl)-1,4,7,10-tetraazacyclodec-1-yl)acetyl (substitutive tetraxetan), (90Y)yttrium(III) chelate. *CAS-943976-23-6*. *Treatment of pancreatic cancer.* hPAM4-Cide (Immunomedics). ✧*hPAM4-DOTA; IMMU-107;* ⁹⁰*hY-PAM4*

Nomenclature

INDEX

This is a cumulative directory for the content of all issues of *PF* beginning with *PF* 35(1).

[*Note—This index covers Vol. 35 No. 1, pp. 1–218; Vol. 35 No. 2, pp. 219–498; Vol. 35 No. 3, pp. 499–784; Vol. 35 No. 4, pp. 785–1050; Vol. 35 No. 5, pp. 1051–1408; Vol. 35 No. 6, pp. 1409–1638.*]

CHROMATOGRAPHIC COLUMNS USED IN *USP–NF* AND *PHARMACOPEIAL FORUM*

This is an update based on the proposals published in this issue of *PF*.

Chromatographic Columns Used in *USP-NF* and *Pharmacopeial Forum*
Nov.–Dec. 2009

BENZALKONIUM CHLORIDE (DSD Mgh #7800)

PF	LGS#	Reagent Brand	Type of Test	Comments
34(6)	L1	Nucleosil 100 C18	Limit of	Limit of benzyl alcohol, benzaldehyde, and (chloromethyl)benzene. 4.6 mm x 15 cm, 5 μm. Manufacturer: Macherey-Nagel
35(6)	L10	Nucleosil CN	Ratio of	Ratio of Alkyl Components. 4.6 mm x 25 cm, 10 μm. Manufacturer: Macherey-Nagel

BENZALKONIUM CHLORIDE SOLUTION (DSD Mgh #7830)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L1	Nucleosil 5 C18	Limit of	Limit of Benzyl Alcohol, Benzaldehyde, and (Chloromethyl)Benzene. 4.6 mm x 15 cm, 5 μm. Manufacturer: Macherey-Nagel
35(6)	G43	DB-624	Alcohol Content	If added. 0.25 mm x 30 cm, 1.4 μm. Manufacturer: J & W Scientific
35(6)	L10	Nucleosil CN	Ratio of	Ratio of Alkyl Components. 4.6 mm x 25 cm, 10 μm. Manufacturer: Macherey-Nagel

BUTYLATED HYDROXYANISOLE (DSD Mgh #11060)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L1	Symmetry C-18	Assay and Identification	4.6 mm x 7.5 cm, 3.5 μm. Manufacturer: Waters Corp.

CAPREOMYCIN FOR INJECTION (DSD Mgh #12362)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L10	Spherisorb CN	Content of	Content of Capreomycin I. 4.6 mm x 25 cm, 5 μm. Manufacturer: Waters Corp.

CAPREOMYCIN SULFATE (DSD Mgh #12358)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L10	Spherisorb CN	Content of	Content of Capreomycin I. 4.6 mm x 25 cm, 5 μm. Manufacturer: Waters Corp.

CARBOMER COPOLYMER (DSD Mgh #13025)

PF	LGS#	Reagent Brand	Type of Test	Comments
26(2)	L1	MicroBondapak C18	Limit of	Limit of Acrylic Acid. 8 mm x 10 cm, 10 μm. Catalog number WAT085721. Manufacturer: Waters Corp.

CETIRIZINE HYDROCHLORIDE AND PSEUDOEPHEDRINE HYDROCHLORIDE EXTENDED-RELEASE TABLETS (DSD Mgh #4576)

PF	LGS#	Reagent Brand	Type of Test	Comments
0(0)	L9	ZORBAX 300 SCX	Dissolution	4.6 mm x 15 cm, 5 μm. Manufacturer: Agilent Technologies

CETIRIZINE HYDROCHLORIDE TABLETS (DSD Mgh #3171)

PF	LGS#	Reagent Brand	Type of Test	Comments
36(1)	L3	LiChrospher Si-100	Organic Impurities	4.0 mm x 25 cm, 5 μm. Manufacturer: Merck KGaA
36(1)	L1	Inertsil ODS-3	Dissolution	4.6 mm x 25 cm, 5 μm. Manufacturer: GL Sciences

CLOTRIMAZOLE CREAM (DSD Mgh #18890)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L1	Purospher STAR RP18e	Assay	4.6 mm x 25 cm, 5 μm. Manufacturer: Merck KGaA

DIVALPROEX SODIUM DELAYED-RELEASE CAPSULES (DSD Mgh #27754)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L1	Inertsil ODS-3	Assay and Dissolution	4.6 mm x 15 cm, 5 μm. Manufacturer: GL Sciences

DIVALPROEX SODIUM EXTENDED-RELEASE TABLETS (DSD Mgh #826)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L11	MicroBondapak Phenyl	Dissolution	3.9 mm x 15 cm, 10 μm. Manufacturer: Waters Corp.

FELODIPINE EXTENDED-RELEASE TABLETS (DSD Mgh #32660)

PF	LGS#	Reagent Brand	Type of Test	Comments
0(0)	L1	Symmetry C-18	Dissolution	Test 3. 4.6 mm x 15 cm, 5 μm. Alternative column: Ace C18, same dimensions. Manufacturer: Waters Corp.
32(1)	L1	Hypersil BDS C-18	Dissolution	Test 2. 4.6 mm x 15 cm. Manufacturer: Thermo Scientific

FEXOFENADINE HYDROCHLORIDE AND PSEUDOEPHEDRINE HYDROCHLORIDE EXTENDED-RELEASE TABLETS (DSD Mgh #33077)

PF	LGS#	Reagent Brand	Type of Test	Comments
0(0)	L1	Partisil 10 ODS	Dissolution	Test 3. 4.6 mm x 25 cm, 10 μm. Manufacturer: Whatman Inc.
0(0)	L7	Hypersil BDS C-8	Dissolution	Test 2. 4.6 mm x 25 cm, 5 μm. Manufacturer: Thermo Scientific

FEXOFENADINE HYDROCHLORIDE TABLETS (DSD Mgh #852)

PF	LGS#	Reagent Brand	Type of Test	Comments
0(0)	L1	Spherisorb ODS-2	Dissolution	Test 3. 4.6 mm x 10 cm, 5 μm. Manufacturer: Waters Corp.

FLAVOXATE HYDROCHLORIDE (DSD Mgh #33185)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L1	Inertsil ODS	Organic Impurities	4.6 mm x 15 cm, 5 μm. Manufacturer: GL Sciences

GLIPIZIDE AND METFORMIN HYDROCHLORIDE TABLETS (DSD Mgh #847)

PF	LGS#	Reagent Brand	Type of Test	Comments
0(0)	L1	YMC 18 ODS-A	Dissolution	Test 2. 4.6 mm x 25 cm. Manufacturer: YMC Corp.

LEVETIRACETAM TABLETS (DSD Mgh #44660)

PF	LGS#	Reagent Brand	Type of Test	Comments
36(1)	L1	Nova-Pak C18	Assay and Organic Impurities	4.6 mm x 25 cm, 4 μm. Manufacturer: Waters Corp.
36(1)	L1	Inertsil ODS-3	Dissolution	4.6 mm x 15 cm, 5 μm. Manufacturer: GL Sciences

LEVOFLOXACIN (DSD Mgh #2861)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L1	Inertsil ODS-3	Assay and Organic Impurities	4.6 mm x 25 cm, 5 μm. Alternative column: Prodigy ODS(3) in the same dimensions, manufactured by Phenomenex. Manufacturer: GL Sciences

METOLAZONE TABLETS (DSD Mgh #53470)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L7	Symmetry C8	Dissolution	4.6 mm x 15 cm, 5 μm. Manufacturer: Waters Corp.

MONTELUKAST SODIUM (DSD Mgh #54774)

PF	LGS#	Reagent Brand	Type of Test	Comments
36(1)	L41	Chiral AGP	Enantiomeric Purity	4.0 mm x 15 cm, 5 μm. Manufacturer: Chrom Tech AB
36(1)	L11	ZORBAX SB Phenyl	Assay and Organic Impurities	4.6 mm x 5 cm, 1.8 μm. Manufacturer: Agilent Technologies

ORLISTAT (DSD Mgh #58790)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L7	Superspher 60 RP-Select B	Limit of	Limit of Orlistat Related Compound D. 4.0 mm x 25 cm, 5 μm. Manufacturer: Merck KGaA

OXACILLIN SODIUM (DSD Mgh #59030)

PF	LGS#	Reagent Brand	Type of Test	Comments
20(1)	L11	MicroBondapak Phenyl	Assay	4 mm x 30 cm Manufacturer: Waters Corp

OXYBUTYNIN CHLORIDE EXTENDED-RELEASE TABLETS (DSD Mgh #59502)

PF	LGS#	Reagent Brand	Type of Test	Comments
0(0)	L7	Symmetry C8	Dissolution	Test 4. 4.6 mm x 15 cm, 5 μm. Manufacturer: Waters Corp.
0(0)	L10	ZORBAX SB-CN	Dissolution	Test 3. 4.6 mm x 15 cm, 5 μm. Manufacturer: Agilent Technologies
33(4)	L7	Spherisorb C8	Dissolution	Test 2. 4.6 mm x 25 cm. Manufacturer: Waters Corp.

PILOCARPINE HYDROCHLORIDE (DSD Mgh #64990)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L11	Luna Phenyl-Hexyl	Assay and Organic Impurities	4.6 mm x 15 cm, 3 μm. Manufacturer: Phenomenex

RISEDRONATE SODIUM TABLETS (DSD Mgh #73736)

PF	LGS#	Reagent Brand	Type of Test	Comments
34(5)	L48	IonPac AG7	Dissolution	4.0 mm x 5 cm, 10 μm. Manufacturer: Dionex

RIVASTIGMINE TARTRATE (DSD Mgh #73772)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L41	Chiral AGP	Enantiomeric Purity	4.0 mm x 10 cm. Manufacturer: Chrom Tech AB

RIZATRIPTAN BENZOATE (DSD Mgh #73775)

PF	LGS#	Reagent Brand	Type of Test	Comments
36(1)	L11	ZORBAX SB Phenyl	Assay and Organic Impurities	4.6 mm x 25 cm, 5 μm. Manufacturer: Agilent Technologies

TERBINAFINE HYDROCHLORIDE (DSD Mgh #80845)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L1	Inertsil ODS-2	Assay	3.0 mm x 15 cm, 5 μm. Manufacturer: GL Sciences

TERBINAFINE TABLETS (DSD Mgh #2860)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L1	XTerra RP 18	Assay and Organic Impurities	Procedure 2. 4.6 mm x 15 cm, 5 μm. Manufacturer: Waters Corp.
36(1)	L7	Symmetry C8	Assay and Organic Impurities	Procedure 1. 3.9 mm x 15 cm, 5 μm. Manufacturer: Waters Corp.

TOBRAMYCIN INHALATION SOLUTION (DSD Mgh #83766)

PF	LGS#	Reagent Brand	Type of Test	Comments
0(0)	L11	Spherisorb P(Phenyl)	Assay and Related Compounds	4.6 mm x 25 cm, 5 μm. Manufacturer: Waters Corp.

TRICLOSAN (DSD Mgh #85150)

PF	LGS#	Reagent Brand	Type of Test	Comments
22(3)	G3	DB-17	Assay and Related Compounds	0.53 mm x 15 cm, 1 μm. Alternative column: AT-50 Manufacturer: J & W Scientific

VENLAFAXINE HYDROCHLORIDE (DSD Mgh #88080)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L7	Inertsil C8	Organic Impurities	4.6 mm x 25 cm, 5 μm. Manufacturer: GL Sciences
35(6)	L7	Kromasil C8	Assay	4.6 mm x 25 cm, 5 μm. Manufacturer: Eka Nobel

VENLAFAXINE TABLETS (DSD Mgh #88083)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(6)	L7	Inertsil C8-3	Organic Impurities	4.6 mm x 25 cm, 5 μm. Manufacturer: GL Sciences
35(6)	L1	ACE C18	Assay	4.6 mm x 25 cm, 5 μm. Manufacturer: Advanced Chrom. Technol.

ZIDOVUDINE ORAL SOLUTION (DSD Mgh #89518)

PF	LGS#	Reagent Brand	Type of Test	Comments
35(5)	L1	Hypersil BDS C-18	Organic Impurities	4.6 mm x 10 cm, 3 μm. Manufacturer: Thermo Scientific
