BRIEFING

Metronidazole Gel, USP 38 page 4384 and PF 40(4) [July–Aug. 2014]. Based on comments received on the PF 40(4) proposal, those revisions are canceled. It is proposed to modernize the monograph with the following changes:

1. Add a validated stability-indicating HPLC procedure for the test for *Organic Impurities*. This procedure uses the Inertsil C8 brand of L7 packing column manufactured by GL Sciences. The typical retention time for metronidazole is about 5.6 min.
2. Replace the *Assay* by HPLC with a new HPLC procedure that uses the same HPLC parameters in the proposed test for *Organic Impurities*.
3. Replace *Identification* test A by TLC with the UV spectrum matching in the proposed *Assay*.
4. Introduce USP Tinidazole Related Compound A RS for system suitability and quantitation in the *Assay* and the test for *Organic Impurities*.

Additionally, minor editorial changes have been made to update the monograph to current USP style.

BRIEFING

Miconazole Nitrate, USP 38 page 4394. As part of the monograph modernization effort, it is proposed to make the following changes:

1. Replace the existing isocratic HPLC *Organic Impurities* test with an HPLC procedure containing a gradient elution for separation of more specified impurities. The HPLC procedure in the test for *Organic Impurities* is based on analyses performed with the Phenomenex Kinetex Phenyl-Hexyl brand of L11 column. The typical retention time for the miconazole peak in the *Organic Impurities* test is 25 min.
2. Replace the titration *Assay* with an HPLC procedure similar to that proposed in the test for *Organic Impurities*.
3. Replace the UV-based *Identification* test *B* with retention time agreement in the proposed HPLC *Assay* method.
4. Update the *USP Reference Standards* section with new Reference Standards to support the test for *Organic Impurities*.

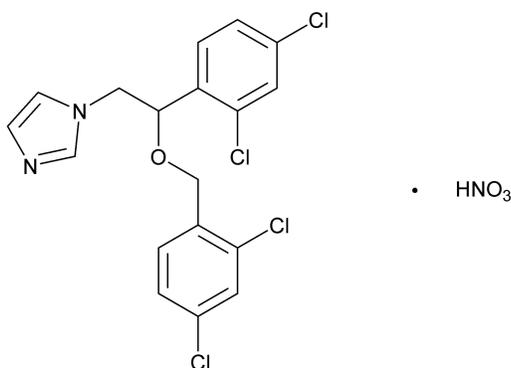

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

BRIEFING

Octreotide Acetate, PF 36(6) [Nov.–Dec. 2010]. On the basis of comments received, the following revisions are proposed:

1. *Identification* test A is deleted, and the test by HPLC retention time agreement is moved from *Identification* test B to *Identification* test A. The *Analysis* is revised to add an *Identification sample solution* and the requirement of sample and Standard peak coelution.
2. The test for *Amino Acid Analysis* is moved from *Specific Tests* to *Identification* test B. The *Acceptance criteria* for *Trp* is revised and the requirement for total peptide content is removed.
3. The liquid chromatographic procedure in the *Assay* and *Octreotide Acetate Related Compounds* is revised by modifying the gradient and adding the injection repeatability requirement. The note for the *Standard solution* is deleted. The test procedure is based on analyses performed with the Phenomenex Synergi Max–RP C12 brand of L87 column. The particle size of the column is added. The typical retention time for the octreotide peak is about 16.5 min.
4. The test procedure for *Trifluoroacetic Acid (TFA)* is revised to use *Trifluoroacetic Acid (TFA) in Peptides* 〈 503.1 〉. A note is added to indicate the test is only required if trifluoroacetic acid is used in the manufacturing process.
5. The gas chromatographic procedure in the *Limit of Triethylamine* is deleted because triethylamine is tested by the manufacturer as in-process control and is not tested on the finished goods.
6. The requirements for *pH* and *Optical Rotation* in the *Specific Tests* section are deleted; the rest of the monograph tests are sufficient.
7. The *Microbial Enumeration Tests* and *Tests for Specified Microorganisms* are added to the *Specific Tests* section.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

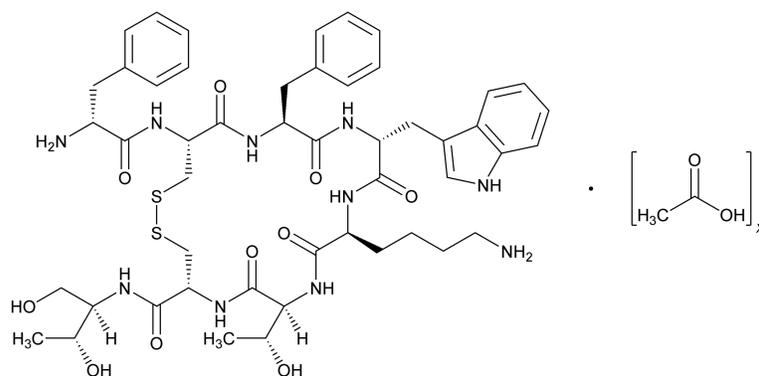

(BIO1: C. Li.)

Correspondence Number—C153058

Comment deadline: September 30, 2015

Add the following:

L-Cysteinamide, d-phenylalanyl-L-cysteinyl-L-phenylalanyl-d-tryptophyl-L-lysyl-L-threonyl-N-[2-hydroxy-1-(hydroxymethyl)propyl]-, cyclic (2→7)-disulfide, [R-(R*,R*)]-, acetate (salt); d-Phenylalanyl-L-cysteinyl-L-phenylalanyl-d-tryptophyl-L-lysyl-L-threonyl-N-[(1R,2R)-2-hydroxy-1-(hydroxymethyl)propyl]-L-cysteinamide cyclic (2→7)-disulfide acetate (salt); d-Phenylalanyl-L-hemicystyl-L-phenylalanyl-d-tryptophyl-L-lysyl-L-threonyl-L-hemicystyl-L-threoninol cyclic (2→7)-disulfide acetate (salt) [79517-01-4].

DEFINITION

Octreotide Acetate is a long-acting synthetic octapeptide with pharmacologic properties mimicking those of the natural hormone somatostatin. It contains NLT 95.0% and NMT 105.0% of octreotide ($C_{49}H_{66}N_{10}O_{10}S_2$), calculated on the anhydrous, acetic acid-free basis.

~~[Note—The following method is given for informational purposes; any validated amino acid analysis method can be used. See *Biotechnology-Derived Articles—Amino Acid Analysis* 1052.]~~

■ 2S (USP39)

Diluent: 0.1 M hydrochloric acid

Standard amino acid mixture: 2500 nmol/mL of *Lys, His, NH₃, Arg, Asp, Thr, Ser, Glu, Pro, Gly, Ala, Val, Met, Ile, Leu, Tyr, Phe*, and 1250 nmol/mL of *Cys-Cys* in *Diluent*

Standard tryptophan solution: 0.2042 mg/mL of tryptophan in *Diluent*. This solution contains 1000 nmol/mL of *Trp*.

Standard threonin-ol solution: 0.1052 mg/mL of *Thr-ol* in *Diluent*. This solution contains 1000 nmol/mL *Thr-ol*. [Note—1000 nmol/mL = 1 mM]

Standard solution: *Diluent, Standard amino acid mixture, Standard tryptophan solution, and Standard threonin-ol solution* (76:4:10:10). The concentration is 100.0 nmol/mL for each amino acid.

Sample solution A: Weigh 1.00–1.50 mg of Octreotide Acetate into a 5-mL ampule. Add 1000 μ L of *Diluent* and 1.2 mL of 30% (w/w) hydrochloric acid, cool the ampule in dry ice, evacuate, and seal by melting. Heat the ampule for 16 h at 115°. Allow to cool and transfer the contents of the ampule quantitatively into a 25-mL round-bottomed flask, rinse with *Diluent*, and evaporate to dryness on a rotary evaporator. Dissolve the residue in 10.00 mL of *Diluent*.

Sample solution B: Weigh 1.00–1.50 mg of Octreotide Acetate into a 5-mL ampule. Add 1000 μ L of *Diluent* and 1.2 mL of 30% (w/w) hydrochloric acid with 1% (v/v) thioglycolic acid, cool the ampule in dry ice, evacuate, and seal by melting. Heat the ampule for 16 h in a heating block at 115°. Allow to cool and transfer the contents of the ampule quantitatively into a 25-mL round-bottomed flask, rinse with *Diluent*, and evaporate to dryness on a rotary evaporator. Dissolve the residue in 10.00 mL of *Diluent*.

Analysis

Samples: *Standard solution, Sample solution A, and Sample solution B*

Standardize the instrument with the *Standard solution*. Inject a suitable volume of *Standard solution, Sample solution A, and Sample solution B*. Evaluate the peak areas of each amino acid found in relation to the peak areas of the respective amino acids in the *Standard solution*, express the content of each amino acid in nmoles.

Calculate A , the average number of nmoles of the amino acids found to be stable under hydrolysis conditions (three stable amino acids—2 *Phe* and 1 *Lys*) taken:

$$A = N_T/3$$

N_T total nmoles of the stable amino acids

Calculate the ratio of the amino acids taken:

$$\text{Result} = N_E/A$$

$N_{\bar{E}}$ nmoles of each amino acid

[Note—For *Trp* use only data obtained with *Sample solution B*. For *Cys* use only data obtained with *Sample solution A*.]

Acceptance criteria: See *Table 1*.

Oxymorphone Hydrochloride Injection

DEFINITION

Oxymorphone Hydrochloride Injection is a sterile solution of Oxymorphone Hydrochloride in Water for Injection. It contains NLT 93.0% and NMT 107.0% of the labeled amount of oxymorphone hydrochloride ($C_{17}H_{19}NO_4 \cdot HCl$).

IDENTIFICATION

Delete the following:

- ● ~~A. The *Sample solution* and *Standard solution* as directed in the *Assay* exhibit maxima and minima at the same wavelengths. ■2S (*USP39*)~~

Add the following:

- ● A. The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ■2S (*USP39*)

Add the following:

- ● B. The UV absorption spectra of the major peak of the *Sample solution* and that of the *Standard solution* exhibit maxima and minima at the same wavelengths, as obtained in the *Assay*. ■2S (*USP39*)

ASSAY**Change to read:**● **Procedure**

Standard stock solution: 0.9 mg/mL of USP Oxymorphone RS in chloroform

Standard solution: 135 µg/mL of USP Oxymorphone RS in chloroform from the *Standard stock solution*

Sample solution: Transfer a volume of Injection nominally equivalent to about 15 mg of oxymorphone hydrochloride to a 125-mL separator, and add water, if necessary, to bring the volume to 15 mL. Adjust with hydrochloric acid to a pH of less than 2, extract with five 15-mL portions of chloroform, and discard the chloroform extracts. Adjust the aqueous phase with ammonium hydroxide to a pH of 9.5, and extract with four 20-mL portions of chloroform. Filter the chloroform extracts through a chloroform-moistened pledget of cotton into a 100-mL volumetric flask, dilute with chloroform to volume, and mix.

Instrumental conditions-

Analytical wavelength: Maximum absorbance at about 282 nm

Cell: 1 cm

Blank: Chloroform

Analysis-

Samples: *Standard solution, Sample solution, and Blank*

Concomitantly determine the absorbances of the solutions.

Calculate the percentage of the labeled amount of oxymorphone hydrochloride ($C_{17}H_{19}NO_4 \cdot HCl$) in the portion of Injection taken:

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

A_U = absorbance of the *Sample solution*

A_S = absorbance of the *Standard solution*

C_S = concentration of USP Oxymorphone RS in the *Standard solution* (µg/mL)

C_U = nominal concentration of oxymorphone hydrochloride in the *Sample solution* (µg/mL)

M_{r1} = molecular weight of oxymorphone hydrochloride, 337.80

M_{r2} = molecular weight of oxymorphone, 301.34

- Protect all solutions containing oxymorphone from light and use clear glass HPLC vials.

Solution A: Dissolve 2.02 g of sodium 1-heptanesulfonate in 900 mL of water. Add 100 mL of acetonitrile. Adjust with phosphoric acid to a pH of 2.1.

Solution B: Dissolve 2.02 g of sodium 1-heptanesulfonate in 750 mL of water. Add 250 mL of acetonitrile. Adjust with phosphoric acid to a pH of 2.1.

Mobile phase: See *Table 1*.

■ **Oxymorphone Hydrochloride Suppositories**

DEFINITION

~~Oxymorphone Hydrochloride Suppositories contain NLT 93.0% and NMT 107.0% of the labeled amount of oxymorphone hydrochloride (C₁₇H₁₉NO₄·HCl).~~

IDENTIFICATION

● **A:**

~~**Standard solution:** Similarly prepared as directed for the *Sample solution* by using USP Oxymorphone RS~~

~~**Sample solution:** Place a number of Suppositories, nominally equivalent to 5 mg of oxymorphone hydrochloride, in a 125-mL separator. Add 25 mL of 0.1 N hydrochloric acid, and shake without heating until the specimen is dissolved. Wash the solution with five 25-mL portions of chloroform, shaking the separator gently to avoid forming emulsions, and discard the chloroform washings. Adjust with 6 N ammonium hydroxide to a pH of 9.5, using short-range pH indicator paper, and extract with three 25-mL portions of chloroform, filtering the extracts through chloroform-moistened glass wool into a 200-mL round-bottom flask. Evaporate the combined extracts to dryness, using a rotary evaporator. Add 25 mL of 0.1 N hydrochloric acid, insert the stopper, and swirl to dissolve the residue.~~

~~**Acceptance criteria:** The UV absorption spectrum of the *Sample solution* exhibits maxima and minima at the same wavelengths as those of the *Standard solution*, concomitantly measured.~~

ASSAY● **Procedure**

Mobile phase: 0.05 M sodium borate adjusted to a pH of 9.1

Internal standard solution: 3 mg/mL of procaine hydrochloride in 0.01 N hydrochloric acid

Standard stock solution: 4.5 mg/mL of USP Oxymorphone RS in 0.01 N hydrochloric acid. Sonicate, if necessary, to effect solution.

Standard solution: 1.8 mg/mL of USP Oxymorphone RS prepared as follows. Transfer 10.0 mL of *Standard stock solution*, 10.0 mL of the *Internal Standard solution*, and 5.0 mL of 0.01 N hydrochloric acid to a 125 mL separator. Extract with four 25 mL portions of chloroform, discarding the chloroform layer each time. Transfer the aqueous layer to a suitable flask, and bubble filtered air through the solution for 10 min to remove final traces of chloroform.

Sample solution: Transfer a number of Suppositories nominally equivalent to about 50 mg of oxymorphone hydrochloride to a 125 mL separator. Add 15.0 mL of 0.01 N hydrochloric acid, 10.0 mL of *Internal Standard solution*, and 25 mL of chloroform. Shake until the Suppositories dissolve. Discard the chloroform layer. Extract the aqueous layer with three 25 mL portions of chloroform, discarding the chloroform each time. Transfer the aqueous layer to a suitable flask, and bubble filtered air through the solution for 10 min to remove final traces of chloroform.

BRIEFING

Oxymorphone Hydrochloride Tablets. Because there is no existing *USP* monograph for this drug product, a new monograph, based on validated test methods, is proposed.

1. The stability-indicating liquid chromatographic procedures in the *Assay* and the test for *Organic Impurities* are based on analyses performed with the Zorbax Eclipse XDB C18 brand of L1 column. The typical retention time for oxymorphone is about 8.3 min in the *Assay* and the test for *Organic Impurities*.
2. The liquid chromatographic procedure in the *Dissolution* test is based on analyses also performed with the Zorbax Eclipse XDB C18 brand of L1 column. The typical retention time for oxymorphone is about 1.5 min.

(SM2: H. Cai.)

Correspondence Number—C127216

Add the following:

■ Oxymorphone Hydrochloride Tablets

DEFINITION

Oxymorphone Hydrochloride Tablets contain NLT 90.0% and NMT 110.0% of the labeled amount of oxymorphone hydrochloride ($C_{17}H_{19}NO_4 \cdot HCl$).

IDENTIFICATION

- **A.** The retention time of the oxymorphone peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.
- **B.** The UV absorption spectra of the oxymorphone peak of the *Sample solution* and that of the *Standard solution* exhibit maxima and minima at the same wavelengths, as obtained in the *Assay*.

ASSAY

● Procedure

Protect all solutions containing oxymorphone from light and to use clear glass HPLC vials.

Solution A: Dissolve 2.02 g of sodium 1-heptanesulfonate in 900 mL of water and add 100 mL of acetonitrile. Adjust with phosphoric acid to a pH of 2.1.

Solution B: Dissolve 2.02 g of sodium 1-heptanesulfonate in 750 mL of water and add 250

mL of acetonitrile. Adjust with phosphoric acid to a pH of 2.1.

Mobile phase: See *Table 1*.

Table 1

Time (min)	Solution A (%)	Solution B (%)
0	100	0
3	100	0
35	0	100
40	0	100
40.1	100	0
50.1	100	0

Standard solution: 0.14 mg/mL of USP Oxymorphone RS in *Solution A*. Sonicate to dissolve if necessary.

Sample solution: Nominally 0.16 mg/mL of oxymorphone hydrochloride in *Solution A* prepared as follows. Transfer NLT 8 Tablets to a suitable volumetric flask and add about 50% of the final volume of *Solution A*. Sonicate for at least 15 min with occasional vigorous shaking until the Tablets disintegrate completely. Then shake for at least 20 min. Immediately dilute with *Solution A* to volume, and mix well. Immediately pass the solution through a suitable filter of 0.45- μ m pore size, discard the first 5 mL of the filtrate, and use the filtrate for analysis.

Chromatographic system

(See *Chromatography* { 621 }, *System Suitability*.)

Mode: LC

Detector

Assay: UV 230 nm

Identification test B: Diode array UV 200–360 nm

Column: 4.6-mm \times 7.5-cm; 3.5- μ m packing L1

Column temperature: 40 $^{\circ}$

Flow rate: 1.0 mL/min

Injection volume: 30 μ L

System suitability

Sample: *Standard solution*

Suitability requirements

Tailing factor: NMT 2.0

Relative standard deviation: NMT 2.0%

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of oxymorphone hydrochloride ($C_{17}H_{19}NO_4 \cdot HCl$) in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

r_U = peak response of oxymorphone from the *Sample solution*

r_S = peak response of oxymorphone from the *Standard solution*

C_S = concentration of USP Oxymorphone RS in the *Standard solution* (mg/mL)

C_U = nominal concentration of oxymorphone hydrochloride in the *Sample solution* (mg/mL)

M_{r1} = molecular weight of oxymorphone hydrochloride, 337.80

M_{r2} = molecular weight of oxymorphone, 301.34

Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS

• Dissolution 〈 711 〉

Medium: 0.1 N hydrochloric acid; 900 mL

Apparatus 2: 50 rpm

Time: 30 min

Mobile phase: Dissolve 2.02 g of sodium 1-heptanesulfonate in 800 mL of water and add 200 mL of acetonitrile. Adjust with phosphoric acid to a pH of 2.1.

Standard stock solution: 0.1 mg/mL of USP Oxymorphone RS in 0.1 N hydrochloric acid

Standard solution: ($L/1000$) mg/mL of USP Oxymorphone RS in water from the *Standard stock solution*, where L is the label claim in mg/Tablet

Sample solution: Pass a portion of the solution under test through a suitable filter of 0.45- μ m pore size.

Chromatographic system

(See *Chromatography* 〈 621 〉, *System Suitability*.)

g 2,2'-Bioxymorphone.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in tight containers. Store at 25°, excursions permitted between 15° and 30°.
- **USP Reference Standards** 〈 11 〉
USP Oxymorphone RS
- 2S (USP39)

BRIEFING

Polyethylene Glycol 3350, PF 39(6) [Nov.–Dec. 2013]. A new monograph proposal was presented in PF 39(6). The procedure in the *Assay* is based on a size exclusion chromatographic (SEC) method of analysis performed using the Waters Ultrahydrogel DP brand of L25 column. The procedure in the test for *Limit of Ethylene Glycol and Diethylene Glycol* is based on an HPLC method of analysis using the Tosoh Bioscience Tskgel G-Oligo-PW aqueous brand of L89 column. The procedure in the test for *Limit of Formaldehyde and Acetaldehyde* is based on an HPLC method of analysis using the Agilent Zorbax Eclipse XDB C8 brand of L7 column.

On the basis of comments and data received, it is proposed to make the following revisions to the proposal in PF 39(6):

1. In *Identification* test A, add *Infrared Absorption* 〈 197A 〉 as an alternative procedure.
2. In the *Assay*, change the *Mobile phase* from water to 50 μ g/mL of sodium azide in water, and modify the column temperature to match the detector temperature of 35°.
3. The implementation date for the deletion of *Heavy Metals* 〈 231 〉 will be updated to January 1, 2018, with the rest of the references to this chapter in USP 39.
4. In the test for *Limit of Formaldehyde and Acetaldehyde*, change the *Acceptance criteria* for formaldehyde from NMT 30 μ g/g to NMT 15 μ g/g.
5. Replace the procedure for *Apparent Weight-Average Molecular Weight and Polydispersity* with a specific test procedure that is based on an SEC method of analysis using the Ultrahydrogel 250 brand of L37 column. The retention time for polyethylene glycol 3350 is about 10 min.
6. Add a specification for *Hydroxyl Value*.

Additionally, minor editorial changes have been made to update the monograph to current USP style.

(EXC: H. Wang.)

Correspondence Number—C142682; C142763; C142772; C144465

Comment deadline: September 30, 2015

Add the following:**■ Polyethylene Glycol 3350**

Poly(oxy-1,2-ethanediyl), α -hydro- ω -hydroxy-;
1,2-Ethanediol, homopolymer [25322-68-3].

DEFINITION

Polyethylene Glycol is an addition polymer of ethylene oxide and water, represented by the formula $H(OCH_2CH_2)_nOH$, in which n represents the average number of oxyethylene groups. The apparent weight-average molecular weight is 3015–3685 g/mol (Da). It contains NLT 97.0% and NMT 103.0% of polyethylene glycol 3350, calculated on the anhydrous basis. It may contain a suitable antioxidant.

■ Mobile phase:

Water

Standard solution: 1.0 mg/mL each of five polyethylene glycol standards with molecular weights of 1000, 2000, 3000, 4000, and 6000 g/mol (Da) in *Mobile phase*. Pass a portion of the solution through a 0.45- μ m PTFE (polytetrafluoroethylene) syringe filter.³ Discard the first 2 mL, and transfer the solution for analysis.

Sample solution: 1.0 mg/mL of Polyethylene Glycol 3350 in *Mobile phase*. Pass a portion of the solution through a 0.45- μ m PTFE (polytetrafluoroethylene) syringe filter.³ Discard the first 2 mL, and transfer the solution for analysis.

Chromatographic system

(See *Chromatography* { 621 }, *System Suitability*.)

Mode: LC

Detector: Differential refractive index

Column: 7.8-mm \times 30-cm; 6- μ m packing L37

Temperatures

Detector: 35 \pm 1 $^\circ$

Column: 35 \pm 1 $^\circ$

Flow rate: 0.8 mL/min

Injection volume: 10 μ L

Run time: 18 min

Analysis

Samples: *Standard solution* and *Sample solution*

Separately inject equal volumes of the *Standard solution* and the *Sample solution* into the chromatograph, record the chromatograms, and determine the elution peak maxima and the corresponding retention times for the five polyethylene glycol standards.

Calibration curve: Plot the retention times on the x-axis against the log M_p (M_p : peak molecular weights) on the y-axis for the peaks from the polyethylene glycol standard to generate a calibration curve using suitable gel permeation chromatography or size exclusion chromatography (GPC/SEC) software.

Calculations: Compute the data using the same GPC/SEC software, and determine the number- and weight-average molecular weights, M_N and M_W , in g/mol (Da), respectively, for the chromatogram of the *Sample solution*.

Calculate the polydispersity for Polyethylene Glycol 3350:

$$\text{Result} = M_W/M_N$$

$M_{\overline{w}}$ weight-average molecular weight from the *Sample solution* (g/mol)

$M_{\overline{n}}$ number-average molecular weight from the *Sample solution* (g/mol)

■ 2S (USP39)

Acceptance criteria: The value of apparent weight-average molecular weight is 3015–3685 g/mol. Polydispersity is 90%–110% of the value stated on the label or within the range indicated on the label.

Add the following:

● **Hydroxyl Value**

Phthalic anhydride solution: Place 49.0 g of phthalic anhydride into an amber bottle, and dissolve in 300 mL of pyridine from a freshly opened bottle or pyridine that has been freshly distilled over phthalic anhydride. Shake vigorously until completely dissolved. Add 7 g of imidazole, swirl carefully to dissolve, and allow to stand for 16 h before using.

Sample solution: Carefully introduce 25.0 mL of *Phthalic anhydride solution* into a dry, heat-resistant pressure bottle. Add 12.0 g of Polyethylene Glycol 3350. Add 25 mL of pyridine, from a freshly opened bottle or pyridine that has been freshly distilled over phthalic anhydride. Swirl to dissolve, insert the stopper in the bottle, and wrap it securely in a cloth bag.

Blank: 25.0 mL of *Phthalic anhydride solution* plus any additional pyridine added to the bottle

Analysis: Immerse the bottle in a water bath maintained at a temperature between 96° and 100°, to the same depth as that of the mixture in the bottle. Remove the bottles from the bath after 5 min and, without unwrapping, swirl for 30 s to homogenize. Heat in the water bath for 60 min, then remove from the bath, and allow it to cool to room temperature. Uncap the bottle carefully to release any pressure, remove from the bag, add 10 mL of water, and swirl thoroughly. Wait 2 min, add 0.5 mL of a solution of phenolphthalein in pyridine (1 in 100), and titrate with 0.5 N sodium hydroxide VS to the first pink color that persists for 15 s. Perform a blank determination. Calculate the hydroxyl value:

$$\text{Result} = [M_r \times (V_B - V_S) \times N]/W$$

M_r molecular weight of potassium hydroxide, 56.11

V_B volume of 0.5 N sodium hydroxide consumed in the blank test (mL)

V_S volume of 0.5 N sodium hydroxide consumed in the actual test (mL)

N exact normality of the sodium hydroxide solution

W weight of Polyethylene Glycol 3350 taken for the test (g)

Acceptance criteria: 30–38 ■ 2S (USP39)

● **Acidity and Alkalinity**

Sample solution: Dissolve 5.0 g of Polyethylene Glycol 3350 in 100 mL of carbon dioxide-free water.

Analysis: Add 0.3 mL of a saturated solution of potassium chloride into the *Sample*

solution. The test solution should be maintained at $25 \pm 2^\circ$ during the measurement.

Measure the pH following *pH* 〈 791 〉.

Acceptance criteria: 4.5–7.5

● **Water Determination** 〈 921 〉, *Method I*

Sample: 2.0 g

Acceptance criteria: NMT 1.0%

Correspondence Number—C158124

Comment deadline: September 30, 2015

Potassium Chloride in Dextrose Injection

DEFINITION

Potassium Chloride in Dextrose Injection is a sterile solution of Potassium Chloride and Dextrose in Water for Injection. It contains NLT 95.0% and NMT 110.0% of the labeled amount of potassium chloride (KCl) and NLT 95.0% and NMT 105.0% of the labeled amount of dextrose ($C_6H_{12}O_6 \cdot H_2O$). It contains no antimicrobial agents.

IDENTIFICATION

• A.

Sample solution: Nominally 50 mg/mL of dextrose from a suitable volume of Injection in water

Analysis: Add a few drops of the *Sample solution* to 5 mL of hot alkaline cupric tartrate TS.

Acceptance criteria: A copious red precipitate of cuprous oxide is formed.

Delete the following:

- ~~• B. Identification Tests—General, Potassium (191): Meets the requirements of the Flame test ■ 2S (USP39)~~

Add the following:

- **B.** The sample imparts a violet color to a nonluminous flame. Since the presence of small quantities of sodium masks the color, screen out the yellow color produced by the sodium by viewing through a blue filter that blocks emission at 589 nm (sodium) but is transparent to emission at 404 nm (potassium). [Note—Traditionally, cobalt glass has been used, but other suitable filters are commercially available.] ■ 2S (USP39)

- **C. Identification Tests—General (191), Chloride:** Meets the requirements

ASSAY

• Dextrose

Sample solution: Nominally 20–50 mg/mL of dextrose from Injection prepared as follows.

Transfer a volume of Injection, containing 2–5 g of dextrose, to a 100-mL volumetric flask.

Add 0.2 mL of 6 N ammonium hydroxide and dilute with water to volume.

Analysis

Sample: *Sample solution*

Determine the angular rotation in a suitable polarimeter tube (see *Optical Rotation (781)*).

Calculate the percentage of the labeled amount of dextrose ($C_6H_{12}O_6 \cdot H_2O$) in the portion of Injection taken:

$$\text{Result} = [(100 \times a)/(l \times \alpha)] \times (1/C_U) \times (M_{r1}/M_{r2}) \times 100$$

a = observed angular rotation of the *Sample solution* ($^{\circ}$)

l = length of the polarimeter tube (dm)

α = midpoint of the specific rotation range for anhydrous dextrose, 52.9°

C_U = nominal concentration of dextrose in the *Sample solution* (g/100 mL)

$M_{\overline{r}}$ = molecular weight of dextrose monohydrate, 198.17

$M_{\overline{z}}$ = molecular weight of anhydrous dextrose, 180.16

Acceptance criteria: 95.0%–105.0%

Change to read:

● **Potassium Chloride**

Sample solution: Transfer a volume of Injection, equivalent to 75–150 mg of potassium chloride, to a conical flask. Add water, if necessary, to bring the volume to 10 mL, and add 10 mL of glacial acetic acid, 75 mL of methanol, and 3 drops of eosin Y TS.

Titrimetric system

Mode: Direct titration

Titrant: 0.1 N silver nitrate VS

Endpoint detection: Visual

Indicator: Eosin Y TS

Analysis

Sample: *Sample solution*

Titrate, with shaking, with *Titrant* to a pink endpoint.

Each mL of *Titrant* is equivalent to 7.455 mg of potassium chloride (KCl).

■ Calculate the percentage of the labeled amount of potassium chloride (KCl) in the portion of Injection taken:

$$\text{Result} = V \times N \times (F/W) \times 100$$

V

= *Titrant* volume consumed by the *Sample solution* (mL)

N

= actual normality of the *Titrant* (mEq/mL)

F

= equivalency factor, 74.55 mg/mEq

W

= nominal amount of potassium chloride in the *Sample solution* (mg)

■ 2S (USP39)

Acceptance criteria: 95.0%–110.0%

IMPURITIES

● **Limit of 5-Hydroxymethylfurfural and Related Substances**

Sample solution: Nominally 2.0 mg/mL of dextrose from Injection in water

Instrumental conditions

Mode: UV

Analytical wavelength: 284 nm

Cell: 1 cm

Blank: Water

Analysis

Samples: *Sample solution and Blank*

Determine the absorbance of the *Sample solution*.

Acceptance criteria: NMT 0.25

SPECIFIC TESTS

- **Bacterial Endotoxins Test** 〈 85 〉: NMT 0.5 USP Endotoxin Units/mL
- **pH** 〈 791 〉
Sample solution: Nominally 5% of dextrose from a portion of Injection in water
Acceptance criteria: 3.5–6.5
- **Other Requirements:** It meets the requirements under *Injections* 〈 1 〉.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in single-dose glass or plastic containers. Glass containers are preferably Type I or Type II.
- **Labeling:** The label states the total osmolar concentration in mOsmol/L. Where the contents are less than 100 mL, or where the label states that the Injection is not for direct injection but is to be diluted before use, the label alternatively may state the total osmolar concentration in mOsmol/mL. The content of potassium, in mEq, is prominently displayed on the label.
- **USP Reference Standards** 〈 11 〉
USP Endotoxin RS

BRIEFING

Potassium Chloride in Dextrose and Sodium Chloride Injection, *USP 38* page 4936. It is proposed to make the following revisions to the monograph.

1. In preparation for the omission of the flame tests from *Identification Tests—General* 〈 191 〉, proposed in *PF 41(2)* [Mar.–Apr. 2015], it is proposed to delete the reference to 〈 191 〉 under *Identification* test *A* and include a complete description of the flame test in the monograph. Manufacturers are encouraged to submit a replacement wet chemistry or an instrumental procedure for consideration by the Expert Committee.
2. An equation is added to calculate the percentage of the labeled amount of chloride in the *Assay* for *Chloride*.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Potassium Chloride in Dextrose and Sodium Chloride Injection

DEFINITION

Potassium Chloride in Dextrose and Sodium Chloride Injection is a sterile solution of Potassium Chloride, Dextrose, and Sodium Chloride in Water for Injection. It contains NLT 95.0% and NMT 110.0% of the labeled amounts of potassium (K) and chloride (Cl) and NLT 95.0% and NMT 105.0% of the labeled amounts of dextrose ($C_6H_{12}O_6 \cdot H_2O$) and sodium (Na). It contains no antimicrobial agents.

IDENTIFICATION

Delete the following:

- ~~A. Identification Tests—General, Sodium (191): Meets the requirements of the flame test. ■ 2S (USP39)~~

Add the following:

- A. The sample imparts an intense yellow color to a nonluminous flame. ■ 2S (USP39)
- B.
Analysis: To 2 mL of Injection, add 5 mL of sodium cobaltinitrite TS.
Acceptance criteria: A yellow precipitate is formed immediately. If necessary, centrifuge the solution and examine the precipitate (presence of potassium).
- C. Identification Tests—General (191), Chloride: Meets the requirements
- D.
Sample solution: Nominally 50 mg/mL of dextrose from a suitable volume of Injection in water
Analysis: Add a few drops of the *Sample solution* to 5 mL of hot alkaline cupric tartrate TS.
Acceptance criteria: A copious red precipitate of cuprous oxide is formed.

ASSAY

Change to read:

- Chloride
Sample solution: Transfer a volume of Injection, equivalent to 55 mg of chloride, to a suitable conical flask. Add 10 mL of glacial acetic acid, 75 mL of methanol, and 3 drops of eosin Y TS.
Titrimetric system
Mode: Direct titration
Titrant: 0.1 N silver nitrate VS
Endpoint detection: Visual
Analysis
Sample: *Sample solution*

Titrate, with shaking, with *Titrant* to a pink endpoint. Each mL of *Titrant* is equivalent to

3.545 mg of chloride (Cl). Each mg of chloride is equivalent to 0.0282 mEq of chloride (Cl).

- Calculate the percentage of the labeled amount of chloride (Cl) in the portion of Injection taken:

$$\text{Result} = V \times N \times (F/W) \times 100$$

V

= *Titrant* volume consumed by the *Sample solution* (mL)

N

= actual normality of the *Titrant* (mEq/mL)

F

= equivalency factor, 35.45 mg/mEq

W

= nominal amount of chloride in the *Sample solution* (mg)

- 2S (USP39)

Acceptance criteria: 95.0%–110.0%

- **Dextrose**

Sample solution: Nominally 20–50 mg/mL of dextrose from Injection prepared as follows.

Transfer a volume of Injection, containing 2–5 g of dextrose, to a 100-mL volumetric flask. Add 0.2 mL of 6 N ammonium hydroxide and dilute with water to volume.

Analysis

Sample: *Sample solution*

Determine the angular rotation in a suitable polarimeter tube (see *Optical Rotation* 〈 781 〉).

Calculate the percentage of the labeled amount of dextrose (C₆H₁₂O₆·H₂O) in the portion of Injection taken:

$$\text{Result} = [(100 \times a)/(l \times \alpha)] \times (1/C_U) \times (M_{r1}/M_{r2}) \times 100$$

a = observed angular rotation of the *Sample solution* (°)

l = length of the polarimeter tube (dm)

α = midpoint of the specific rotation range for anhydrous dextrose, 52.9°

C_U = nominal concentration of dextrose in the *Sample solution* (g/100 mL)

M_{r1} = molecular weight of dextrose monohydrate, 198.17

M_{r2} = molecular weight of anhydrous dextrose, 180.16

Acceptance criteria: 95.0%–105.0%

Change to read:

- **Potassium and Sodium**

Internal standard solution: 1.04 mg/mL of lithium nitrate in water prepared as follows.

Transfer 1.04 g of lithium nitrate to a 1000-mL volumetric flask, add a suitable nonionic

surfactant, and dilute with water to volume.

Potassium stock solution: 74.56 mg/mL of potassium chloride (equivalent to 1 mEq/mL of potassium) prepared as follows. Transfer 18.64 g of potassium chloride, previously dried at 105° for 2 h, to a 250-mL volumetric flask. Dilute with water to volume.

Sodium stock solution: 58.44 mg/mL of sodium chloride

■(equivalent to 1 mEq/mL of sodium) ■2S (USP39)

prepared as follows. Transfer 14.61 g of sodium chloride, previously dried at 105° for 2 h, to a 250-mL volumetric flask. Dilute with water to volume.

Standard stock solution: 0.0391J mg/mL of potassium (K) from the *Potassium stock solution* and 0.02299J' mg/mL of sodium (Na) from the *Sodium stock solution* prepared as follows. Transfer 0.1J mL of the *Potassium stock solution* and 0.1J' mL of the *Sodium stock solution* to a 100-mL volumetric flask, where J and J' are the labeled amounts in (mEq/L) of potassium and sodium, respectively, in the Injection. Dilute with water to volume.

Standard solution: Transfer 5.0 mL of the *Standard stock solution* to a 500-mL volumetric flask, and dilute with the *Internal standard solution* to volume.

Sample solution: Transfer 5.0 mL of Injection to a 500-mL volumetric flask, and dilute with the *Internal standard solution* to volume.

Instrumental conditions

Mode: Flame photometer

Analytical wavelengths

Potassium: 766 nm

Sodium: 589 nm

Lithium: 671 nm

Blank: *Internal standard solution*

Analysis

Samples: *Standard solution*, *Sample solution*, and *Blank*

Use the *Blank* to zero the instrument. Concomitantly determine the flame emission readings for the *Standard solution* and the *Sample solution*.

Calculate the percentage of the labeled amount of potassium (K) in the portion of Injection taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_{\bar{U}}$ emission reading ratio of potassium to lithium from the *Sample solution*

$R_{\bar{S}}$ emission reading ratio of potassium to lithium from the *Standard solution*

$C_{\bar{S}}$ concentration of potassium (K) in the *Standard stock solution* (mg/mL)

$C_{\bar{U}}$ nominal concentration of potassium (K) in the *Sample solution* (mg/mL)

[Note—Each mg of potassium is equivalent to 0.02558 mEq of potassium.]

Calculate the percentage of the labeled amount of sodium (Na) in the portion of Injection taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_{\bar{U}}$ emission reading ratio of sodium to lithium from the *Sample solution*

$R_{\bar{S}}$ emission reading ratio of sodium to lithium from the *Standard solution*

$C_{\bar{S}}$ concentration of sodium (Na) in the *Standard stock solution* (mg/mL)

$C_{\bar{c}}$ nominal concentration of sodium (Na) in the *Sample solution* (mg/mL)

[Note—Each mg of sodium is equivalent to 0.04350 mEq of sodium.]

Acceptance criteria

Potassium: 95.0%–110.0%

Sodium: 95.0%–105.0%

IMPURITIES

Delete the following:

•• Heavy Metals 〈 231 〉

Sample solution: Transfer a volume of Injection as determined by the calculation below to an appropriate vessel.

Calculate the volume of Injection to use to two significant figures:

$$\text{Result} = 0.2 / [(G_K L_K) + (G_D L_D) + (G_S L_S)]$$

G_K labeled amount of potassium chloride in each 100 mL of Injection (g)

L_K limit of heavy metals for potassium chloride, 0.001%

G_D labeled amount of dextrose in each 100 mL of Injection (g)

L_D limit of heavy metals for dextrose, 0.0005%

G_S labeled amount of sodium chloride in each 100 mL of Injection (g)

L_S limit of heavy metals for sodium chloride, 0.0005%

Adjust the volume by evaporation or addition of water to 25 mL, as necessary: it passes the test.

Acceptance criteria: Meets the requirements • (Official 1-Dec-2015)

• 5-Hydroxymethylfurfural and Related Substances

Sample solution: Nominally 2.0 mg/mL of dextrose from Injection in water

Instrumental conditions

Analytical wavelength: 284 nm

Cell: 1 cm

Blank: Water

Analysis

Samples: *Sample solution* and *Blank*

Acceptance criteria: NMT 0.25

SPECIFIC TESTS

- **Bacterial Endotoxins Test** 〈 85 〉: NMT 0.5 USP Endotoxin Units/mL
- **pH** 〈 791 〉: 3.5–6.5
- **Other Requirements:** It meets the requirements under *Injections* 〈 1 〉.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in single-dose glass or plastic containers. Glass

containers are preferably of Type I or Type II glass.

- **Labeling:** The label states the potassium, sodium, and chloride contents in terms of mEq in a given volume. The label also states the total osmolar concentration in mOsmol/L. Where the contents are less than 100 mL, the label alternatively may state the total osmolar concentration in mOsmol/mL.

BRIEFING

Potassium Chloride in Lactated Ringer's and Dextrose Injection, USP 38 page 4937. It is proposed to make the following revisions to the monograph:

1. In preparation for the omission of the flame tests from *Identification Tests—General* 〈 191 〉, proposed in PF 41(2) [Mar.–Apr. 2015], it is proposed to delete the references to *Sodium* and *Potassium* in 〈 191 〉 under *Identification* test *B*, and include a complete description of each flame test in the monograph. Manufacturers are encouraged to submit replacement wet chemistry or instrumental procedures for consideration by the Expert Committee.
2. Update the *Assay* procedure for *Calcium* by removing an unneeded reference to the equivalent amount of calcium in the *Sample solution*.
3. Add or revise equations in the *Assay* procedures for *Calcium*, for *Chloride*, for *Lactate*, for *Potassium Chloride*, and for *Sodium* to be consistent with the *Definition* section.

Additionally, minor editorial changes have been made to update the monograph to current USP style.

Potassium Chloride in Lactated Ringer's and Dextrose Injection

DEFINITION

Potassium Chloride in Lactated Ringer's and Dextrose Injection is a sterile solution of Calcium Chloride, Potassium Chloride, Sodium Chloride, and Sodium Lactate in Water for Injection. It contains, in each 100 mL, NLT 285.0 mg and NMT 315.0 mg of sodium [as sodium chloride (NaCl) and anhydrous sodium lactate (C₃H₅NaO₃)], NLT 4.90 mg and NMT 6.00 mg of calcium (Ca) [equivalent to NLT 18.0 mg and NMT 22.0 mg of calcium chloride (CaCl₂·2H₂O)], and NLT 231.0 mg and NMT 261.0 mg of lactate (C₃H₅O₃) [equivalent to NLT 290.0 mg and NMT 330.0 mg of anhydrous sodium lactate (C₃H₅NaO₃)]. It contains NLT 95.0% and NMT 105.0% of the labeled amount of potassium chloride (KCl), NLT 90.0% and NMT 105.0% of the labeled amount of dextrose (C₆H₁₂O₆·H₂O), and NLT 90.0% and NMT 110.0% of the labeled amount of chloride (Cl) [as sodium chloride (NaCl), potassium chloride (KCl), and calcium chloride (CaCl₂·2H₂O)]. It contains no antimicrobial agents.

IDENTIFICATION

- **A.**

Sample solution: Nominally 50 mg/mL of dextrose from a suitable volume of Injection in water

Analysis: Add a few drops of *Sample solution* to 5 mL of hot alkaline cupric tartrate TS.

Acceptance criteria: A copious red precipitate of cuprous oxide is formed.

Change to read:

- **B. Identification Tests—General** (191), ~~Sodium, (191) Potassium,~~

- **2S (USP39)**

Calcium and Chloride: Meets the requirements of the flame tests for ~~Sodium and Potassium,~~

- **2S (USP39)**

of the ammonium oxalate test for *Calcium* and the test for *Chloride*.

Add the following:

- **C. Sodium:** The sample imparts an intense yellow color to a nonluminous flame. ■ **2S (USP39)**

Add the following:

- **D. Potassium:** The sample imparts a violet color to a nonluminous flame. Because the presence of small quantities of sodium masks the color, screen out the yellow color produced by sodium by viewing through a blue filter that blocks the emission at 589 nm (sodium), but is transparent to emission at 404 nm (potassium). [Note—Traditionally, cobalt glass has been used, but other suitable filters are commercially available.]

- **2S (USP39)**

Change to read:

- **E.** ■ **2S (USP39)**

The retention time of the lactate peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay for Lactate*.

ASSAY

Change to read:

- **Calcium**

[Note—Concentrations of the *Standard solution* and the *Sample solution* may be modified to fit the linear or working range of the atomic absorption spectrophotometer.]

Lanthanum chloride solution: 88.45 g/L of *lanthanum chloride* prepared as follows.

Transfer a suitable quantity of lanthanum chloride to an appropriate volumetric flask. Add 50% of the final flask volume of water. Carefully add 25% of the final flask volume of hydrochloric acid. Mix, and allow to cool. Dilute with water to volume.

Calcium stock solution: 1 mg/mL of calcium (Ca) prepared as follows. Transfer 499.5 mg of primary standard calcium carbonate to a 200-mL volumetric flask, and add 10 mL of water. Carefully add 5 mL of *diluted hydrochloric acid*, and swirl to dissolve the calcium carbonate. Dilute with water to volume.

Standard solutions: 0.010, 0.015, and 0.020 mg/mL of calcium prepared as follows. To three separate 100-mL volumetric flasks, each containing 5.0 mL of *Lanthanum chloride solution*, add 1.0, 1.5, and 2.0 mL of *Calcium stock solution*, respectively. Dilute the contents of each flask with water to volume.

Sample solution: Transfer 30.0 mL of Injection (~~equivalent to about 1.6 mg of calcium~~)

■ ■ 2S (USP39)

to a 100-mL volumetric flask containing 5.0 mL of *Lanthanum chloride solution*. Dilute with water to volume.

Blank: Transfer 5.0 mL of *Lanthanum chloride solution* to a 100-mL volumetric flask and dilute with water to volume.

Instrumental conditions

(See *Atomic Absorption Spectroscopy* { 852 } .)

Mode: Atomic absorption spectrophotometry

Analytical wavelength: Calcium emission line at 422.7 nm

Lamp: Calcium hollow-cathode

Flame: Air-acetylene

Analysis

Samples: *Standard solutions*, *Sample solution*, and *Blank*

Plot the absorbances of the *Standard solutions* versus the concentration, in mg/mL, of calcium, and draw the straight line best fitting the three plotted points. From the graph so obtained, determine the concentration (*C*), in mg/mL, of calcium in the *Sample solution*.

Calculate the quantity (mg) of calcium (Ca) in each 100 mL of Injection taken:

$$\text{Result} = C/3$$

~~C = concentration of calcium in the *Sample solution*, as determined from the graph (mg/mL)~~

■

$$\text{Result} = C \times D \times F$$

C

= concentration of calcium in the *Sample solution*, as determined from the graph (mg/mL)

D

= dilution factor of the *Sample solution*, 3.3

F

= conversion factor for each 100 mL of Injection, 100 mL

■ 2S (USP39)

Acceptance criteria: 4.90–6.00 mg of calcium (Ca) in each 100 mL

Change to read:

● **Chloride**

Sample solution: Transfer 10 mL of Injection into a conical flask. Add 10 mL of glacial acetic acid, 75 mL of methanol, and 3 drops of eosin Y TS.

Titrimetric system

Mode: Direct titration

Titrant: 0.1 N silver nitrate VS

Endpoint detection: Visual

Analysis

Sample: *Sample solution*

Titrate, with shaking, with *Titrant* to a pink endpoint. ~~Each mL of 0.1 N silver nitrate is equivalent to 3.545 mg of chloride (Cl).~~

- Calculate the percentage of the labeled amount of chloride (Cl) in the portion of Injection taken:

$$\text{Result} = V \times N \times (F/W) \times 100$$

V

= volume of *Titrant* consumed by the *Sample solution* (mL)

N

= actual normality of the *Titrant* (mEq/mL)

F

= equivalency factor, 35.45 mg/mEq

W

= nominal amount of chloride in the *Sample solution* (mg)

- 2S (USP39)

Acceptance criteria: 90.0%–110.0%

- **Dextrose**

Sample solution: Transfer a volume of Injection containing 2–5 g of dextrose to a 100-mL volumetric flask. Add 0.2 mL of 6 N ammonium hydroxide, and dilute with water to volume.

Analysis

Sample: *Sample solution*

Determine the angular rotation in a suitable polarimeter tube (see *Optical Rotation* 〈 781 〉).

Calculate the percentage of the labeled amount of dextrose ($C_6H_{12}O_6 \cdot H_2O$) in the portion of Injection taken:

$$\text{Result} = [(100 \times a)/(l \times \alpha)] \times (1/C_U) \times (M_{r1}/M_{r2}) \times 100$$

a = observed angular rotation of the *Sample solution*, in degrees

l = length of the polarimeter tube, in decimeters

α = midpoint of the specific rotation range for anhydrous dextrose, 52.9°

C_U = nominal concentration of dextrose in the *Sample solution*, g/100 mL

M_{r1} = molecular weight of dextrose monohydrate, 198.17

M_{r2} = molecular weight of anhydrous dextrose, 180.16

Acceptance criteria: 90.0%–105.0%

Change to read:

Potassium Chloride in Sodium Chloride Injection**DEFINITION**

Potassium Chloride in Sodium Chloride Injection is a sterile solution of Potassium Chloride and Sodium Chloride in Water for Injection. It contains NLT 95.0% and NMT 110.0% of the labeled amounts of potassium (K) and chloride (Cl) and NLT 95.0% and NMT 105.0% of the labeled amount of sodium (Na). It contains no antimicrobial agents.

IDENTIFICATION**Delete the following:**

- ~~**A. Identification Tests—General, Sodium** { 191 }:~~ Meets the requirements of the flame test ■ 2S (*USP39*)

Add the following:

- **A. Sodium:** The sample imparts an intense yellow color to a nonluminous flame. ■ 2S (*USP39*)

- **B.**

Analysis: To 2 mL of Injection add 5 mL of sodium cobaltinitrite TS.

Acceptance criteria: A yellow precipitate is formed immediately. If necessary, centrifuge the solution and examine the precipitate (presence of potassium).

- **C. Identification Tests—General** (191), *Chloride*: Meets the requirements

ASSAY

Change to read:

- **Potassium and Sodium**

Internal standard solution: 1.04 mg/mL of lithium nitrate in water prepared as follows.

Transfer 1.04 g of lithium nitrate to a 1000-mL volumetric flask, add a suitable nonionic surfactant, and dilute with water to volume.

Potassium stock solution: 74.56 mg/mL of potassium chloride (equivalent to 1 mEq/mL of potassium) prepared as follows. Transfer 18.64 g of potassium chloride, previously dried at 105° for 2 h, to a 250-mL volumetric flask. Dilute with water to volume.

Sodium stock solution: 58.44 mg/mL of sodium chloride

■ (equivalent to 1 mEq/mL of sodium) ■ 2S (USP39)

prepared as follows. Transfer 14.61 g of sodium chloride, previously dried at 105° for 2 h, to a 250-mL volumetric flask. Dilute with water to volume.

Standard stock solution: 0.0391J mg/mL of potassium (K) from the *Potassium stock solution* and 0.02299J' mg/mL of sodium (Na) from the *Sodium stock solution* prepared as follows. Transfer 0.1J mL of *Potassium stock solution* and 0.1J' mL of *Sodium stock solution* to a 100-mL volumetric flask, where J and J' are the labeled amounts (in mEq/L) of potassium and sodium, respectively, in the Injection. Dilute with water to volume.

Standard solution: Transfer 5.0 mL of the *Standard stock solution* to a 500-mL volumetric flask, and dilute with the *Internal standard solution* to volume.

Sample solution: Transfer 5.0 mL of Injection to a 500-mL volumetric flask, and dilute with the *Internal standard solution* to volume.

Instrumental conditions

Mode: Flame photometer

Analytical wavelengths

Potassium: 766 nm

Sodium: 589 nm

Lithium: 671 nm

Blank: *Internal standard solution*

Analysis

Samples: *Standard solution*, *Sample solution*, and *Blank*

Use the *Blank* to zero the instrument. Concomitantly determine the flame emission readings for the *Standard solution* and the *Sample solution*.

Calculate the percentage of the labeled amount of potassium (K) in the portion of Injection taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_{\overline{K}}$ emission reading ratio of potassium to lithium from the *Sample solution*

$R_{\overline{S}}$ emission reading ratio of potassium to lithium from the *Standard solution*

$C_{\overline{S}}$ concentration of potassium (K) in the *Standard solution* (mg/mL)

$C_{\overline{U}}$ nominal concentration of potassium (K) in the *Sample solution* (mg/mL)

[Note—Each mg of potassium is equivalent to 0.02558 mEq of potassium.]

Calculate the percentage of the labeled amount of sodium (Na) in the portion of Injection taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

$R_{\overline{Na}}$ emission reading ratio of sodium to lithium from the *Sample solution*

$R_{\overline{S}}$ emission reading ratio of sodium to lithium from the *Standard solution*

$C_{\overline{S}}$ concentration of sodium (Na) in the *Standard solution* (mg/mL)

$C_{\overline{U}}$ nominal concentration of sodium (Na) in the *Sample solution* (mg/mL)

[Note—Each mg of sodium is equivalent to 0.04350 mEq of sodium.]

Acceptance criteria

Potassium: 95.0%–110.0%

Sodium: 95.0%–105.0%

Change to read:

• Chloride

Sample solution: Transfer a volume of Injection, equivalent to 55 mg of chloride, to a suitable conical flask. Add 10 mL of glacial acetic acid, 75 mL of methanol, and 3 drops of eosin Y TS.

Titrimetric system

Mode: Direct titration

Titrant: 0.1 N silver nitrate VS

Endpoint detection: Visual

Analysis

Sample: *Sample solution*

Titrate, with shaking, with *Titrant* to a pink endpoint.

- Calculate the percentage of the labeled amount of chloride (Cl) in the portion of Injection taken:

$$\text{Result} = V \times N \times (F/W) \times 100$$

V

= *Titrant* volume consumed by the *Sample solution* (mL)

N

= actual normality of the *Titrant* (mEq/mL)

F

= equivalency factor, 35.45 mg/mEq

W

= nominal amount of chloride in the *Sample solution* (mg)

■ 2S (USP39)

[Note—Each mL of *Titrant* is equivalent to 3.545 mg of chloride (Cl).]

■ 2S (USP39)

Each mg of chloride is equivalent to 0.0282 mEq of chloride (Cl).]

Acceptance criteria: 95.0%–110.0%

IMPURITIES

Delete the following:

●● Heavy Metals 〈 231 〉

Sample solution: Transfer a volume of Injection as determined by the calculation below to an appropriate vessel. Adjust the volume by evaporation or addition of water to 25 mL, as necessary.

Calculate the volume of Injection to use to two significant figures.

$$\text{Result} = 0.2 / [(G_K L_K) + (G_S L_S)]$$

G_K labeled amount of potassium chloride in each 100 mL of Injection (g)

L_K limit of heavy metals for potassium chloride, 0.001%

G_S labeled amount of sodium chloride in each 100 mL of Injection (g)

L_S limit of heavy metals for sodium chloride, 0.0005%

Acceptance criteria: Meets the requirements ● (Official 1-Dec-2015)

SPECIFIC TESTS

- **Bacterial Endotoxins Test** 〈 85 〉: NMT 0.5 USP Endotoxin Units/mL

SPECIFIC TESTS

- **pH** 〈 791 〉: 3.5–6.5
- **Other Requirements:** It meets the requirements under *Injections* 〈 1 〉.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in single-dose containers, preferably of Type I or Type II glass, or of a suitable plastic.
- **Labeling:** The label states the potassium, sodium, and chloride contents in terms of mEq in a given volume. The label also states the total osmolar concentration in mOsmol/L. Where the contents are less than 100 mL, the label alternatively may state the total osmolar concentration in mOsmol/mL.
- **USP Reference Standards** 〈 11 〉
USP Endotoxin RS

BRIEFING

Promethazine Hydrochloride, *USP* 38 page 5027. As part of the *USP* monograph modernization effort, the following changes are proposed.

1. The nonspecific titrimetric procedure for the *Assay* is replaced with a specific liquid chromatographic procedure that is based on validated methods of analysis performed with the Waters μ Bondapak C18 brand of L1 column. The typical retention time for promethazine is about 4 min.
2. The TLC test for *Organic Impurities* is replaced with a stability-indicating liquid chromatographic procedure. This procedure was validated using the Phenomenex Luna C18 (2) brand of L1 column. The typical retention time for promethazine is about 8 min.
3. *Identification* test C, based on a retention time match in the *Assay*, is added as an orthogonal identification procedure to strengthen the monograph.
4. The test for *Completeness and Clarity of Solution* is deleted because the monograph contains sufficient tests and specifications to ensure the quality of the article. The test for *Completeness and Clarity of Solution* is a nonspecific test that does not provide any added value to the monograph.
5. *USP* Promethazine Related Compound B RS is added to the *USP Reference Standards* section to support the proposed procedures in the *Assay* and in the test for *Organic Impurities*.

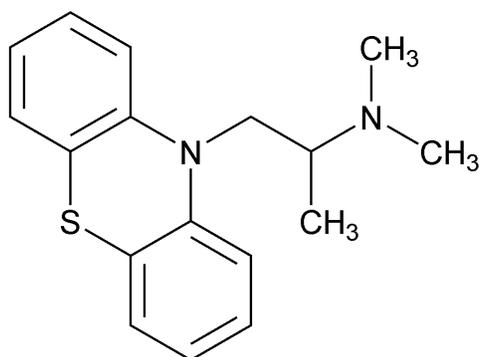

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Promethazine Hydrochloride Injection

DEFINITION

Promethazine Hydrochloride Injection is a sterile solution of Promethazine Hydrochloride in Water for Injection. It contains NLT 95.0% and NMT 110.0% of the labeled amount of promethazine hydrochloride ($C_{17}H_{20}N_2S \cdot HCl$).

[Note—Throughout the following procedures, protect the samples, the Reference Standards, and the solutions containing them, by conducting the procedures without delay under subdued light or using low-actinic glassware.]

IDENTIFICATION

Change to read:

- **A.**

~~**Sample solution:** Nominally 2.5 mg/mL of promethazine hydrochloride from a volume of Injection prepared as follows. Add 50 mg of promethazine hydrochloride from a volume of Injection to 20 mL of dilute hydrochloric acid (1 in 1000) in a separator.~~

~~**Analysis:** Wash the solution with a 20 mL portion of methylene chloride, discarding the washing. Add 2 mL of 1 N sodium hydroxide and 20 mL of methylene chloride, and shake for 2 min. Evaporate the methylene chloride extract on a steam bath with the aid of a stream of nitrogen to dryness. Dissolve the residue in 4 mL of carbon disulfide, filter through paper, if necessary, and determine the IR absorption spectrum as directed under *Identification—Organic Nitrogenous Bases* (181), obtaining the spectrum of USP Promethazine Hydrochloride RS as directed.~~

~~**Acceptance criteria:** The Injection meets the requirements of the test.~~

- The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ■ 2S (USP39)

Add the following:

- • **B.** The UV spectrum of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ■ 2S (USP39)

BRIEFING

Promethazine Hydrochloride Tablets, *USP 38* page 5029. As part of the USP monograph modernization effort, the following changes are proposed:

1. The nonspecific UV-Vis procedure for the *Assay* is replaced with a specific liquid chromatographic procedure that is based on validated methods of analysis performed with the Waters μ Bondapak C18 brand of L1 column. The typical retention time for promethazine is about 4 min.
2. *Identification* test *B*, based on a retention time match in the *Assay*, is added as an orthogonal procedure to strengthen the monograph.
3. A stability-indicating liquid chromatographic procedure in the test for *Organic*

Impurities is added. This procedure was validated using the Phenomenex Luna C18 (2) brand of L1 column. The typical retention time for promethazine is about 8 min.

4. The reference to *Spectrophotometry and Light-Scattering* 〈 851 〉 is deleted from *Dissolution* tests 1 and 2, and an equation to calculate the amount of promethazine hydrochloride dissolved is added to *Dissolution Test 1*.
5. The *Procedure for content uniformity* in the test for *Uniformity of Dosage Units* is deleted to allow flexibility in performing the test.
6. The *Packaging and Storage* section is updated to be consistent with approved manufacturers' package inserts.
7. USP Promethazine Related Compound B RS is added to the *USP Reference Standards* section to support the proposed procedures for the *Assay* and the test for *Organic Impurities*.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Promethazine Hydrochloride Tablets

DEFINITION

Promethazine Hydrochloride Tablets contain NLT 95.0% and NMT 110.0% of the labeled amount of promethazine hydrochloride ($C_{17}H_{20}N_2S \cdot HCl$).

[Note—Throughout the following procedures, protect the samples, the Reference Standards, and the solutions containing them, by conducting the procedures without delay under subdued light or using low-actinic glassware.]

IDENTIFICATION

• **A.**

Standard solution: In a separator, dissolve 50 mg of USP Promethazine Hydrochloride RS in 40 mL of dilute hydrochloric acid (1 in 1000).

Sample solution: Shake a quantity of powdered Tablets, equivalent to 50 mg of promethazine hydrochloride, with 30 mL of chloroform, and filter into a beaker. Evaporate the chloroform, dissolve the residue in 40 mL of dilute hydrochloric acid (1 in 1000), and transfer the liquid to a separator.

Analysis: Separately treat the *Sample solution* and the *Standard solution* as follows. Add 2 mL of 1 N sodium hydroxide and 15 mL of carbon disulfide to the separators, and shake for 2 min. Centrifuge if necessary to clarify the lower phase, and pass through a dry filter, collecting the filtrate from each separator in a small flask provided with a glass stopper. Reduce the volume of the carbon disulfide extracts to 4–5 mL, and proceed as directed in *Identification—Organic Nitrogenous Bases* 〈 181 〉, beginning with "Determine the absorption spectra".

Acceptance criteria: Meet the requirements

Add the following:

Mobile phase: Acetonitrile, water, and *triethylamine* (850:270:1)

System suitability stock solution: 1.2 mg/mL of USP Promethazine Hydrochloride Related Compound B RS in *Diluent*. Sonicate to dissolve.

Standard solution: 0.1 mg/mL of USP Promethazine Hydrochloride RS in *Diluent*. Sonicate to dissolve.

System suitability solution: 0.09 mg/mL of USP Promethazine Hydrochloride RS and 0.12 mg/mL of USP Promethazine Hydrochloride Related Compound B RS in *Diluent* from the *Standard solution* and *System suitability stock solution*, respectively.

Sample stock solution: Nominally 2.5–5.0 mg/mL of promethazine hydrochloride prepared as follows. Transfer 20 Tablets to a volumetric flask of an appropriate size and add 50% of the flask volume of *Diluent*. Sonicate with swirling for NLT 20 min, or until the Tablets have fully disintegrated. Shake the flask for NLT 15 min and dilute with *Diluent* to volume.

Sample solution: Nominally 0.1 mg/mL of promethazine hydrochloride in *Diluent* from the *Sample stock solution*. Pass a portion through a filter of 0.45- μ m pore size and use the clear filtrate.

Chromatographic system

(See *Chromatography* { 621 }, *System Suitability*.)

Mode: LC

Detector: UV 254 nm

Column: 3.9-mm \times 30-cm; 10- μ m packing L1

Flow rate: 2.5 mL/min

Injection volume: 20 μ L

Run time: NLT 2.5 times the retention time of promethazine

System suitability

Samples: *System suitability solution* and *Standard solution*

[Note—The relative retention times for promethazine related compound B and promethazine are 0.82 and 1.0, respectively.]

BRIEFING

Oral Rehydration Salts, *USP 38* page 5145. In preparation for the omission of the flame tests from *Identification Tests—General* (191), proposed in *PF 41(2)* [Mar.–Apr. 2015], it is proposed to delete the references to *Sodium* and *Potassium* under *Identification* test A and include a complete description of each flame test in the monograph. Manufacturers are encouraged to submit replacement wet chemistry or instrumental procedures for consideration by the Expert Committee.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Oral Rehydration Salts

DEFINITION

Oral Rehydration Salts is a dry mixture of Sodium Chloride, Potassium Chloride, Sodium Bicarbonate, and Dextrose (anhydrous). Alternatively, it may contain Sodium Citrate (anhydrous or dihydrate) instead of Sodium Bicarbonate. It may contain Dextrose (monohydrate) instead of Dextrose (anhydrous), provided that the Sodium Bicarbonate or Sodium Citrate is packaged in a separate, accompanying container. It contains the equivalent of NLT 90.0% and NMT 110.0% of the amounts of sodium (Na), potassium (K), chloride (Cl), and bicarbonate (HCO_3) or citrate ($C_6H_5O_7$) calculated from the labeled amounts of Sodium Chloride, Potassium Chloride, and Sodium Bicarbonate [or Sodium Citrate (anhydrous or dihydrate)]. It contains NLT 90.0% and NMT 110.0% of the labeled amounts of anhydrous dextrose ($C_6H_{12}O_6$) or dextrose monohydrate ($C_6H_{12}O_6 \cdot H_2O$). It may contain suitable flavors.

IDENTIFICATION

Change to read:

- **A.** ~~*Identification Tests—General, Sodium* (191) and *Potassium* (191)~~

■ **Sodium:** ■ 2S (USP39)

~~**Acceptance criteria:** Meets the requirements of the flame tests~~

■ The sample imparts an intense yellow color to a nonluminous flame. ■ 2S (USP39)

Add the following:

- **B. Potassium:** The sample imparts a violet color to a nonluminous flame. Since the presence of small quantities of sodium masks the color, screen out the yellow color produced by sodium by viewing through a blue filter that blocks the emission at 589 nm

(sodium), but is transparent to emission at 404 nm (potassium). [Note—Traditionally, cobalt glass has been used, but other suitable filters are commercially available.]

Identification Tests—General 〈 191 〉, *Citrate*

Sample solution: Constitute the Oral Rehydration Salts as directed in the labeling.

Analysis: Add 3–5 drops of the *Sample solution* to 20 mL of the mixture of pyridine and acetic anhydride.

Acceptance criteria: Where it contains Sodium Citrate, it meets the requirements.

Change to read:

• ~~E.~~

■ F. ■ 2S (USP39)

Sample solution: Constitute the Oral Rehydration Salts as directed in the labeling.

Analysis: Add a few drops of the *Sample solution* to 5 mL of hot alkaline cupric tartrate TS.

Acceptance criteria: Where it contains Dextrose, a copious red precipitate of cuprous oxide is formed (presence of dextrose).

ASSAY

Change to read:

• **Dextrose**

Sample stock solution: Nominally 200 mg/mL of dextrose from Oral Rehydration Salts prepared as follows. Transfer the contents of 1 or more unit-dose containers of Oral Rehydration Salts, or a portion of the contents of 1 multiple-unit container equivalent to 20 g of dextrose, to a 100-mL volumetric flask. Dilute with water to volume.

Sample solution: Nominally 100 mg/mL of dextrose from the *Sample stock solution* prepared as follows. Transfer 50.0 mL of the *Sample stock solution* to a 100-mL volumetric flask. Add 0.2 mL of 6 N ammonium hydroxide, and dilute with water to volume.

[Note—Reserve the remaining *Sample stock solution* for the *Assay* procedures for *Sodium and Potassium, Chloride, Bicarbonate, and Citrate*.]

Analysis: Determine the angular rotation in a suitable polarimeter tube (see *Optical*

Rotation (781A), Angular Rotation).

Sample: Sample solution

Where Oral Rehydration Salts is labeled to contain anhydrous dextrose, calculate the observed concentration (g/100 mL) of anhydrous dextrose ($C_6H_{12}O_6$) in the portion of Oral Rehydration Salts taken:

$$\text{Result} = A \times R \times (1/F)$$

~~A = 100 mm divided by the length of the polarimeter tube (mm)~~

~~R = observed rotation (degrees)~~

~~F = midpoint of the specific rotation range for anhydrous dextrose, 52.9°~~

$$\text{Result} = (100 \times a)/(l \times \alpha)$$

a

= observed angular rotation of the *Sample solution* ($^\circ$)

l

= length of the polarimeter tube (dm)

α

= midpoint of the specific rotation range for anhydrous dextrose, 52.9°

■ 2S (USP39)

Where Oral Rehydration Salts is labeled to contain dextrose monohydrate, calculate the observed concentration (g/100 mL) of dextrose monohydrate ($C_6H_{12}O_6 \cdot H_2O$) in the portion of Oral Rehydration Salts taken:

$$\text{Result} = A \times R \times (M_{r1}/M_{r2}) \times (1/F)$$

~~A = 100 mm divided by the length of the polarimeter tube (mm)~~

~~R = observed rotation (degrees)~~

~~M_{r1} = molecular weight of dextrose monohydrate, 198.17~~

~~M_{r2} = molecular weight of anhydrous dextrose, 180.16~~

~~F = midpoint of the specific rotation range for anhydrous dextrose, 52.9°~~

$$\text{Result} = [(100 \times a)/(l \times \alpha)] \times (M_{r1}/M_{r2})$$

a

= observed angular rotation of the *Sample solution*, in degrees

l

= length of the polarimeter tube, in decimeters

α

= midpoint of the specific rotation range for anhydrous dextrose, 52.9°

M_{r1}

= molecular weight of dextrose monohydrate, 198.17

 M_{r2}

= molecular weight of anhydrous dextrose, 180.16

■ 2S (USP39)

Calculate the percentage of the labeled amount of anhydrous dextrose ($C_6H_{12}O_6$) or dextrose monohydrate ($C_6H_{12}O_6 \cdot H_2O$) in the portion of Oral Rehydration Salts taken:

$$\text{Result} = (C_{U1}/C_{U2})$$

■ $\times 100$ ■ 2S (USP39) C_{U1} = observed concentration of the *Sample solution* (g/100 mL) C_{U2} = nominal concentration of the *Sample solution* (g/100 mL)**Acceptance criteria:** 90.0%–110.0%**Change to read:**● **Sodium and Potassium****Sodium stock solution:** 58.44 mg/mL of sodium chloride prepared as follows. Analysis

Samples: Standard solution, Sample solution A, Sample solution B, and Blank

Use the *Blank* to zero the instrument. Measure the emission responses for the *Standard solution*, *Sample solution A*, and *Sample solution B*.

Calculate the percentage of the labeled amount of sodium (Na) in the unit-dose container or containers taken or in the portion of Oral Rehydration Salts taken from the multiple-unit container:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U photometer reading of sodium from *Sample solution A*

r_S photometer reading of sodium from the *Standard solution*

C_S concentration of sodium in the *Standard solution* (mg/mL)

C_U nominal concentration of sodium in *Sample solution A* (mg/mL)

Calculate the percentage of the labeled amount of potassium (K) in the unit-dose container or containers taken or in the portion of Oral Rehydration Salts taken from the multiple-unit container:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U photometer reading of potassium from *Sample solution B*

r_S photometer reading of potassium from the *Standard solution*

C_S concentration of potassium in the *Standard solution* (mg/mL)

C_U nominal concentration of potassium in *Sample solution B* (mg/mL)

Acceptance criteria

Potassium: 90.0%–110.0%

Sodium: 90.0%–110.0%

● **Chloride**

Sample solution: Transfer a volume of the *Sample stock solution* remaining from the *Assay for Dextrose*, containing nominally 55 mg of chloride (Cl), to a suitable container.

Titrimetric system

Mode: Direct titration

Titrant: 0.1 N silver nitrate VS

Endpoint detection: Visual

Analysis

Sample: *Sample solution*

Titrate with *Titrant* until the silver chloride flocculates and the mixture acquires a faint pink color, using potassium chromate TS as the indicator.

Calculate the percentage of the labeled amount of chloride (Cl) in the unit-dose container or containers taken or in the portion of Oral Rehydration Salts taken from the multiple-unit container:

$$\text{Result} = V \times N \times (F/W) \times 100$$

V = volume of *Titrant* consumed (mL)

N = normality of *Titrant* (mEq/mL)

F = equivalent weight of chloride, 35.45 mg/mEq

W = nominal amount of chloride in the *Sample solution* (mg)

Acceptance criteria: 90.0%–110.0%

- **Bicarbonate** (if present)

Sample solution: Transfer a volume of the *Sample stock solution* remaining from the *Assay for Dextrose*, containing nominally 100 mg of bicarbonate, to a suitable beaker.

Titrimetric system

Mode: Direct titration

Titrant: 0.1 N hydrochloric acid VS

Endpoint detection: Visual

Analysis

Sample: *Sample solution*

Add 25 mL of water and 3 drops of methyl orange TS to the *Sample solution*. Titrate the resulting solution with *Titrant*.

Calculate the percentage of the labeled amount of bicarbonate (HCO_3) in the unit-dose container or containers taken or in the portion of Oral Rehydration Salts taken from the multiple-unit container:

$$\text{Result} = V \times N \times (F/W) \times 100$$

V = volume of *Titrant* consumed (mL)

N = normality of *Titrant* (mEq/mL)

F = equivalent weight of bicarbonate, 61.02 mg/mEq

W = nominal amount of bicarbonate in the *Sample solution* (mg)

Acceptance criteria: 90.0%–110.0%

Change to read:

- **Citrate** (if present)

Mobile phase, Standard preparation 1, and Chromatographic system: Proceed as directed in *Assay for Citric Acid/Citrate and Phosphate* 〈 345 〉.

Sample solution: Transfer a volume of the *Sample stock solution* remaining from the *Assay for Dextrose*, containing nominally 180 mg of citrate, to a suitable volumetric flask, and proceed as directed in *Assay for Citric Acid/Citrate and Phosphate* 〈 345 〉, ~~*Assay Preparation for Citric Acid/Citrate Assay*~~

■ *Procedure.* ■ 2S (USP39)

Analysis

Samples: *Standard preparation 1* and *Sample solution*

Proceed as directed in *Assay for Citric Acid/Citrate and Phosphate* 〈 345 〉, *Procedure*. Calculate the percentage of the labeled amount of citrate ($C_6H_5O_7$) in the portion of Oral Rehydration Salts taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response of citrate from the *Sample solution*

r_S = peak response of citrate from *Standard preparation 1*

C_S = concentration of citrate in the *Standard preparation 1* ($\mu\text{g/mL}$)

C_U = nominal concentration of citrate in the *Sample solution* ($\mu\text{g/mL}$)

Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS

- **Minimum Fill** 〈 755 〉: Proceed as directed, except the average net weight of the contents of the 10 containers is NLT the labeled amount, and the net weight of the contents of any single container is NLT 95% and NMT 105% of the labeled amount. If the contents of NMT 1 container are less than 95% but NLT 90% of the labeled amount, or more than 105% but NMT 110% of the labeled amount, determine the net weight of the contents of 20 additional containers. The average net weight of the contents of 30 containers is NLT the labeled amount, and the net weight of the contents of NMT 1 of the 30 containers is less than 95% but NLT 90% of the labeled amount, or more than 105% but NMT 110% of the labeled amount.

[Note—In performing the *Assay* procedures for *Sodium and Potassium, Chloride*, and *Bicarbonate* or *Citrate*, calculate from the labeled amounts of sodium chloride, potassium chloride, and sodium bicarbonate or sodium citrate the total equivalent amounts of sodium (Na), potassium (K), chloride (Cl), and bicarbonate (HCO_3) or citrate ($C_6H_5O_7$) contained therein (see *Table 1*).]

Table 1. mg Equivalent of Each g of Component

Component	Na	K	Cl	HCO_3	$C_6H_5O_7$
Sodium chloride	393.4	—	606.6	—	—
Potassium chloride	—	524.4	475.6	—	—
Sodium bicarbonate	273.6	—	—	726.4	—
Anhydrous sodium citrate	267.2	—	—	—	732.8
Sodium citrate dihydrate	234.5	—	—	—	643.0

SPECIFIC TESTS

- **pH** 〈 791 〉
Sample solution: Constitute the Oral Rehydration Salts as directed in the labeling.
Acceptance criteria: 7.0–8.8
- **Loss on Drying** 〈 731 〉
Analysis: Dry at 50° to constant weight.

Acceptance criteria: NMT 1.0%

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in tight containers, and avoid exposure to temperatures in excess of 30°. The Sodium Bicarbonate or Sodium Citrate component may be omitted from the mixture and packaged in a separate, accompanying container.
- **Labeling:** The label indicates prominently whether Sodium Bicarbonate or Sodium Citrate is a component by the placement of the word "Bicarbonate" or "Citrate", as appropriate, in juxtaposition to the official title. The label states the name and quantity, in g, of each component in each unit-dose container, or in a stated quantity, in g, of Oral Rehydration Salts in a multiple-unit container. The label states the net weight in each container and provides directions for constitution. Where packaged in individual unit-dose pouches, the label instructs the user not to open the pouch until the time of use. The label also states that any solution that remains unused 24 h after constitution is to be discarded.

Ringer's and Dextrose Injection

DEFINITION

Ringer's and Dextrose Injection is a sterile solution of Sodium Chloride, Potassium Chloride, Calcium Chloride, and Dextrose in Water for Injection. It contains, in each 100 mL, NLT 323.0 mg and NMT 354.0 mg of sodium (Na) [equivalent to NLT 820.0 mg and NMT 900.0 mg of sodium chloride (NaCl)], NLT 14.9 mg and NMT 16.5 mg of potassium (K) [equivalent to NLT 28.5 mg and NMT 31.5 mg of potassium chloride (KCl)], NLT 8.20 mg and NMT 9.80 mg of

calcium (Ca) [equivalent to NLT 30.0 mg and NMT 36.0 mg of calcium chloride ($\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$)], and NLT 523.0 mg and NMT 608.5 mg of chloride (Cl) [as sodium chloride (NaCl), potassium chloride (KCl), and calcium chloride ($\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$)]. It contains NLT 95.0% and NMT 105.0% of the labeled amount of dextrose ($\text{C}_6\text{H}_{12}\text{O}_6 \cdot \text{H}_2\text{O}$). It contains no antimicrobial agents.

[Note—The potassium, calcium, sodium, and chloride ion contents of Ringer's and Dextrose Injection are approximately 4, 4.5, 147.5, and 156 mEq/L, respectively.]

IDENTIFICATION

Change to read:

- **A.**

Sample solution: ~~1 in 20~~

■ Nominally 50 mg/mL of dextrose from a suitable volume of Injection in water ■ 2S (USP39)

Analysis: Add a few drops of *Sample solution* to 5 mL of hot alkaline cupric tartrate TS.

Acceptance criteria: A copious red precipitate of cuprous oxide is formed.

Change to read:

- **B. Identification Tests—General**, ~~Sodium~~ ~~(191)~~, ~~Potassium~~ ~~(191)~~,

■ 2S (USP39)

~~(191)~~, *Calcium* and *Chloride*: Meets the requirements of the flame tests for ~~Sodium~~ and ~~Potassium~~,

■ 2S (USP39)

of the ammonium oxalate test for *Calcium*, and the test for *Chloride*.

Add the following:

■ **C. Sodium:** The sample imparts an intense yellow color to a nonluminous flame. ■ 2S (USP39)

Add the following:

■ **D. Potassium:** The sample imparts a violet color to a nonluminous flame. Because the presence of small quantities of sodium masks the color, screen out the yellow color produced by sodium by viewing through a blue filter that blocks the emission at 589 nm (sodium), but is transparent to emission at 404 nm (potassium). [Note—Traditionally, cobalt glass has been used, but other suitable filters are commercially available.]

ASSAY

Change to read:

- **Calcium**

[Note—Concentrations of the *Standard solution* and the *Sample solution* may be modified to fit the linear or working range of the atomic absorption spectrophotometer.]

Lanthanum chloride solution: 88.45 g/L of lanthanum chloride prepared as follows.

Transfer a suitable quantity of lanthanum chloride to an appropriate volumetric flask. Add 50% of the final flask volume of water. Carefully add 25% of the final flask volume of hydrochloric acid. Mix, and allow to cool. Dilute with water to volume.

Calcium stock solution: 1 mg/mL of calcium (Ca) prepared as follows. Transfer 499.5 mg of primary standard calcium carbonate to a 200-mL volumetric flask, and add 10 mL of

water. Carefully add 5 mL of diluted hydrochloric acid, and swirl to dissolve the calcium carbonate. Dilute with water to volume.

Standard solutions: 0.010, 0.015, and 0.020 mg/mL of calcium (Ca) prepared as follows. To three separate 100-mL volumetric flasks, each containing 5.0 mL of *Lanthanum chloride solution*, add 1.0, 1.5, and 2.0 mL, respectively, of *Calcium stock solution*. Dilute the contents of each flask with water to volume.

Sample solution: Transfer 20.0 mL of Injection (~~equivalent to about 1.8 mg of calcium~~)

■ ■ 2S (USP39)

to a 100-mL volumetric flask containing 5.0 mL of *Lanthanum chloride solution*. Dilute with water to volume.

Blank: Transfer 5.0 mL of *Lanthanum chloride solution* to a 100-ml volumetric flask and dilute with water to volume.

Instrumental conditions

(See *Atomic Absorption Spectroscopy* 〈 852 〉 .)

Mode: Atomic absorption spectrophotometry

Analytical wavelength: Calcium emission line at 422.7 nm

Lamp: Calcium hollow-cathode

Flame: Air-acetylene

Analysis

Samples: *Standard solutions*, *Sample solution*, and *Blank*

Plot the absorbances of the *Standard solutions* versus the concentration, in mg/mL, of calcium, and draw the straight line best fitting the three plotted points. From the graph so obtained, determine the concentration (*C*), in mg/mL, of calcium in the *Sample solution*.

Calculate the quantity (mg) of calcium (Ca) in each 100 mL of Injection taken:

$$\text{Result} = C \times 0.5$$

~~C = concentration of calcium in the *Sample solution*, as determined from the graph ($\mu\text{g/mL}$)~~

■

$$\text{Result} = C \times D \times F$$

C

= concentration of calcium in the *Sample solution*, as determined from the graph (mg/mL)

D

= dilution factor of the *Sample solution*, 5

F

= conversion factor for each 100 mL of Injection, 100 mL

■ 2S (USP39)

Acceptance criteria: 8.20–9.80 mg of calcium (Ca) in each 100 mL

Change to read:

• Chloride

Sample solution: Transfer 10 mL of Injection into a conical flask. Add 10 mL of glacial acetic acid, 75 mL of methanol, and 3 drops of eosin Y TS.

Titrimetric system**Mode:** Direct titration**Titrant:** 0.1 N silver nitrate VS**Endpoint detection:** Visual**Analysis****Sample:** *Sample solution*

Titrate, with shaking, with *Titrant* to a pink endpoint. ~~Each mL of 0.1 N silver nitrate is equivalent to 3.545 mg of chloride (Cl).~~

- Calculate the amount, in mg, of chloride (Cl) in each 100 mL of Injection taken:

$$\text{Result} = V \times N \times D \times F$$

$$V$$

= volume of *Titrant* consumed by the *Sample solution* (mL)

$$N$$

= actual normality of the *Titrant* (mEq/mL)

$$D$$

= dilution factor of the *Sample solution*, 10

$$F$$

= equivalency factor, 35.45 mg/mEq

- 2S (USP39)

Acceptance criteria: 523.0–608.5 mg of chloride (Cl) in each 100 mL

- **Dextrose**

Sample solution: Transfer a volume of Injection containing 2–5 g of dextrose to a 100-mL volumetric flask. Add 0.2 mL of 6 N ammonium hydroxide, and dilute with water to volume.

Analysis**Sample:** *Sample solution*

Determine the angular rotation in a suitable polarimeter tube (see *Optical Rotation* 〈 781 〉).

Calculate the percentage of the labeled amount of dextrose ($C_6H_{12}O_6 \cdot H_2O$) in the portion of Injection taken:

$$\text{Result} = [(100 \times a)/(l \times \alpha)] \times (1/C_U) \times (M_{r1}/M_{r2}) \times 100$$

a = observed angular rotation of the *Sample solution* ($^\circ$)

l = length of the polarimeter tube (dm)

α = midpoint of the specific rotation range for anhydrous dextrose, 52.9°

C_U = nominal concentration of dextrose in the *Sample solution*, g/100 mL

M_{r1} = molecular weight of dextrose monohydrate, 198.17

M_{r2} = molecular weight of anhydrous dextrose, 180.16

Acceptance criteria: 95.0%–105.0%

Change to read:

• **Potassium**

Solution A: Suitable nonionic wetting agent (1 in 500)

Lactated Ringer's Injection

DEFINITION

Lactated Ringer's Injection is a sterile solution of Calcium Chloride, Potassium Chloride, Sodium Chloride, and Sodium Lactate in Water for Injection. It contains, in each 100 mL, NLT 285.0 and NMT 315.0 mg of sodium [as sodium chloride (NaCl) and sodium lactate ($\text{C}_3\text{H}_5\text{NaO}_3$)], NLT 14.2 and NMT 17.3 mg of potassium (K) [equivalent to NLT 27.0 and NMT 33.0 mg of potassium chloride (KCl)], NLT 4.90 and NMT 6.00 mg of calcium (Ca) [equivalent to NLT 18.0 and NMT 22.0 mg of calcium chloride ($\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$)], NLT 368.0 and NMT 428.0 mg of chloride (Cl) [as sodium chloride (NaCl), potassium chloride (KCl), and calcium chloride ($\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$)], and NLT 231.0 and NMT 261.0 mg of lactate ($\text{C}_3\text{H}_5\text{O}_3$) [equivalent to NLT 290.0 and NMT 330.0 mg of sodium lactate ($\text{C}_3\text{H}_5\text{NaO}_3$)]. It contains no antimicrobial agents.

[Note—The calcium, potassium, and sodium contents of Lactated Ringer's Injection are approximately 2.7, 4, and 130 mEq/L, respectively.]

Lactated Ringer's and Dextrose Injection

DEFINITION

Lactated Ringer's and Dextrose Injection is a sterile solution of Calcium Chloride, Potassium Chloride, Sodium Chloride, Sodium Lactate, and Dextrose in Water for Injection. It contains, in each 100 mL, NLT 285.0 and NMT 315.0 mg of sodium (Na) [as sodium chloride (NaCl) and sodium lactate ($C_3H_5NaO_3$)], NLT 14.2 and NMT 17.3 mg of potassium (K) [equivalent to NLT 27.0 and NMT 33.0 mg of potassium chloride (KCl)], NLT 4.90 and NMT 6.00 mg of calcium (Ca) [equivalent to NLT 18.0 and NMT 22.0 mg of calcium chloride ($CaCl_2 \cdot 2H_2O$)], NLT 368.0 and NMT 428.0 mg of chloride (Cl) [as sodium chloride (NaCl), potassium chloride (KCl), and calcium chloride ($CaCl_2 \cdot 2H_2O$)], and NLT 231.0 and NMT 261.0 mg of lactate ($C_3H_5O_3$) [equivalent to NLT 290.0 mg and NMT 330.0 mg of sodium lactate ($C_3H_5NaO_3$)]. It contains NLT 90.0% and NMT 105.0% of the labeled amount of dextrose ($C_6H_{12}O_6 \cdot H_2O$). It contains no antimicrobial agents.

[Note—The calcium, potassium, and sodium contents of Lactated Ringer's and Dextrose Injection are approximately 2.7, 4, and 130 mEq/L, respectively.]

IDENTIFICATION

- **A.**

Sample solution: Nominally 50 mg/mL of dextrose from a suitable volume of Injection

Analysis: Add a few drops of the *Sample solution* to 5 mL of hot alkaline cupric tartrate TS.

Acceptance criteria: A copious red precipitate of cuprous oxide is formed.

- **Calcium**

[Note—Concentrations of the *Standard solutions* and the *Sample solution* may be modified to fit the linear or working range of the atomic absorption spectrophotometer.]

Solution A: 88.45 g/L of lanthanum chloride prepared as follows. Transfer a suitable quantity of lanthanum chloride to an appropriate volumetric flask. Add 50% of the final flask volume of water. Carefully add 25% of the final flask volume of hydrochloric acid. Mix, and allow to cool. Dilute with water to volume.

Calcium stock solution: 1000 $\mu\text{g/mL}$ of calcium, prepared as follows. Transfer 499.5 mg of primary standard calcium carbonate to a 200-mL volumetric flask and add 10 mL of water. Carefully add 5 mL of dilute hydrochloric acid, and swirl to dissolve the calcium carbonate. Dilute with water to volume.

Standard solutions: 0.010, 0.015, and 0.020 mg/mL of calcium (Ca), prepared as follows. To three separate 100-mL volumetric flasks, each containing 5.0 mL of *Solution A*, add 1.0, 1.5, and 2.0 mL, respectively, of *Calcium stock solution*. Dilute the contents of each flask with water to volume.

Sample solution: Nominally 0.014 mg/mL of calcium, prepared as follows. Transfer 50.0 mL of Injection, equivalent to 1.4 mg of calcium, to a 100-mL volumetric flask containing 5.0 mL of *Solution A*, and dilute with water to volume.

Blank: 5.0 mL of *Solution A* diluted with water to 100.0 mL

Instrumental conditions

BRIEFING

Modified Lactated Ringer's and Dextrose Injection, *USP 38* page 5187. It is proposed to revise the monograph as follows:

1. In preparation for the omission of the flame tests from *Identification Tests—General* 〈 191 〉, proposed in *PF 41(2)* [Mar.–Apr. 2015], delete the reference to 〈 191 〉 flame tests for sodium and potassium in *Identification* test *B* and include a complete description of the flame test for the two elements in the monograph. Manufacturers are encouraged to submit a replacement wet-chemistry or an instrumental procedure for the Expert Committee's consideration.
2. In the *Assay Analysis* for *Calcium*, revise the equivalent amount of calcium in the *Sample solution* to get the solution within the linearity range evaluated. A clarifying statement is also added, describing how absorbance data are used to calculate the concentration of calcium.
3. Add the equation for calculating the concentration of potassium in the *Assay* for *Potassium*.
4. Add the equation for calculating the concentration of sodium in the *Assay* for *Sodium*.
5. Update the equation in the *Assay* for *Dextrose* to be consistent with current *USP* style.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Modified Lactated Ringer's and Dextrose Injection

DEFINITION

Modified Lactated Ringer's and Dextrose Injection is a sterile solution of Calcium Chloride, Potassium Chloride, Sodium Chloride, Sodium Lactate, and Dextrose in Water for Injection. It contains, in each 100 mL, NLT 57.0 and NMT 63.0 mg of sodium (Na) [as sodium chloride (NaCl) and sodium lactate, (C₃H₅NaO₃)], NLT 2.82 and NMT 3.46 mg of potassium (K) [equivalent to NLT 5.4 and NMT 6.6 mg of potassium chloride (KCl)], NLT 0.98 and NMT 1.20 mg of calcium (Ca) [equivalent to NLT 3.6 and NMT 4.4 mg of calcium chloride (CaCl₂·2H₂O)], NLT 73.6 and NMT 85.6 mg of chloride (Cl) [as sodium chloride (NaCl), potassium chloride (KCl), and calcium chloride (CaCl₂·2H₂O)], NLT 46.2 and NMT 52.20 mg of lactate (C₃H₅O₃) [equivalent to NLT 58.0 and NMT 66.0 mg of sodium lactate (C₃H₅NaO₃)]. It contains NLT 90.0% and NMT 105.0% of the labeled amount of dextrose (C₆H₁₂O₆·H₂O). It contains no antimicrobial agents.

[Note—The calcium, potassium, and sodium contents of Modified Lactated Ringer's and Dextrose Injection are approximately 0.5, 0.8, and 26 mEq/L, respectively.]

IDENTIFICATION

• A.

Sample solution: Nominally 50 mg/mL of dextrose from a suitable volume of Injection

Analysis: Add a few drops of the *Sample solution* to 5 mL of hot alkaline cupric tartrate TS.

Acceptance criteria: A copious red precipitate of cuprous oxide is formed.

Delete the following:

- ~~• B. Identification Tests—General (191): Meets the requirements of the flame tests for Sodium (191) and Potassium (191), of the test for Chloride (191), and of the test for ammonium oxalate for Calcium (191) ■ 2S (USP39)~~

Add the following:

- **B. Identification Tests—General (191), Chloride and Calcium:** Meets the requirements of the test for *Chloride* and the test for ammonium oxalate in *Calcium* ■ 2S (USP39)

Add the following:

- **C. Potassium:** The sample imparts a violet color to a nonluminous flame. Because the presence of small quantities of sodium masks the color, screen out the yellow color produced by sodium by viewing through a blue filter that blocks the emission at 589 nm (sodium), but is transparent to emission at 404 nm (potassium). [Note—Traditionally, cobalt glass has been used, but other suitable filters are commercially available.] ■ 2S (USP39)

Add the following:

- **D. Sodium:** The sample imparts an intense yellow color to a nonluminous flame. ■ 2S (USP39)

Change to read:

• E.

- **E.** ■ 2S (USP39)

The retention time of the lactate peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay for Lactate*.

Acceptance criteria: 90.0%–105.0%

IMPURITIES

Delete the following:

- **Heavy Metals** $\langle 231 \rangle$: Transfer to a suitable vessel a volume, in mL, of Injection, calculated to two significant figures:

$$\text{Result} = 0.2 / [(G_{S-L_S}) + (G_{K-L_K}) + (G_{C-L_C}) + (G_{L-L_L}) + (G_{D-L_D})]$$

G_S labeled amount of sodium chloride in each 100 mL of Injection (g)

L_S limit for *Heavy Metals* specified under *Sodium Chloride* (percentage)

G_K labeled amount of potassium chloride in each 100 mL of Injection (g)

L_K limit for *Heavy Metals* specified under *Potassium Chloride* (percentage)

G_C labeled amount of calcium chloride in each 100 mL of Injection (g)

L_C limit for *Heavy Metals* specified under *Calcium Chloride* (percentage)

G_L labeled amount of sodium lactate in each 100 mL of Injection (g)

L_L limit for *Heavy Metals* specified under *Sodium Lactate* (percentage)

G_D labeled amount of dextrose in each 100 mL of Injection (g)

L_D limit for *Heavy Metals* specified under *Dextrose* (percentage)

Adjust the volume by evaporation or addition of water to 25 mL, as necessary: it meets the requirements of the test. ● (Official 1-Dec-2015)

- **Limit of 5-Hydroxymethylfurfural and Related Substances**

Sample solution: Nominally 2.0 mg/mL of dextrose ($C_6H_{12}O_6 \cdot H_2O$) from a suitable volume of Injection, in water

Instrumental conditions

Analytical wavelength: Maximum transmittance at 284 nm

Cell: 1 cm

Blank: Water

Analysis

Samples: *Sample solution* and *Blank*

Acceptance criteria: The absorbance is NMT 0.25.

SPECIFIC TESTS

- **Bacterial Endotoxins Test** 〈 85 〉: NMT 0.5 USP Endotoxin Units/mL
- **pH** 〈 791 〉: 4.0–6.5
- **Other Requirements:** It meets the requirements in *Injections* 〈 1 〉.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in single-dose glass or plastic containers. Glass containers are preferably of Type I or Type II glass.
- **Labeling:** The label states the total osmolar concentration in mOsmol/L. Where the contents are less than 100 mL, the label alternatively may state the total osmolar concentration in mOsmol/mL. The label also includes the warning: "Not for use in the treatment of lactic acidosis".

BRIEFING

Sodium Nitroprusside, *USP 38* page 5327. In preparation for the omission of the flame tests from *Identification Tests—General* 〈 191 〉, proposed in *PF 41(2)* [Mar.–Apr. 2015], it is proposed to replace the flame test for sodium in *Identification* test C with a colorimetric test using zinc uranyl acetate. This test is adopted from the identity tests described in the *Sodium Nitroprusside* monograph in the fourth edition of *The International Pharmacopoeia*.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

(SM2: S. Ramakrishna.)

Sodium Nitroprusside

$\text{Na}_2[\text{Fe}(\text{CN})_5\text{NO}] \cdot 2\text{H}_2\text{O}$ 297.95

$\text{Na}_2[\text{Fe}(\text{CN})_5\text{NO}]$ 261.92

Ferrate(2-), pentakis(cyano-C)nitrosyl-, disodium, dihydrate, (OC-6-22)-;
Disodium pentacyanonitrosylferrate(2-) dihydrate;
Sodium nitroferricyanide dihydrate [13755-38-9].
Anhydrous [14402-89-2].

DEFINITION

Sodium Nitroprusside contains NLT 99.0% of sodium nitroprusside ($\text{Na}_2[\text{Fe}(\text{CN})_5\text{NO}] \cdot 2\text{H}_2\text{O}$).

IDENTIFICATION

- **A. Ultraviolet Absorption** 〈 197U 〉
Use low-actinic glassware.

Sample solution: 0.74 mg/mL in water

Wavelength range: 350–700 nm

Acceptance criteria: Meets the requirements

- **B.** Dissolve 5 mg of Sodium Nitroprusside in 2 mL of water. Add 2 drops of acetone and 0.5 mL of 2 N sodium hydroxide. An orange color is produced that changes to a purple color upon adding 2 mL of acetic acid.

Change to read:

- **C.** ~~Identification Tests—General (191), Sodium~~

~~**Sample solution:** 250 mg/mL~~

~~**Acceptance criteria:** Meets the requirements~~

■ **Sample solution:** 100 mg/mL of Sodium Nitroprusside solution acidified with 5 N acetic acid

Analysis: Treat the *Sample solution* with *zinc uranyl acetate TS*.

Acceptance criteria: A yellow crystalline precipitate is produced. ■2S (USP39)

ASSAY

- **Procedure**

Sample: 500 mg of Sodium Nitroprusside

Titrimetric system

Mode: Direct titration

Titrant: 0.1 N silver nitrate VS

Endpoint detection: Potentiometric

Analysis: Dissolve the *Sample* in 130 mL of chloride-free water. Titrate with *Titrant*, using a silver–silver chloride electrode system, and determine the endpoint. Each mL of 0.1 N silver nitrate is equivalent to 14.90 mg of sodium nitroprusside ($\text{Na}_2[\text{Fe}(\text{CN})_5\text{NO}] \cdot 2\text{H}_2\text{O}$).

Acceptance criteria: NLT 99.0%

IMPURITIES

- **Insoluble Substances**

Sample solution: Dissolve 10.0 g of Sodium Nitroprusside in 50 mL of water.

Analysis: Heat the *Sample solution* on a steam bath for 30 min. Filter, wash the residue with water, and dry at 105° to constant weight.

Acceptance criteria: NMT 1 mg (0.01%)

- **Chloride**

Solution A: 83 mg/mL of cupric sulfate

Standard chloride solution: Dissolve 42.4 mg of potassium chloride in water to make a 100.0 mL solution. This solution contains 0.2 mg/mL of chloride.

Sample: 1.0 g of Sodium Nitroprusside

Analysis: Transfer the *Sample* and 1.0 mL of *Standard chloride solution* to two separate 250-mL conical flasks and add 85 mL of water to each flask. To the flask containing the substance under analysis, add 15 mL of *Solution A*, and allow any undissolved particles to settle. Carefully add *Solution A* to the flask containing the *Standard chloride solution* by mixing, so that its color matches that of the flask containing the *Sample*. Filter the contents of each flask, and discard the first 25 mL of the filtrate. To 10 mL of the subsequent filtrate from each flask, add 2 mL of nitric acid, add 1 mL of 1 N silver nitrate

and mix again.

Acceptance criteria: The *Sample* so treated becomes no more turbid than the treated *Standard chloride solution* (0.02%).

- **Sulfate**

Standard sulfate solution: Dissolve 15 mg of anhydrous sodium sulfate in water to make a 100.0 mL solution. This solution contains 0.1 mg/mL of sulfate.

Sample solution: Dissolve 5.0 g of Sodium Nitroprusside in water to make a 250.0 mL solution.

Analysis: Filter the *Sample solution* into a flat-bottom 250-mL graduated flask. Transfer 5.0 mL of *Standard sulfate solution* to a similar flask, and dilute to the same volume as the sample under test. To each flask add 10 drops of glacial acetic acid and 5 mL of 1 N barium chloride, and allow to stand for 10 min. Place both flasks over a fluorescent light source, and observe.

Acceptance criteria: The turbidity in the treated *Sample solution* is not more intense than that of the treated *Standard sulfate solution* (0.01%).

- **Limit of Ferricyanide**

Sample solution: Dissolve 500 mg of Sodium Nitroprusside in 20 mL of ammonium acetate TS, previously adjusted with 1 N acetic acid to a pH of 4.62.

Blank solution: Dissolve 250 mg of Sodium Nitroprusside in 10 mL of ammonium acetate TS, previously adjusted with 1 N acetic acid to a pH of 4.62, and dilute with water to 50 mL.

Analysis: Divide the *Sample solution* into halves, and transfer each half into individual 50-mL volumetric flasks. Identify the flasks as A and B. To flask B add 1.0 mL of a freshly prepared 78 µg/mL potassium ferricyanide solution. To both flasks add 5 mL of 1 mg/mL of ferrous ammonium sulfate solution, and dilute with water to volume. Allow the flasks to stand for 1 h, and concomitantly measure the absorbance of the solutions at the wavelength of maximum absorbance at about 720 nm using the *Blank solution* as a blank.

Acceptance criteria: The absorbance of the solution in flask A is NMT the absorbance of the solution in flask B minus the absorbance of the solution in flask A (0.02% of ferricyanide).

- **Limit of Ferrocyanide**

Sample solution: Dissolve 2.0 g of Sodium Nitroprusside in 40 mL of water.

Blank solution: Dissolve 1.0 g of Sodium Nitroprusside in water to make 50 mL.

Analysis: Divide the *Sample solution* into halves, and transfer each half into individual 50-mL volumetric flasks. Identify the flasks as A and B. To flask B add 2 mL of a freshly prepared 200 µg/mL of potassium ferrocyanide solution. To both flasks add 0.2 mL of ferric chloride TS, dilute with water to volume, and mix. Allow to stand for 20 min, accurately timed, and concomitantly measure the absorbance of the solutions at the wavelength of maximum absorbance at about 695 nm using the *Blank solution* as the blank.

Acceptance criteria: The absorbance of the solution in flask A is NMT the absorbance of the solution in flask B minus the absorbance of the solution in flask A (0.02% of ferrocyanide).

SPECIFIC TESTS

- **Water Determination** { 921 }, *Method I*: 9.0%–15.0%

- **Sterility Tests** { 71 } : Where the label states that Sodium Nitroprusside is sterile, it meets the requirements.

- **Bacterial Endotoxins Test** 〈 85 〉: Where the label states that it is sterile or must be subjected to further processing during the preparation of injectable dosage forms, it contains NMT 0.05 USP Endotoxin Units/μg of sodium nitroprusside.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in tight, light-resistant containers. Store at 25°; excursions permitted between 15° and 30°.
- **Labeling:** Where it is intended for use in preparing injectable dosage forms, the label states that it is sterile or must be subjected to further processing during the preparation of injectable dosage forms.

 - USP Sodium Nitroprusside RS

BRIEFING

Silver Sulfadiazine, *USP 38* page 5383. As part of USP monograph modernization efforts, the following revisions are proposed:

1. Replace the TLC procedure using hazardous solvent (chloroform) in *Identification* test *B* with the retention time agreement proposed in the HPLC-based *Assay*.
2. A more selective, single HPLC procedure is used for both the *Assay* and *Organic Impurities* test. The liquid chromatographic procedure is based on analyses performed with the YMC Pack Pro brand of L1 column. The typical retention time for silver sulfadiazine is about 13 min. The Purospher star LP RP-18 brand of L1 column is a suitable alternate column for this test.
3. Replace the TLC procedure in the test for *Organic Impurities* with a validated HPLC procedure that uses the same chromatographic procedure as proposed for the *Assay*. The *Acceptance criteria* for specified and individual unspecified impurities are proposed based on International Conference on Harmonization guidelines. Stakeholders with different impurities and/or limits than those in this revision are strongly encouraged to submit their FDA-approved acceptance criteria, along with the list of specified degradation products, for the Expert Committee's consideration.
4. Add USP Sulfanilic Acid RS and USP Sulfanilamide RS to the *USP Reference Standards* section to support the proposed revision in the test for *Organic Impurities*.

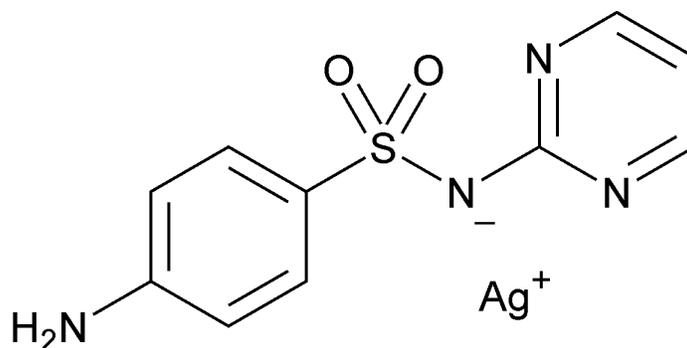

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Silver Sulfadiazine

$C_{10}H_9AgN_4O_2S$ 357.14

Benzenesulfonamide, 4-amino-*N*-2-pyrimidinyl-, monosilver(1+) salt;
*N*¹-2-Pyrimidinylsulfanilamide monosilver(1+) salt [22199-08-2].

DEFINITION

Silver Sulfadiazine contains NLT 98.0% and NMT 102.0% of silver sulfadiazine ($C_{10}H_9AgN_4O_2S$), calculated on the dried basis.

IDENTIFICATION

• A. Infrared Absorption (197K)

Change to read:

- B. The R_f value of the principal spot of the *Sample solution* corresponds to that of *Standard solution A*, as obtained in the test for *Organic Impurities*.
- The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ■ 2S (USP39)

• C. Identification Tests—General (191), Silver

Sample: 1 g

Analysis: Dissolve the *Sample* in 15 mL of *ammonium hydroxide* and 15 mL of water in a 50-mL volumetric flask, dilute with water to volume, and mix.

Acceptance criteria: Meets the requirements

ASSAY

Change to read:

• Procedure

Mobile phase: Acetonitrile, phosphoric acid, and water (99:1:900)

Diluent: Transfer 100 mL of ammonium hydroxide to a 1-L volumetric flask, and dilute with water to volume.

Internal standard solution: 10 mg/mL of sulfamerazine in *Diluent*

Standard stock solution: 1.25 mg/mL of USP Silver Sulfadiazine prepared as follows.

Dissolve 250 mg of USP Silver Sulfadiazine RS in 100 mL of *Diluent* in a 200-mL volumetric flask, and sonicate for 5 min. Add 25.0 mL of *Internal standard solution*, and dilute with *Diluent* to volume.

Standard solution: ~~0.05 mg/mL of USP Silver Sulfadiazine RS prepared as follows. Pipet 2.0 mL of *Standard stock solution* into a 50-mL volumetric flask, and dilute with *Mobile phase* to volume.~~

Sample stock solution: ~~Transfer 250 mg of Silver Sulfadiazine to a 50-mL round-bottom centrifuge tube. Add 35 mL of methanol, tightly seal the tube with a cap containing an inert liner, and mix using a vortex mixer for about 15 s. Centrifuge for 15 min to separate the liquid and solid phases. Aspirate, and discard the methanol supernatant layer. Care should be taken to avoid aspirating any of the residue. Pipet 25.0 mL of *Internal standard solution* into a 200-mL volumetric flask. Add 30 mL of *Diluent* to the centrifuge tube, replace the cap, and mix using a vortex mixer, for about 15 s. Quantitatively transfer the contents to the 200-mL volumetric flask, using the *Diluent* to rinse the tube. Repeat the addition of 30 mL of *Diluent*, mixing and quantitatively transferring three more times. Dilute with *Diluent* to volume, and mix. Sonicate if necessary to obtain dissolution of the residue.~~

Sample solution: ~~0.05 mg/mL of Silver Sulfadiazine prepared as follows. Pipet 2.0 mL of *Sample stock solution* into a 50-mL volumetric flask, and dilute with *Mobile phase* to volume.~~

BRIEFING

Teriparatide Injection. Because there is no existing *USP* monograph for this drug product, a new monograph based on validated methods of analysis is being proposed. The liquid chromatographic procedure in the *Assay* and the test for *Product-Related Impurities* is based on analyses performed with the Zorbax 300SB-C18 brand of L1 column. In the *Assay*, the retention time for the teriparatide peak is approximately 8 min.

(BIO1: E. Chang.)

Correspondence Number—C151705

Comment deadline: September 30, 2015

Add the following:

- **Teriparatide Injection**

DEFINITION

Teriparatide Injection is a sterile solution of Teriparatide in Water for Injection. It contains NLT 90.0% and NMT 105.0% of the labeled amount of teriparatide ($\text{C}_{181}\text{H}_{291}\text{N}_{55}\text{O}_{51}\text{S}_2$).

IDENTIFICATION

- **A.** The ratio of the retention time of the main peak of the *Sample solution* to that of the *Standard solution* is 1.00 ± 0.03 , as obtained in the *Assay*.

ASSAY

- **Procedure**

0.2 M sulfate buffer: 28.4 g/L of anhydrous sodium sulfate in water. Adjust with 85% phosphoric acid to a pH of 2.3.

Solution A: Acetonitrile and 0.2 M sulfate buffer (10:90)

Solution B: Acetonitrile and 0.2 M sulfate buffer (50:50)

Mobile phase: *Solution A* and *Solution B* (61:39). [Note—The *Mobile phase* composition may be adjusted to obtain the retention time of approximately 8 min for the teriparatide main peak.]

Diluent for Standard solution: Acetonitrile and 0.2 M sulfate buffer (25:75)

0.27 M sulfate buffer: 38.8 g/L of anhydrous sodium sulfate in water. Adjust with 85% phosphoric acid to a pH of 2.3.

Diluent for Sample solution: Acetonitrile and 0.27 M sulfate buffer (31:69)

Standard solutions: Prepare three solutions, each containing approximately 100 µg/mL of USP Teriparatide RS in *Diluent for Standard solution*. *Standard solutions* are stable for 48 h when stored at 2°–8° in a sealed container.

Sample solutions: Prepare two dilutions of approximately 50–100 µg/mL of teriparatide in *Diluent for Sample solution*. *Sample solutions* are stable for 48 h when stored at 2°–8° in a sealed container.

Chromatographic system

(See *Chromatography* { 621 }, *System Suitability*.)

Mode: LC

Detector: UV 214 nm

Column: 4.6-mm × 15-cm; 3.5-µm packing L1

Temperatures

Column: 40°

Autosampler: 5°

Flow rate: 0.8 mL/min

Injection volume: 25 µL

Run time: 20 min

System suitability

Sample: *Standard solution*

Suitability requirements

Tailing factor: NMT 1.5 for the teriparatide peak

Relative standard deviation: NMT 1.25% calculated from three injections of one *Standard solution*

Analysis

Samples: *Standard solutions* and *Sample solutions*

Measure the peak responses corresponding to teriparatide.

Calculate the concentration of teriparatide (C_S), in µg/mL, in each of the *Standard solutions*:

$$C_S = (L_S/V_S)$$

L_S content of teriparatide in USP Teriparatide RS (µg)

V_S volume of *Diluent for Standard solution* used for each *Standard solution* (mL)

Determine the average concentration of teriparatide (C_M) for all three *Standard*

solutions.

Calculate the mean response factor (F_M) for all three *Standard solutions*:

$$F_M = (r_M/C_M)$$

$r_{\overline{M}}$ average peak response of teriparatide from the *Standard solutions*

$C_{\overline{M}}$ average concentration of teriparatide in the *Standard solutions* ($\mu\text{g/mL}$)

Calculate the concentration of teriparatide (C_U), in $\mu\text{g/mL}$, in the portion of Injection taken:

$$C_U = (r_U \times F)/F_M$$

r_U peak response of teriparatide from the *Sample solution*

F = dilution factor used to prepare the *Sample solution*

$F_{\overline{M}}$ mean response factor for all three *Standard solutions*

Calculate the percentage of the label claim of teriparatide in the portion of Injection taken:

$$\text{Result} = (C_U/C_L) \times 100$$

C_U concentration of teriparatide in the portion of Injection taken ($\mu\text{g/mL}$)

C_L labeled concentration of teriparatide in the portion of Injection taken ($\mu\text{g/mL}$)

Acceptance criteria: 90.0%–105.0%

PRODUCT RELATED SUBSTANCES IMPURITIES

• Product-Related Impurities

0.2 M sulfate buffer: 28.4 g/L of anhydrous sodium sulfate in water. Adjust with 85% phosphoric acid to a pH of 2.3.

Solution A: Acetonitrile and 0.2 M sulfate buffer (10:90)

Solution B: Acetonitrile and 0.2 M sulfate buffer (50:50)

[Note—If the sodium sulfate precipitates, gentle heating and continuous stirring may be required. The sodium sulfate should not re-precipitate if this procedure is followed.]

Mobile phase: See Table 1. [Note—The *Mobile phase* composition may be adjusted to obtain the desired retention time of the teriparatide peak. *Solution B* (%) at 8 and 68 min may also be changed, if necessary, to obtain the desired retention time, but the same gradient slopes should be maintained. A change of 0.5% of *Solution B* will alter the retention time of the main peak approximately 100 s.]

Table 1

Time (min)	Solution A (%)	Solution B (%)
0	100	0
2	100	0
8	76	24
68	60	40
75	0	100
80	0	100

System suitability solution: Use an appropriate solution containing approximately 0.8% of the first post-main peak in *Solution A*. [Note—Teriparatide containing the first post-main peak may be prepared by dissolving teriparatide in water to obtain a concentration of 2 mg/mL. Adjust with hydrochloric acid to a pH of 3.0. Incubate this solution at 50° for 9 days. The solution may be aliquotted and stored frozen. Dilute 1:1 with *Solution A* prior to injection. The first post-main peak is a degradation product resulting from this process and elutes immediately after the teriparatide peak.]

Sample solution: Use the solution from an undiluted Injection container.

Blank: *Solution A*

Chromatographic system

(See *Chromatography* { 621 }, *System Suitability*.)

Mode: LC

Detector: UV 214 nm

Column: 4.6-mm × 15-cm; 3.5-μm packing L1

Temperatures

Column: 40°

Autosampler: 5°

Flow rate: 1.0 mL/min

Injection volume: 50 μL

System suitability

Sample: *System suitability solution*

[Note—The retention time for teriparatide is 60.83–66.67 min.]

Suitability requirements

Peak-to-valley ratio: The ratio of the height of the first post-main peak to the valley between the teriparatide peak and the first post-main peak is NLT 1.5.

Tailing factor: NMT 2.0 for the teriparatide peak

Analysis

Sample: *Sample solution*

Measure the peak responses for all integrated peaks.

Calculate the percentage of a related impurity, rhPTH(1–30) (a cleavage product of teriparatide at Asn 30), in the portion of Injection taken:

$$\text{Result} = (r_{rhPTH(1-30)} / r_T) \times 100$$

$r_{rhPTH(1-30)}$ = peak response of rhPTH(1–30)

r_T = sum of all the peak responses

Calculate the percentage of a related impurity, teriparatide succinimide(30) (formation of succinimide on Asn 30), in the portion of Injection taken:

$$\text{Result} = (r_{Suc} / r_T) \times 100$$

r_{Suc} = peak response of teriparatide succinimide(30)

r_T = sum of all the peak responses

Calculate the percentage of the largest other related impurity of teriparatide in the portion of Injection taken:

$$\text{Result} = (r_i/r_T) \times 100$$

$r_{\overline{T}}$ peak response of the largest other related impurity of teriparatide

$r_{\overline{T}}$ sum of all the peak responses

Calculate the percentage of total related impurities in the portion of Injection taken:

$$\text{Result} = [(r_T - r_S)/r_T] \times 100$$

$r_{\overline{T}}$ sum of all the peak responses

$r_{\overline{S}}$ peak response of teriparatide

Acceptance criteria: See Table 2.

Table 2

Name	Relative Retention Time	Acceptance Criteria, NMT (%)
rhPTH(1-30)	0.77-0.78	1.2
Teriparatide succinimide(30)	0.98-0.99	1.2
Teriparatide	1.0	—
Largest other individual related impurity	—	1.0
Total impurities	—	7.0

SPECIFIC TESTS

- **pH** 〈 791 〉: 3.8–4.5
- **Bacterial Endotoxins Test** 〈 85 〉: NMT 100 USP Endotoxin Units/mg of teriparatide
- **Sterility Tests** 〈 71 〉, *Test for Sterility of the Product to Be Examined, Membrane Filtration*: Meets the requirements
- **Particulate Matter in Injections** 〈 788 〉: Meets the requirements for small-volume injections

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Unless otherwise prescribed, store in a sterile, airtight, tamper-proof container, protected from light, at a temperature of 2°–8°. The Injection is not to be frozen.
- **Labeling:** Label it to indicate that the material has been produced by methods based on recombinant DNA technology.
- **USP Reference Standards** 〈 11 〉
 - USP Endotoxin RS
 - USP Teriparatide RS

■ 2S (USP39)

BRIEFING

Testosterone, USP 38 page 5500. As part of USP monograph modernization efforts, the following changes are proposed.

1. The nonspecific UV absorption procedure in the *Assay* is replaced with a specific liquid chromatographic procedure that is based on validated methods of analysis performed with the Waters Symmetry C18 brand of L1 column. The typical retention time for testosterone is about 4 min.
2. *Identification* test *A* is revised to reference *Infrared Absorption* 〈197〉 to allow for more flexibility in performing the analysis.
3. *Identification* test *B*, which uses UV absorption, is replaced with a retention time match of the testosterone peak from the *Assay*.
4. A stability-indicating liquid chromatographic procedure for the *Organic Impurities* test is added. This procedure was validated using the Phenomenex Gemini NX-C18 brand of L1 column. The typical retention time for testosterone is about 16 min.
5. The nonspecific test for *Melting Range or Temperature* is deleted. It is no longer needed because the proposed test for *Organic Impurities* is sufficient.
6. USP Testosterone Related Compound A RS, USP Testosterone Related Compound C RS, USP Exemestane Related Compound C RS, and USP Testosterone Related Compound I RS are added to the *USP Reference Standards* section to support the proposed test for *Organic Impurities*.

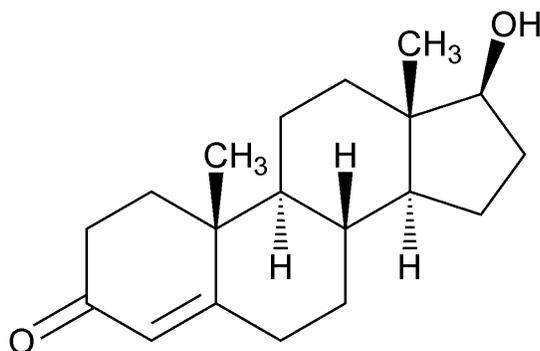

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Thiotepa for Injection

DEFINITION

Thiotepa for Injection contains NLT 95.0% and NMT 110.0% of the labeled amount of thiotepa ($C_6H_{12}N_3PS$).

IDENTIFICATION

- **A. Infrared Absorption** $\langle 197K \rangle$
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

ASSAY

• Procedure

Buffer: 13.6 g/L of monobasic potassium phosphate in water. Adjust with 35 g/L of dibasic sodium phosphate in water to a pH of 7.0.

Mobile phase: Acetonitrile and *Buffer* (13:87)

System suitability solution: Transfer 10 mg of USP Thiotepa RS to a 4-mL vial, add 2 mL of methanol, and mix. Add 50 μ L of 0.1% phosphoric acid solution. Place a cap on the vial, and heat at 65 $^{\circ}$ for 50 s. Cool the solution, add 1 mL of methanol, and mix. [Note—The preparation generates methoxythiotepa.]

Standard solution: 1.5 mg/mL of USP Thiotepa RS in water

Sample solution: Nominally 1.5 mg/mL of thiotepa in water from Thiotepa for Injection

Chromatographic system

(See *Chromatography* { 621 }, *System Suitability*.)

Mode: LC

Detector: UV 215 nm

Column: 4.6-mm \times 15-cm; 5- μ m packing L1

Flow rate: 1 mL/min

Injection volume: 20 μ L

System suitability

Samples: *System suitability solution* and *Standard solution*

[Note—The relative retention times for thiotepa and methoxythiotepa are about 1.0 and 1.3, respectively.]

Suitability requirements

Resolution: NLT 3 between methoxythiotepa and thiotepa, *System suitability solution*

Relative standard deviation: NMT 2.0%, *Standard solution*

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of thiotepa ($C_6H_{12}N_3PS$) in the portion of Thiotepa for Injection taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response of thiotepa from the *Sample solution*

r_S = peak response of thiotepa from the *Standard solution*

C_S = concentration of USP Thiotepa RS in the *Standard solution* (mg/mL)

C_U = nominal concentration of thiotepa in the *Sample solution* (mg/mL)

Acceptance criteria: 95.0%–110.0%

IMPURITIES

• **Organic Impurities**

Buffer, Mobile phase, and System suitability solution: Proceed as directed in the *Assay*.

Peak identification solution: Dissolve 15 mg of USP Thiotepa RS in 10 mL of water, add 1 g of sodium chloride, boil in a water bath for 10 min, and cool. [Note—The preparation generates thiotepa chloroethyl analog.]

Standard solution: 3.75 μ g/mL of USP Thiotepa RS in water

Sample solution: Nominally 3.75 mg/mL of thiotepa in water from Thiotepa for Injection. Pass through a suitable filter, and use the filtrate.

Chromatographic system: Proceed as directed in the *Assay*. In addition, the run time is NLT 4 times the retention time of the thiotepa peak.

System suitability

Sample: *System suitability solution*

Suitability requirements

Resolution: NLT 3 between methoxythiotepa and thiotepa

Analysis

Samples: *Peak identification solution, Standard solution, and Sample solution*

Calculate the percentage of each impurity in the portion of thiotepa taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U peak response of each impurity from the *Sample solution*

r_S peak response of thiotepa from the *Standard solution*

C_S concentration of USP Thiotepa RS in the *Standard solution* (mg/mL)

C_U nominal concentration of thiotepa in the *Sample solution* (mg/mL)

Acceptance criteria: See *Table 1*. Disregard any impurity peaks less than 0.1%.

Table 1

Name	Relative Retention Time	Acceptance Criteria, NMT (%)
Thiotepa	1.0	—
Thiotepa chloroethyl analog ^a	3.75	0.15
Any individual unspecified impurity	—	0.2
Total impurities ^b	—	0.4

^a *P,P*-Bis(aziridin-1-yl)-*N*-(2-chloroethyl)phosphinothioic amide.
^b The impurity thiotepa chloroethyl analog is excluded.

PERFORMANCE TESTS

- **Uniformity of Dosage Units** (905): Meets the requirements

SPECIFIC TESTS

- **Bacterial Endotoxins Test** (85): NMT 6.25 USP Endotoxin Units/mg of thiotepa
- **Sterility Tests** (71): Meets the requirements
- **pH** (791)

Sample solution: 10 mg/mL of thiotepa constituted as directed in the labeling

Acceptance criteria: 5.5–7.5

Delete the following:

- **Completeness of Solution** (641): The contents of one container dissolved in Sterile Water for Injection, or other diluent as directed in the labeling, to obtain a solution containing 3.75 mg/mL of thiotepa yields a clear solution. ■ 2S (USP39)

Add the following:

- **Injections and Implanted Drug Products** (1), *Product Quality Tests Common to Parenteral Dosage Forms, Specific Tests, Completeness and clarity of solutions:* At the

time of use, it meets the requirements. ■2S (USP39)

- **Other Requirements:** It meets the requirements in *Injections* 〈 1 〉, *Labels and Labeling*.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve as described in *Injections* 〈 1 〉, *Packaging, Containers for Sterile Solids*, and store in a refrigerator, protected from light.
- **USP Reference Standards** 〈 11 〉
 - USP Endotoxin RS
 - USP Thiotepa RS

BRIEFING

Tinidazole, *USP 38* page 5587. On the basis of comments received, the following changes are proposed to modernize the monograph:

1. The nonspecific *Identification* test *B* is replaced with a HPLC retention time agreement from the *Assay*.
2. The nonspecific *Identification* test *C* is deleted as the other two tests are sufficient.
3. The titration procedure in the *Assay* is replaced with an HPLC procedure based on the validated methods of analysis.
4. The acceptance criteria in the *Definition* and the *Assay* are revised from NLT 98.0% and NMT 101.0% to NLT 98.0% and NMT 102.0%, which is typical for chromatographic procedures.
5. The TLC procedure in the test for *Organic Impurities* is replaced with an HPLC procedure similar to the *Assay*.
6. The HPLC procedures in the *Assay* and test for *Organic Impurities* are based on analyses performed using the Zorbax SB C8 brand of L7 column. The typical retention time for tinidazole is about 6 min.
7. The *Melting Range or Temperature* test is deleted as the HPLC procedure for *Organic Impurities* is sufficient.

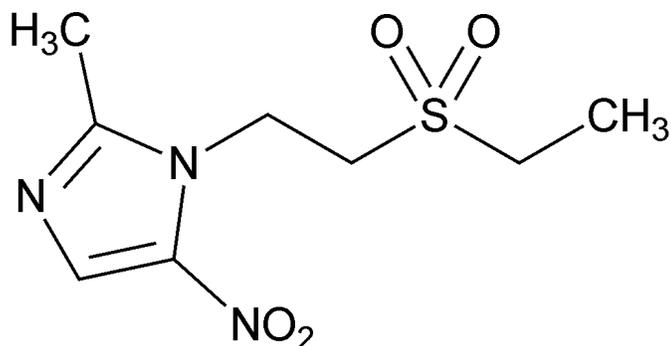

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

BRIEFING

Tretinoin, *USP 38* page 5654. As part of USP monograph modernization efforts, it is proposed to revise the monograph as follows:

1. Replace the current titration-based *Assay* with a stability-indicating HPLC procedure. The procedure was validated using the Cosmosil Cholester brand of L## column manufactured by Nacalai Tesque in which tretinoin elutes at about 8 min.
2. Replace the UV-based *Identification* test *B* with the retention time agreement proposed in the *Assay*.
3. Replace the current normal-phase HPLC procedure in the test for *Limit of Isotretinoin* with a more specific and reversed-phase HPLC procedure. The proposed test for

Organic Impurities uses the same chromatographic parameters as those proposed in the *Assay*.

- The *Acceptance criteria* for specified, unspecified, and total impurities is proposed based on the limits of the *Tretinoin* monograph in the current edition of the *European Pharmacopoeia*. Manufacturers are strongly encouraged to submit their approved specifications to USP if they are different from those proposed in this revision.

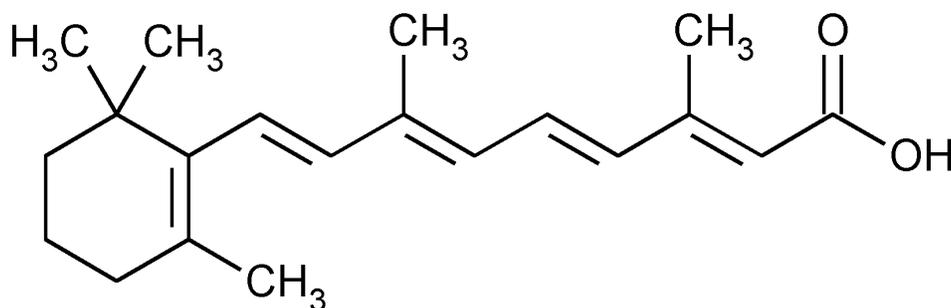

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Samples: *Standard solution* and *Sample solution*

Concomitantly determine the absorbances of the *Sample solution* and the *Standard solution*.

Calculate the percentage of the labeled amount of vinblastine sulfate ($C_{46}H_{58}N_4O_9 \cdot H_2SO_4$) in the portion of Vinblastine Sulfate for Injection taken:

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times 100$$

$A_{\bar{U}}$ absorbance of the *Sample solution*

$A_{\bar{S}}$ absorbance of the *Standard solution*

$C_{\bar{S}}$ concentration of USP Vinblastine Sulfate RS in the *Standard solution* (mg/mL)

$C_{\bar{U}}$ nominal concentration of vinblastine sulfate in the *Sample solution* (mg/mL)

Acceptance criteria: Meets the requirements

IMPURITIES

• Organic Impurities

Mobile phase, System suitability solution, and System suitability: Prepare as directed in the *Assay*.

Sample solution A: Use the *Sample solution*, prepared as directed in the *Assay*.

Sample solution B: 16 µg/mL of vinblastine sulfate in water, from *Sample solution A*

Chromatographic system: Proceed as directed in the *Assay*, except use an injection volume of 200 µL.

Analysis

Samples: *Sample solution A* and *Sample solution B*

Calculate the percentage of each impurity in the portion of Vinblastine Sulfate for Injection taken:

$$\text{Result} = [r_U/(\sum r_U + 25r_S)] \times 100$$

$r_{\bar{U}}$ peak response of each impurity appearing after the solvent peak from *Sample solution A*

$r_{\bar{S}}$ peak response of vinblastine from *Sample solution B*

Calculate the percentage of total impurities:

$$\text{Result} = [\sum r_U/(\sum r_U + 25r_S)] \times 100$$

$r_{\bar{U}}$ peak response of each impurity appearing after the solvent peak from *Sample solution A*

$r_{\bar{S}}$ peak response of vinblastine from *Sample solution B*

Acceptance criteria

Individual impurities: NMT 2.0%

Total impurities: NMT 5.0%

SPECIFIC TESTS

- **Bacterial Endotoxins Test** (85): It contains NMT 10.0 USP Endotoxin Units/mg of vinblastine sulfate.
- **Sterility Tests** (71): Meets the requirements

Delete the following:

- ~~● **Constituted Solution:** At the time of use, it meets the requirements for *Injections* $\langle 1 \rangle$, *Constituted Solutions*. ■ 2S (USP39)~~

Add the following:

- ● **Injections and Implanted Drug Products** $\langle 1 \rangle$, *Product Quality Tests Common to Parenteral Dosage Forms, Specific Tests, Completeness and clarity of solutions:* At the time of use, it meets the requirements. ■ 2S (USP39)

Delete the following:

- ● ~~● **Completeness of Solution** $\langle 641 \rangle$: A 10 mg portion dissolves in 10 mL of Water for Injection to yield a clear solution. ■ 2S (USP39)~~

- **Other Requirements:** It meets the requirements for *Injections* $\langle 1 \rangle$, *Labeling*.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve as described under *Injections* $\langle 1 \rangle$, *Containers for Sterile Solids*, and store in a refrigerator.
- **Labeling:** The label states: "For Intravenous Use Only–Fatal If Given By Other Routes." When dispensed, the container or syringe (holding the individual dose prepared for administration to the patient) must be enclosed in an overwrap bearing the statement: "Do Not Remove Covering Until Moment of Injection. For Intravenous Use Only–Fatal If Given By Other Routes."

Stage 4 Harmonization

This section contains monographs or chapters undergoing harmonization by the Pharmacopoeial Discussion Group (PDG). The PDG consists of the United States Pharmacopeia (USP), the European Pharmacopoeia (EP), and the Japanese Pharmacopoeia (JP). The process of harmonization consists of several steps (**Stages 1** through **7**, as defined below). Stage 4 drafts are available for comments. Below are descriptions of the developmental Stages as defined by the United States Pharmacopeia, the European Pharmacopoeia, and the Japanese Pharmacopoeia.

Stage 1: Identification The PDG identifies items to be harmonized and designates a coordinating pharmacopeia for each item. The PDG distributes the work by consensus among the three participating pharmacopeias. Harmonization may be carried out retrospectively for existing monographs or chapters, or prospectively for new monographs or chapters.

Stage 2: Investigation The investigation process conducted by the coordinating pharmacopeia results in the preparation of a Stage 3 draft monograph or chapter accompanied by a report giving the rationale for the proposal and including validation data where appropriate. This report is based on input that comes from users, authorities, producers, associations, literature, experts, and staff.

Stage 3: Proposal The Stage 3 draft is reviewed and commented on by the other two pharmacopeias. The coordinating pharmacopeia reviews those comments, prepares a harmonized Stage 4 draft, and sends it to the other two participating pharmacopeias.

Stage 4: Official Inquiry The Stage 4 draft is published in the Forum of each pharmacopeia. In *PF*, this stage appears as OFFICIAL INQUIRY STAGE 4 in the *Harmonization* section. Each pharmacopeia analyzes the comments it receives and submits the consolidated comments to the coordinating pharmacopeia, which then reviews those comments, prepares a harmonized Stage 5A draft, and sends it to the other two participating pharmacopeias.

Stage 5: Consensus

A. Provisional

The Stage 5A draft is reviewed and commented on by the other two pharmacopeias. When consensus is reached, a CONSENSUS STAGE 5B document is prepared by the coordinating pharmacopeia.

B. Final

The Stage 5B draft (consensus document) is sent by the coordinating pharmacopeia to the other two participating pharmacopeias for final approval.

Stage 6: Adoption Each pharmacopeia incorporates the harmonized Stage 5B draft according to its own procedure. Adopted items are published by the three pharmacopeias in their Supplements or, where applicable, in a new edition of their Pharmacopeias.

Stage 7: Date of Implementation The pharmacopeias inform each other of the date of implementation in the particular region.

STIMULI TO THE REVISION PROCESS

Stimuli articles do not necessarily reflect the policies of the USPC or the USP Council of Experts

STIMULI TO THE REVISION PROCESS

This section may contain the following:

- reports or statements of Expert Committees
- original research reports
- evaluations of new and existing pharmacopeial methods
- commentaries
- articles relevant to compendial issues.

These items are published to stimulate discussion and continual review of Pharmacopeial standards. Generally, if an Expert Committee publishes an article on which they are specifically seeking comment, this will be clearly stated in the article. Readers may submit comments on issues raised in this section, but comment is not as critical as that for the *In-Process Revision* section. Readers interested in submitting comments should see *Instructions to Authors*.

Instructions to Authors

Contributions in the form of original research reports, evaluations of new and existing compendial methods, and other commentaries and articles relevant to drug standards or to *USP-NF* revision will be considered for publication in *Pharmacopeial Forum* under the section *Stimuli to the Revision Process*. Manuscripts are received with the explicit understanding that they have not been published previously in any language or medium and that they are not simultaneously under consideration by any other publication. All manuscripts are subject to review by USP headquarters staff, Committee members, or qualified outside referees, and if accepted for publication they will be subject to editing by USP staff. Accepted manuscripts become the property of the USP Convention (USPC) and may not be subsequently published elsewhere without written permission from the USPC. Authors are also responsible for obtaining permission for reprinting any illustrations that have been published elsewhere.

Abstract—Include an abstract of not more than 250 words stating the purpose and the results or conclusions of the article.

Style and Usage—*Stimuli* articles generally follow the current *Chicago Manual of Style* except in scientific usage (numbers, abbreviations, etc.). For the latter, authors should use the current *AMA Manual of Style* or the current *ACS Style Guide*. Authors may usefully consult a current edition of *Pharmacopeial Forum*.

References—Consult the current *AMA Manual of Style*, which is generally consistent with the National Library of Medicine's *Recommended Formats for Bibliographic Citation*. A current edition of *Pharmacopeial Forum* will offer examples of reference formats.

Copyright—Copyright transfer documents will be sent to authors after manuscripts have been accepted for publication.

Disclosure of Potential Conflicts of Interest—Maintaining independence and impartiality are critical to the integrity and credibility of USP's public health mission. Accordingly, authors are expected to conform to the Conflict of Interest provisions of the USP Code of Ethics (see link below), including as part of their manuscript submission disclosure of all financial and personal relationships that may potentially influence, or be perceived to influence, their article. USP staff are available to provide additional guidance to authors on the range of disclosure that would be appropriate. Although USP *Stimuli* articles are not the type of source likely to be relied on as a basis for governmental actions (e.g., not a vehicle for reports of human clinical research), USP nevertheless supports the overall policies of the International Committee of Medical Journal Editors (ICMJE) regarding Uniform Requirements for Manuscripts Submitted to Biomedical Journals and Ethical Considerations in the Conduct and Reporting of Research (links below).

USP Code of Ethics:

<http://www.usp.org/aboutUSP/governance/policies/codeOfEthics.html>

ICMJE Uniform Requirements:

http://www.icmje.org/urm_main.html

ICMJE Conflicts of Interest:

<http://www.icmje.org/conflicts-of-interest/>

Contact Person—USP will designate a Scientific Liaison in the Documentary Standards Division as the corresponding author. This ensures that USP receives all comments generated by the *Stimuli* article. Authors should contact the Scientific Liaison if they would like to receive copies of comments generated by their *Stimuli* articles.

Submission Instructions—Manuscripts must be submitted both as an electronic file and as a printed copy of the electronic file. Submit the text in Microsoft® Word or another current word-processing application. The preferred format for graphics submitted electronically is tagged image file format (TIFF). Photocopies are not acceptable. Manuscripts submitted for publication should be addressed to:

A Rational Approach to Cascade Impactor Mensuration in a Good Cascade Impactor Practice Environment

Steven C Nichols^a and Jolyon P Mitchell^{b,c}

ABSTRACT This article was initially published in *PF* 40(1) [Jan.–Feb. 2014] and comments were received. The authors have revised the article to address comments received. The purpose of this *Stimuli* article is to provide the framework in support of a regimen of stage mensuration for both new and used cascade impactor systems as the principal means of assuring the suitability (aerodynamic particle size accuracy) of these apparatuses when used as a compendial method. The traceability chain is now uninterrupted from the determination of stage aerodynamic performance, as represented by its cut-point size, via the effective diameter of the nozzles of the stage in question to the international length standard. This part of the Good Cascade Impactor Practice regimen may also be used as a good laboratory practice by establishing a standard operating procedure, in which stage mensuration takes place both on receipt of a new cascade impactor and also periodically throughout its lifetime in use.

INTRODUCTION

The multi-stage cascade impactor (CI) is used widely to determine aerodynamic particle size distributions (APSDs) of orally inhaled products (OIPs) (1). The CI size-fractionating capability at a given volumetric flow rate depends primarily on the size of the nozzles at each stage (2). The accuracy of these particle size fractionating apparatuses is ultimately determined through calibration using monodisperse standards of known aerodynamic diameter that possess traceability to the international standard of length (3). The archival calibrations of the Next Generation Pharmaceutical Impactor (NGI), with stage nozzle diameters selected to be as close as possible to the nominal sizes at 15, 30, 60, and 100 L/min nominal flow rates, represent the current state of the art in this respect (4,5). Such calibrations, however, are extremely laborious and exacting to perform because they require specialized facilities capable of generating and delivering the calibration aerosols. The size range of these particles needs to encompass the overall operating range of the CI and provide a minimum of five data points from which the cut-point size at which a given stage is 50% efficient (d_{50}) can be determined as the calibration constant for that stage (4,5).

RECENT DEVELOPMENTS REGARDING STAGE MENSURATION

Since the mid-1990s, the United States Pharmacopeia (USP) and European Pharmacopoeia (Ph.Eur.) methods for APSD measurement have sanctioned the use of stage mensuration as a surrogate for formal recalibration. Currently, *Inhalation and Nasal Drug Products: Aerosols, Sprays, and Powders—Performance Quality Tests* { 601 } of the USP and monograph 2.9.18 of the Ph.Eur. provide wording to the effect that stage mensuration should be performed periodically, together with confirmation of other dimensions critical to the effective operation of the impactor (6,7).

Until recently, it was not possible to relate a measure of “average” nozzle diameter for a multi-

nozzle CI in an unambiguous way to d_{50} . However, in 2005, Roberts and Romay (8) showed that the "effective diameter, D_{eff} " could be used to describe the multi-nozzle set for the stage in question, where:

$$D_{eff} = (D^*)^{2/3} \times (D_{median})^{1/3} \quad [1]$$

D^* = area mean

D_{median} = area mean diameter

Later, Roberts (9) went on to show analytically that D_{eff} and d_{50} can be related through the expression of eq. 2 (with variables as defined in eq. 3, in numerator order):

$$D_{eff} = \left(\frac{Q}{n} \right)^{1/3} \left\{ \frac{4C_{50}\rho_p}{9\pi\eta St_{50}} \right\}^{1/3} (d_{50})^{2/3} \quad [2]$$

from which, by rearranging eq. [2]:

$$d_{50} = (D_{eff})^{3/2} \left\{ \frac{9\pi\eta n St_{50}}{4QC_{50}\rho_p} \right\}^{1/2} \quad [3]$$

d_{50} = a minimum of five data points from which the cut-point size at which a given stage is 50% efficient

D_{eff} = effective diameter

η = air viscosity, 1.807 Pa·s at 20° C

n = number of nozzles for the stage in question

St_{50} = dimensionless Stokes number at which the stage is 50% efficient at capturing incoming particles (typically close to 0.24 for round nozzles and neglecting the effect of gravity)

Q = volumetric rate through the CI

C_{50} = dimensionless slip correction term, which can be treated as equivalent to unity for particles that are >10 μm , increasing to 1.15 for particles that are 1.3 μm in diameter and to 2.0 for particles that are 0.13 μm in diameter

ρ_p = particle density, dependent upon the aerosol being sampled

Apart from Q , which can be set to within $\pm 5\%$ between 15 and 100 L/min, encompassing the range of flow rates associated with the impactor apparatuses defined in the pharmacopeial compendia, and using readily available laboratory equipment (10), the other terms are constants for particular measurement conditions and therefore need not be considered further when considering CI system verification. Nichols et al. (11) have since provided data for all of the multi-stage CIs that are designated apparatuses for OIP APSD measurement, linking the manufacturers' tolerances for the various stages to their equivalents in terms of deviations in stage d_{50} from the nominal value.

From the foregoing, it is possible to define the limits for D_{eff} in the compendia that relate to a

known accuracy for each stage in terms of its d_{50} size. The problem, however, has now become one of defining a meaningful specification for each stage and ultimately the overall accuracy for the CI apparatus as a whole in terms of stage d_{50} values. This goal is potentially achievable for the NGI, because this apparatus has a known "archival calibration". This calibration is based on a single representative instrument with stage nozzle diameters (and therefore its D_{eff} values) intentionally selected to have values as close as possible to nominal (4,5). Such rigor, however, is lacking with all other compendial apparatuses. There is currently little stakeholder support for undertaking archival calibrations of these CIs; therefore, the best that can be done is to relate mensurated stage D_{eff} values to the nominal mean diameters that are published in the pharmacopeias. The situation has been improved marginally by the addition of manufacturer-specified tolerances associated with the stage nozzle diameters for all apparatuses in the latest revision of $\langle 601 \rangle$ (7).

PROPOSED MENSURATION SCHEME

The complete manufacturing tolerances for the nozzles of all stages of all compendial apparatuses have been defined by Nichols et al. (11), with the intention that this information will, in due course, appear in future revisions to both $\langle 601 \rangle$ of the *USP* and monograph 2.9.18 of the *Ph.Eur*. It is important to note that although these tolerances are definitive in terms of the manufacturer's specifications, they need not necessarily be the same as those used to define internal "at mensuration" specification limits. It can be advantageous to set tighter limits to avoid the situation where a particular CI fails to meet the manufacturer's specifications at a given routine mensuration. Such a situation would result in uncertainty about the value of data that were obtained by that apparatus between the current mensuration and the elapsed time since the previous mensuration in which its performance was deemed to be acceptable. Given this reality, the scheme shown in *Figure 1* is a proposed revision to the current texts for both compendia. Guidance can be provided to the user on "practical" best practice to ensure that the quality of data produced by a given CI may not come into question as the result of a failed stage mensuration based on manufacturer tolerances.

The key parts of the mensuration process are as follows:

1. At receipt of a new CI, ensure, as part of installation qualification, that new CI apparatuses are compliant with manufacturers' dimensional specifications that ideally should be based on measurements for each and every nozzle, thereby confirming acceptance and establishing baseline mensuration data for each stage of each individual CI. As a minimum, this should include an assessment of mean diameter and its associated tolerance for the group of nozzles associated with each stage, as defined as pharmacopeial specifications in $\langle 601 \rangle$ of the *USP*. If a particular stage does not conform to specification, for instance because of missing or obstructed nozzles, reject the CI for remediation or replacement by the supplier/manufacturer. It is preferable to calculate D_{eff} from the mensuration data for each stage as the primary metric, against which its acceptance against the manufacturer-specified tolerance, as well as its future performance while in use, can be judged.
2. For stages that are acceptable in terms of the manufacturer's specifications, establish the in-use stage mensuration regimen. This process will always include measuring the individual impactor nozzle diameters and, for the reason given above, should normally be extended to determine D_{eff} at each mensuration after acceptance. Guidance on the

accuracy and precision of currently available optical microscopy-image analysis techniques that are recommended for stage mensuration has been provided by Chambers et al. (12). Note that the entity conducting the stage mensuration should be instructed to make these measurements before cleaning the stages so that the "as received" condition may be established. The manufacturer-established specifications will likely be used initially as benchmarks for the parameters that are used to judge whether the stage(s) affected requires remediation or replacement. Note that remediation could be as simple as careful cleaning to remove deposits that may be plugging nozzles. Acquisition of data from several subsequent mensuration exercises after exposure to the product(s) being evaluated in the typical testing environment may also provide the opportunity to develop meaningful in-service "at mensuration" limits that will likely be chosen to be tighter than those used to begin with. These internal limits can subsequently be used to indicate the need for remediation before the stage D_{eff} breaches either the upper or lower boundary of the tolerance range.

3. For those stages that are not acceptable in terms of the manufacturer's specifications, remove the CI from service and either recondition the CI or replace it altogether.
4. Establish the frequency between mensuration events. Although annual evaluation will be sufficient for most users, the duration between mensuration exercises should ideally be governed by the frequency of CI use, the type of compounds being collected, and the solvents/reagents used to recover the collected particulate matter.
5. Ensure that other non-nozzle dimensional data for the CI apparatus are checked and confirmed as being acceptable through a mensuration or appropriate visual inspection process. Guidance on the important dimensions for ancillary equipment, such as the induction port and pre-separator (if used), has been provided by Nichols et al. (11). If at any time the data are deemed to be unacceptable, it may be possible to take remedial action, for example by cleaning the affected component. Under such circumstances, discussion with the manufacturer to establish the most appropriate procedure beforehand is strongly recommended. However, if remedial action does not resolve the problem, then the individual component should be replaced before the apparatus is placed back into service.
6. If the stage or ancillary equipment fails specification, establish an appropriate remediation strategy; note that this process may include the supplier/manufacturer. A detailed description of what might be done to refurbish equipment that is out of specification cannot be provided here because there are many potential causes of changes to critical dimensions that are based on the usage regimen, for example solvent/reagent types used for cleaning and/or recovery of active pharmaceutical ingredient(s), as well as the physicochemical nature of the products themselves.

CONCLUSIONS

A regimen for CI apparatus stage mensuration has been provided to guide users in the continued assurance of CI suitability (aerodynamic particle size accuracy) for the routine assessment of OIP-generated aerosols through the apparatus life cycle. The underlying theory governing the operation of CIs has advanced to the point at which there is the potential for implementation in the pharmacopeial compendia of a robust calibration chain for these apparatuses. Such a scheme links the critical multi-nozzle dimensions using D_{eff} as the collective measure for a given size-fractionation stage to its size-fractionation performance based on stage d_{50} values that are directly relatable to APSD measurement accuracy.

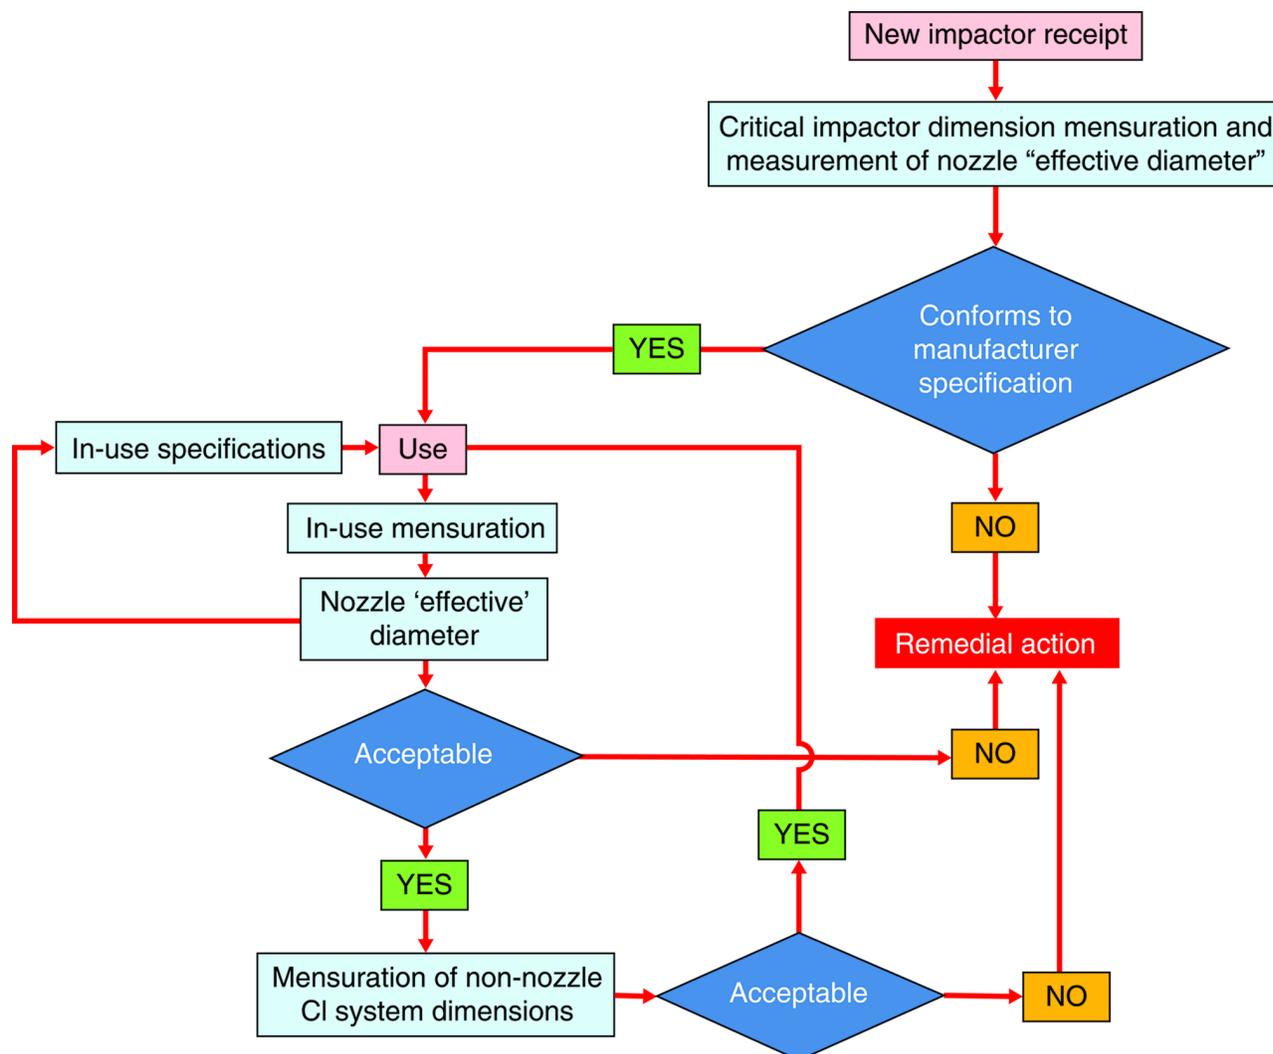

Figure 1. Scheme for the application of stage mensuration to confirm suitability for use of compendial CI apparatuses. [Note—The frequency of the "In-use mensuration" check is determined by the amount of impactor use and the product/solvent characteristics.]

Total Parenteral Nutrition: Position of the USP Elemental Impurities Expert Panel^a

USP Elemental Impurities Expert Panel^a

ABSTRACT The work performed to revise *Elemental Impurities—Limits* 〈 232 〉 and *Elemental Impurities—Procedures* 〈 233 〉 has opened discussions about harmonization with The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH). Although much progress has been made toward harmonization, a divide remains regarding the classification and treatment of total parenteral nutrition (TPN). This *Stimuli* article describes and contrasts the USP approach and ICH approach to TPN and presents recommendations from the USP Elemental Impurities Expert Panel for accomplishing harmonization. USP is seeking feedback regarding the ICH Q3D approach to TPN and the Panel's recommendations regarding TPN. In particular, what impact will limits for doses of 2 L or more have on industry?

INTRODUCTION

As USP worked to finalize *Elemental Impurities—Limits* 〈 232 〉 and *Elemental Impurities—Procedures* 〈 233 〉, efforts were made to harmonize with The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH) Q3D—Elemental Impurities. Many areas required considerable discussion and negotiation between the two groups, and much progress has been made in harmonizing the approach to monitoring pharmaceuticals for elemental impurities.

One area where a divide remains is the treatment of total parenteral nutrition (TPN). Although the ICH approach is for TPN to remain within the scope of Q3D—Elemental Impurities and to treat TPN similarly to large-volume parenterals (LVPs), USP has chosen to remove TPN from the scope of 〈 232 〉.

There is clearly a difference between the USP approach and the ICH approach to TPN. The USP Elemental Impurities Expert Panel thinks that the 2-L reference volume for LVPs, as proposed by ICH, may be too onerous for some TPN products. Although the arguments presented by the Elemental Impurities Expert Panel in support of excluding TPN from the scope of 〈 232 〉 may also apply for LVPs, the nature of the matrix of most TPN solutions makes their analysis even more difficult than the analysis of LVPs. As a result, in an effort to harmonize as much as possible, the Elemental Impurities Expert Panel adopted the ICH requirements for LVPs but presents the following rationale for excluding TPN from the scope of 〈 232 〉.

THE CONCERNS OF THE USP ELEMENTAL IMPURITIES EXPERT PANEL REGARDING THE ICH APPROACH

The concerns of the USP Elemental Impurities Expert Panel about the ICH approach for including TPN within LVPs and the 2-L reference volume for LVPs focus on three main areas:

1. The nature of TPN
2. Dosing considerations
3. Analytical considerations

The Nature of TPN

TPN products are prepared from carbohydrates, amino acids, lipids, and electrolytes in various formulations consisting of single components or mixtures. Specific volumes and component concentrations vary, but from an analytical standpoint, TPN products are very highly dissolved solids, often with major concentrations of inorganic salts. Volumes range from 100 mL to several liters.

TPN solutions are classified by ICH as a subclass of all LVP solutions because:

1. Unlike the majority of therapeutic LVP solutions, TPN contains very high concentrations of dissolved salts, carbohydrates, amino acids, and lipids, either individually or in combinations, sometimes in excess of 50% of the total dissolved solids.
2. Many TPN units are produced in volumes of 2 L or more.

The parenteral permissible daily exposure (PDE) values for the elemental impurities are quite low for many elements. A general rule for introduction of a sample solution to an inductively coupled plasma (ICP)–mass spectrometer (MS) is that the dissolved solids are not in excess of a few tenths of a percentage. For example, in the case of a normal saline solution at 0.9% sodium chloride (NaCl) (w/w), an analyst would likely apply a 10-fold dilution to the test subject before analysis. For the purpose of this example, we will ignore any analytical considerations regarding the analysis of any specific target elements (e.g., analysis of arsenic in a TPN solution containing a chloride salt).

The applied 0.5J spiking concentrations, as required in § 233 to demonstrate accuracy and sensitivity, are displayed in *Table 1* for a 2-L daily dose and an applied 10-fold dilution. Note that many TPN formulations have inorganic salt concentrations far in excess of 0.9% and would correspondingly require higher rates of dilution. A complete digestion preparation would not lessen the amount of inorganic salts in the test material—only the carbohydrate/amino acid/lipid components. Mixtures of amino acids, carbohydrates, and electrolyte salts with total dissolved solids in excess of 20% are common. Some manufacturers' formulations have total dissolved solids that are much higher. Therefore, the required spiking limits at the 0.5J level are presented in *Table 1* for 25-, 50-, 100-, and 200-fold dilutions.

Table 1. Spiking Limits per § 233 for Demonstrating Accuracy/Sensitivity of an ICP–MS Method Based on a 2-L Daily Dose

Element	Parenteral PDE (µg/day)	2000-mL TPN Component Limit (µg/mL)	DF = 10	DF = 25	DF = 50	DF = 100	DF = 200
			0.5J (µg/L)

Dosing Considerations

TPN solutions are commonly administered through a bedside metering pump that mixes the various solutions and delivers them at a prescribed rate of infusion. Large-volume units of high-concentration solutions, for example a 2-L bag of 70% dextrose, may actually be administered to the patient for more than a 24-h period. This period of time should be considered when establishing limits.

Another consideration related to dosing is the acute nature of TPN administration. In most cases, TPN can be assumed to be an acute or short-term treatment. Most patients will receive TPN at relatively high volumes of solution over a relatively short period of time. PDEs are calculated as daily doses that would be acceptable with lifetime daily exposure. Different safety factors may therefore apply to pharmaceutical products administered for shorter treatment periods. This is already addressed in the ICH Q3D document: paragraph 3.3, Justification for Elemental Impurity Levels Higher Than an Existing PDE.

If the PDEs for parenteral administration are to be applied to TPN solutions, then the USP Elemental Impurities Expert Panel recommends that the volume limit for the maximum daily dose be set at 500 mL. Spiking concentrations at the 0.5J level are presented in *Table 2* below.

Table 2. Spiking Limits per $\langle 233 \rangle$ for Demonstrating Accuracy/Sensitivity of an ICP-MS Method Based on a 500-mL Daily Dose

Element	Parenteral PDE (µg/day)	500-mL TPN Component Limit (µg/mL)	DF = 10	DF = 25	DF = 50	DF = 100	DF = 200

Analytical Considerations

The USP Elemental Impurities Expert Panel thinks that the analytical limits that would be imposed on products with a 2-L daily dose (as illustrated in *Table 1*) would be arduous, even for laboratories that are well versed in the use of ICP-MS. Capabilities for routine detection in parts per trillion (ppt) will rely heavily on the cleanliness of the laboratory—perhaps more so than on the ICP-MS instrumentation itself. The average ICP-MS laboratory is not a class-100 clean room. For routine ppt detection, some laboratory facilities will need to be retrofitted for a manufacturer to perform the required analyses for LVPs using a 2-L daily dose. In such instances, it is essential to minimize metal surfaces in the laboratory. Although it is possible to coat metals with plastic, this is not the best option. Selection of hoods, cabinets, drawer pulls, benchtops, and other items must be made to eliminate as much metal as possible from the laboratory. Ceiling tiles must be removed, and sheetrock ceilings must be installed. An air lock between other areas and the ICP-MS laboratory is recommended, as is the use of a sticky pad at every entrance to the laboratory. Laboratory air should be brought in directly from outside, and access to the laboratory should be limited.

Beyond the actual laboratory facility, the reagents, labware, and other materials used must be of the best quality for trace-metals work. Ultra-pure acids must be used. To reduce the costs of such acids, laboratories may find it necessary to distill their own, thereby requiring additional safety considerations. Once the physical laboratory and equipment have been considered, the capabilities of the instrumentation must be considered.

On the basis of the limits presented in *Table 1*, it is clear that the 2-L dose limits—even for a 10-fold dilution and even if one regards all other analytical considerations—are very arduous for many of the elements.

USP ELEMENTAL IMPURITIES EXPERT PANEL RECOMMENDATIONS ON TPN

A more useful approach may be to change the PDE-per-dose paradigm and adopt limits similar to the aluminum (Al) rule that states that LVP TPN shall not contain >25 ppb of Al, irrespective

of dose or volume administered. The following URL provides additional details:
<https://www.federalregister.gov/articles/2001/01/26/01-2125/aluminum-in-large-and-small-volume-parenterals-used-in-total-parenteral-nutrition-delay-of-effective>.
 It would be prudent to apply these “fixed” limits to the elements with the lowest PDEs. Suggested applied fixed limits are presented in *Table 3*.

Table 3. Suggested “Fixed” Elemental Impurities Limits per the Aluminum Rule Paradigm

Element	TPN Limit (ppb)
As	30
Cd	6
Hg	6
Pb	10
Co	10
V	24
Ir	20
Os	20
Pd	20
Pt	20
Rh	20
Ru	20
Tl	16
Ni	40

The Panel is hopeful that USP will receive feedback regarding the ICH Q3D approach to TPN and the Panel’s recommendations regarding TPN. In particular, what impact will limits for doses of 2 L or more have on industry?

^a Correspondence should be addressed to: Kahkashan Zaidi, PhD, Principal Scientific Liaison, US Pharmacopeial Convention, 12601 Twinbrook Parkway, Rockville, MD 20852-1790; tel. 301.816.8269; e-mail kxz@usp.org.

Please address comments on *Pharmacopeial Forum* content to
USP Executive Secretariat
12601 Twinbrook Parkway
Rockville, MD 20852
execsec@usp.org

ISSN: 1542-1945

Pharmacopeial Forum is covered in *Current Contents/Life Sciences* and in the *Science Citation Index (SCI)*, in *International Pharmaceutical Abstracts*, and in *Current Awareness in Biological Sciences*.

The United States Pharmacopeial Convention comprises representatives from academic institutions; health practitioner and scientific associations; consumer organizations; manufacturer and trade associations; government bodies and associations; and non-governmental standards-setting and conformity assessment bodies. It publishes the U.S. Pharmacopeia and National Formulary, the legally recognized compendia of standards for drugs and products of other health care technologies. The USP and NF include assays and tests for the determination of strength, quality, and purity and requirements for packaging and labeling. **Pharmacopeial Forum's Public Review and Comment Process**

This section presents an overview of the public review and comment process, conducted through *Pharmacopeial Forum (PF)*, for the development of official standards in the *United States Pharmacopeia* and the *National Formulary (USP–NF)*.

USP publishes *PF* on a bimonthly basis to provide an opportunity to review and comment on new or revised standards.

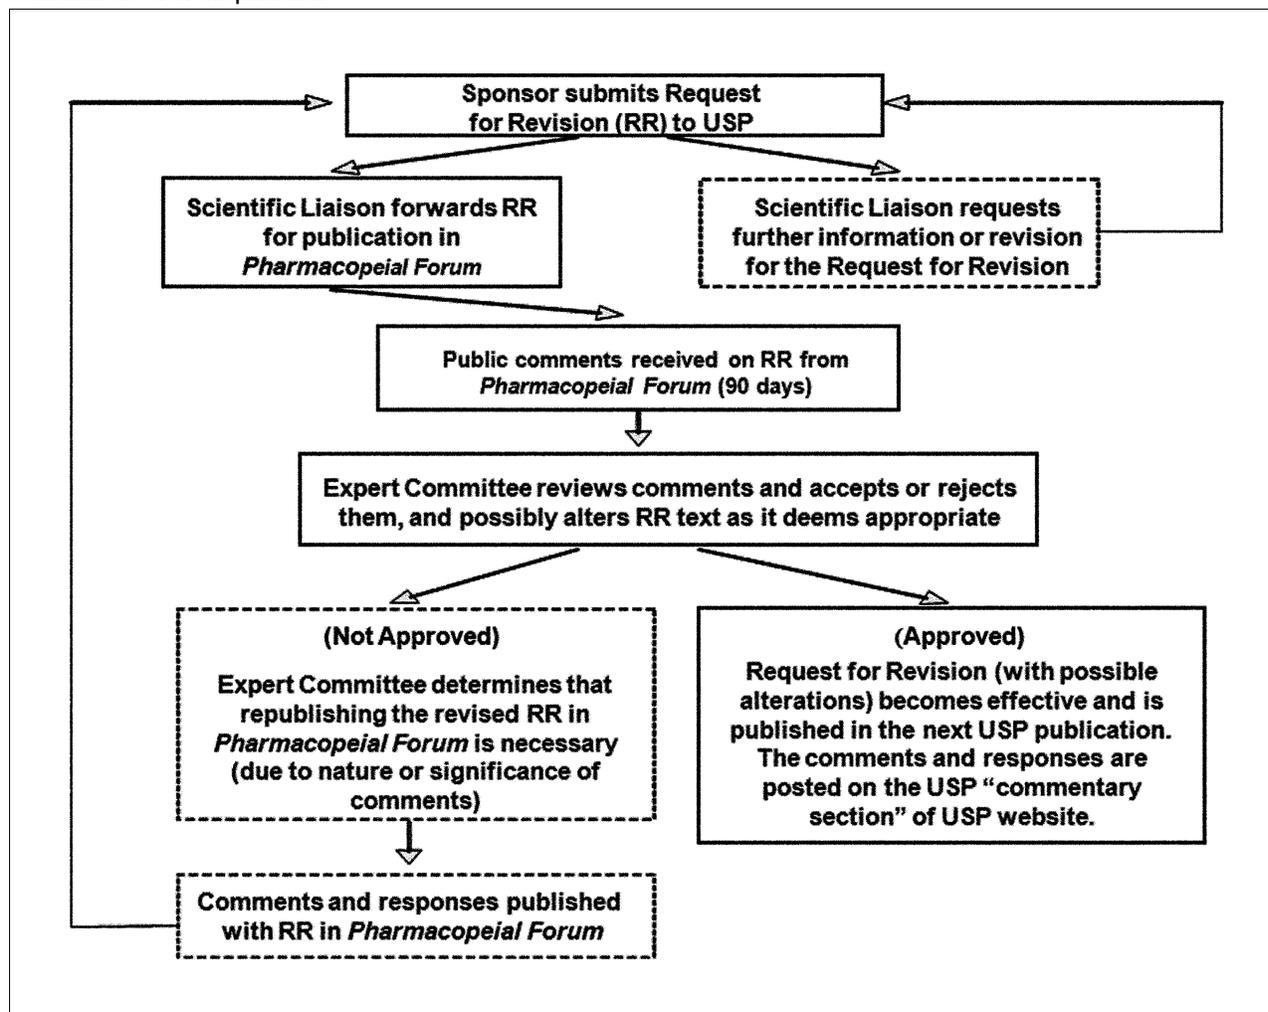

There are two types of proposed revisions in *PF*:

1. **Proposed Revisions**—New or revised standards targeted for adoption through USP's Standard Revision Process. USP's Revision Process calls for publication of a proposed revision in *PF* for a 90-day notice and comment period. After the comment period and subsequent review of comments and approval by the relevant USP Expert Committee, the official standard is published in the next available *USP–NF* or *Supplement*. If comments received are significant, or if the Expert Committee's consideration of comments results in significant additional changes, the Expert Committee may determine that republishing in *PF* is necessary prior to the revision becoming official. See the *In-Process Revision* section for current proposed revisions.
2. **Proposed Interim Revision Announcements**—New or revised standards that become official through an accelerated process in accordance with USP's Guideline on Accelerated Revisions (available on the USP Web site). *Interim Revision Announcements (IRAs)* allow for a revision to become official prior to the next *USP–NF* or *Supplement*. *IRAs* are first presented for a 90-day public comment period in the *Proposed Interim Revision Announcement* section of the *PF*. Note that final *IRAs*, as well as *Errata*, and *Revision Bulletins*, which also are defined in the Accelerated Revision Guideline, appear

only on the USP Web site.

USP welcomes comments and data on proposed revisions. A summary of comments received, along with USP's responses, will be published in the *Revisions and Commentary* section of the USP website (<http://www.usp.org/USPNF/revisions/>).

The chart below shows the public review and comment process and its relationship to standards development.

Questions on the process should be addressed to the USP Executive Secretariat, United States Pharmacopeia, 12601 Twinbrook Parkway, Rockville, MD 20852 (e-mail: execsec@usp.org).

HOW TO USE PF

The various sections of *PF* are briefly described below. A more detailed description of each section is provided at the beginning of that section. A general description of the types and amount of information expected in a *Request for Revision* is available in the *Guideline for Submitting Requests for Revision to the USP-NF* on the USP Web site (www.usp.org/USPNF/submitMonograph/subGuide.html). Note that the Expert Committee listing and the Scientific Staff Directory also are located on the USP Web site (see below for links).

Proposed and Adopted Revisions to the *USP-NF*

(<http://www.usp.org/USPNF/devProcess/contactScientists.html>)

Proposed Interim Revision Announcements

This section includes proposals for *Interim Revision Announcements (IRAs)* that will be published as official *USP* or *NF* standards. There is a 90-day comment period for these proposals (see <http://www.usp.org/USPNF/pf/pfRedesign.html> for the *PF* comment schedule). Readers should review material in this section and provide comments to the Scientific Liaison using the contact information appearing at the end of each proposed *IRA*. Information on how to comment can be found under the "Participation" section of www.usp.org. It is important to send comments promptly so that the Expert Committee members can consider reader's input as they are deciding whether to advance standards to official status. The approved official text will be published under *IRAs* in the "New Official Text" section of USP's Web site.

Each proposal is preceded by a Briefing that indicates the proposed revisions.

Symbols—New text is enclosed in symbols and set off from the current official text as shown in the following example: •new text•. Where the symbols appear together with no enclosed text, such as ••, it means that text has been deleted and no new text was proposed to replace it. In all revisions, the closing symbol is accompanied by an identifier that indicates the date the proposal, if approved, will become official as an *IRA*. For example, •(IRA 1-Apr-2011)

BRIEFING

Dutasteride, *USP 38* page 3247. On the basis of a comment received, it is proposed to revise the monograph as indicated in item 1 below. Additional minor changes are also proposed (items 2–5).

1. Move dihydrodutasteride from *Organic Impurities, Procedure 1* to *Organic Impurities, Procedure 2*. USP has been informed that *Organic Impurities, Procedure 1* is not suitable for quantitating dihydrodutasteride and that *Organic Impurities, Procedure 2* should be used instead. Dihydrodutasteride has been removed from *Table 3* and added into *Table 4* along with its associated relative response factor.
2. Change the resolution between the dutasteride α -dimer and dutasteride β -dimer peaks in the *Suitability requirements* under *Organic Impurities, Procedure 2* from NLT 2.0 to NLT 1.5.
3. Include text in the *Identification* indicating that *Infrared Absorption (197A)* may be used.
4. Remove redundant text from the *Limit of quantitation* section under the *Limit of Platinum* test and change platinum to Dutasteride in the definition of C_S .
5. Remove the *Standard solution* from the *Organic Impurities* section, as it is not used.
6. The procedure in the *Water Determination* test has been clarified to correspond to that used by the sponsor.
7. Clarify the listing of the USP Dutasteride Resolution Mixture RS contents to indicate that it includes dutasteride.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

The comment period for this revision ends on November 30, 2015. In the absence of any significant adverse comments, it is proposed to implement this revision via an *Interim Revision*

Announcement to the Second Supplement to USP 39–NF 34, with an official date of March 1, 2016.

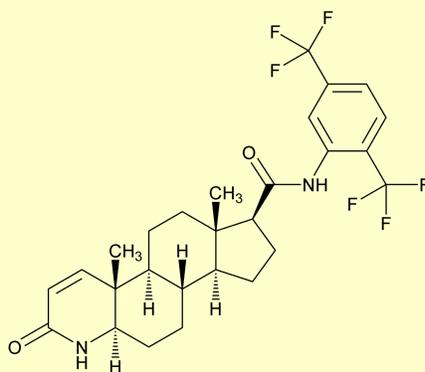

(CHM5: D. Porter.)

Correspondence Number—C157906

Comment deadline: November 30, 2015

Add the following:

▲ Dutasteride

$C_{27}H_{30}F_6N_2O_2$ 528.53

(5 α ,17 β)-*N*-[2,5-Bis(trifluoromethyl)phenyl]-3-oxo-4-azaandrost-1-ene-17-carboxamide;
 $\alpha,\alpha,\alpha,\alpha',\alpha',\alpha'$ -Hexafluoro-3-oxo-4-aza-5 α -androst-1-ene-17 β -carboxy-2',5'-xylylide [164656-23-9].

DEFINITION

Dutasteride contains NLT 97.0% and NMT 102.0% of dutasteride ($C_{27}H_{30}F_6N_2O_2$), calculated on the anhydrous and solvent-free basis.

IDENTIFICATION

Change to read:

- **A. Infrared Absorption** (197K) or (197M).
 - (197A) may be used. •(IRA 1-Mar-2016)
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.

ASSAY

• **Procedure**

Diluent: *Acetonitrile* and water (60:40)

Mobile phase: *Acetonitrile*, water, and *trifluoroacetic acid* (52: 48: 0.025)

System suitability solution: 0.5 mg/mL of USP Dutasteride Resolution Mixture RS in *Diluent*. Sonicate to dissolve.

Standard solution: 0.5 mg/mL of USP Dutasteride RS in *Diluent*. Sonicate to dissolve.

Sample solution: 0.5 mg/mL of Dutasteride in *Diluent*. Sonicate to dissolve.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 220 nm

Column: 4.6-mm × 25-cm; 5-µm packing L1

Column temperature: 35°

Flow rate: 1 mL/min

Injection volume: 10 µL

Run time: 1.5 times the retention time of dutasteride

System suitability

Samples: *System suitability solution* and *Standard solution*

[Note—See *Table 3* for the relative retention times.]

Suitability requirements

Resolution: NLT 1.5 between dutasteride 17α-epimer and dutasteride, *System suitability solution*

Relative standard deviation: NMT 1.5%, *Standard solution*

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of dutasteride (C₂₇H₃₀F₆N₂O₂) in the portion of Dutasteride taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*

r_S = peak response from the *Standard solution*

C_S = concentration of USP Dutasteride RS in the *Standard solution* (mg/mL)

C_U = concentration of Dutasteride in the *Sample solution* (mg/mL)

Acceptance criteria: 97.0%–102.0% on the anhydrous and solvent-free basis

IMPURITIES

- **Residue on Ignition** (281): NMT 0.1%

Change to read:

- **Limit of Platinum**

[Note—Perform this test only if platinum is a known inorganic impurity of the manufacturing process.]

Diluent: *Hydrochloric acid* and *dimethyl sulfoxide* (2:98). Prepare in a plastic volumetric flask.

Standard stock solution: 10 µg/mL of platinum in *Diluent*. Prepare by diluting (1:100) a 1000-µg/mL commercially available platinum standard.

Standard solution 1: 1.0 µg/mL of platinum in *Diluent* from the *Standard stock solution*

Standard solution 2: 0.1 µg/mL of platinum in *Diluent* from *Standard solution 1*

Sample solution: 0.01 g/mL of Dutasteride in *Diluent*. Sonicate to dissolve.

Instrumental conditions

(See *Plasma Spectrochemistry* (730).)

Mode: ICP-OES

Analytical wavelength: 306.471 nm

Spectrophotometric system: Use an inductively coupled plasma-optical emission spectrophotometric system, and construct a calibration curve using the response from the *Diluent*, *Standard solution 1*, and *Standard solution 2*.

System suitability

Samples: *Diluent*, *Standard solution 1*, and *Standard solution 2*

Suitability requirements

Limit of quantitation: 3 µg/g for platinum. ~~Use the standard deviation, in µg/mL, of the platinum concentration obtained from the Diluent.~~

- (IRA 1-Mar-2016)

Calculate the limit of quantitation from the *Diluent*:

$$\text{Result} = 10 \times (SD/C_S)$$

SD = standard deviation of platinum from *Diluent* (µg/mL)

C_S = nominal concentration of platinum

- dutasteride•(IRA 1-Mar-2016)
in the *Sample solution* (g/mL)

Correlation coefficient: NLT 0.99 from the *Diluent*, *Standard solution 1*, and *Standard solution 2*

Analysis

Samples: *Diluent*, *Standard solution 1*, *Standard solution 2*, and *Sample solution*

Plot the responses of the *Diluent*, *Standard solution 1*, and *Standard solution 2* versus their content (0, 0.1, and 1.0 µg/mL) of platinum. Determine the concentration, in µg/mL, of platinum in the *Sample solution* from the calibration curve.

Calculate the concentration, in µg/g, of platinum in the portion of Dutasteride taken:

$$\text{Result} = C_S/C_U$$

C_S = concentration of platinum in the *Sample solution* (µg/mL)

C_U = concentration of Dutasteride in the *Sample solution* (g/mL)

Acceptance criteria: NMT 5 µg/g

- **Limit of Residual Solvents**

Standard stock solution: 5 mg/mL each of *acetonitrile*, *ethyl acetate*, *pyridine*, *toluene*, *dioxane*, and *n-heptane* in *dimethyl sulfoxide*

Standard solution: 10 µg/mL each of acetonitrile, ethyl acetate, pyridine, toluene, dioxane, and *n*-heptane in dimethyl sulfoxide from the *Standard stock solution*

Sample solution: 10 mg/mL of Dutasteride in *dimethyl sulfoxide*

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: GC

Detector: Flame ionization

Column: 0.32-mm × 30-m; capillary coated with 5-µm film of G1

Temperatures

Injection port: 180°

Detector: 260°

Column: See *Table 1*.

Table 1

Initial Temperature (°)	Temperature Ramp (°/min)	Final Temperature (°)	Hold Time at Final Temperature (min)
50	—	50	3
50	10	200	2

Carrier gas: Helium

Flow rate: Head pressure at 12 psi

Split flow: 10 mL/min

Septum purge: 2 mL/min

Injector type: Headspace

Sample volume: 2 µL

Sample temperature: 85°

Equilibration time: 1 min

Thermostating time: 15 min

Needle temperature: 100°

Transfer line temperature: 110°

System suitability

Sample: *Standard solution*

Suitability requirements

Resolution: NLT 1.2 between *n*-heptane and dioxane peaks

Relative standard deviation: NMT 5% for each solvent

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of each solvent in the portion of Dutasteride taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response of each solvent from the *Sample solution*

r_S = peak response of each solvent from the *Standard solution*

C_S = concentration of each solvent in the *Standard solution* (mg/mL)

C_U = concentration of Dutasteride in the *Sample solution* (mg/mL)

Acceptance criteria: See *Table 2*.

Table 2

Name	Relative Retention Time	Acceptance Criteria, NMT (%)
Acetonitrile	0.30	0.3
Ethyl acetate	0.60	0.2
Dioxane	0.83	0.1

▲USP38

BRIEFING

Methylphenidate Hydrochloride Extended-Release Tablets, USP 38 page 4348. On the basis of comments received, it is proposed to revise the monograph as follows:

1. Replace the existing HPLC procedure in the *Assay* with the procedure used in the test for *Organic Impurities*. The proposed method does not require the use of an internal standard. Internal standards are not typically used in LC analyses unless the sample preparation involves extensive isolation techniques. The procedure is based on analyses using the Waters Symmetry C18 brand of L1 column. The typical retention time for methylphenidate is about 12 min.
2. Expand the brief cross reference to the current *Assay* in *Dissolution Test 1* to include the procedure details.
3. Replace the reference to the *Organic Impurities* test in *Identification test B* with a reference to the proposed *Assay*.
4. Include the approved storage condition in the *Packaging and Storage* section.

Additionally, minor editorial changes have been made to update the monograph to current USP style.

The comment period for the above revision ends November 30, 2015. In the absence of significant adverse comments, it is proposed to implement this revision via an *Interim Revision Announcement* in the *Second Supplement to USP 39-NF 34*, with an official date of March 1, 2016.

Comment deadline: November 30, 2015

Methylphenidate Hydrochloride Extended-Release Tablets

DEFINITION

Methylphenidate Hydrochloride Extended-Release Tablets contain NLT 90.0% and NMT 110.0% of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$).

IDENTIFICATION

• A. Infrared Absorption

Sample: Place a portion of powdered Tablets, equivalent to 100 mg of methylphenidate hydrochloride, in a 100-mL beaker. Add 20 mL of chloroform, stir for 5 min, and filter, collecting the filtrate. Evaporate the filtrate to about 5 mL. Add ethyl ether slowly, with stirring, until crystals form. Filter the crystals, wash with ethyl ether, and dry at 80° for 30 min.

Acceptance criteria: The IR absorption spectrum of a mineral oil dispersion of the crystals so obtained exhibits maxima only at the same wavelengths as those of a similar preparation of USP Methylphenidate Hydrochloride RS.

Change to read:

- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *test for Organic Impurities*
 - *Assay.* • (IRA 1-Mar-2016)

ASSAY

Change to read:

- **Procedure**

~~**Buffer:** Dissolve 1.64 g of anhydrous sodium acetate in 900 mL of water. Adjust with acetic acid to a pH of 4.0, and dilute with water to 1000 mL.~~

~~**Mobile phase:** Methanol, acetonitrile, and *Buffer* (4:3:3)~~

~~**Internal standard solution:** 0.4 mg/mL of phenylephrine hydrochloride in *Mobile phase*~~

~~**Standard stock solution:** 0.2 mg/mL of USP Methylphenidate Hydrochloride RS in *Mobile phase*~~

~~**Standard solution:** Transfer 10.0 mL of the *Standard stock solution* to a glass-stoppered, 25-mL conical flask, add 5.0 mL of the *Internal standard solution*, and mix.~~

~~**Sample stock solution:** Nominally 0.2 mg/mL of methylphenidate hydrochloride in *Mobile phase*, prepared as follows. Finely powder NLT 20 Tablets. Transfer a suitable amount of the powder to a suitable volumetric flask to obtain the nominal concentration. Add 70% of the flask volume of *Mobile phase*, and sonicate for 15 min. Cool to room temperature, dilute with *Mobile phase* to volume, and mix. Pass a portion of this solution through a suitable membrane filter, discarding the first portion of the filtrate. [Note—Avoid the use of glass filters. Polypropylene filters are suitable for use.]~~

~~**Sample solution:** Transfer 10.0 mL of the clear filtrate to a glass-stoppered, 25-mL conical flask, and add 5.0 mL of the *Internal standard solution*.~~

~~**Chromatographic system**~~

~~(See *Chromatography* (621), *System Suitability*.)~~

~~**Mode:** LC~~

~~**Detector:** UV 210 nm~~

~~**Column:** 4.6 mm × 25 cm; packing L10~~

~~**Flow rate:** 1.5 mL/min~~

~~**Injection volume:** 50 µL~~

~~**System suitability**~~

Sample: ~~Standard solution~~

~~[Note—The relative retention times for phenylephrine hydrochloride and methylphenidate hydrochloride are 0.8 and 1.0, respectively.]~~

Suitability requirements

Resolution: ~~NLT 2.0 between the analyte and internal standard peaks~~

Relative standard deviation: ~~NMT 2.0% for the peak response ratios of the analyte to the internal standard~~

Analysis

Samples: ~~Standard solution and Sample solution~~

Calculate the percentage of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$) in the portion of Tablets taken:

$$\text{Result} = (R_U/R_S) \times (C_S/C_U) \times 100$$

R_U = peak response ratio of methylphenidate hydrochloride to the internal standard from the ~~Sample solution~~

R_S = peak response ratio of methylphenidate hydrochloride to the internal standard from the ~~Standard solution~~

C_S = concentration of USP Methylphenidate Hydrochloride RS in the ~~Standard solution~~ (mg/mL)

C_U = nominal concentration of methylphenidate hydrochloride in the ~~Sample solution~~ (mg/mL)

•Mobile phase: Dissolve 2 g of octanesulfonic acid sodium salt in 730 mL of water. Adjust with phosphoric acid to a pH of 2.7. Mix with 270 mL of acetonitrile.

Solution A: Acidified water; adjusted with phosphoric acid to a pH of 3

Diluent A: Acetonitrile and Solution A (25:75)

Diluent B: Acetonitrile and methanol (50:50)

System suitability solution: 80 µg/mL of USP Methylphenidate Hydrochloride RS, 1 µg/mL of methylphenidate hydrochloride erythro isomer from USP Methylphenidate Hydrochloride Erythro Isomer Solution RS, and 2 µg/mL of USP Methylphenidate Related Compound A RS in Diluent A

Standard solution: 0.1 mg/mL of USP Methylphenidate Hydrochloride RS in Diluent A

Sample stock solution: Nominally 1 mg/mL of methylphenidate hydrochloride prepared as follows. Dissolve NLT 10 Tablets in a suitable volumetric flask with 20% of the total flask volume of Diluent B. [Note—Alternatively, a portion of powder from NLT 10 Tablets may be transferred to a suitable volumetric flask and suspended in 20% of the total flask volume of Diluent B.] Stir for 4 h. Dilute with Solution A to volume.

Sample solution: Nominally 0.1 mg/mL of methylphenidate hydrochloride in Solution A from the Sample stock solution. [Note—Centrifuge before chromatographic analysis.]

Chromatographic system

(See Chromatography (621), System Suitability.)

Mode: LC

Detector: UV 210 nm

Column: 3.9-mm × 15-cm; 5-µm packing *L1*

Column temperature: 30°

Flow rate: 1 mL/min

Injection volume: 25 µL

Run time: 2 times the retention time of methylphenidate

System suitability

Samples: *System suitability solution* and *Standard solution*

[Note—See *Table 6* for relative retention times.]

Suitability requirements

Resolution: NLT 4.0 between methylphenidate related compound A and methylphenidate hydrochloride erythro isomer; NLT 6.0 between the methylphenidate and erythro isomer peaks, *System suitability solution*

Tailing factor: NMT 2.0 for the methylphenidate peak, *Standard solution*

Relative standard deviation: NMT 2.0% for the methylphenidate peak, *Standard solution*

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$) in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*

r_S = peak response from the *Standard solution*

C_S = concentration of USP Methylphenidate Hydrochloride RS in the *Standard solution* (mg/mL)

C_U = nominal concentration of methylphenidate hydrochloride in the *Sample solution* (mg/mL)

•(IRA 1-Mar-2016)

Acceptance criteria: 90.0%–110.0%

PERFORMANCE TESTS

Change to read:

- **Dissolution** <711>

Test 1

Medium: Water; 500 mL

Apparatus 2: 50 rpm

Times: 1, 2, 3.5, 5, and 7 h

Sample solution: Use portions of the solution under test passed through a suitable filter of 0.45-µm pore size. Do not use glass fiber filters.

•**Buffer:** Dissolve 1.6 g of *anhydrous sodium acetate* in 900 mL of water. Adjust with *acetic acid* to a pH of 4.0 and dilute with water to 1000 mL.

Mobile phase: Methanol, acetonitrile, and *Buffer* (40:30:30)

Internal standard solution: 0.4 mg/mL of phenylephrine hydrochloride in *Mobile phase*

Standard stock solution: $(1.5 \times [L/500])$ mg/mL of USP Methylphenidate Hydrochloride RS in *Mobile phase* where *L* is the label claim of methylphenidate hydrochloride in mg/Tablet

Standard solution: Transfer 10.0 mL of the *Standard stock solution* to a glass-stoppered, 25-mL conical flask, add 5.0 mL of the *Internal standard solution*, and mix.

Sample stock solution: Use portions of the solution under test passed through a suitable filter of 0.45- μ m pore size. Do not use glass fiber filters.

Sample solution: Transfer 10.0 mL of the *Sample stock solution* to a glass-stoppered, 25-mL conical flask, add 5.0 mL of the *Internal standard solution*, and mix. •(IRA 1-Mar-2016)

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 210 nm

Column: 4.6-mm \times 25-cm; packing *L10*

Flow rate: 1.5 mL/min

Injection volume: 50 μ L

System suitability

Sample: *Standard solution*

[Note—The relative retention times for phenylephrine hydrochloride and methylphenidate hydrochloride are 0.8 and 1.0, respectively.]

Suitability requirements

Resolution: NLT 2.0 between the analyte and internal standard peaks

Relative standard deviation: NMT 2.0% for the peak response ratios of the analyte to the internal standard

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$) dissolved by using the procedure in the *Assay*, making any necessary volumetric adjustments.

Tolerances: See *Table 1*.

Table 1

Time (h)	Amount Dissolved (%)
1	25–45
2	40–65
3.5	55–80
5	70–90
7	NLT 80

The percentages of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$) dissolved at the times specified conform to *Dissolution* (711), *Acceptance Table 2*.

For products labeled for dosing every 24 h

Test 2: If the product complies with this test, the labeling indicates that it meets USP *Dissolution Test 2*.

Medium: Acidified water; adjusted with phosphoric acid to a pH of 3; 50 mL at $37 \pm 0.5^\circ$

Apparatus 7 (see *Drug Release* (724)): 30 cycles/min; 2–3 cm amplitude. Follow *Sample Preparation A* using a metal spring sample holder (*Figure 5d*). (ERR 1-Jun-2015) Place one Tablet in the holder with the Tablet orifice facing down, and cover the top of the holder with Parafilm™. At the end of each specified test interval, the systems are transferred to the next row of new test tubes containing 50 mL of fresh *Medium*.

Times: 1-h intervals for a duration of 10 h

Calculate the percentage of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$) dissolved by using the following method.

Solution A: Dissolve 2.0 g of *sodium 1-octanesulfonate* in 700 mL of water, mix well, and adjust with *phosphoric acid* to a pH of 3.0.

Mobile phase: Acetonitrile and *Solution A* (30:70)

Diluent: Acetonitrile and *Medium* (25:75)

Standard stock solution: 0.3 mg/mL of USP Methylphenidate Hydrochloride RS in *Diluent*

Standard solutions: Prepare at least six solutions by making serial dilutions of the *Standard stock solution* in *Diluent* to bracket the expected drug concentration range.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 220 nm

Column: 3.2-mm \times 5-cm; 5- μ m packing *L1*

Column temperature: 30°

Flow rate: 1 mL/min

Injection volume: 25 μ L

System suitability

Sample: Middle range concentration of the *Standard solutions*

Suitability requirements**Capacity factor:** NLT 2

• (IRA 1-Mar-2016)

Tailing factor: NMT 2**Relative standard deviation:** NMT 2% for the peak response of the analyte; NMT 2% for the retention time of the analyte**Analysis****Samples:** *Standard solutions* and the solution under test

Construct a calibration curve by plotting the peak response versus the concentration of the *Standard solutions*. Determine the amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$) in each interval by linear regression analysis of the standard curve.

Tolerances: See *Table 2*.**Table 2**

Time (h)	Amount Dissolved (%)
1	12–32
4	40–60
10	NLT 85
3–6 (avg)	9–15 (/h)

The percentages of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$) dissolved at the times specified conform to *Dissolution (711)*, *Acceptance Table 2*.

Calculate the average percentage released from 3–6 h:

$$\text{Result} = (Y - X) / 3$$

Y = cumulative drug released from 0–6 h

X = cumulative drug released from 0–3 h

For products labeled for dosing every 24 h**Test 3:** If the product complies with this test, the labeling indicates that it meets USP *Dissolution Test 3*.**Medium:** pH 6.8 phosphate buffer (6.8 g/L of *monobasic potassium phosphate* in water; adjusted with 2 N sodium hydroxide or 10% phosphoric acid to a pH of 6.80); 900 mL**Apparatus 1:** 100 rpm**Times:** 0.75, 4, and 10 h**Buffer:** pH 4.0 phosphate buffer (2.72 g/L of *monobasic potassium phosphate* in water; adjusted with 2 N sodium hydroxide or 10% phosphoric acid to a pH of 4.00)**Mobile phase:** Acetonitrile and *Buffer* (17.5: 82.5)**Standard solution:** 0.06 mg/mL of USP Methylphenidate Hydrochloride RS in 0.1 N

hydrochloric acid

Sample solution: Pass a portion of the solution under test through a suitable polytetrafluoroethylene (PTFE) filter of 0.45- μm pore size.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 210 nm

Column: 3.0-mm \times 5-cm; 2.5- μm packing *L1*

Column temperature: 50°

Flow rate: See *Table 3*.

Table 3

Time (min)	Flow Rate (mL/min)
0.0	0.75
2.5	0.75
3.0	2.00
6.0	2.00
6.5	0.75
7.0	0.75

Injection volume: 10 μL

System suitability

Sample: *Standard solution*

[Note—The relative retention times for methylphenidate related compound A, the erythro isomer, and methylphenidate are 0.47, 0.65, and 1.0, respectively.]

Suitability requirements

Relative standard deviation: NMT 2.0%

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the concentration (C_i) of methylphenidate hydrochloride ($\text{C}_{14}\text{H}_{19}\text{NO}_2 \cdot \text{HCl}$) in the sample withdrawn from the vessel at each time point (i) shown in *Table 4*:

$$\text{Result}_i = (r_U/r_S) \times C_S$$

r_U = sum of the peak responses of methylphenidate and methylphenidate related compound A from the *Sample solution*

r_S = peak response of methylphenidate from the *Standard solution*

C_S = concentration of USP Methylphenidate Hydrochloride RS in the *Standard solution*

Calculate the percentage of the labeled amount of methylphenidate hydrochloride ($\text{C}_{14}\text{H}_{19}\text{NO}_2 \cdot \text{HCl}$) dissolved at each time point (i) shown in *Table 4*:

$$\text{Result}_1 = C_1 \times V \times (1/L) \times 100$$

$$\text{Result}_2 = \{[C_2 \times (V - V_S)] + [C_1 \times V_S]\} \times (1/L) \times 100$$

$$\text{Result}_3 = \{C_3 \times [V - (2 \times V_S)]\} + [(C_2 + C_1) \times V_S] \times (1/L) \times 100$$

C_i = concentration of methylphenidate hydrochloride in the portion of sample withdrawn at time point (i) (mg/mL)

V = volume of *Medium*, 900 mL

L = label claim (mg/Tablet)

V_S = volume of the *Sample solution* withdrawn from the *Medium* (mL)

Tolerances: See *Table 4*.

Table 4

Time Point (i)	Time (h)	Amount Dissolved (%)
1	0.75	12–30
2	4	55–80
3	10	NLT 80

The percentages of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$) dissolved at the times specified conform to *Dissolution* (711), *Acceptance Table 2*.

Test 4: If the product complies with this test, the labeling indicates that it meets USP *Dissolution Test 4*.

Medium: 0.001 N hydrochloric acid; 500 mL

Apparatus 2: 50 rpm

Times: 1, 2, 6, and 10 h

Mobile phase: Acetonitrile and water (20:80). For every L of *Mobile phase* add 1.0 mL of *formic acid* and 0.2 mL of *trifluoroacetic acid*.

Standard solution: 0.02 mg/mL of USP Methylphenidate Hydrochloride RS in *Mobile phase*

Sample solution: Pass a portion of the solution under test through a suitable PTFE filter of 0.45- μ m pore size. Do not use glass fiber filters.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 220 nm

Column: 3.0-mm \times 15-cm; 3- μ m packing *L1*

Column temperature: 40°

Flow rate: 0.75 mL/min

Injection volume: 10 μ L

System suitability

Sample: *Standard solution*

Suitability requirements

Relative standard deviation: NMT 5.0%

Analysis

Samples: *Standard solution and Sample solution*

Calculate the concentration (C_i) of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$) in the sample withdrawn from the vessel at each time point (i) shown in *Table 5*:

$$\text{Result}_i = (r_U/r_S) \times C_S$$

r_U = peak response of methylphenidate from the *Sample solution*

r_S = peak response of methylphenidate from the *Standard solution*

C_S = concentration of USP Methylphenidate Hydrochloride RS in the *Standard solution*

Calculate the percentage of the labeled amount of methylphenidate hydrochloride ($C_{14}H_{19}NO_2 \cdot HCl$) dissolved at each time point (i) shown in *Table 5*:

$$\text{Result}_1 = C_1 \times V \times (1/L) \times 100$$

$$\text{Result}_2 = \{[C_2 \times (V - V_S)] + [C_1 \times V_S]\} \times (1/L) \times 100$$

$$\text{Result}_3 = \{C_3 \times [V - (2 \times V_S)]\} + [(C_2 + C_1) \times V_S] \times (1/L) \times 100$$

$$\text{Result}_4 = \{C_4 \times [V - (3 \times V_S)]\} + [(C_3 + C_2 + C_1) \times V_S] \times (1/L) \times 100$$

C_i = concentration of methylphenidate hydrochloride in the portion of sample withdrawn at time point (i) (mg/mL)

V = volume of *Medium*, 500 mL

L = label claim (mg/Tablet)

V_S = volume of the *Sample solution* withdrawn from the *Medium* (mL)

Tolerances: See *Table 5*.

Table 5

Time Point (i)	Time (h)	Amount Dissolved (%)

IMPURITIES

Change to read:

- **Organic Impurities**

Mobile phase: Dissolve 2 g of *sodium-1-octanesulfonate* in 730 mL of water. Adjust with *phosphoric acid* to a pH of 2.7. Mix with 270 mL of acetonitrile.

Solution A: Acidified water; adjusted with *phosphoric acid* to a pH of 3

Diluent A: Acetonitrile and *Solution A* (25:75)

Diluent B: Acetonitrile and methanol (50:50)

System suitability solution: 80 µg/mL of USP Methylphenidate Hydrochloride RS, 1 µg/mL of methylphenidate hydrochloride erythro isomer from USP Methylphenidate Hydrochloride Erythro Isomer Solution RS, and 2 µg/mL of USP Methylphenidate Related Compound A RS in *Diluent A*

Standard solution: 0.2 µg/mL of USP Methylphenidate Hydrochloride RS, 0.5 µg/mL of methylphenidate hydrochloride erythro isomer from USP Methylphenidate Hydrochloride Erythro Isomer Solution RS, and 1.5 µg/mL of USP Methylphenidate Related Compound A RS in *Diluent A*

Sample stock solution: Nominally 1 mg/mL of methylphenidate hydrochloride prepared as follows. Dissolve NLT 10 Tablets in a suitable volumetric flask with 20% of the total flask volume of *Diluent B*. [Note—Alternatively, a portion of powder from NLT 10 Tablets may be transferred to a suitable volumetric flask and suspended in 20% of the total flask volume of *Diluent B*.] Stir for 4 h. Dilute with *Solution A* to volume.

Sample solution: 0.1 mg/mL of methylphenidate hydrochloride in *Solution A* from the *Sample stock solution*. [Note—Centrifuge before chromatographic analysis.]

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 210 nm

Column: 3.9-mm × 15-cm; 5-µm packing *L1*

Column temperature: 30°

Flow rate: 1 mL/min

Injection volume: 25 µL

Run time: 2 times the retention time of methylphenidate

System suitability

Sample: *System suitability solution*

Suitability requirements

Resolution: NLT 6.0 between the methylphenidate and erythro isomer peaks

Tailing factor: NMT 2.0 for the methylphenidate peak

Relative standard deviation: NMT 2.0% for the methylphenidate peak; NMT 4.0% each for the methylphenidate related compound A and erythro isomer peaks

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of methylphenidate related compound A or erythro isomer in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response of methylphenidate related compound A or erythro isomer from the *Sample solution*

r_S = peak response of methylphenidate related compound A or erythro isomer from the *Standard solution*

C_S = concentration of USP Methylphenidate Related Compound A RS or methylphenidate hydrochloride erythro isomer in the *Standard solution* (mg/mL)

C_U = nominal concentration of methylphenidate hydrochloride in the *Sample solution* (mg/mL)

Calculate the percentage of any unspecified degradation product in the portion of Tablets taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response of each unspecified degradation product from the *Sample solution*

r_S = peak response of USP Methylphenidate Hydrochloride RS from the *Standard solution*

C_S = concentration of USP Methylphenidate Hydrochloride RS in the *Standard solution* (mg/mL)

C_U = nominal concentration of methylphenidate hydrochloride in the *Sample solution* (mg/mL)

Acceptance criteria: See Table 6.

In-Process Revision

This section contains proposals for adoption as official *USP* or *NF* standards (either proposed *new* standards or proposed *revisions* of current *USP* or *NF* standards). These may be any of the following: (1) proposed revisions placed directly under *In-Process Revision*, (2) modifications of revisions previously proposed under *In-Process Revision*, or (3) proposed revisions for articles awaiting approval by FDA. Readers should review material in this section and provide comments to the Scientific Liaison using the contact information appearing at the end of each proposal. Information on how to comment can be found under the "Participation" section of www.usp.org. It is important to send comments promptly, before the comment deadline listed after each title.

Briefings Each Proposal is preceded by a Briefing in the following format:

Briefing
Name of Item , citations of the most recent USP publications in which this item appeared. Rationale for the revision. Other relevant information. (For example, if a chromatographic method is being proposed, column specifications and retention times for compounds of interest.) Finally, the Expert Committee acronym (the name of the Scientific Liaison who handled the particular monograph or general chapter, and the USP tracking correspondence number, as shown in the example below:
(Expert Committee Acronym: Liaison Name.)
Correspondence Number—CXXXXX

Symbols Proposed revisions are shown with language proposed for deletion or replacement crossed out. All *USP-NF* revisions use the following symbols that indicate the final destination of the official text: •new text• if slated for an *IRA*; ▲new text▲ if slated for *USP-NF*; ■new text■ if slated for a *Supplement* to *USP-NF*; ►new text◄ for articles awaiting approval by FDA. The same symbols indicate recent revisions that are already official. Where the symbols appear together with no enclosed text, such as ••, or ■■, or ▲▲, or ►◄, it means that text has been deleted and no new text was proposed to replace it.

In revisions, the closing symbol is accompanied by an identifier that indicates the particular *IRA*, *Supplement*, or the *USP* or *NF* as the publication where the revision will appear if approved. For example, ■_{2S} (*USP 34*) indicates that the proposed revision is slated for the *Second Supplement to USP 34*, and ▲_{USP35} and ▲_{NF30} indicates that the revisions are proposed for *USP 35* and *NF 30*, respectively. In the case of revisions for articles awaiting approval by FDA, the symbols are followed by TBD indicating that the official publication is To Be Determined. For example, ◄(TBD) does not yet have a target official publication.

Official Title Changes Where the specification "**Monograph title change**" is found, it indicates that the official title stated after that specification will be substituted for the former title in the appropriate places throughout that monograph once this revision becomes official.

BRIEFING

⟨1⟩ **Injections and Implanted Drug Products (Parenterals)—Product Quality Tests**, *USP* 38 page 53 and *PF* 39(5) [Sept.–Oct. 2013]. There are five *USP* general chapters that link with *USP*'s taxonomy for pharmaceutical dosage forms: *Injections and Implanted Drug Products* ⟨1⟩, *Oral Drug Products—Product Quality Tests* ⟨2⟩, *Topical and Transdermal Drug Products—Product Quality Tests* ⟨3⟩, *Mucosal Drug Products—Product Quality Tests* ⟨4⟩, and *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* ⟨5⟩. This taxonomy describes five routes of administration: injection or parenteral; gastrointestinal or oral; topical (dermal and transdermal); mucosal; and lungs or inhalation (for more information, see the *Stimuli* article titled *Product Quality and Product Performance General Chapters* in *PF* 39(3) [May–June 2013]). The five general chapters provide critical product quality attributes for the various dosage forms by the various routes of administration. In addition to these five chapters, *Ophthalmic Ointments* ⟨771⟩ outlines the critical product quality attributes for the various dosage forms that can be applied to the eye. Product quality tests assess physical, chemical, and microbial attributes. Taken together, the tests help ensure identity, strength, quality, and purity of a dosage form. The General Chapters—Dosage Forms Expert Committee is proposing the following revision to ⟨1⟩, ⟨2⟩, ⟨3⟩, ⟨4⟩, ⟨5⟩, and ⟨771⟩, to clarify the applicability of these chapters.

Additionally, minor editorial changes have been made to update this chapter to current *USP* style.

(GCDF: D. Hunt.)

Comment deadline: November 30, 2015

Change to read:

⟨1⟩ INJECTIONS ▲ AND IMPLANTED DRUG PRODUCTS (PARENTERALS)—PRODUCT QUALITY TESTS

(Chapter to become official May 1, 2016)

(Current chapter name is ⟨1⟩ Injections)

Change to read:

INTRODUCTION

Parenteral drug products include both injections and implanted drug products that are injected through the skin or other external boundary tissue, or implanted within the body to allow the direct administration of the active drug substance(s) into blood vessels, organs, tissues, or lesions. Injections may exist as either immediate- or extended-release dosage forms. Implanted parenteral drug products are long-acting dosage forms that provide continuous release of the active drug substance(s), often for periods of months to years. For systemic delivery, they may be placed subcutaneously; for local delivery, they may be placed in a specific region of the body. Routes of administration for parenteral drug products include intravenous, intraventricular, intra-arterial, intra-articular, subcutaneous, intramuscular, intrathecal, intracisternal, and intraocular.

Parenteral dosage forms include solutions, suspensions, emulsions, sterile powders for solutions and suspensions (including liposomes), implants (including microparticles), and products that consist of both a drug and a device such as drug-eluting stents. The reader is directed to *Pharmaceutical Dosage Forms* (1151) and to the later sections of this chapter for additional descriptions of dosage forms that fall into the general category of parenteral drug products. *Nomenclature* (1121) provides information on nomenclature used to establish USP names and monograph titles for parenteral drug products. [Note—All references to chapters above 1000 are for informational purposes only, for use as a helpful resource. These chapters are not mandatory unless explicitly called out for application.]

~~Chapter (1) provides a framework to support the revision and the development of individual monographs, and is not meant to replace individual monographs.~~

■ **2S (USP39)**

Chapter (1) provides lists of

■ **consolidated 2S (USP39)**

common product quality test requirements in a concise and a coherent fashion. The chapter is divided into four main sections: 1) universal product quality tests that are applicable to parenteral dosage forms; 2) specific product quality tests, which are tests that should be considered in addition to *Universal Tests*; 3) product quality tests for specific dosage forms, which lists all the applicable tests (Universal and Specific) for the specific dosage form; and 4) product performance tests.

~~If a monograph exists, it will reference (1) or indicated chapter parts. If a specific drug product monograph is missing (not in existence), the general chapters provide the quality tests that can be used by manufacturers until the dosage form monograph is developed by USP.~~

■ This chapter applies, in part or in its entirety, when referenced in a drug product monograph and includes the quality tests for the specific route of administration. The quality tests listed can be used, as appropriate, by manufacturers toward the development of new drug product monographs for submission to USP. ■ **2S (USP39)**

The Pharmacopeial definitions for sterile preparations for parenteral use may not apply to some biologics because of their special nature and licensing requirements (see *Biologics* (1041)). However, some biological finished drug products containing "Injection" in the monograph title must meet the requirements of (1) or indicated chapter subparts, where it is specified in the monograph.

Drug Product Quality and Drug Product Performance Tests

Procedures and acceptance criteria for testing parenteral drug products are divided into two categories: 1) those that assess product quality attributes, e.g., identification, sterility, and particulate matter, and are contained in this chapter; and 2) those that assess product performance, e.g., in vitro release of the drug substance from the drug product. Whereas quality tests assess the integrity of the dosage form, the performance tests assess performance (bioavailability) after the product has been administered to the patient. A product performance test, i.e., drug release test for suspensions, emulsions, powder for suspension (including microparticles and liposomes), and drug-eluting stents, should be carried out using appropriate test procedures.

PRODUCT QUALITY TESTS COMMON TO PARENTERAL DOSAGE FORMS

Universal Tests

Universal tests are listed below and are applicable to parenteral dosage forms.

DESCRIPTION

A qualitative description of the dosage form should be provided. The acceptance criteria should include the final acceptable appearance. If color changes during storage, a quantitative or a semiquantitative procedure may be appropriate. This section specifies the content or the label claim of the article (see *Labeling* (7)). Additional information about commonly used terms and definitions can be found in (1121).

IDENTIFICATION

Identification tests are discussed in *General Notices and Requirements 5.40*. Identification tests should establish the identity of the drug or drugs present in the article and should discriminate between compounds of closely related structure that are likely to be present. The most conclusive test for identity is the infrared (IR) absorption spectrum (see *Spectrophotometry and Light-Scattering* (851) and *Spectrophotometric Identification Tests* (197)). If no suitable IR spectrum can be obtained, other analytical methods can be used. Near-infrared or Raman spectrophotometric methods also could be acceptable for the sole identification of the drug product formulation (see *Near-Infrared Spectroscopy* (1119) and *Raman Spectroscopy* (1120)). Identification solely by a single chromatographic retention time is not regarded as specific. However, the use of two chromatographic procedures in which the separation is based either on different principles or a combination of tests in a single procedure can be acceptable (see *Chromatography* (621) and *Thin-Layer Chromatographic Identification Test* (201)). Additional information regarding identification tests can be found in *Identification Tests—General* (191) and *Mass Spectrometry* (736).

ASSAY

A specific and stability-indicating test should be used to determine the strength (content) of the drug product. In cases where the use of a nonspecific assay is justified, other supporting analytical procedures should be used to achieve overall specificity. A specific procedure should be used when there is evidence of excipient interference with the nonspecific assay.

IMPURITIES

Tests for impurities are discussed in *General Notices and Requirements 5.60*. All articles should be tested to ensure that they meet the requirements.

FOREIGN AND PARTICULATE MATTER

Articles intended for parenteral administration should be prepared in a manner designed to exclude particulate matter as defined in *Subvisible Particulate Matter in Therapeutic Protein Injections* (787), *Particulate Matter in Injections* (788), and *Particulate Matter in Ophthalmic Solutions* (789), as well as excluding other foreign matter as appropriate for the dosage form. Each final container of all parenteral preparations should be inspected to the extent possible for

the presence of observable foreign and particulate matter (hereafter termed visible particulates) in its contents. The inspection process should be designed and qualified to ensure that every lot of all parenteral preparations is essentially free from visible particulates, as defined in *Visible Particulates in Injections* (790). Qualification of the inspection process should be performed with reference to particulates in the visible range and those particulates that might emanate from the manufacturing or filling process. Every container in which the contents show evidence of visible particulates must be rejected. The inspection for visible particulates may take place during examination for other critical defects such as cracked or defective containers or seals or when characterizing the appearance of a lyophilized product. When the nature of the contents or the container-closure system permits only limited inspection of the total contents, the 100% inspection of a lot should be supplemented with the inspection of constituted (e.g., dried) or withdrawn (e.g., from a dark amber container) contents of a sample of containers from the lot.

Large-volume injections for single-dose infusion, small-volume injections, and pharmacy bulk packages (PBP) are subject to the light obscuration or microscopic procedures and limits for subvisible particulate matter set forth in (788), unless otherwise specified in the chapter or in the individual monograph. An article packaged as both a large-volume and a small-volume injection meets the requirements set forth for small-volume injections where the container is labeled as containing 100 mL or less. It meets the requirements set forth for large-volume injections for single-dose infusion where the container is labeled as containing more than 100 mL.

STERILITY

The sterility of all drug products intended for parenteral administration should be confirmed by the use of methods described in *Sterility Tests* (71) or by an approved alternative method.

BACTERIAL ENDOTOXINS

All articles intended for parenteral administration should be prepared in a manner designed to limit bacterial endotoxins as defined in *Bacterial Endotoxins Test* (85) or *Pyrogen Test* (151).

CONTAINER CONTENT

Container contents should be determined when appropriate (see the proposed general chapter *Container Content for Injections* (697)).

LEACHABLES AND EXTRACTABLES

The packaging system should not interact physically or chemically with the preparation to alter its strength, quality, or purity beyond the official or established requirements. The packaging system should meet the requirements in *Elastomeric Closures for Injections* (381), *Packaging and Storage Requirements* (659), *Containers—Glass* (660), *Containers—Plastics* (661), *Plastic Materials of Construction* (661.1), and *Plastic Packaging Systems for Pharmaceutical Use* (661.2). Further information regarding packaging systems testing may be found in *Assessment of Extractables Associated with Pharmaceutical Packaging/Delivery Systems* (1663) and *Assessment of Drug Product Leachables Associated with Pharmaceutical Packaging/Delivery Systems* (1664).

CONTAINER-CLOSURE INTEGRITY

The packaging system should be closed or sealed in such a manner as to prevent contamination or loss of contents. Validation of container integrity must demonstrate no penetration of microbial contamination or gain or loss of any chemical or physical parameter deemed necessary to protect the product (see *Sterile Product Packaging—Integrity Evaluation* (1207)).

LABELING

All articles intended for parenteral administration should meet the labeling requirements defined in (7).

Specific Tests

In addition to the *Universal Tests* listed above, the following *Specific Tests* may be considered on a case-by-case basis and, when appropriate, are referenced in the *USP–NF* monograph.

PHYSICOCHEMICAL PROPERTIES

These include such properties as *Osmolality and Osmolarity* (785), *pH* (791), *Specific Gravity* (841), and *Viscosity—Capillary Methods* (911).

UNIFORMITY OF DOSAGE UNITS

This test is applicable for parenteral drug products and dosage forms packaged in single-unit containers. It includes both the mass of the dosage form and the content of the active substance in the dosage form (see *Uniformity of Dosage Units* (905)).

VEHICLES AND ADDED SUBSTANCES

There are other vehicles, both aqueous and nonaqueous, beyond those that are discussed below. All vehicles should be suitable for their intended use and not impact drug product quality.

Aqueous vehicles: Aqueous vehicles must meet the requirements of (151) or (85), whichever is specified in the monograph. *Water for Injection* is generally used as the vehicle. Sodium chloride or dextrose may be added to render the resulting solution isotonic, and Sodium Chloride Injection or Ringer's Injection may be used in whole or in part instead of *Water for Injection*.

Nonaqueous vehicles: Fixed oils are classified under *Nonaqueous vehicles*. Fixed oils used as vehicles are of vegetable origin and are odorless. They meet the requirements in the test for *Solid Paraffin* in the *Mineral Oil* monograph with the cooling bath maintained at 10°.

Also meet the requirements of the following tests:

- *Saponification Value* (see *Fats and Fixed Oils* (401), *Saponification Value*): Between 185 and 200
- *Iodine Value* (see *Fats and Fixed Oils* (401), *Iodine Value*): Between 79 and 141
- *Unsaponifiable Matter* (see *Fats and Fixed Oils* (401), *Unsaponifiable Matter*): NMT 1.5%
- *Acid Value* (see *Fats and Fixed Oils* (401), *Acid Value (Free Fatty Acids)*): NMT 0.2
- *Peroxide Value* (see *Fats and Fixed Oils* (401), *Peroxide Value*): NMT 5.0
- *Water, Method Ic* (from *Water Determination* (921), *Method Ic (Coulometric Titration)*): NMT 0.1%
- *Limit of Copper, Iron, Lead, and Nickel*: [Note—The test for nickel is not required if the

oil has not been subjected to hydrogenation, or a nickel catalyst has not been used in processing.] Proceed as directed in *Fats and Fixed Oils* (401), *Trace Metals or Elemental Impurities—Procedures* (233). Meet the requirements in *Elemental Impurities—Limits* (232).

Synthetic mono- or diglycerides of fatty acids may be used provided they are liquid and remain clear when cooled to 10° and have an *Iodine Value* of NMT 140.

Added substances: Suitable substances may be added to preparations to increase stability or usefulness unless they are proscribed in the monograph. No coloring agent may be added to a preparation solely for the purpose of coloring the finished preparation (see *General Notices and Requirements 5.20* and *Antimicrobial Effectiveness Testing* (51)).

Observe special care in the choice and use of added substances in preparations with volumes that exceed 5 mL. The following limits prevail unless otherwise directed:

- Mercury and cationic surface-active agents: NMT 0.01%
- Chlorobutanol, cresol, phenol, and similar substances: NMT 0.5%
- Sulfur dioxide or an equivalent amount of sulfite, bisulfite, or metabisulfite of potassium or sodium: NMT 0.2%

ANTIMICROBIAL PRESERVATIVES

Antimicrobial agents must be added to preparations intended for injection that are packaged in multiple-dose containers unless one of the following conditions prevails: 1) there are different directions in the individual monograph; 2) the substance contains a radionuclide with a physical half-life of less than 24 h; or 3) the active ingredients are themselves antimicrobial. Substances must meet the requirements of (51) and *Antimicrobial Agents—Content* (341).

WATER CONTENT

The water content of freeze-dried (lyophilized) products should be determined when appropriate (see (921)).

BIOLOGICAL REACTIVITY

Implantable and combination drug products (drug/device) that contain a polymeric material should meet the requirements of *Biological Reactivity Tests, In Vivo* (88).

GLOBULE SIZE DISTRIBUTION

Emulsions should meet the requirements of *Globule Size Distribution in Lipid Injectable Emulsions* (729).

ALUMINUM CONTENT

Large-volume parenterals used to make total parenteral nutrition therapy (TPN) are limited to 25 µg/L. Small-volume parenterals and pharmacy bulk packages used to make TPN must state on the immediate container label the maximum level of aluminum at expiry if the maximum level exceeds 25 µg/L.

COMPLETENESS AND CLARITY OF SOLUTIONS

The following tests are performed to demonstrate suitability of constituted solutions prepared before administration. Constitute the solution as directed in the labeling supplied by the manufacturer:

- The solid dissolves completely, leaving no undissolved matter.
- The constituted solution is not significantly less clear than an equal volume of the diluent or of *Purified Water* contained in a similar vessel and examined similarly. Protein solutions may exhibit an inherent opalescence.

The constituted solution is free from particulate matter that can be observed on visual inspection (see <790>).

PRODUCT QUALITY TESTS FOR SPECIFIC PARENTERAL DOSAGE FORMS

Product quality tests for the specific dosage forms are listed below. Specific chapter(s) referenced for the test can be found in the *Universal Tests* and *Specific Tests* sections. When there is no compendial test available, a validated procedure with acceptance criteria should be used.

Solutions

A solution is a clear, homogeneous liquid dosage form that contains one or more chemical substances (e.g., drug substances or excipients) dissolved in a solvent (aqueous or nonaqueous) or a mixture of mutually miscible solvents. Solutions intended for parenteral administration (e.g., by injection or for irrigation) must be sterile and biocompatible with the intended administration site. This includes consideration of factors such as tonicity, pH, pyrogenicity, extraneous particulate matter, and physicochemical compatibility, among others. Unless otherwise justified, the following tests are required for solutions for injection:

- *Universal Tests*
- *Specific Tests*
 - *Physicochemical Properties*: Specific Gravity, Viscosity, pH, Osmolarity and Osmolality
 - *Antimicrobial Preservatives*

Sterile Powders for Solution

Sterile powders for solution (also referred to as sterile powders for injection) consist of drug substances and other components as dry-formulation ingredients to ensure the chemical and physical stability of the presentation within a final-use container. Companion sterile diluent or diluent compartments may be provided to facilitate constitution to the desired final volume. The sterile article for injection may be presented in several forms: lyophilized powder intended for final solution, powdered solids intended for final solution, or dry solids that form viscous liquids upon constitution.

The description should include a section that deals with ease of dispersion and reconstitution. The dosage form is a homogeneous solid that is readily constituted to the final form with the specified diluent, and dispersion is completed with gentle agitation.

Unless otherwise justified, the following tests apply to sterile powders for injection:

- *Universal Tests*
- *Specific Tests*
 - *Physicochemical Properties*: Specific Gravity, Viscosity, pH, Osmolarity and Osmolality

The following applies to constituted solutions:

- (905): To ensure the consistency of dosage units, each unit in a batch should have a drug substance content within a narrow range around the label claim. Dosage units are defined as dosage forms that contain a single dose or a part of a dose of drug substance in each unit. For liquid dosage forms, analysts should conduct the assay on an amount of well-mixed constituted material that is removed from an individual container under conditions of normal use, should express the results as delivered dose, and should calculate the acceptance value.
- *Loss on Drying* (731): The procedure set forth in this chapter determines the amount of volatile matter of any kind that is driven off under the conditions specified.
- (921): Water or solvent content may have important effects on reconstitution and stability. For articles that require water or solvent content control, analysts should perform one of the following methods or a suitable replacement.
- *Appearance*: Analysts should assess the level of and the unit variation for the following parameters:
 - Color of cake: Varies within target parameters
 - Texture and homogeneity of cake: Varies within target parameters
 - Presence of foreign material: All units with visible foreign material must be rejected
 - Particle size and distribution (dry powder): Evaluation of the powder solids for proper solid form and crystallinity is a measure of process control and consistency.
- *Particle Size Distribution Estimation by Analytical Sieving* (786): This chapter can be used for loose powders.

CRYSTALLINITY

The crystallinity of a material can be characterized to determine compliance with the crystallinity requirement where stated in the individual monograph of a drug substance.

- *Optical Microscopy* (776): Crystallinity can be characterized by polarized light microscopy for qualitative evaluation of the size, shape, and crystallinity of solids. Unless otherwise specified in the individual monograph, analysts should mount a solid specimen in mineral oil on a clean glass slide or cover slip and should examine the mixture using a polarizing microscope. The particles show birefringence (interference colors) and extinction positions when the microscope stage is revolved.

VEHICLES AND DILUENTS

Guidelines for constitution and suspension of dry powders are found in the specific monographs. If there is a specific packaged diluent for use with a particular product that is not included in a monograph, then the final article is prepared with that diluent.

Suspensions

Parenteral suspensions are liquid dosage forms that contain solid particles in a state of uniform dispersion. Suspensions for parenteral administration must be sterile and compatible with the administration site. Consideration should be given to pH and pyrogenicity, and appropriate limits should be identified. Physical stability evaluations of parenteral suspension preparations should include evaluations to confirm that the particle size range of suspended matter does not change with time and to confirm that the solids in the preparation can be readily resuspended to yield a uniform preparation.

In addition to the tests for injectable solutions, the following tests are required for suspensions for injection unless otherwise justified:

- *Universal Tests*
- *Specific Tests*
 - *Physicochemical Properties: pH*
 - *Uniformity of Dosage Units*
 - *Antimicrobial Preservatives*

Liposomes

Liposomes are unique drug products with unique properties that can be either solutions or suspensions. Liposomes are aqueous dispersions of amphiphilic lipids and have low water solubility. They are organized as a bilayer sheet that encloses an internal aqueous compartment and are known as lipid bilayer vesicles. Liposomes can have a single lipid bilayer (unilamellar vesicle) or can have an onion-like multilayered structure (multilamellar vesicle). The amphiphilic lipids comprise a hydrated head group at the water interface of the bilayer attached to a hydrophobic group that forms the interior of the bilayer by association with the hydrophobic group of lipids from the opposite leaflet of the bilayer. The physical properties of the liposome and its bilayer can vary widely and depend on lipid composition, aqueous composition, and temperature relative to the acyl components' phase transition points. Because of the central aqueous compartment, a simple test for the presence of liposomes in a lipid dispersion is to determine the presence of an entrapped aqueous phase.

A liposome drug product consists of the drug substance, liposome components, and other inactive but critical ingredients such as an aqueous dispersion unless the contents are a lyophilized product.

Unless otherwise justified, the following tests are required for liposomes:

- *Universal Tests*
- *Specific Tests*
 - *Physicochemical Properties: pH*
 - *Lipid and Fatty Acid Composition, including degree of unsaturation and positional specificity in acyl side chains and critical degradation products such as lysolipids¹*
 - *Particle Size¹*
 - *Particle Size Distribution of Liposomal Vesicles¹*
 - *Lamellarity¹*
 - *Phospholipid Composition¹*
 - *Percent Free vs. Percent Encapsulated Lipids¹*
 - *Free Drug vs. Encapsulated Drug*
 - *Ionic Strength and Osmotic Strength¹*

Sterile Powders for Suspension

Sterile powders for suspension consist of drug substances and other components as dry-formulation ingredients to ensure the chemical and physical stability of the presentation within a final-use container. Companion sterile diluent or diluent compartments may be provided to facilitate constitution to the desired final volume.

The sterile article for injection may be presented in several forms: lyophilized powder intended for final suspension, powdered solids intended for final suspension, and microparticles that retain their integrity and are delivered as a sterile suspension. The description should include a section that deals with ease of dispersion and reconstitution. The dosage form is a homogeneous solid that is readily constituted to the final form with the specified diluent, and dispersion is completed with gentle agitation.

Unless otherwise justified, the following tests apply to sterile powders for injection:

- *Universal Tests*
- *Specific Tests*
- *Bacterial Endotoxins*
 - *Physicochemical Properties: pH, Osmolarity and Osmolality*

The following applies to constituted suspensions:

- (905): To ensure the consistency of dosage units, each unit in a batch should have a drug substance content within a narrow range around the label claim. Dosage units are defined as dosage forms that contain a single dose or a part of a dose of drug substance in each unit. For liquid dosage forms, analysts should conduct the assay on an amount of well-mixed constituted material that is removed from an individual container under conditions of normal use, should express the results as delivered dose, and should calculate the acceptance value.
- (731): The procedure set forth in this chapter determines the amount of volatile matter of any kind that is driven off under the conditions specified.
- (921): Water or solvent content may have important effects on reconstitution and stability. For articles that require water or solvent content control, analysts should perform one of the following methods or a suitable replacement.
- *Appearance*: Analysts should assess the level of and the unit variation for the following parameters:
 - Color of cake: Varies within target parameters
 - Texture and homogeneity of cake: Varies within target parameters
 - Presence of foreign material: All units with visible foreign material must be rejected.
 - Particle size and distribution (dry powder): Evaluation of the powder solids for proper solid form and crystallinity is a measure of process control and consistency.
- (786): This chapter can be used for loose powders.

CRYSTALLINITY

The crystallinity of a material can be characterized to determine compliance with the crystallinity requirement where stated in the individual monograph of a drug substance.

- (776): Crystallinity can be characterized by polarized light microscopy for qualitative evaluation of the size, shape, and crystallinity of solids. Unless otherwise specified in the individual monograph, analysts should mount a solid specimen in mineral oil on a

clean glass slide or cover slip and should examine the mixture using a polarizing microscope: The particles show birefringence (interference colors) and extinction positions when the microscope stage is revolved.

VEHICLES AND DILUENTS

Guidelines for constitution and suspension of dry powders are found in the specific monographs. If there is a specific packaged diluent for use with a particular product that is not included in a monograph, then the final article is prepared with that diluent.

MICROPARTICLES

Some microparticles are provided as a sterile powder to be reconstituted as a suspension before injection. Major microparticle preparations are for reconstitution as a suspension for injection. For quality test requirements, please refer to *Implants*.

Emulsions

Emulsions for parenteral dosage forms are liquid preparations of drug substances dissolved or dispersed in a suitable emulsion medium. Oil-in-water or water-in-oil emulsions typically entrap the drug substance.

Emulsions typically are white, turbid, homogeneous liquid dosage forms that contain one or more chemical substances (e.g., drug substances and excipients) dissolved in a solvent (aqueous or nonaqueous) or mixture of mutually miscible solvents. Emulsions intended for intravenous administration must be sterile and must be compatible with the intended administration site.

Unless otherwise justified, the following tests are required for emulsions for injection:

- *Universal Tests*
- *Specific Tests*
 - *Physicochemical Properties*: pH, Osmolarity and Osmolality
 - *Globule Size Distribution*
 - Amount of Fat Globules (lipids)¹
 - Percent Free vs. Percent Encapsulated Lipids¹
 - Free Drug vs. Encapsulated Drug

Implants

Implants for extended release consist of a matrix of drug substance and polymeric excipient that may or may not have an outer rate-controlling membrane. The polymeric excipient must be biocompatible but may or may not be bioresorbable. Some implants are made from medical-grade metal with an osmotic pump inside that effects the extended release of the drug substance. Implants must be sterile and usually are formed in the shape of a cylinder, although other shapes are used. Solvents used to dissolve the formulation can lead to sterilization, and thus the internal sterility test method should demonstrate that the sample preparation does not lead to sterilization of the test sample.

Cylindrically shaped implants for systemic delivery usually are provided in an inserter for subcutaneous or local administration such as local ocular delivery. Implants also can be surgically implanted for local delivery, e.g., ocular delivery.

Unless otherwise justified, the following tests are required for implants:

- *Universal Tests*
- *Specific Tests*
 - *Uniformity of Dosage Units*

Depending on the drug product, the following tests may be required:

- *Water Content*

IN SITU GELS

Sterile in situ gels are liquid preparations that are intended for injection into specific therapeutic targets. Typically they consist of polymers in organic solvents, and upon injection the solvents migrate away from the site, leaving a gelled mass. The preparations may be injected as-is, upon reconstitution, from in situ formation, or from chemically initiated catalysis that results in the final form.

Unless otherwise justified, the following tests are required for in situ gels:

- *Universal Tests*
- *Specific Tests*
 - *Physicochemical Properties: Viscosity*
 - *Antimicrobial Preservatives*
 - *Catalyst Initiator Content and Activity¹*
 - *Residual Monomer¹*
 - *Time to Gel Formation¹*

MICROPARTICLES

Injectable, resorbable microparticles for extended release generally range from 20 to 100 µm in diameter. They consist of drug substances embedded within a biocompatible, bioresorbable polymeric excipient, e.g., polyester excipients. Microparticles are provided as a sterile powder in a vial or syringe.

Just before intramuscular or subcutaneous administration, the microparticle powder should be suspended in an aqueous injection vehicle (diluent). The injection vehicle usually consists of *Water for Injection*, surfactant, and a viscosity enhancer, and the vehicle may contain a compound that adjusts osmolality, e.g., a sugar with or without a compound that controls pH, e.g., an acid. The injection vehicle must be sterile and must be tested according to requirements for solutions that are intended for parenteral administration.

Unless otherwise justified, the following tests are required for microparticles for injection:

- *Universal Tests*
- *Specific Tests*
 - *Uniformity of Dosage Units*
 - *Water Content*
 - *Residual Solvents*

Depending on the drug product, the following tests may be required:

- *Particle Size Distribution*
- *Physicochemical Properties: pH, Osmolality and Osmolarity*

Drug-Eluting Stents

Drug-eluting stents are tiny metal or polymer scaffolds used to keep arteries open following a

medical intervention, in which a drug substance is incorporated into or onto the stent platform. Drug-eluting stents typically have two components of testing: 1) functional tests that generally are American Society for Testing and Materials (ASTM) International methods that fall outside the scope of this chapter, and 2) analytical tests.

Unless otherwise justified, the following tests are required for drug-eluting stents:

- *Universal Tests*
- *Specific Tests*
 - *Uniformity of Dosage Units*: The content of the active substance in the dosage form is applicable for drug-eluting stents packaged in single-unit containers. The test can be performed by either content uniformity or weight variation (see <905>). With appropriate justification, the number of stents needed for this test may be fewer than the recommended number of stents in <905>.
 - Biological Reactivity
 - Particulates
 - Coating Thickness(es)¹
 - Coating Robustness and Susceptibility to Cracking on Expansion¹
 - Free Drug vs. Encapsulated Drug¹
 - Morphology (surface and cross section)¹
 - Polydispersity¹
 - Copolymer Ratio¹
 - Glass Transition Point¹
 - Coating Adhesion to Stent Surface¹
 - Tissue Reaction Tests¹
 - Polymer Molecular Weight¹

PRODUCT PERFORMANCE TESTS

A performance test for injection and implanted products must have the ability to measure drug release from the manufactured pharmaceutical dosage forms. It must be reproducible and reliable, and although it is not a measure of bioavailability, the performance test must be capable of detecting changes in drug release characteristics from the finished product. These changes have the potential to alter the biological performance of the drug in the dosage form. They may be related to active or inactive/inert ingredients in the formulation, physical or chemical attributes of the finished formulation, manufacturing variables, shipping and storage effects, aging effects, and other formulation factors critical to the quality characteristics of the finished drug product.

Please refer to *The Dissolution Procedure: Development and Validation* <1092> while developing the drug release test, selecting the drug release medium, apparatus or procedure, and analytical method. Product performance tests can serve many useful purposes in product development and in post-approval drug product monitoring. They provide assurance of equivalent performance for products that have undergone post-approval raw material changes, relocation or change in manufacturing site, and other changes as detailed in the FDA SUPAC Guidances for Industry (SUPAC-IR, SUPAC-MR, and SUPAC-SS; available at www.fda.gov/cder/guidance). In this chapter, a USP performance test for injection and implanted products forms to support batch release is to be considered. ▲USP38

¹ No compendial test available; a validated procedure with acceptance criteria should be used.

BRIEFING

⟨2⟩ **Oral Drug Products—Product Quality Tests**, *USP 38* page 66 and *PF 38(4)* [Jul.–Aug. 2012]. There are five *USP* general chapters that link with *USP*'s taxonomy for pharmaceutical dosage forms: *Injections and Implanted Drug Products* ⟨1⟩, *Oral Drug Products—Product Quality Tests* ⟨2⟩, *Topical and Transdermal Drug Products—Product Quality Tests* ⟨3⟩, *Mucosal Drug Products—Product Quality Tests* ⟨4⟩, and *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* ⟨5⟩. This taxonomy describes five routes of administration: injection or parenteral; gastrointestinal or oral; topical (dermal and transdermal); mucosal; and lungs or inhalation (for more information, see the *Stimuli* article titled *Product Quality and Product Performance General Chapters* in *PF 39(3)* [May–June 2013]). The five chapters provide critical product quality attributes for the various dosage forms by the various routes of administration. In addition to these five chapters, *Ophthalmic Ointments* ⟨771⟩ outlines the critical product quality attributes for the various dosage forms that can be applied to the eye. Product quality tests assess physical, chemical, and microbial attributes. Taken together, the tests help ensure identity, strength, quality, and purity of a dosage form. The General Chapters—Dosage Forms Expert Committee is proposing the following revision to ⟨1⟩, ⟨2⟩, ⟨3⟩, ⟨4⟩, ⟨5⟩, and ⟨771⟩, in this issue of *PF*, to clarify the applicability of these chapters.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

(GCDF: A. Hernandez-Cardoso.)

Comment deadline: November 30, 2015

⟨2⟩ ORAL DRUG PRODUCTS—PRODUCT QUALITY TESTS

Change to read:

INTRODUCTION

Oral delivery is the most common route of administration for drug products. All oral drug products lead to systemic and/or local action in the oral cavity and/or gastrointestinal tract. Oral drug products fall into two main categories: solids and liquids. Solid oral drug products include but are not restricted to capsules, tablets, granules, and powders. Similarly, liquid oral drug products include but are not restricted to solutions, suspensions, and emulsions. The definitions and descriptions of these dosage forms and brief information about their composition and manufacturing process are found in *Pharmaceutical Dosage Forms* ⟨1151⟩. [Note—All references to chapters above ⟨1000⟩ are for informational purposes only, for use as a helpful resource. These chapters are not mandatory unless explicitly called out for application.] Chapter *Oral Drug Products—Product Quality Tests* ⟨2⟩ focuses on the product quality tests that are generally necessary for oral drug products for a single or combination of small molecules of active ingredients. Biologics in solid dosage forms are not considered. In this chapter, the terms “drug substance” and “active ingredient” are used interchangeably. The contents of this chapter do not necessarily apply to drug products that are intended for use other than by oral administration. For example, the chapter does not address oromucosal

dosage forms. Some of the tests indicated in this chapter may be performed on an in-process basis or omitted as routine tests based on process validation. However, the product must meet USP compendial requirements when sampled and tested, once the product is on the market.

~~Chapter (2) provides a framework to support new individual monographs; these are “moving forward” documents, and are not intended to move away from individual monographs (not replacing individual monographs).~~

■ **2S (USP39)**

~~Chapter (2) provides lists of consolidated common product quality test requirements in a concise and coherent fashion. If a monograph exists, it will contain all of the tests required for the dosage form. If a specific drug product monograph is missing (not in existence), the general chapter provides specific quality tests that are available to manufacturers as a resource until particular monographs needed for the dosage form are developed by USP.~~

■ The general chapter applies, in part or whole, when referenced in a drug product monograph. The general chapter includes the quality tests for the specific route of administration. The quality tests listed can be used as appropriate by manufacturers toward the development of new drug product monographs for submission to the USP. ■ **2S (USP39)**

If a validated performance test procedure is available for the specific drug product, it is identified in a general chapter below (1000). In cases where a validated procedure cannot be recommended, but if the information is available for a product quality and/or product performance test, it is described in an informational chapter above (1000).

Drug Product Quality Tests and Performance Tests

Monograph tests, analytical procedures, and acceptance criteria for testing oral drug products are divided into two categories: 1) those that assess general product quality attributes, and 2) those that assess product performance, which is a specific quality attribute typically linked to bioavailability and bioequivalence studies (see *Assessment of Drug Product Performance—Bioavailability, Bioequivalence, and Dissolution* (1090)). Drug product quality tests are intended to assess attributes such as identification, strength (assay), impurities (universal tests), dose content uniformity, pH, minimum fill, alcohol content, volatile content, and microbial content (specific tests). Drug product performance tests are designed to assess in vitro drug release from dosage forms, e.g., *Dissolution* (711) and *Drug Release* (724). For liquid oral drug products in solution, performance is considered optimal, and a monograph performance test is not included.

Each of these attributes is important for a primary understanding of the quality and performance of a drug product. Thus, they form the basis for the monograph. A compendial product should meet all drug product quality tests and drug product performance tests contained in its monograph.

[Note—Dissolution tests, specifically dissolution profile similarity between higher strengths and lower strengths of a given manufacturer’s product and dissolution profile similarity between the generic product and the reference product, are used for granting biowaivers. See (1090).]

PRODUCT QUALITY TESTS FOR ORAL DRUG PRODUCTS

Drug product quality tests for oral drug products fall into two categories: 1) universal tests that are applicable to all oral drug products and should be included in the monograph, and 2)

specific tests that should be considered for inclusion for specific types of oral products.

Universal Tests

Product quality attributes for oral dosage forms are important to ensure that commercialized products meet minimum quality requirements. Universal tests should be applied to all oral dosage forms and include *Description*, *Identification*, *Strength (Assay test)*, and *Impurities* (organic, inorganic, and residual solvents).

DESCRIPTION

Description is general in nature and is not a standard in itself. It communicates the appearance of an article that complies with monograph standards.

IDENTIFICATION

The identification test is defined in *General Notices*, 5.40 *Identity*. It is included in a monograph as an aid to confirm that the article contains the labeled drug substance by providing a positive identification of the drug substance or substances in a drug product.

One method of confirming the identity is to compare the retention time of the sample with that obtained for the standard injections in a chromatographic assay procedure. Other methods often used to orthogonally confirm the identity of the active ingredient are: *Thin-Layer Chromatographic Identification Test* (201), *Spectrophotometric Identification Tests* (197), *Nuclear Magnetic Resonance Spectroscopy* (761), *Near-Infrared Spectroscopy* (1119), and *Raman Spectroscopy* (1120), among others. The analytical procedure must be able to distinguish the active ingredient from all excipients that are present or from potential degradation products likely to be present. Care must also be taken to ensure that the chromatographic system separates the article from other closely related drug substances, impurities, and additives. Infrared and ultraviolet absorption also can be used for identification (see (197)), if the procedure has been demonstrated to be selective for the drug substance via an appropriate validation or verification study. The results of the identification test must be compared to the results obtained from a similarly prepared, suitable reference standard.

ASSAY

The assay is a specific and stability-indicating test to determine the potency (content) of the drug product. When a nonspecific assay (e.g., titration) is justified, other supporting analytical procedures should ensure that any interfering species can be detected. In general the *a priori* acceptance of $\pm 10\%$ variation in limits of a quality attribute (e.g., assay) from the target label claim (100%) in most cases is intended to account for manufacturing variability and shelf-life stability and is primarily based on the notion that such variation in a quality attribute is less likely to have any noticeable adverse impact on the desired clinical outcome. Acceptance criteria of 95.0%–105.0% are used with justification (e.g., for drug products with narrow therapeutic index). Activity assays and absolute content assays also are acceptable when justified.

IMPURITIES

Process impurities, synthetic by-products, and other inorganic and organic impurities may be

present in the drug substance and in the excipients used in the manufacture of the drug product. These impurities are limited by drug substance and excipient monographs. During product manufacture and over the shelf life of the product, degradation products can form. These can be a result of degradation of the drug substance or from interactions between the drug substance and excipient(s), among other factors. The procedures and acceptance criteria should specifically limit toxic materials. See specific requirements in the *General Notices 5.60 Impurities and Foreign Substances*, . [Note—For additional information, see *Impurities in Drug Substances and Drug Products* (1086).]

Specific Tests for Tablets

In addition to the *Universal Tests* described above, the following specific tests for tablets should be considered, depending upon the nature of the drug substance and formulation.

VOLATILE CONTENT

The test and the specific method depend on the nature of the article. Special consideration should be given to dosage forms for which water content has been shown to be a potential quality attribute and to products where solvent is used in the manufacture of the drug product. When the presence of moisture or other volatile material may become critical, analysts must determine the amount of unbound volatile solvents or volatile matter of any kind that is driven off by *Loss on Drying* (731) or another suitable technique (e.g., water activity). For substances that appear to contain water as the only volatile constituent, the procedure given in *Water Determination* (921) may be appropriate. For drug products, analysts also should consult *Residual Solvents* (467).

DISINTEGRATION

Disintegration is an essential attribute of oral solids, except for those intended to be chewed before being swallowed and for delayed- or extended-release products. This test measures the time it takes for the dosage unit to disintegrate in an aqueous medium and is described in detail in *Disintegration* (701). For certain dosage forms, e.g., effervescent tablets, disintegrating tablets, soluble tablets, and others, the *European Pharmacopoeia* describes the disintegration test in great detail. The disintegration test for some of the dosage forms in this chapter is included for completeness. For detailed procedures, please refer to (701) or the *European Pharmacopoeia*. The disintegration test, if included, is used only as a quality control test and not as a product performance test and should conform with the specifications in the monograph. Only when disintegration has been correlated with dissolution of a dosage form can a disintegration test be used as a product performance test (ICH Guidance Q6A, available at www.ich.org). In all other instances, a dissolution test should be considered as a product performance test.

TABLET FRIABILITY

The test procedure is applicable to most compressed, uncoated tablets. Friability determines the ability of tablets to withstand mechanical stresses and their resistance to chipping and surface abrasion. [Note—For additional information, see *Tablet Friability* (1216).]

TABLET BREAKING FORCE

Tablet breaking force measures the mechanical integrity of tablets, which is the force required to cause them to fail (i.e., break) in a specific plane. [Note—For additional information, see *Tablet Breaking Force* (1217).]

UNIFORMITY OF DOSAGE UNITS

Uniformity of dosage units must be demonstrated by either content uniformity or weight variation. Content uniformity is based on the assay of the individual content of drug substance(s) in a number of dosage units to determine whether the individual contents are sufficiently close to label claim. Weight variation can be used as an alternative to estimate content uniformity under certain conditions (see *Uniformity of Dosage Units* (905)).

Uncoated Tablets

Uncoated tablets include single-layer tablets that result from a single compression of particles and multilayer tablets that consist of concentric or parallel layers obtained by successive compression of particles of different composition. The excipients used generally are not specifically intended to modify the release of the active substance in the digestive fluids. Uncoated tablets include but are not limited to: effervescent tablets, buccal tablets, sublingual tablets, chewable tablets, disintegrating tablets, orally disintegrating tablets, boluses, soluble tablets, tablets for oral solution, and tablets for oral suspension. Boluses, large elongated tablets intended for administration to animals, should be considered uncoated tablets and must be in compliance with the product quality requirements. For uncoated tablets, disintegration should be tested as directed in (701).

BUCCAL, SUBLINGUAL, AND ORALLY DISINTEGRATING (ORODISPERSIBLE) TABLETS

These dosage forms will be discussed in a future new chapter that appears in this *PF, Mucosal Drug Products—Product Quality Tests* (4). They are listed here for informational purposes and completeness.

CHEWABLE TABLETS

Chewable tablets are not required to comply with the disintegration test. Chewable tablets (intact) should undergo dissolution testing, as a product performance test (if cited in the monograph), because they might be swallowed without proper chewing by a patient. In general, the dissolution test conditions for chewable tablets should be the same as for nonchewable tablets of the same active ingredient or moiety.

DISINTEGRATING OR DISPERSIBLE TABLETS

These are tablets intended to be dispersed in water before administration, giving a homogeneous dispersion.

Dispersion fineness: Place 2 tablets in 100 mL of water, and stir until completely dispersed. A smooth dispersion that passes through a No. 25 sieve (710 μm) is obtained.

TABLETS FOR ORAL SOLUTION AND TABLETS FOR ORAL SUSPENSION

Dispersion fineness: Place 2 tablets in 100 mL of water, and stir until completely dispersed. A smooth dispersion that passes through a No. 25 sieve (710 µm) is obtained.

Coated Tablets

Coated tablets are tablets covered with one or more layers of mixtures of various substances such as natural or synthetic resins, gums, gelatin, inactive and insoluble fillers, sugars, plasticizers, polyols, waxes, coloring matter authorized by the competent authority, and sometimes flavoring substances and active substances. Tablets coated by sugar or film include but are not limited to: plain coated tablets, extended-release tablets, and delayed-release tablets. A disintegration test, when applicable, should be performed as directed in <701>. There are no additional specific quality tests for extended-release tablets and delayed-release tablets. Universal quality tests should be applied to these products.

Specific Tests for Capsules

In addition to the *Universal Tests* described above, the following *Specific Tests for Capsules* should be considered, depending on the nature of the drug substance and formulation. Product quality tests that are considered specific to the type of capsule include those for volatile content (<731> and <921>). One-piece capsules typically are used to deliver a drug substance as a solution or suspension. Two-piece capsules consist of two telescoping cap-and-body pieces in a range of standard sizes and are used to deliver solid material as powder, granules, or small tablets. Modified-release capsules include but are not limited to: delayed-release capsules and extended-release capsules.

Disintegration: Proceed as directed in *Dissolution* <701>, *Soft Gelatin Capsules*, for one-piece capsules and *Dissolution* <701>, *Hard Gelatin Capsules* for two-piece capsules. Disintegration for modified-release capsules is described in great detail in the *European Pharmacopoeia*. There are no additional specific quality tests for extended-release capsules and delayed-release capsules. Universal quality tests should be applied to these products.

Specific Tests for Granules

In addition to the *Universal Tests* described above, the following *Specific Tests for Granules* should be considered, depending on the nature of the drug substance and formulation. Granules are solid dosage forms that are composed of agglomerations of smaller particles. Granules include but are not limited to: effervescent granules, coated granules, extended-release granules, and delayed-release granules. Tests that are considered specific to the type of granules include volatile content (<731> and <921>). Disintegration for effervescent granules is described in great detail in the *European Pharmacopoeia*. On the basis of the nature of the article and scientific criteria, additional tests may apply, including powder fineness and others.

Specific Tests for Powders

Oral powders should indicate: "For Oral Use Only". Tests that are considered specific to the

type of powders include: *Minimum Fill* (755) and volatile content ((731) and (921)). Chapter (755) has specifications that apply to oral powders.

On the basis of the nature of the article and scientific criteria, additional tests may apply, including pH in an aqueous solution, powder fineness, microbial limits, and others.

Specific Tests for Liquids

The recommended product quality tests for a liquid drug product include the *Universal Tests* described above and the specific tests included below. Most of the quality tests for liquids require the evaluation of single-dose products to estimate the quality attribute. Specific directions to perform the quality tests for either single-dose or multiple-dose products are provided in the monograph or the general chapter. For example, weight variation may be used when adequacy of mix for the active substance(s) and excipients in the blend is well controlled to ensure their uniform distribution, as in solutions.

DELIVERABLE VOLUME

When the liquid formulation is packaged in a multiple-dose container, compliance with *Deliverable Volume* (698) is required.

ALCOHOL DETERMINATION

If the liquid formulation contains a quantity of alcohol, *Alcohol Determination* (611) should be included. The limits may be an absolute concentration, in percentage, or relative to a labeled content.

PH

Liquid oral products typically are aqueous formulations that are susceptible to pH changes from exposure to atmospheric CO₂. The uptake of atmospheric CO₂ and pH change of oral liquid products is only relevant to aqueous-based products. Although it is less critical than in ophthalmic preparations, the pH of a liquid formulation can affect flavor and stability. The pH range as outlined in *pH* (791) is indicated in the monograph.

MICROBIAL CONTENT

The presence of certain microorganisms in nonsterile preparations may have the potential to reduce or even inactivate the therapeutic activity of the product and has a potential to adversely affect the health of the patient. Some liquid oral products can be subject to extreme microbiological control, and others require none. The needed microbial specification for a given liquid oral product depends on its formulation and use and is indicated in the monograph.

[Note—For additional information, see *Microbiological Examination of Nonsterile Products: Acceptance Criteria for Pharmaceutical Preparations and Substances for Pharmaceutical Use* (1111).]

ANTIOXIDANT

Release testing should be performed. Shelf-life testing may be unnecessary where justified by

development and stability data (ICH Guidance Q6A).

EXTRACTABLES

Where development and stability data show no significant evidence of extractables, elimination of this test may be proposed. Where data demonstrate the need and acceptance criteria for oral solutions—rubber stopper, cap liner, plastic bottle—data should be collected as early in the development process as possible (ICH Guidance Q6A).

Types of Liquid Dosage Forms

Specific quality tests for these dosage forms are provided in their respective monographs.

ORAL SOLUTIONS AND POWDERS AND GRANULES FOR SOLUTION

Tests of “for Solution” formulations are conducted on a well-mixed solution of the drug product constituted as described in the labeling.

EMULSIONS, SUSPENSIONS, AND POWDERS AND GRANULES FOR SUSPENSION

Tests of “for Suspension” formulations are conducted on a well-mixed suspension of the drug product constituted as described in the labeling. Product quality tests for suspensions should include a test of suspendability.

POWDERS AND GRANULES FOR SYRUPS AND POWDERS FOR ORAL DROPS

After dissolution or suspension, they comply with monograph requirements for the final dosage form. Volatile content (<731) and (<921) may be an additional quality test for powders and granules for reconstitution.

Specific Tests for Miscellaneous Oral Dosage Forms

LYOPHILIZED ORAL PRODUCTS

Chapter *Water Determination* (<921), *Method Ia*: Lyophilized oral products comply with the test. The limits are approved as indicated in the specific monograph.

BRIEFING

<3> **Topical and Transdermal Drug Products—Product Quality Tests**, *USP* 38 page 71 and *PF* 41(2) [Mar.–Apr. 2015]. There are five USP general chapters that link with USP’s taxonomy for pharmaceutical dosage forms: *Injections and Implanted Drug Products* (1), *Oral Drug Products—Product Quality Tests* (2), *Topical and Transdermal Drug Products—Product Quality Tests* (3), *Mucosal Drug Products—Product Quality Tests* (4), and *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* (5). This taxonomy describes five routes of administration: injection or parenteral; gastrointestinal or oral; topical (dermal and transdermal); mucosal; and lungs or inhalation (for more information, see the *Stimuli* article titled *Product Quality and Product Performance General Chapters* in *PF* 39(3) [May–June 2013]). The five chapters provide critical product quality attributes for the various dosage

forms by the various routes of administration. In addition to these five chapters, *Ophthalmic Ointments* (771) outlines the critical product quality attributes for the various dosage forms that can be applied to the eye. Product quality tests assess physical, chemical, and microbial attributes. Taken together, the tests help ensure identity, strength, quality, and purity of a dosage form. The General Chapters—Dosage Forms Expert Committee is proposing the following revision to (1), (2), (3), (4), (5), and (771), in this issue of *PF*, to clarify the applicability of these chapters.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

(3) TOPICAL AND TRANSDERMAL DRUG PRODUCTS—PRODUCT QUALITY TESTS

Change to read:

INTRODUCTION

Topically applied drug products fall into two general categories: those applied to achieve local action and those applied to achieve systemic effects after absorption through the skin into the blood circulation. Local action can occur at or on the surface of the application site (e.g., stratum corneum-ocular epithelium ■ 2S (USP39)); in the underlying tissues (e.g., epidermis and/or dermis); and on ■ in ■ 2S (USP39) subcutaneous tissues (e.g., muscle or joint). Topically applied drug products include, but are not limited to, creams, gels, ointments, pastes, suspensions, lotions, foams, sprays, aerosols, solutions, and transdermal delivery systems (TDS, also known as patches ■ 2S (USP39)). The definitions and descriptions of these dosage forms, as well as brief information on their composition and/or manufacturing processes, can be found in *Pharmaceutical Dosage Forms* (1151).

Procedures and acceptable criteria for testing topically applied drug products can be divided into those that assess general product quality attributes and those that assess product performance. The product quality attributes include the following: description, identification, assay (strength), impurities, physicochemical properties, uniformity of dosage units, water content, pH, apparent viscosity, microbial limits, antimicrobial preservative content, antioxidant content, sterility (if applicable), and other tests that may be product specific. Product performance testing assesses drug release and other attributes that affect drug release from the finished dosage form.

■ Chapter *Topical and Transdermal Drug Products—Product Quality Tests* (3) provides lists of consolidated common product quality test requirements in a concise and coherent fashion. This chapter applies, in whole or in part, when referenced in a drug product monograph and includes the quality tests for the specific route of administration. The quality tests listed can be used as appropriate by manufacturers toward the development of new drug product monographs for submission to *USP*.

■ 2S (USP39)

Although most topically applied drug products are semisolids, liquids, or suspensions, TDS are physical devices that are applied to the skin and vary in their composition and method of fabrication. ■ ■2S (USP39) TDS release their active ingredients by different mechanisms. They can be passive or active. This chapter covers only the tests related to passive TDS.

Change to read:

**PRODUCT QUALITY TESTS FOR TOPICALLY APPLIED ■ TOPICAL AND TRANSDERMAL
■2S (USP39) DRUG PRODUCTS**

Universal Tests

Universal tests (see *ICH Guidance Q6A—Specifications: Test Procedures and Acceptance Criteria for New Drug Substances and New Drug Products: Chemical Substances*, available at www.ich.org) are listed as follows and are applicable to all topically applied drug products.

DESCRIPTION

A qualitative description of the drug product should be provided. The acceptance criteria should include the final acceptable appearance of the finished dosage form and packaging. A visual examination should identify changes in color, adhesive migration (i.e., cold flow; see *Cold Flow Test*) for TDS, separations, crystallization, and others that are specific to the drug product. The description should specify the content or the label claim of the article. ■ For TDS, a visual examination should also be done to assess potential use issues with the product. The examination should include an assessment of the difficulty of removing the TDS from the pouch (e.g., due to adhesive migration adhering the system to the pouch); inability to remove the TDS from the pouch without damage to the system; and adhesive residue remaining on the pouch after removal of the TDS. ■2S (USP39) This is not a compendial test but is part of the manufacturer's specification for the drug product.

IDENTIFICATION

Identification tests are discussed in *General Notices and Requirements, Monograph Components, Identity 5.40*. Identification tests should establish the identity of the drug or drugs present in the article and should discriminate between compounds of closely related structures that are likely to be present. Identity tests should be specific for the drug substance(s) (e.g., infrared spectroscopy). Near-infrared (NIR) or Raman spectrophotometric methods also could be acceptable for the identification of the drug product (for additional information, see *Near-Infrared Spectroscopy* (1119) and *Raman Spectroscopy* (1120)). Identification solely by a single chromatographic retention time is not specific.

ASSAY

A specific and stability-indicating test should be used to determine the strength (content) of the drug product. ■ This assay requirement can be satisfied for topical products containing antibiotics by a standard microbiological method (see *Antibiotics—Microbial Assays* (81)). ■2S (USP39) In cases when the use of a nonspecific assay (e.g., *Titrimetry* (541)) is justified, other supporting analytical procedures should be used to achieve overall specificity.

IMPURITIES

Process impurities, synthetic byproducts, impurities associated with the adhesive (e.g., residual monomers), residual solvents (see *Residual Solvents* (467)), heavy metals (see *Heavy Metals* (231) (Official 1-Dec-2015)), and other inorganic and organic impurities may be present in the drug substance and in the excipients used in the manufacture of the drug product and should be assessed and controlled. Impurities arising from the degradation of the drug substance and those arising during the manufacturing process of the drug product also should be assessed and controlled.

Specific Tests

In addition to the *Universal Tests* listed previously, the following *Specific Tests* should be considered on a case-by-case basis:

UNIFORMITY OF DOSAGE UNITS

This test is applicable for TDS and for ■ topical ■ 2S (USP39) dosage forms packaged in single-dose ■ unit ■ 2S (USP39) containers, ■ such as sachets/packets ■ 2S (USP39) (see *Uniformity of Dosage Units* (905)).

WATER CONTENT

A test for water content should be included when appropriate (see *Water Determination* (921)). This test is generally formulation dependent. Therefore, it is not included in the compendial drug product monograph but is part of the manufacturer's specification for the drug product.

MICROBIAL LIMITS

Microbial examination of nonsterile drug products is performed according to the methods given in *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* (61) and *Microbiological Examination of Nonsterile Products: Tests for Specified Microorganisms* (62), unless the formulation itself is demonstrated to have antimicrobial properties. Acceptance criteria for nonsterile pharmaceutical products based on total aerobic microbial count and total combined yeasts and molds count are given in *Microbiological Examination of Nonsterile Products: Acceptance Criteria for Pharmaceutical Preparations and Substances for Pharmaceutical Use* (1111).

ANTIMICROBIAL PRESERVATIVE CONTENT

Acceptance criteria for antimicrobial preservative content in ■ multidose ■ multi-unit ■ 2S (USP39) products should be established. They should be based on the levels of antimicrobial preservative necessary to maintain the product's microbiological quality at all stages throughout its proposed usage and shelf life (see *Antimicrobial Effectiveness Testing* (51)).

ANTIOXIDANT CONTENT

If antioxidants are present in the drug product, tests of their content should be established unless oxidative degradation can be detected by another test method such as impurity testing. Acceptance criteria for antioxidant content should be established. They should be based on the levels of antioxidant necessary to maintain the product's stability at all stages throughout the product's proposed usage and shelf life.

STERILITY

Depending on the use of the dosage form (e.g., ~~ophthalmic preparations,~~ ^{■ 2S (USP39)} products that will be applied to open wounds or burned areas), sterility of the product should be demonstrated as appropriate (see *Sterility Tests* (71)).

PH

When applicable, topically applied drug products should be tested for pH. ~~at the time of batch release and at designated stability time points for batch-to-batch monitoring.~~ ^{■ 2S (USP39)} Because some topically applied drug products contain very limited quantities of water or aqueous phase, pH measurements may not always be warranted. This test is generally formulation dependent. Therefore, it is not included in the compendial drug product monograph but is part of the manufacturer's specification for the drug product.

PARTICLE SIZE

■ When the finished product contains a suspended solid drug substance, the product should be examined for particle size. ^{■ 2S (USP39)} The particle size of the active drug substance(s) in topically applied drug products is usually ~~determined~~ ^{■ established} ^{■ 2S (USP39)} and controlled at the formulation development stage. However, topically applied drug products should be examined for evidence of particle ^{■ size} ^{■ 2S (USP39)} alteration (i.e., ^{■ drug polymorphic form,} ^{■ 2S (USP39)} ~~appearance of particles, changes in particle form,~~ ^{■ 2S (USP39)} ~~size, shape, habit, or~~ ^{■ morphology, agglomeration, or} ^{■ 2S (USP39)} ~~aggregation~~) of the drug substance that may occur during the course of product processing and storage. ~~Such examinations should be conducted at the time of batch release and at designated stability test time points for batch-to-batch monitoring because changes that are visually (macro and microscopically) observable would likely compromise the integrity and/or performance of the drug product.~~ ^{■ 2S (USP39)} These types of tests are generally formulation dependent. Therefore, such tests are not included in compendial monographs but are part of the manufacturer's specification for the drug product.

CRYSTAL FORMATION

When ^{■ the drug substance is dissolved in} ^{■ 2S (USP39)} ~~the finished product, does not contain a suspended active drug substance but rather contains a dissolved active drug substance~~ ^{■ 2S (USP39)} the product should be ^{■ microscopically} ^{■ 2S (USP39)} ~~examined for evidence of crystal formation of the active drug substance. Such examinations should be done microscopically and conducted at the time of batch release and at designated stability test time points.~~ ^{■ 2S (USP39)} This test is generally formulation dependent. Therefore, it is not included in the compendial drug product monograph but is part of the manufacturer's specification for the drug product. It is recommended that the potential for the drug product to form crystals of drug substance be examined during product development using conditions of stress. ^{■ 2S (USP39)}

Change to read:

SPECIFIC TESTS FOR OPHTHALMIC DRUG PRODUCTS

~~Ophthalmic dosage forms must meet the requirements of *Sterility Tests* (71). If the specific ingredients used in the formulation do not lend themselves to routine sterilization techniques,~~

ingredients that meet the sterility requirements described in (71), along with aseptic manufacture, may be used. Multiple-use ophthalmic preparations must contain a suitable substance or mixture of substances to prevent growth of, or to destroy, microorganisms accidentally introduced during the use of the product (see *Added Substances in Ophthalmic Ointments* (771)), unless otherwise directed in the individual monograph or unless the formula itself is bacteriostatic and/or the delivery system promotes bacteriostasis. The finished ophthalmic preparation must be free from large particles and must meet the requirements for *Leakage* and for *Metal Particles* in (771). The immediate containers for ophthalmic preparations shall be sterile at the time of filling and closing. It is mandatory that the immediate containers for ophthalmic preparations be sealed and tamper proof so that sterility is ensured at the time of first use.

■ See *Ophthalmic Ointments* (771). ■ 2S (USP39)

Change to read:

SPECIFIC TESTS FOR TOPICALLY APPLIED SEMISOLID DRUG PRODUCTS

■

Minimum Fill

This test applies only to multiple-dose containers, such as tubes and jars (see *Minimum Fill* (755)). ■ Single- and multiple-unit containers must meet minimum fill requirements as established by testing described in *Minimum Fill* (755). ■ 2S (USP39) For single-dose ■ unit ■ 2S (USP39) containers, such as sachets, see chapter ■ where the test for ■ 2S (USP39) (905) is applied, the test for (755) is not required. ■ 2S (USP39)

Apparent Viscosity

Viscosity is a measure of a formulation's resistance to flow and is an assessment of the rheological properties of the dosage form (e.g., semisolid dosage form). Because only Newtonian fluids possess a measurable viscosity that is independent of shear rate, semisolid pharmaceutical dosage forms that are non-Newtonian products exhibit an apparent viscosity. ■ of a rheological property of a semisolid dosage form. The term "apparent viscosity" applies to non-Newtonian fluids, which comprise the majority of semisolid pharmaceutical dosage forms. ■ 2S (USP39)

The apparent viscosity of semisolid drug products should be tested at the time of batch release and initially at designated stability test time points to set specifications for batch-to-batch and shelf-life monitoring. ■ ■ 2S (USP39) Measurement procedures should be developed as outlined in • *Viscosity—Capillary Methods* (911) • (CN 1-May-2015) , ■ *Viscosity—Rotational Methods* (912), and *Viscosity—Rolling Ball Method* (913). ■ 2S (USP39) For semisolids that show thixotropy and/or irreversible changes in viscosity after shearing, specific attention should be given to sample preparation procedures to minimize variability in the measurement of apparent viscosity caused by variable shear histories (e.g., mixing speed and temperature, filling operation, and sample handling). Furthermore, for some products it may be warranted to have apparent viscosity specifications at more than ■ one stage of the manufacturing process or with more than ■ 2S (USP39) one set of ■ test ■ 2S (USP39) conditions (e.g., bulk in-process stage, final packaged

product, high and low shear rates, and different temperatures).

~~Apparent viscosity specifications based on data obtained during product development and shelf-life testing should be established for batch release and throughout the proposed shelf life.~~

~~■ An acceptable range for apparent viscosity should be established based on data obtained during product development and based on statistical assessment of multiple product batches over the product's shelf life. ■ 2S (USP39) The apparent viscosity test is formulation and/or process dependent. Therefore, it is not included in compendial drug product monographs but is part of the manufacturer's specification for the drug product. Furthermore, the specifications for apparent viscosity of semisolid dosage forms at batch release and during stability testing may be different. Although the apparent viscosity of the finished drug product at the time of batch release must conform to the product development specifications, for stability testing, the apparent viscosity specifications for the drug product should be based on statistical assessment of the product over its shelf life. ■ 2S (USP39)~~

■ Apart from single-point viscosity measurements, more advanced rheological techniques (flow, oscillatory, creep, and stress relaxation testing) can be applied to develop a mechanistic understanding of a formulation and its structure. These techniques may be useful for product development using the principles of quality by design or for comparative physicochemical characterization of the test and reference formulations in the case of a biowaiver argument in a generic drug application. However, these techniques are not generally suitable for routine quality testing. Common parameters derived from rheological testing of semisolid pharmaceutical dosage forms that may be useful for characterization and comparison are the storage modulus, loss modulus, relaxation modulus, compliance, thixotropic index, and yield stress. Acceptance criteria are product specific and defined to ensure that the apparent viscosity of each batch of semisolid drug product is within the range defined by the product design and is consistent between batches based on the product development specifications and statistical assessment of multiple product batches over the product's shelf life. ■ 2S (USP39)

Uniformity in Containers

Typically applied semisolid drug products may show physical separation during manufacturing processes and during their shelf life. To ensure the integrity of the drug product, it is essential to evaluate the uniformity of the finished product. ~~at the time of batch release and throughout its assigned shelf life.~~ ■ This test applies only to multiple-dose ■ unit ■ 2S (USP39) containers, such as tubes and jars. ~~For single-dose containers, such as sachets, see chapter *Uniformity of Dosage Units* (905).~~ ■ 2S (USP39) This test does not apply to more fluid topical drug products in multiple-unit containers, such as emulsions, lotions, two-phase gels, or topical suspensions, in which the labeling directs the user to mix the product (e.g., shake well) before use. ■ 2S (USP39)

PRODUCTS PACKAGED IN TUBES

~~Within-tube content uniformity can be assessed in the following manner.~~

~~Carefully remove or cut off the bottom tube seal and make a vertical cut from the bottom to the top of the tube. Carefully cut the tube around the upper rim, open the two flaps, and lay the flaps open to expose the product.~~

~~Inspect the product visually for the presence of phase separation, change in physical appearance and texture, and other properties described in the product test for *Description*. If~~

~~there is no observable phase separation or change in physical appearance and texture, and if the product meets the *Description* acceptance criteria, proceed as described in the following sections. If the product exhibits phase separation and/or change in physical appearance or texture, the product fails the tube content uniformity test.~~

~~The procedures described as follows can be modified depending on the sensitivity of the quantitative procedure used to determine the amount of the drug substance(s) present in the formulation.~~

~~For multiple-dose products that contain 5 g or more~~

~~Procedure 1~~

- ~~1. Using a single tube, after visually inspecting the product, remove an appropriate amount of product from the top, middle, and bottom portions of the tube. The sample size should be sufficient for at least one quantitative determination of the active ingredient(s). Determine the amount of the active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results using *Acceptance criteria A*.~~
- ~~2. If the product fails *Acceptance criteria A*, test three additional tubes from the same batch following step 1 described above, and evaluate all 12 test results using *Acceptance criteria B*.~~

~~Procedure 2~~

- ~~1. Using two tubes, after visually inspecting the product, remove an appropriate amount of product from the top, middle, and bottom portions of each tube. The sample size should be sufficient for at least one quantitative determination of the active ingredient(s). Determine the amount of the active ingredient(s) in each portion of the tube using any appropriate validated quantitative procedure, and evaluate the test results using *Acceptance criteria A*.~~
- ~~2. If the product fails *Acceptance criteria A*, test two additional tubes from the same batch following step 1 described above, and evaluate all 12 test results using *Acceptance criteria B*.~~

~~For multiple-dose products that contain less than 5 g of product~~

- ~~1. Test the top and bottom portions of two tubes using *Procedure 1* or *Procedure 2* as described above. Evaluate the test results using *Acceptance criteria A*.~~
- ~~2. If the product fails *Acceptance criteria A*, test two additional tubes from the same batch following step 1 described above, and evaluate all eight test results using *Acceptance criteria B*.~~

~~Tube (container) content uniformity test acceptance criteria:~~ ~~In determining the relative standard deviation (RSD) from multiple tubes, first determine the variance from the three measurements for each tube and average across the tubes. The RSD is calculated using this average variance.~~

~~*Acceptance criteria A*—All results are within the product assay range, and the RSD is NMT 6% or as specified in the product specification or in the compendial monograph. If the RSD is greater than 6%, use *Acceptance Criteria B*.~~

~~Acceptance criteria B—All results are within the product assay range, and the RSD of the 12 assay results is NMT 6% or as specified in the product specification or in the compendial monograph.~~

■

VISUAL UNIFORMITY

Carefully remove or cut off the bottom tube seal and make a vertical cut from the bottom to the top of the tube. Carefully cut the tube around the upper rim, open the two flaps, and lay the flaps open to expose the product. Repeat this procedure for a total of three tubes. ■

■_{2S (USP39)}

Inspect the product visually for the presence of phase separation, change in physical appearance and texture (e.g., color change, crystallization, lumping), and other properties described in the product specification for *Description*. If there is no observable ■ significant ■_{2S (USP39)} phase separation or significant ■ ■_{2S (USP39)} change in physical appearance and texture, and if the product meets the *Description* criteria, the product passes the test. If the product exhibits ■ significant ■_{2S (USP39)} phase separation and significant ■ or ■_{2S (USP39)} change in physical appearance or texture, the product fails the test.

UNIFORMITY OF ACTIVE INGREDIENT(S)

The following procedures can be modified depending on the sensitivity of the quantitative procedure used to determine the amount of the drug substance(s) present in the formulation.

For multiple-dose ■ unit ■_{2S (USP39)} tubes that contain 5 g or more of product:

Stage 1:

1. Using three tubes ■ a single tube, ■_{2S (USP39)} after performing the test for *Visual Uniformity*, remove an appropriate amount of the product from the top (i.e., cap end), middle, and bottom (i.e., seal end) portions of the tube. The sample size should be sufficient for at least one quantitative determination of the active ingredient(s) ■ and should not exceed the maximum dose recommended by the product labeling for a single application. ■_{2S (USP39)}
2. Determine the amount of the active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the single tube using the *Stage 1* acceptance criteria outlined in number 3.
3. The *Stage 1* acceptance criteria are met if:
 - None of the nine results (i.e., three each from three tubes) are outside of the product assay range by $\pm 5.0\%$ (e.g., if the product assay range is 90.0%–120.0%, the range will be 85.0%–125.0%), ■ three results are outside of the product assay range, ■_{2S (USP39)} and
 - The maximum difference in the amount of active ingredient(s) determined within each tube, for each of the three tubes tested, is NMT 10.0%. For example, if the three measurements within a tube are 87.0%, 95.2%, and 89.7%, the maximum difference would be 8.2% (i.e., $95.2\% - 87.0\% = 8.2\%$). ■ the tube is NMT 10.0%. For example, if the three measurements within the tube are 97.0%, 95.2%, and 99.7%, the maximum difference would be 4.5% (i.e., $99.7\% - 95.2\% = 4.5\%$). ■_{2S (USP39)}
4. Proceed to *Stage 2* testing if NMT one of the nine test results is outside of the product assay range by $\pm 5.0\%$, and none are outside the product assay range by $\pm 15.0\%$, and

the maximum difference of the amount of active ingredient(s) measured within each tube is NMT 15.0%, none of the test results are outside the product assay range by NMT 5.0% (e.g., if the product assay range is 90.0%–120%, the range will be 85.0%–125.0%), and the maximum difference in the amount of active ingredient(s) measured within the tube is NMT 10.0%.

5. Proceed to *Stage 3* testing if NMT one of the three test results is outside of the product assay range by $\pm 5.0\%$, none are outside the product assay range by $\pm 15.0\%$, and the maximum difference of the amount of active ingredient(s) measured within the tube is NMT 15.0%.

■ 2S (USP39)

Stage 2:

1. Test an additional seven ■ two ■ 2S (USP39) tubes for *Visual Uniformity* and *Uniformity of Active Ingredient(s)* for a total of three samples from 10 ■ each from three ■ 2S (USP39) tubes.
2. ■ Determine the amount of the active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the three tubes using the *Stage 2* acceptance criteria. ■ 2S (USP39)
3. *Stage 2* acceptance criteria are met if:
 - The *Visual Uniformity* test is met for all tubes;
 - 29 of 30 test results are within the product assay range by $\pm 5.0\%$, and none are outside of the product assay range by $\pm 15.0\%$; and ■ None of the nine results (i.e., three each from three tubes) are outside of the product assay range by NMT 5.0%, and ■ 2S (USP39)
 - The maximum difference of the amount of active ingredient(s) measured within each tube, for each of the 10 tubes tested, is NMT 15.0% ■ samples tested, is NMT 10.0%.
4. Proceed to *Stage 3* testing if NMT one of the nine test results is outside of the product assay range by $\pm 5.0\%$, none are outside the product assay range by $\pm 15.0\%$, and the maximum difference of the amount of active ingredient(s) measured within each tube is NMT 15.0%.

Stage 3:

1. Test an additional seven tubes for *Visual Uniformity* and *Uniformity of Active Ingredient(s)* for a total of three samples each from 10 tubes.
2. Determine the amount of active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the 10 tubes using the *Stage 3* acceptance criteria as outlined in number 3..
3. *Stage 3* acceptance criteria are met if:
 - The *Visual Uniformity* test is met for all tubes; and
 - 29 of the 30 test results are within the product assay range by $\pm 5.0\%$, and none are outside of the product assay range by $\pm 15.0\%$; and
 - The maximum difference of the amount of active ingredient(s) measured within each tube, for each of the 10 tubes tested, is NMT 15.0%.

■ 2S (USP39)

For multiple-dose ■ unit ■_{2S} (USP39) tubes that contain less than 5 g of product:

Stage 1:

1. Using ~~three tubes~~ ■ a single tube, ■_{2S} (USP39) after performing the test for *Visual Uniformity*, remove an appropriate amount of product from the top (i.e., cap end) and bottom (i.e., seal end) portions of the tube. The sample size should be sufficient for at least one quantitative determination of the active ingredient(s) ■ and should not exceed the maximum dose recommended by the product labeling for a single application. ■_{2S} (USP39)
2. Determine the amount of the active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the tube using the *Stage 1* acceptance criteria outlined in number 3.
3. *Stage 1* acceptance criteria are met if:
 - ~~None of the six test results (i.e., two each from three tubes) are outside of the product assay range by ±5.0% (e.g., if the product assay range is 90.0%–120.0%, the product assay range ±5% is 85.0%–125.0%), and~~ ■ Neither result is outside of the product assay range; and ■_{2S} (USP39)
 - The difference between the amount of active ingredient(s) determined for the two samples within ~~each tube, for each of the three tubes~~ ■ the tube ■_{2S} (USP39) tested is NMT 10.0%. For example, if the two measurements within a tube were 95.2% and 89.7%, the difference would be 5.5%.
4. Proceed to *Stage 2* testing if ~~NMT one of the six tests results is outside of the product assay range by ±5.0%, and none are outside of the product assay range by ±15.0%, and the maximum difference of the amount of active ingredient(s) measured within each tube is NMT 15.0%~~ ■ neither of the test results are outside the product assay range by ±5.0% (e.g., if the product assay range is 90.0%–120.0%, the range will be 85.0%–125.0%), and the difference between the amounts of active ingredient(s) measured within the tube is NMT 10.0%.
5. Proceed to *Stage 3* testing if NMT one of the test results is outside of the product assay range by ±5.0%, and none are outside the product assay range by ±15.0%, and the difference between the amounts of active ingredient(s) measured within the tube is NMT 15.0%. ■_{2S} (USP39)

Stage 2:

1. Test an additional ~~seven~~ ■ two ■_{2S} (USP39) tubes for *Visual Uniformity* and *Uniformity of Active Ingredient(s)* for a total of two samples each from ~~±0~~ ■ three ■_{2S} (USP39) tubes ■
2. Determine the amount of the active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the three tubes using the *Stage 2* acceptance criteria as outlined in number 3. ■_{2S} (USP39)
3. *Stage 2* acceptance criteria are met if:
 - The *Visual Uniformity* test is met for all tubes; and
 - ~~19 of 20 test results are within the product assay range by ±5.0%, and none are outside of the product assay range by ±15.0%; and~~ ■ None of the six test results (i.e., two each from three tubes) are outside of the product assay range by ±5.0%; and ■_{2S} (USP39)

- The difference between the amount of active ingredient(s) determined for the two samples within each tube, for each of the ~~10 tubes tested~~, is NMT 15.0% ■
three tubes tested is NMT 10.0%.
4. Proceed to *Stage 3* testing if NMT one of the six test results is outside of the product assay range by $\pm 5.0\%$, none are outside of the product assay range by $\pm 15.0\%$, and the difference between the amounts of active ingredient(s) measured within each tube is NMT 15.0%.

Stage 3:

1. Test an additional 7 tubes for *Visual Uniformity* and *Uniformity of Active Ingredient(s)* for a total of 20 samples, 2 samples each from 10 tubes.
2. Determine the amount of active ingredient(s) in each portion of the product using any appropriate validated quantitative procedure, and evaluate the test results from the 10 tubes using the *Stage 3* acceptance criteria as outlined in number 3.
3. *Stage 3* acceptance criteria are met if:
 - The *Visual Uniformity* test is met for all tubes; and
 - 19 of 20 test results are within $\pm 5.0\%$ of the product assay range, and none are outside of the product assay range by $\pm 15.0\%$; and
 - The difference between the amount of active ingredient(s) determined for the two samples within each tube, for each of the 10 tubes tested, is NMT 15.0%.

■ 2S (USP39)

PRODUCTS PACKAGED IN CONTAINERS OTHER THAN TUBES

For semisolid products packaged in a container other than a tube when the sampling method presented previously cannot be used, other sampling methods are acceptable, such as this method described for a jar:

1. Select a suitable syringe of sufficient length to extend to the bottom of the container.
2. Remove and set aside the syringe plunger, and cut off the bottom of the syringe barrel. Sampling should take place from a location to the left or right of the mid-line of the jar surface to preserve an undisturbed region on the other side for any additional investigation (see *Figure 1*).

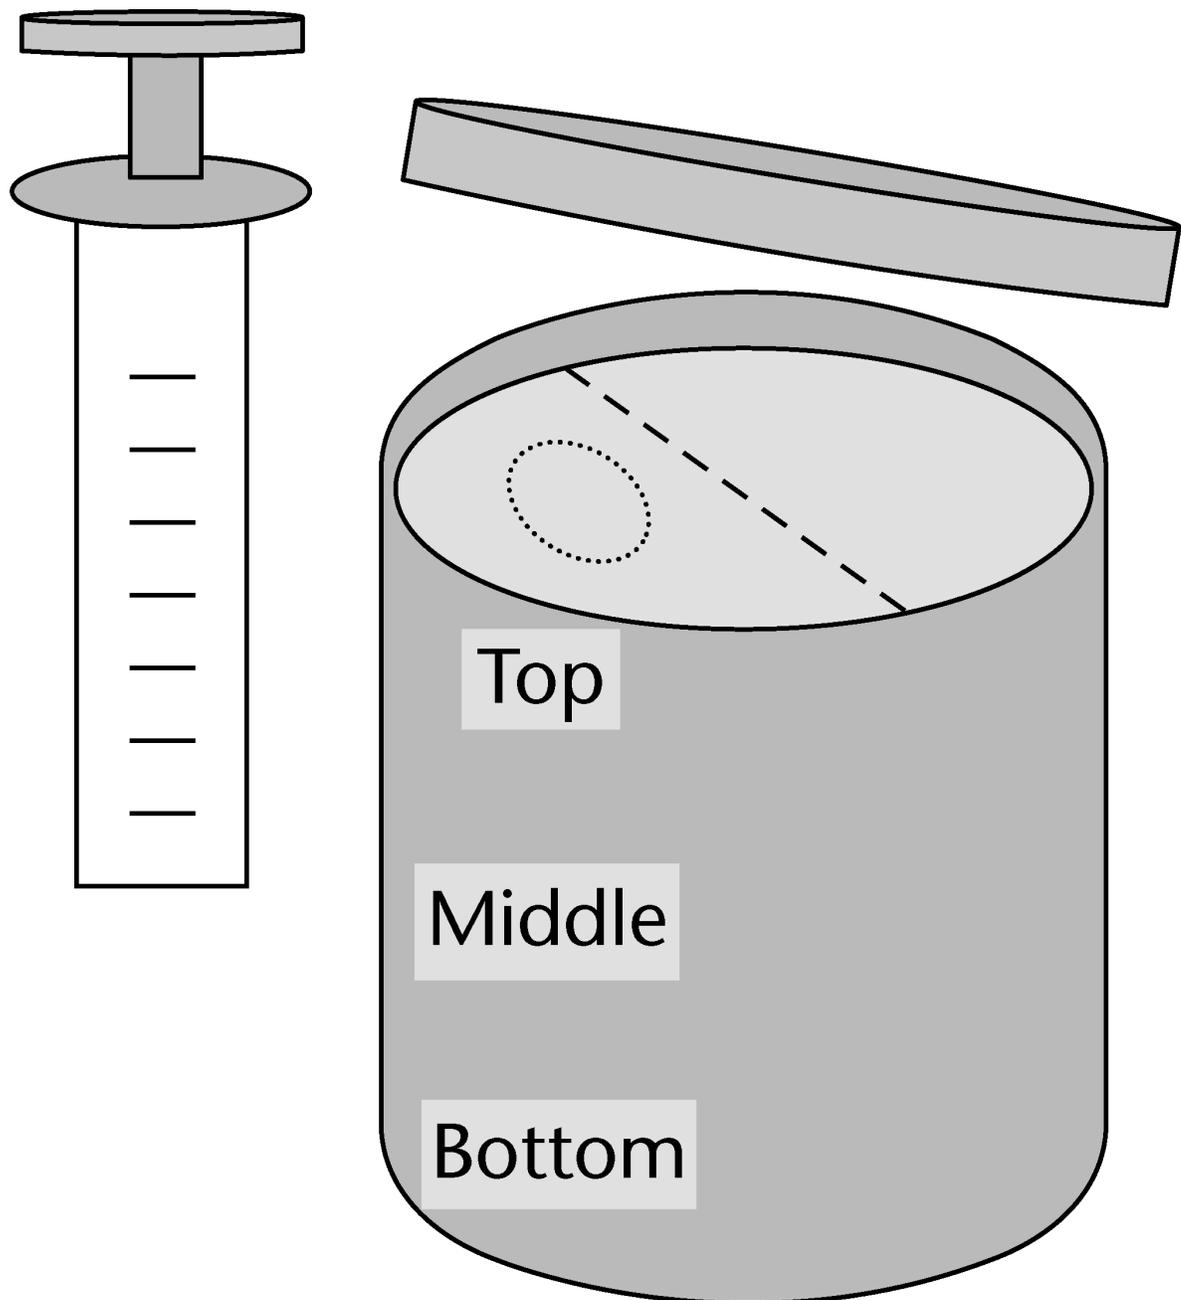

Figure 1. Sampling from a jar container.

3. Slowly push the syringe barrel into the container until it reaches the bottom. Then twist the syringe barrel containing the sample core, and remove the syringe from the container.
4. Insert the syringe plunger into the barrel, and carefully extrude the sample core onto a clean surface in three equal portions to represent the top, middle, and bottom portions of the container.
5. Remove an appropriate sample representative of the top, middle, and bottom portions of the container samples, and test according to the instructions outlined in *Products Packaged in Tubes*.

SPECIFIC TESTS FOR TDS

~~TDS or patches~~ ■ TDS ■ 2S (USP39) are formulated with an adhesive layer to ensure intimate contact with the skin and allow the delivery of the desired dose of the drug. Adhesives in TDS must permit easy removal of the release liner before use, adhere properly to human skin upon application, maintain adhesion to the skin during the prescribed period of use, and permit easy removal of the TDS at the end of use without leaving a residue or causing damage to the skin or other undesirable effect(s). Additionally, adhesives must be able to maintain the performance of the TDS throughout the shelf life of the drug product.

~~Three types of TDS adhesion tests are generally used: peel adhesion test (from a standard substrate), release liner peel test, and tack test.~~

■ Testing of the physical properties of the TDS generally include peel adhesion, release liner peel, tack, cold flow, shear, and crystal formation (see *Crystal Formation*). The peel adhesion, release liner peel, and tack tests measure the adhesion properties of the TDS. Each of these tests measures the force required to separate the TDS from another surface. The cold flow and shear tests measure the cohesive properties of the TDS. These latter tests measure the resistance to flow of the adhesive matrix. ■ 2S (USP39)

Acceptance criteria are product specific and defined to ensure that adhesion of each batch of TDS is within the range defined by the product design and is consistent between batches based on the product development specifications or ■ and ■ 2S (USP39) statistical assessment of multiple product batches over the product's shelf life.

■ In addition to physical testing, this section also discusses the *Leak Test* applicable to form-fill-seal-type (reservoir or pouched) TDS. ■ 2S (USP39)

Peel Adhesion Test

This test measures the force required to remove (peel away) a TDS attached to a standard substrate surface (e.g., polished stainless steel). The TDS is applied to the substrate using specified techniques for application and is conditioned at a specified temperature and time. Then the TDS is peeled away from the substrate with an instrument that allows for control of the peel angle (e.g., 90° or 180°) and peel rate (e.g., 300 mm/min), and the peel force is recorded. This procedure is repeated using a minimum of five independent samples. The product fails the test if the mean peel force is outside the acceptable range determined during product development and/or ■ ■ 2S (USP39) based on statistical assessment of multiple product batches over the product's shelf life.

Release Liner Peel Test

This test measures the force required to separate the release liner from the adhesive layer of the TDS. The test is performed with a finished product sample. The test sample is conditioned using specific procedures (temperature and time). Then, the release liner is pulled away from the TDS with an instrument that allows for control of the peel angle (e.g., 90° or 180°) and peel rate (300 mm/min), and the peel force is recorded. This procedure is repeated using a minimum of five independent samples. The product fails the test if the mean peel force is outside the acceptable range determined during product development and/or ■ ■ 2S (USP39) based on statistical assessment of multiple product batches over the product's shelf life.

Tack Test

Several methods of tack tests have been developed. Examples include the *Probe Tack Method* and the *Rolling Ball Method*. It is up to the TDS manufacturer to decide which ~~one~~ **tack test** ~~is more~~ **most** ~~is~~ **2S (USP39)** appropriate for each drug product.

PROBE TACK METHOD

This test measures the force required to separate the tip of the test probe from the adhesive layer of the TDS. This test uses an instrument designed to create a bond between the tip of the stainless steel test probe (of defined geometry) and the TDS using a controlled force (light pressure) and specified test conditions (i.e., rate, contact time, contact pressure, and temperature). Then while controlling the rate of probe removal, the test measures the profile of force required to separate the probe tip from the TDS and the maximum force required to break the bond (tack). This procedure is repeated using a minimum of five independent samples. The product fails the test if the mean test result [force profile(s) and/or tack] is outside the acceptable range determined during product development and/or **2S (USP39)** based on statistical assessment of multiple product batches over the product's shelf life.

ROLLING BALL METHOD

This test measures the distance traveled by a defined ball, on the adhesive layer of the TDS under defined conditions, as a parameter dependent on the tack properties of the adhesive layer. This test uses a setup designed to roll a ball (of defined material, weight, size, and surface) from a ramp (of defined angle and length) onto the adhesive layer (with defined orientation) under specified test conditions (e.g., temperature; see *ASTM D3121* for more details). The distance traveled by the ball on the adhesive layer is measured using a suitable measuring device. This procedure is repeated using a minimum of five independent samples. The product fails the test if the mean distance traveled is outside the acceptable range determined during product development and/or **2S (USP39)** based on statistical assessment of multiple product batches over the product's shelf life.

■

Cold Flow Test

Cold flow is the migration of the adhesive matrix beyond the edge of the TDS backing, ~~and through the slit in the release liner,~~ **2S (USP39)** which may occur during the course of product processing and storage. Cold flow is an inherent property of TDS due to the use of pressure-sensitive adhesives that flow when force is applied (i.e., if the adhesive matrix did not flow, the TDS would not stick). The magnitude of the cold flow is generally dependent on the product formulation, storage conditions, and storage time. Cold flow ~~can be~~ **should be** ~~quantitatively and~~ **2S (USP39)** ~~quantitatively measured as an amount (i.e., the region of cold flow can be carefully isolated from the transdermal system and weighed or assayed), an area (i.e., the region of cold flow can be imaged, with suitable magnification, and the area of the cold flow measured using image analysis software), or, most commonly, as a distance (i.e., the distance the adhesive has migrated beyond the edge of the TDS backing, typically NMT a few millimeters, can be measured with suitable magnification; this method is described in further detail below).~~ **by a** ~~suitable method.~~ **It is up to the TDS manufacturer to determine the most suitable cold flow test for each drug product. Acceptance criteria are product specific and defined to ensure that the cold flow of each batch of TDS is within the range defined by the product design and is consistent between batches based on the product development specifications and statistical**

assessment of multiple batches over the product's shelf life. ■ 2S (USP39)

Assessing cold flow through a combination of qualitative and quantitative methods may be needed. The method(s) chosen to assess cold flow must demonstrate discerning capabilities and be scientifically justified throughout the shelf life of the drug product.

DISTANCE METHOD

Samples to be tested should be carefully handled so as not to disturb the cold flow (if present). If the TDS to be tested is not adhered to the pouching material, carefully remove the TDS without disturbing the cold flow. If the TDS to be tested is adhered to the pouching materials, carefully cut around the perimeter of the pouch so that all edges of the pouch are open. Then carefully peel the front and back of the pouch apart, exposing the TDS, which may be adhered to the inside of the front or back pouch film. A minimum of three TDS should be prepared for testing.

With the aid of magnification (~20–100×) and appropriate lighting, a measurement of the distance the adhesive matrix has migrated beyond the edge of the TDS backing should be taken. A minimum of four measurements should be taken from each TDS. The positions on the TDS where the measurements are to be taken should be evenly spaced and predefined. For example, with the TDS oriented with the printing, measurements could be taken at the 3:00, 6:00, 9:00, and 12:00 positions. Measurements may be taken with the use of a graduated eye piece, through the use of a camera with suitable software, or other appropriate approach.

The product fails if the overall average measured cold flow is outside the acceptable range determined during product development and based on statistical assessment of multiple product batches over the product's shelf life.

Note that the test for cold flow provides a direct measure of the cohesive properties of the adhesive matrix, which is a quality attribute that is correlated to shear. Although the shear test has some value during product development as a rudimentary predictor of the potential for cold flow, with the inclusion of cold flow as a product quality test, shear is not recommended as a test to control the quality of the finished product.

■ ■ 2S (USP39)

Shear Test

The *Shear Test* measures the cohesive strength of a TDS. It can be measured under static (see *Static Shear Test*) or dynamic conditions. Shear testing may not be feasible for all TDS because the presence of multiple layers of adhesive in the system, the presence of a membrane or scrim, or the use of an emulsion adhesive system may result in the inability to achieve cohesive failure. TDS that are constructed with a peripheral adhesive ring or form-fill-seal TDS may not be suitable for this test. ■ It is up to the TDS manufacturer to decide if a shear test is appropriate, and if so, which shear test is most appropriate for each drug product. Acceptance criteria are product specific and defined to ensure that the shear of each batch of TDS is within the range defined by the product design and is consistent between batches based on the product development specifications and statistical assessment of multiple product batches over the product's shelf life. ■ 2S (USP39)

Static Shear Test

For the *Static Shear Test*, the time required to remove a standard area of the TDS from the substrate (i.e., stainless steel test panel) under a standard load (e.g., 250 g) is measured. The TDS is applied to a test panel, that is at an angle 2° from the vertical ■ ■2S (USP39) and the sample is subjected to a shearing force by means of a given weight suspended from the TDS. The test apparatus holds the test panels at ■ 0°–■2S (USP39) 2° from vertical to ensure that the TDS will not experience peeling action when the weight is attached. Dwell time, weight used, test panel type, mode of failure, and sample size should be noted; the time taken for the TDS sample to detach from the test panel is reported. This procedure is repeated using a minimum of five independent samples yielding valid results (see *Determination of the Validity of Static Shear Test*). The product fails the test if the mean shear force ■ (i.e., arithmetic mean or geometric mean as determined by the manufacturer) ■2S (USP39) is outside the acceptable range determined during product development and based on statistical assessment of multiple product batches over the product's shelf life.

DETERMINATION OF THE VALIDITY OF STATIC SHEAR TEST

Cohesion is the preferred ■ desired ■2S (USP39) failure mode for the static shear test. Cohesive failure is indicated when adhesive is left on the TDS and on the stainless steel test panel. In contrast, an adhesive failure occurs when: 1) the TDS strips cleanly from the stainless steel panel, leaving no visible adhesive on the stainless steel panel; 2) the adhesive transfers to the stainless steel test panel, leaving no adhesive on the TDS; or 3) the TDS delaminates at an interface (e.g., between a membrane and an adhesive layer, or between the two different adhesive layers of a bilayer product). If adhesive failure is indicated, the sample test is invalid. In addition, if the TDS breaks or tears before detaching from the stainless steel test panel or the TDS slides out of the clamp before detaching from the stainless steel test panel, ■ ■2S (USP39) or the hanging weight does not hang freely, the sample test is invalid.

■2S (USP39)

Leak Test

This test is applicable only for form-fill-seal-type (reservoir or pouched) TDS. Form-fill-seal TDS must be manufactured with zero tolerance for leaks because of their potential for dose dumping if leaking occurs.

In-process control methods to examine TDS for leaks or potential leaks are needed and require considerable development on the part of TDS manufacturers.

IN-PROCESS TESTING

During the manufacturing process, the presence of leakage (or potential for leakage) due to TDS perforation, cuts, and faulty seals resulting from failures such as air bubbles, gel splash, or misalignment of a TDS backing and release liner layers must be examined. Unless automated process analytical technology is implemented, in-process testing to identify these defects should be performed using the following test procedures.

Visual inspection:

- A specified number of TDS, defined on the basis of batch size, should be examined randomly.
- Each sampled TDS should be thoroughly visually inspected for leakage.
- The product fails if any of the TDS examined are detected with a leak.

Seal integrity: TDS seals should be stress tested to ensure that the application of pressure does not force seals to open, thereby leading to leakage.

- A specified number of TDS, defined on the basis of batch size, should be randomly examined.
- Each sampled TDS should be thoroughly visually inspected for leakage.
- Each sampled TDS is placed on a hard, flat surface and overlaid with a weight so that it is subjected to 13.6 kg. The weight should be left in place for 2 min. Upon removal of the weight, the TDS should be visually inspected for leakage.
- The product fails if the number of TDS detected with a leak is greater than the acceptable limit established by the manufacturer.

Packaged product testing: TDS may leak after they have been individually placed in the primary packaging material as a result of the packaging operation itself or by a user opening the packaging. Therefore, TDS should be tested for leakage after they have been manufactured and packaged in their primary packaging material.

- A specified number of TDS, defined on the basis of batch size, should be randomly examined after they have been placed in their primary packaging material.
- The sampled TDS should be removed from their packaging and thoroughly visually inspected for leakage.
- Each sampled TDS should then be uniformly wiped with a solvent-moistened swab. Both the backing side and the release liner side of the TDS should be wiped. The inside surface of the pouch should also be wiped. The swab(s) is then extracted and assayed for the drug.
- The product fails if the total amount of drug from the TDS, and the corresponding pouch, exceed the acceptable limit established by the manufacturer.

BRIEFING

⟨4⟩ **Mucosal Drug Products—Product Quality Tests**, *USP* 38 page 76 and *PF* 40(1) [Jan.–Feb. 2014]. There are five *USP* general chapters that link with *USP*'s taxonomy for pharmaceutical dosage forms: *Injections and Implanted Drug Products* ⟨1⟩, *Oral Drug Products—Product Quality Tests* ⟨2⟩, *Topical and Transdermal Drug Products—Product Quality Tests* ⟨3⟩, *Mucosal Drug Products—Product Quality Tests* ⟨4⟩, and *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* ⟨5⟩. This taxonomy describes five routes of administration: injection or parenteral; gastrointestinal or oral; topical (dermal and transdermal); mucosal; and lungs or inhalation (for more information, see the *Stimuli* article titled *Product Quality and Product Performance General Chapters* in *PF* 39(3) [May–June 2013]). The five general chapters provide critical product quality attributes for the various dosage forms by the various routes of administration. In addition to these five chapters, *Ophthalmic Ointments* ⟨771⟩ outlines the critical product quality attributes for the various dosage forms that can be applied to the eye. Product quality tests assess physical, chemical, and microbial attributes. Taken together, the tests help ensure identity, strength, quality, and purity of a dosage form. The General Chapters—Dosage Forms Expert Committee is proposing the following revision to ⟨1⟩, ⟨2⟩, ⟨3⟩, ⟨4⟩, ⟨5⟩, and ⟨771⟩, in this issue of *PF*, to clarify the applicability of these chapters.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

Add the following:**▲ (4) MUCOSAL DRUG PRODUCTS—PRODUCT QUALITY TESTS****Change to read:****INTRODUCTION**

The mucosal route of drug administration is subdivided into seven membrane surfaces for the purposes of taxonomic distinction of dosage forms by route of administration. These membrane surfaces are characterized as otic, ophthalmic, nasal, oropharyngeal, urethral, vaginal, and rectal. This grouping does not include the pulmonary mucosal route addressed in *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* (5). A drug product is administered to any of these seven mucosal surfaces to effect either local action or systemic absorption. Local action is to the area proximate to application. Where local action is intended, systemic absorption is not typically desired and is unnecessary for therapeutic effect. In some cases, however, the mucosal delivery of a drug for systemic absorption is used because it avoids first-pass metabolism, it provides more rapid systemic delivery, or it provides an alternative when oral delivery (to the gastrointestinal tract) is not possible due to a disease state. A large number of the dosage forms listed in *Pharmaceutical Dosage Forms* (1151) can be delivered by way of the various membrane surfaces in the mucosal category. [Note—All references to chapters above 1000 are for informational purposes only, for use as a helpful resource. These chapters are not mandatory unless explicitly called out for application.] Analytical procedures and acceptance criteria for testing drug products are divided into two categories: those that assess general product quality attributes and those that assess product performance. Drug product quality tests assess attributes such as identification, assay (strength), dose content uniformity, and impurities and are usually part of the compendial monograph. Product performance tests include the dissolution test for a solid oral dosage form, *Dissolution* (711), and the drug release test, *Drug Release* (724). Taken together, quality and performance tests ensure the identity, strength, quality, and purity of a mucosal drug product.

~~This chapter also provides lists of consolidated, common product quality tests and certain specific tests based on route of drug administration requirements. Existing monographs contain all the tests required for the article. For new, specific drug product monographs or where a monograph is not available, the chapter provides specific quality tests as a resource for manufacturers until particular monographs for the specific product are developed by USP.~~

■ Chapter (4) provides lists of consolidated common product quality test requirements in a concise and coherent fashion. This chapter applies, in part or in its entirety, when referenced in a drug product monograph, and includes the quality tests for the specific route of administration. The quality tests listed can be used, as appropriate, by manufacturers toward the development of new drug product monographs for submission to the USP. ■2S (USP39)

Change to read:**PRODUCT QUALITY TESTS FOR MUCOSAL DRUG PRODUCTS**

This chapter provides product quality tests that are generally necessary, tests that apply to specific products, and tests that apply to one or more of the specific mucosal routes. Quality tests listed under a specific mucosal route in this chapter represent expectations for any dosage form administered by that specific route.

Generally Necessary Tests

Product quality attributes for mucosal dosage forms should reflect acceptable requirements for marketed products. The following tests should be generally applied to all dosage forms intended for mucosal delivery. Tests that are generally necessary for any article include: *Definition*, *Identification*, *Assay*, and *Impurities* (organic, inorganic, and residual solvents). *Uniformity of Dosage Units* (905) is typically included in a *USP* product monograph.

DEFINITION

The *Definition* section (see *General Notices and Requirements 4.10*) in a *USP* monograph describes the drug product and specifies the range of acceptable assayed content of the drug substance(s) present in the dosage form. For certain products, the *Definition* includes any relevant additional information, such as the presence or absence of other components, excipients, or adjuvants, and cautionary statements on toxicity and stability. Appearance information is used in a regulatory submission to aid in product identification. Because the size, shape, color, etc.,

■ and other attributes ■ 2S (*USP39*)

are attributes of individual marketed products, a qualitative description is typically not required as part of a *USP* monograph (see (1151)).

IDENTIFICATION

Identification is included in a monograph as an aid in verifying the identity of the article and to provide a positive identification of the drug substance or substances in a drug product (see *General Notices and Requirements 5.40*).

ASSAY

The assay is used to determine the strength (content) of the drug product. Typically, the assay is specific and stability-indicating. When a nonspecific assay is justified, other supporting analytical procedures should ensure that any interfering species will be detected and can be limited. Assay results are often reported as a percentage of the label claim, with acceptance criteria that are typically in the range from 90.0% to 110.0%. For some antibiotic products, the range may be wider. The width of these limits is intended to allow for manufacturing variability, including changes in stability, as well as analytical variation. The narrower acceptance range of 95.0%–105.0% is used less often and with justification.

IMPURITIES

Process impurities include those arising from starting materials, synthetic byproducts, and other inorganic and organic impurities that may be present in the drug substance and in the excipients used in the manufacture of the drug product. These impurities are controlled by using the appropriate test, as specified within the drug substance and excipient monographs. Impurities in the drug product may also result from degradation of the drug substance or

excipients, from interactions between the drug substance and an excipient, or from interactions between the drug substance and the packaging components. The procedures and acceptance criteria should specifically limit toxic degradation products as well as degradation products that endanger

■ compromise ■ 2S (USP39)

the quality of the article if they exceed certain levels. Limits should be provided for process impurities that are found to be present during the test for degradation products. A more complete discussion of impurities is provided in *Impurities in Drug Substances and Drug Products* (1086)¹ and in ICH Q3B Impurities in New Drug Products.¹

UNIFORMITY OF DOSAGE UNITS

Chapter (905) is used to ensure the consistency of drug substance content in dosage units within a narrow range around the label claim. The test is applied only to dosage forms containing a single dose or a part of a dose of the drug substance in each unit. Uniformity of dosage units may be demonstrated by one of two methods: content uniformity or weight variation. Content uniformity is based on the assays of a number of individual dosage units. Weight variation can be used to estimate content uniformity under certain conditions.

Dosage Forms by Specific Mucosal Route and Product-Specific Tests

In addition to the generally necessary product quality tests already discussed, the dosage form may require specific quality tests that are common across routes of administration. *Injections and Implanted Drug Products* (1) provides testing requirements common to injectable and implantable products. *Oral Drug Products—Product Quality Tests* (2) provides testing requirements for tablets and lozenges. *Topical and Transdermal Drug Products—Product Quality Tests* (3) provides testing requirements common to semi-solids (creams, ointments, and gels). Chapter (5) presents testing requirements for sprays and aerosols. Where a dosage form has no specific test given in this chapter, no additional test is required unless included in the individual monograph specification.

OTIC ROUTE

The otic route is characterized by administration of a preparation into, or by way of, the ear. Demonstration of sterility (see *Sterility Tests* (71)) is not always required for products delivered to the ear. Typically, sterility is required where the product is administered to the inner ear or where the eardrum is damaged. Where sterility is not required, the quantitative enumeration of mesophilic bacteria and fungi that grow under anaerobic conditions, *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* (61), or the determination of the absence or limited occurrence of specified organisms, *Microbiological Examination of Nonsterile Products: Tests for Specified Microorganisms* (62), may be required.

If an antimicrobial preservative is used, *Antimicrobial Effectiveness Testing* (51) and *Antimicrobial Agents—Content* (341) may be required.

Dosage forms given by the otic route include liquids, solutions, and suspensions.

OPHTHALMIC ROUTE

The ophthalmic route is to the eye. In addition to the generally necessary tests, the following specific tests for ophthalmic drug products should be considered (see *Table 1*). For products

that are injected or implanted into the eye, see (1). Some of the important product quality tests for products administered by the ophthalmic route are listed below. See *Ophthalmic Ointments* (771) for details and other product quality information.

- Foreign and Particulate Matter
- Sterility
- Particle Size and Particle Size Distribution
- Antimicrobial Preservative

Table 1. Drug Products Administered by the Ophthalmic Route, with Product-Specific Tests

Ophthalmic Route	
Dosage Form	Product-Specific Tests
Gels	<i>Minimum Fill</i> (755)

	<i>Viscosity—Rotational Methods</i> (912)
	<i>Viscosity—Rolling Ball Method</i> (913)

NASAL ROUTE

The nasal route is administration to the nose, or by way of the nose, for local or systemic effect (see *Table 2*).

Table 2. Drug Products Administered by the Nasal Route, with Product-Specific Tests

Nasal Route	
Dosage Form	Product-Specific Tests
Aerosols	<i>Inhalation and Nasal Drug Products—General Information and Product Quality Tests (5)</i>
Gels (Jelly)	<i>Minimum Fill (755)</i>
	<i>Topical and Transdermal Drug Products—Product Quality Tests (3)</i>
Ointments	<i>Minimum Fill (755)</i>
	<i>Topical and Transdermal Drug Products—Product Quality Tests (3)</i>
Sprays	<i>Inhalation and Nasal Drug Products—General Information and Product Quality Tests (5)</i>
Solutions	<i>Inhalation and Nasal Drug Products—General Information and Product Quality Tests (5)</i>

OROPHARYNGEAL ROUTE

The oropharyngeal route is into the oral cavity and/or pharyngeal region. The oropharyngeal route is subclassified by the specific intra-oral surfaces, such as buccal or sublingual. Buccal and sublingual administrations are typically intended to promote systemic absorption by permeation through the respective mucosa. However, in this context, oral administration may mean topical application for local action (see *Table 3*). Product quality tests for products administered to oropharyngeal surfaces often conform to those for oral administration to the gastrointestinal tract (see (2)).

Table 3. Drug Products Administered by the Oropharyngeal Route, with Product-Specific Tests

Oropharyngeal Route	
Dosage Form	Product-Specific Tests
Buccal patches	See <i>Topical and Transdermal Drug Products—Product Quality Tests</i> (3) for testing requirements common to patches.
Films	Currently no specific tests (additional specific monograph requirements may apply)
Gels	<i>Minimum Fill</i> (755)
	<i>Topical and Transdermal Drug Products—Product Quality Tests</i> (3)
Gums	Currently no specific tests (additional specific monograph requirements may apply)
Lozenges	Currently no specific tests (additional specific monograph requirements may apply)
Ointments	<i>Topical and Transdermal Drug Products—Product Quality Tests</i> (3)
	<i>Minimum Fill</i> (755)
Solutions (Rinses)	Currently no specific tests (additional specific monograph requirements may apply)
Sprays	<i>Inhalation and Nasal Drug Products—General Information and Product Quality Tests</i> (5)
Tablets	<i>Oral Drug Products—Product Quality Tests</i> (2)

URETHRAL ROUTE

The urethral route is into the urethra, typically for local action, but systemic distribution is also possible. Chapters (61) and chapter

- 2S (USP39)

(62) may apply. Drug products in this category include urethral inserts.

VAGINAL ROUTE

The vaginal route is into the vagina, typically for local action, but systemic distribution is also possible. Chapters (61) and chapter

■ 2S (USP39)

(62) may apply (see Table 4).

Relative foam density: Determine relative foam density by weighing a mass of foam (*m*) and a mass of the same volume of water (*e*) in a flat-bottom dish. Relative foam density = *m/e*.

Volume of foam expansion: Estimate the volume of foam expansion at 25° using a graduated buret and a foam-generating container equipped with a dose-actuating device and fitted to the buret.

Table 4. Drug Products Administered by the Vaginal Route, with Product-Specific Tests

Vaginal Route	
Dosage Form	Product-Specific Tests
Creams	Minimum Fill (755)
	Topical and Transdermal Drug Products—Product Quality Tests (3)
Foams	Minimum Fill (755)
	Physical appearance (of the foam and of the collapsed foam)
	Relative foam density
	Volume of foam expansion
Gels	Minimum Fill (755)
	Topical and Transdermal Drug Products—Product Quality Tests (3)
Inserts	Currently no specific tests (additional specific monograph requirements may apply)

RECTAL ROUTE

The rectal route is into the rectum. Rectally administered products may produce local effect(s) or delivery to the systemic circulation.

Softening time determination

■ ■2S (USP39)

of lipophilic suppositories: The test is intended to determine, under defined conditions, the time that elapses until a suppository maintained in water at $37 \pm 0.5^\circ$ softens to the extent that it no longer offers resistance when a defined weight is applied (see *Table 5*).

Relative foam density: Determine relative foam density by weighing a mass of foam (*m*) and a mass of the same volume of water (*e*) in a flat-bottom dish. Relative foam density = m/e .

Volume of foam expansion: Estimate the volume of foam expansion at 25° using a graduated buret and a foam-generating container equipped with a dose-actuating device and fitted to the buret.

■ ■2S (USP39)

⟨5⟩ Inhalation and Nasal Drug Products—General Information and Product Quality Tests, *USP* 38 page 80 and *PF* 39(1) [Jan.–Feb. 2013]. There are five USP general chapters that link with USP’s taxonomy for pharmaceutical dosage forms: *Injections and Implanted Drug Products* ⟨1⟩, *Oral Drug Products—Product Quality Tests* ⟨2⟩, *Topical and Transdermal Drug Products—Product Quality Tests* ⟨3⟩, *Mucosal Drug Products—Product Quality Tests* ⟨4⟩, and *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* ⟨5⟩. This taxonomy describes five routes of administration: injection or parenteral; gastrointestinal or oral; topical (dermal and transdermal); mucosal; and lungs or inhalation (for more information, see the *Stimuli* article titled *Product Quality and Product Performance General Chapters* in *PF* 39(3) [May–June 2013]). The five chapters provide critical product quality attributes for the various dosage forms by the various routes of administration. In addition to these five chapters, *Ophthalmic Products—Quality Tests* ⟨771⟩ outlines the critical product quality attributes for the various dosage forms that can be applied to the eye. Product quality tests assess physical, chemical, and microbial attributes. Taken together, the tests help ensure identity, strength, quality, and purity of a dosage form. The General Chapters—Dosage Forms Expert Committee is proposing the following revision to ⟨1⟩, ⟨2⟩, ⟨3⟩, ⟨4⟩, ⟨5⟩, and ⟨771⟩, in this issue of *PF*, to clarify the applicability of these chapters.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

⟨5⟩ INHALATION AND NASAL DRUG PRODUCTS—GENERAL INFORMATION AND PRODUCT QUALITY TESTS

Change to read:

1. INTRODUCTION

Inhalation drug products deliver a drug substance into the lungs by oral inhalation and include inhalation aerosols, inhalation powders, inhalation sprays, inhalation solution, inhalation suspension, solution for inhalation, and drug for inhalation solution dosage forms. Nasal drug products deliver drugs into the nasal cavity and include nasal aerosols, nasal sprays, nasal solutions, and nasal powder dosage forms. This chapter does not address nasal products in the gels and ointments form. See *Table 1* for established names and definitions of these dosage forms. Definitions of these drug product dosage forms, brief information about their manufacture, and a glossary of dosage form names can be found in *Pharmaceutical Dosage Forms* ⟨1151⟩.

■ [Note—All references to chapters above 1000 are for informational purposes only, for use as a helpful resource. These chapters are not mandatory unless explicitly called out for application.] ■_{2S} (*USP39*)

Table 1. Established Names and Definitions

Established Name	Definition
Inhalation Aerosol	A drug product for oral inhalation that is packaged under pressure and delivers a specified amount of therapeutically active ingredient(s) upon activation of an accurately metered valve system. Inhalation aerosols are more commonly known as metered-dose inhalers or MDIs.
Inhalation Powder	Drug powder for oral inhalation with the use of a device that aerosolizes and delivers an accurately metered amount of the therapeutically active ingredient(s). Inhalation Powders are more commonly known as dry powder inhalers or DPIs.
Inhalation Spray	A nonpressurized, accurately metered, liquid drug dosage form for oral inhalation that is packaged in a container that upon activation delivers fine droplets of the formulation
Inhalation Solution	A drug solution for oral inhalation with the use of a nebulization system
Inhalation Suspension	A drug suspension for oral inhalation with the use of a nebulization system
Solution for Inhalation	A drug solution for oral inhalation that must be diluted before it is administered with the use of a nebulization system
[Drug] for Inhalation Solution	A drug powder that, upon the addition of a suitable vehicle, yields a solution conforming in all respects to an Inhalation Solution
Nasal Aerosol	A drug product for local application into the nasal passages that is packaged under pressure and delivers a specified amount of therapeutically active ingredient(s) upon activation of an accurately metered valve system
Nasal Spray	A nonpressurized, accurately metered, liquid drug dosage form for local application into the nasal passages that is packaged in a container that upon activation delivers droplets of the formulation
Nasal Solution	A nonpressurized, liquid drug dosage form for local application into the nasal passages
Nasal Powder	Drug powder for local application into the nasal passages with the use of a device that delivers and aerosolizes an accurately metered amount of the therapeutically active ingredient(s)

General chapter (5) provides a framework to support new individual monographs. These are “moving forward” documents and are not intended to replace the need for individual monographs. Chapter (5) provides pick lists of consolidated common product quality test requirements in a concise and coherent fashion. If a monograph exists, it should contain all the tests required for the dosage form. If a specific drug product monograph is missing (not in existence), the general chapter provides the quality tests that can be used by manufacturers until the monograph needed for the dosage form appears in *USP-NF*. If a validated performance test procedure is available for the specific drug product, it is identified in a general chapter below (1000). Additional information, or information on promising technologies that have not yet been fully validated, may be presented in informational chapters above (1000).¹

- General chapter (5) provides lists of consolidated common product quality test requirements in a concise and coherent fashion. This general chapter applies, in part or in its entirety, when

referenced in a drug product monograph, and includes the quality tests for the specific route of administration. The quality tests listed can be used, as appropriate, by manufacturers toward the development of new drug product monographs for submission to the USP. If a validated performance test procedure is available for the specific drug product, it is identified in a general chapter below 1000. Additional information, or information on promising technologies that have not yet been fully validated, may be presented in informational chapters above 1000. ■2S (USP39)

Drug Product General Quality Tests and Performance Quality Tests

A USP drug product monograph contains tests, analytical procedures, and acceptance criteria. Drug products tests are divided into two categories: 1) those that assess general quality attributes, and 2) those that assess product performance quality, e.g., delivered dose uniformity and its physical characteristics, such as aerodynamic particle size distribution. General quality tests assess the integrity of the dosage form, whereas performance quality tests assess delivery of the drug and other attributes that may relate to in vivo drug performance.

Taken together, quality and performance tests ensure the identity, strength, quality, and purity of inhalation and nasal drug products.

The next two sections of this chapter list product quality attributes for inhalation drug products and for nasal drug products, respectively. The final section describes in greater detail the quality tests for inhalation and nasal drug products. *Inhalation and Nasal Drug Products: Aerosols, Sprays, and Powders—Performance Quality Tests* (601) contains product performance tests for inhalation and nasal drug products and should be used in conjunction with (5).

2. GENERAL QUALITY TESTS FOR INHALATION DRUG PRODUCTS

Inhalation Aerosol

DESCRIPTION

Aerosol in this context is a dosage form consisting of a liquid or solid preparation packaged under pressure and intended for administration as a fine mist. The descriptive term aerosol also refers to the fine mist of small droplets or solid particles that are emitted from the product. Inhalation aerosols, also known as MDIs, are preparations characterized by dispersion of the active pharmaceutical ingredient into the airways during oral inspiration for either local or systemic effect, and nasal aerosols, also known as nasal MDIs, are characterized by deposition in the nasal cavity for either local or systemic effect.

An aerosol formulation typically contains drug substance(s) dissolved or suspended in a propellant(s) or a mixture of propellant(s) and co-solvent(s) and possibly other suitable excipients. An inhalation aerosol drug product, commonly known as an MDI, delivers a specified amount and quality of therapeutically active ingredient(s) upon activation of an accurately metered valve system. General quality tests for inhalation aerosol drug products should include the following (see section IV later in this chapter for more detailed discussions of each test):

- Identification
- Assay
- Impurities and Degradation Products
- Water Content
- Foreign Particulate Matter

- Leachables
- Spray Pattern
- Microbial Limit
- Alcohol Content (if present)
- Net Fill Weight
- Leak Rate
- For performance quality tests, refer to <601>.

Inhalation Solution

DESCRIPTION

Inhalation solution drug products typically are water-based and are sterile preparations. They are intended for delivery to the lungs by nebulization with a specified external nebulizer. Such drug preparations typically are packaged in single-dose semipermeable containers and also include protective packaging to minimize ingress of volatile foreign contaminants, loss of solvent, and exposure to oxygen and light. Nebulization involves continuous generation and delivery to the patient of a fine mist of aqueous droplets containing a drug solution by means of ultrasonic energy, Venturi effect, or other appropriate mechanical/electrical means. General quality tests for inhalation solutions should include the following (see section IV later in this chapter for more detailed discussions of each test):

- Identification
- Assay
- Impurities and Degradation Products
- Content Uniformity (premetered)
- Assay for Antimicrobial Preservative and Stabilizing Excipients (if present)
- Sterility
- Foreign Particulate Matter
- pH
- Osmolality
- Leachables
- Net Fill Weight
- Weight Loss
- For performance quality tests, refer to *Products for Nebulization—Characterization Tests* <1601>.

Inhalation Suspension

DESCRIPTION

Inhalation suspension drug products typically are water-based and are sterile preparations. They are intended for delivery to the lungs by nebulization with a specified external nebulizer. Such drug preparations typically are packaged in single-dose semipermeable containers and also include protective packaging to minimize ingress of volatile foreign contaminants, loss of solvent, and exposure to oxygen and light. Nebulization involves continuous generation and delivery to the patient of a fine mist of aqueous droplets containing the formulation components by means of ultrasonic energy, Venturi effect, or other appropriate mechanical means. General quality tests for inhalation suspensions should include the following (see section IV later in this chapter for more detailed discussions of each test):

- Particle size distribution of the formulation in the immediate container

- For all other general quality attributes, refer to the previous *Inhalation Solution* attributes.

Solution for Inhalation

DESCRIPTION

Solution for inhalation drug products typically are water-based and are sterile preparations. Upon dilution, in accordance with labeling, including identity and amount of dilution vehicle, they are intended for delivery to the lungs by nebulization using an external nebulizer. Such drug preparations typically are packaged in single-dose semipermeable containers and also include a protective packaging to minimize ingress of volatile foreign contaminants, loss of solvent, and exposure to oxygen and light. Nebulization involves continuous generation and delivery to the patient of a fine mist of aqueous droplets containing the formulation components by means of ultrasonic energy, Venturi effect, or other appropriate mechanical/electrical means. General quality tests for solutions for inhalation should include the following (see section *IV* later in this chapter for more detailed discussions of each test):

- Clarity and color of solution upon dilution in accordance with the labeling
- For all other general quality attributes, refer to the previous *Inhalation Solution* attributes.

Drug for Inhalation Solution

DESCRIPTION (POWDER)

Drug for Inhalation Solution is a (specified color) drug powder formulation that upon the addition of a suitable vehicle, in accordance with labeling, including identity and amount of dilution vehicle, yields a solution conforming in all respects to the *Inhalation Solution* requirements. General quality tests for drug for inhalation solutions should include the following (see section *IV* later in this chapter for more detailed discussions of each test):

- Water content
- Clarity, color, and completeness of solution within specified time, upon reconstitution
- For all other general quality attributes, refer to the previous *Inhalation Solution* attributes upon (re)constitution of the drug product.

Inhalation Spray

DESCRIPTION

Inhalation spray drug products typically are water-based liquid formulations packaged in a compact container-closure system containing an integral spray pump unit that, upon activation, delivers an accurately metered amount of fine mist of droplets of the formulation. The droplets can be generated by various means such as mechanical action, power assistance, or energy from the patient's inspiration. The mechanisms by which they generate droplets distinguish the various types of inhalation sprays. These drug products may be unit-dose or multidose presentations. Inhalation spray drug products may be designed as premeasured or device-metered presentations. A premeasured unit contains a previously measured amount of liquid formulation in an individual container (e.g., a blister) that is inserted in the device by the patient before use. A device-metered product contains a sufficient amount of liquid formulation for a prescribed number of doses in a reservoir, and each dose is delivered as an accurately

metered spray by the device throughout the unit's life. General quality tests for inhalation sprays should include the following (see section *IV* later in this chapter for more detailed discussions of each test):

- Plume geometry
- For all other general quality attributes, refer to the previous *Inhalation Solution* attributes.
- For performance quality tests, refer to (601).

Inhalation Powder

DESCRIPTION

Inhalation powder drug products, commonly known as dry powder inhalers (DPIs), dispense powders for inhalation with the use of a device that aerosolizes and delivers an accurately metered amount of active ingredient(s) with consistent physical characteristics alone or with a suitable excipient(s). Current designs include premetered and device-metered DPIs, all of which rely on various energy sources to create and disperse the aerosol during patient inspiration. Premetered DPIs contain previously measured amounts of formulation in individual containers (e.g., capsules or blisters) that are inserted into the device before use. Premetered DPIs also may contain premetered dose units as ordered multidose assemblies in the delivery system. Device-metered DPIs have an internal reservoir that contains a sufficient quantity of formulation for multiple doses that are metered by the device itself during actuation by the patient. General quality tests for inhalation powders should include the following (see section *IV* later in this chapter for more detailed discussions of each test):

- Identification
- Assay
- Impurities and Degradation Products
- Content Uniformity (premetered)
- Water Content
- Foreign Particulate Matter
- Microbial Limit
- Net Content (device-metered)
- Residual Solvents
- Volatile and Semivolatile Leachables
- For performance quality tests, refer to (601).

3. GENERAL QUALITY TESTS FOR NASAL DRUG PRODUCTS

Nasal Aerosol

Refer to the previous *Inhalation Aerosol* attributes.

Nasal Spray

DESCRIPTION

Nasal spray drug products typically are water-based liquid formulations applied to the nasal cavity for local and/or systemic effects. They contain therapeutically active ingredient(s) dissolved or suspended in solution or mixtures of excipients in a nonpressurized compact

container–closure system. The container–closure system includes an integral spray pump unit that upon activation delivers a spray containing an accurately metered amount of fine mist of droplets of the formulation. Dispersion of the formulation as a spray typically is accomplished by forcing the formulation through the nasal actuator and its orifice. Often, such drug products are multidose device-metered (see *Inhalation Spray*) presentations in which the dose is metered by the spray pump. Nasal spray drug products also may be designed as premetered presentations. General quality tests for nasal sprays should include the following (see section IV later in this chapter for more detailed discussions of each test):

- Identification
- Assay
- Impurities and Degradation Products
- Assay for Preservative and Stabilizing Excipients (if present)
- Content Uniformity (premetered)
- Particle Size Distribution (for suspensions)
- Foreign Particulate Matter

Nasal Powder

Refer to the previous *Inhalation Powder* quality attributes.

Nasal Solution

DESCRIPTION

Nasal solutions are drug products that typically are water-based liquid formulations applied to the nasal cavity for local effect. They may contain drug substance(s) dissolved in solution or mixtures of excipients in a nonpressurized compact container–closure system. The container–closure system includes a delivery system that administers nonmetered amounts of drops or a fine mist of droplets of the formulation. Typically, such drug products are multidose presentations. General quality tests for nasal solution drug products should include the following (see section IV later in this chapter for more detailed discussions of each test):

- Identification
- Assay
- Impurities and Degradation Products
- Assay for Preservative and Stabilizing Excipients (if present)
- Foreign Particulate Matter
- Microbial Limit
- Leachables
- Net Fill Weight
- pH

- Osmolality
- Viscosity

Change to read:**4. DESCRIPTION OF PRODUCT QUALITY TESTS**

Product quality tests are listed as follows, and should be applied to inhalation and nasal drug products and to products for nebulization. Product-specific quality tests are addressed in product monographs.

Description

See the previous corresponding dosage forms and the respective labels for the monograph of a drug product.

Alcohol Content (if present)

If alcohol is used in a drug product formulation, a specific assay with appropriate acceptance criteria should be included.

Assay (strength and content uniformity)

The USP Assay test of a drug substance in the drug product container is determined by means of a validated stability-indicating procedure following *Validation of Compendial Procedures* (1225). The Assay test should measure available drug substance and its stability, including adherence of the drug substance to the container and closure components. Appropriate acceptance criteria can provide added assurance of manufacturing reproducibility and may ensure better conformance in other performance attributes (e.g., delivered dose uniformity). If a drug product is labeled to contain a single enantiomer of a chiral drug substance, analysts can use a chiral assay or a combination of an achiral assay and a validated procedure to control the presence of the undesired enantiomer as an impurity.

Assay for Preservative and Stabilizing Excipients (if present)

The assay of any preservative (e.g., an antimicrobial) or stabilizing excipient (e.g., an antioxidant, an agent specifically added to minimize or prevent degradation) in a multidose container should be determined analytically, typically with a validated stability-indicating procedure following current ICH Q2 guidance. The corresponding acceptance criteria normally are based on appropriate preservative effectiveness demonstrated by a microbial challenge test.

Content Uniformity for Premetered Dosage Forms

See *Uniformity of Dosage Units* (905).

Clarity and Color of Solution upon Dilution

Solution for inhalation and drug for inhalation solution dosage forms must be diluted and reconstituted in accordance with labeling before administration by nebulization. The type and amount of the vehicle used for dilution and reconstitution must be specified on the labeling. Appropriate studies must be undertaken to fully assess the clarity and color of the solution upon dilution and reconstitution. The studies also should include appropriate physical and chemical stability studies, as well as studies of performance characteristics.

Foreign Particulate Matter

Foreign particulate matter in these drug products should be adequately controlled. Particulate matter in inhalation and nasal drug products may originate during manufacturing and from formulation and container-closure components. For toxicological assessment, the type, origin, amount, and size of foreign particulates, including fine particulates (e.g., less than 10 μm), should be determined throughout the stability storage period.

Identification

A specific identification test or tests are used to verify the identity of the drug substance in the drug product. If a nonspecific method is used for identification, then it should be combined with a second independent and complementary method. A specific identification test for polymorphic forms should be carried out. Moreover, if the drug substance is a salt, an appropriate identification test also should be included for the counterion.

Impurities and Degradation Products

Validated stability-indicating analytical procedure(s) following current (1225) should be used to determine the levels of impurities and degradation products in a drug product. Typically, the acceptance criteria are set for individual, total unspecified, and total impurities and degradation products following current ICH Q3B. For reporting, identification, and qualification thresholds and other relevant information, follow current ICH Q3B guidance.

Leachables

Inhalation and nasal drug products should be evaluated for compounds that may leach from elastomeric and plastic components and from coatings of components of the container-closure system in direct contact with the formulation. Additionally, the drug product inadvertently may contain other residual contaminants from manufacturing and processing. Leachables may include polynuclear aromatics, nitrosamines, monomers, plasticizers, accelerators, antioxidants, and vulcanizing agents. Processing contaminants may include surface-treatment or processing agents that may dissolve, chemically associate, or become suspended in the formulation. Thus, throughout the expiration-dating period, the drug product should be evaluated for compounds that can migrate into the formulation from a variety of sources. The type of testing that should be performed depends on whether the formulation is a powder or a liquid and the composition of the container-closure system, e.g., a drug product packaged in a semipermeable container should be evaluated for ingress of volatile leachables. Appropriate specifications using validated analytical procedures should be applied to identify, monitor, and quantify the compounds in the drug product with appropriate minimum levels of quantification. Corresponding acceptance criteria should be established and justified from toxicological and safety

perspectives.

Leak Rate

Leak rate studies of inhalation and nasal aerosol drug products can be used during drug product development and characterization to support the selection of appropriate container–closure components (e.g., valve and canister) and drug product manufacturing parameters, including the crimping process. The specifications for the USP Leak Rate testing studies can include multiple units from each batch based on weight difference determination with time at a specified temperature. See *Leak Rate* (604) for additional information.

Microbial Limits

The microbial quality of dosage forms where indicated in *General Quality Tests for Inhalation Drug Products* and *General Quality Tests for Nasal Drug Products* normally is controlled by appropriate validated test(s) and acceptance criteria for total aerobic count, total yeasts and molds count, and freedom from designated indicator pathogens. Acceptance criteria can be expressed on a per-container basis. Refer to *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* (61) and *Alternative Microbiological Sampling Methods for Nonsterile Inhaled and Nasal Products* (610) for additional information.

Net Fill Weight

The total net weight of the formulation in the container should be assessed and controlled with a test and acceptance criteria.

Osmolality

To control the tonicity of the formulation of dosage forms where indicated in *General Quality Tests for Inhalation Drug Products*, the product should be tested for osmolality with appropriate specifications as described in *Osmolality and Osmolarity* (785).

pH

Appropriate specification for the pH of the formulation of dosage forms where indicated in *General Quality Tests for Inhalation Drug Products* and *General Quality Tests for Nasal Drug Products* should be established as described in *pH* (791).

Particle Size Distribution

For inhalation suspension and suspension nasal spray drug products, appropriate method(s) and corresponding acceptance criteria can be used for the determination of the particle size distribution of the drug substance particles in the formulation within the container.

Plume Geometry

Because various factors can affect the plume characteristics of the spray of an inhalation aerosol, inhalation spray, nasal aerosol, or nasal spray drug product, its full characterization is important for assessing the performance of the delivery system. Plume geometry can be

determined by a variety of procedures using appropriately validated methods. Plume geometry also can be controlled by appropriate acceptance criteria that measure spray pattern characteristics, including shape and size of the evolving spray plume under defined experimental and instrumental test conditions.

Reconstitution and Time (powder)

Drug for inhalation solution dosage forms must be (re)constituted before administration with the use of a specified nebulization system. Hence, appropriate compatibility studies should be undertaken to fully assess the type and amount of the solvent(s), as well as (re)constitution time for preparation of the final solution for patient administration. The compatibility studies also should include appropriate physical and chemical stability studies on the reconstituted solution, including its performance characterization.

Residual Solvent

Suitable and validated tests should be used to determine the levels of any solvent(s) in the drug product. Refer to *Residual Solvents* (467) for additional information.

Spray Pattern

Because various factors can affect the spray pattern of an inhalation aerosol, nasal aerosol, or nasal spray drug product, full spray pattern characterization is important for assessing the performance of the specific valve and the actuator or the pump. The spray pattern can be determined using appropriately validated methods and corresponding acceptance criteria that measure the shape, density, and size of the pattern. The test procedure for spray patterns normally is specific to the drug product and may include, among others, the distance between the mouthpiece and the measurement plane or collection surface, minimum number of actuations per spray pattern to enable discrimination, orientation of the collection surface relative to the mouthpiece, and visualization procedure(s).

Sterility

All inhalation water-based dosage forms are sterile preparations and should meet the requirements of *Sterility Tests* (71).

Viscosity

A test for viscosity with appropriate acceptance criteria should be included for dosage forms where indicated in *General Quality Tests for Inhalation Drug Products* and *General Quality Tests for Nasal Drug Products* as appropriate (see **•Viscosity—Capillary Methods (911)•**(CN 1-May-2015)).

Water Content

Appropriate specification for water content of dosage forms where indicated in *General Quality Tests for Inhalation Drug Products* and *General Quality Tests for Nasal Drug Products* should be established to ensure the drug product's continued stability and acceptable performance of the drug product. Validated analytical procedures should be used as described in *Water*

Determination (921). Proceed as directed in (921) with the following modification: provide the closed-system titrating vessel with an opening through which passes a coarse-porosity gas dispersion tube connected to a sampling cylinder.

Weight Loss

Drug products should be evaluated for weight loss, e.g., drug products packaged in semipermeable containers, to assess the moisture-loss protective properties of the overall container–closure system.

BRIEFING

(89.1) **Collagenase I**. This new proposed general chapter is to provide analytical procedures to aid in the assessment of quality for collagenase I isolated from *Clostridium histolyticum*. This chapter, *Collagenase I* (89.1), is part of a series of general chapters that are under development to address the qualities of the enzymes used as ancillary material in pharmaceutical manufacturing. Another proposed chapter in the series, *Collagenase II* (89.2), also appears in this issue of *PF*. Recombinant trypsin was the first enzyme to be introduced in this manner, and is published in *Enzymes Used As Ancillary Material in Pharmaceutical Manufacturing* (89).

This chapter does not discuss the applications of collagenase I but rather focuses on tests to assess the qualities as a process material. Furthermore, this chapter does not provide ways to limit the application of collagenase I in the final medicinal product. The activity of collagenase I is determined by using the chromogenic peptide substrate 4-phenylazobenzoyloxycarbonyl-Pro-Leu-Gly-Pro-d-Arg. The liquid chromatographic procedure in the test for *Purity* is based on analyses performed with the GE Healthcare Mono Q 5/50 GL brand of L91 column. New Reference Standards, USP Collagenase I RS and USP Collagenase II RS, are proposed for use during assessment of the system suitability for the proposed *Assay* and test for *Purity*.

C₅₀₉₉H₇₇₇₁N₁₃₂₉O₁₆₁₀S₁₄ 113,897 daltons (for β subtype)
 [[9001-12-1]].

DEFINITION

Collagenase I (EC 3.4.24.3), isolated from *Clostridium histolyticum* and encoded by *colG* gene (GenBank accession number BAA77453.1), is a key raw material used in the dissociation or destruction of a broad range of tissue types. Collagenase I is a metallo protease that acts as an endoprotease and also exhibits a tripeptidylcarboxypeptidase activity. It shows endopeptidic activity with the main cleavage site found in front of the human collagen duplex amino acids glycine–proline. Hydrolysis takes place near the ends of the triple helical domains of collagen. Collagenase I is also known as class I collagenase and consists of three subtypes: α , β , and Γ . Collagenase I β is the full-length enzyme while collagenase I α (68,000 Da) and collagenase I Γ (79,000 Da) are thought to be proteolytic degradation products of collagenase I β caused by other proteases present in *C. histolyticum* (mainly a trypsin-like enzyme and clostripain/endoproteinase Arg C).

Collagenase I can be provided in a liquid formulation consisting of 5 mM *N*-2-hydroxyethylpiperazine-*N'*-2-ethanesulfonic acid (HEPES) and 1 mM calcium chloride pH 7.5, and stored as a frozen liquid. The specific activity of collagenase I is 0.10–0.60 Units/mg of protein using 4-phenylazobenzoyloxycarbonyl-Pro-Leu-Gly-Pro-d-Arg as the substrate described in the *Assay*. The peak area for collagenase I is NLT 90% as determined by HPLC described in the test for *Purity*. The test for *Clostripain activity* is used to assess the activity of the clostripain impurity and the acceptance criterion is NMT 0.5 Units/mg of protein. The test for *Trypsin Activity* is used to assess the activity of the trypsin-like enzyme impurity and the acceptance criterion is NMT 0.5 Units/mg of protein.

IDENTIFICATION

- **A.** It meets the requirements in the *Assay*.
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the test for *Purity*.

ASSAY

• Procedure

Tris buffer: 0.1 M Tris pH 7.1, prepared as follows. Dissolve 6.05 g of tris(hydroxymethyl)aminomethane (Tris) in 400 mL of water, and adjust with 2 N hydrochloric acid to a pH of 7.1 (at 25 ± 1°). Dilute with water to a final volume of 500

mL.

Substrate solution: Dissolve 10 mg of 4-phenylazobenzoyloxycarbonyl (PZ)-Pro-Leu-Gly-Pro-d-Arg in 0.2 mL of methanol, and dilute this solution with *Tris buffer* to a final volume of 10 mL. [Note—Use a freshly prepared solution only.]

Calcium chloride solution: 0.1 M, prepared as follows. Weigh 1.47 g of calcium chloride dihydrate in a volumetric flask, and dilute with water to a final volume of 100 mL.

Citric acid solution: 0.025 M, prepared as follows. Weigh 525 mg of citric acid monohydrate in a volumetric flask, and dilute with water to a final volume of 100 mL.

Extraction mixture: To one test tube per sample to be assayed, pipet 5.0 mL of ethyl acetate, and 1.0 mL of *Citric acid solution*. [Note—Use a freshly prepared mixture only.]

Drying tube: Into one test tube per sample to be assayed, add 0.35–0.40 g of sodium sulfate anhydrous. Seal the test tube with parafilm.

Standard solution: Dilute USP Collagenase I RS with *Tris buffer* in the range of 1:50 to 1:100 (v/v). [Note—Avoid freezing and thawing USP Collagenase I RS. After withdrawing USP Collagenase I RS, wipe off the outside of the plastic pipette tips to remove any residual solution.]

Sample solution: Dilute Collagenase I with *Tris buffer* to an appropriate dilution to achieve the absorbance range of 0.3–0.9 from the *Analysis*. Prepare in triplicate. [Note—Avoid freezing and thawing the collagenase I sample. After withdrawing the collagenase I sample, wipe off the outside of the tip to remove any residual solution.]

Instrumental conditions

(See *Ultraviolet-Visible Spectroscopy* (857).)

Mode: UV

Analytical wavelength: 320 nm

Pathlength: 1 cm

Temperature: 25°

Analysis

Samples: *Standard solution* and *Sample solution*

Transfer 1.0 mL of *Substrate solution* and 0.2 mL of *Calcium chloride solution* into a test tube, and equilibrate the test tube to 25°. Start the reaction by adding 0.05 mL of *Standard solution* or *Sample solution*. Prepare a blank by replacing the *Standard solution* or *Sample solution* with 0.05 mL of *Tris buffer*. Mix and incubate for exactly 15 min at 25°. Transfer 0.5 mL of the reaction to the test tube containing 6.0 mL of *Extraction mixture*. Vortex immediately for 20 s. Transfer 3 mL of the ethyl acetate phase (upper layer) into a *Drying tube* using a glass pipette, and vortex thoroughly. Transfer the supernatant to a disposable, semi-micro cuvette suitable for UV absorbance with a Pasteur pipette. Record the absorbance.

Calculate the activity of collagenase I in Units/mL:

$$\text{Result} = (A - A_B) \times [V_T \times V_E / (\epsilon \times V \times V_R \times B \times T)] \times D$$

A = absorbance of the *Standard solution* or *Sample solution*

A_B = absorbance of the blank

V_T = volume of the reaction mixture, 1.25 mL

V_E = volume of ethyl acetate in the *Extraction mixture*, 5.0 mL

ϵ = extinction coefficient for 320 nm, 21 ($\mu\text{mol}^{-1}\cdot\text{cm}^{-1}$)

V = volume of the *Standard solution* or *Sample solution*, 0.05 mL

V_R = volume of the reaction transferred to *Extraction mixture*, 0.5 mL

B = absorption pathlength, 1 cm

T = incubation time, 15 min

D = dilution factor

[Note—One Unit will release the equivalent of 1 μmol of PZ-Pro-Leu from PZ-Pro-Leu-Gly-Pro-d-Arg per min under the conditions of the Assay.]

Calculate the specific activity of collagenase I in Units/mg of protein:

$$\text{Result} = \text{Activity}/C$$

Activity = activity of collagenase I (Units/mL)

C = protein concentration (mg/mL)

System suitability

Samples: *Standard solution* and *Sample solution*

Suitability requirements

Average calculated activity: 90%–110% of the value on the label, *Standard solution*

Absorbance: 0.3–0.9, *Standard solution* and *Sample solution*

Acceptance criteria: 0.10–0.60 Units/mg of protein

PURITY

• Procedure

Solution A: 20 mM Tris and 1 mM calcium chloride pH 7.5, prepared as follows. Dissolve 2.42 g of Tris and 147 mg of calcium chloride dihydrate in 900 mL of water. Adjust with 2 N hydrochloric acid to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

Solution B: 20 mM Tris, 1 mM calcium chloride, and 1 M sodium chloride pH 7.5, prepared as follows. Dissolve 2.42 g of Tris, 147 mg of calcium chloride dihydrate, and 58.44 g of sodium chloride in 900 mL of water. Adjust with 2 N hydrochloric acid to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

Mobile phase: See *Table 1*.

Table 1

Time (min)	Solution A (%)	Solution B (%)
0	100	0
2	100	0
22	85	15
32	0	100
34	100	0
40	100	0

Storage buffer: 5 mM HEPES and 1 mM calcium chloride pH 7.5, prepared as follows. Dissolve 1.19 g of HEPES and 147 mg of calcium chloride dihydrate in 900 mL of water. Adjust with 4 N sodium hydroxide solution to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

Standard solution: Thaw USP Collagenase I RS at room temperature shortly before use and mix. Store on ice or at 5°. Dilute with *Storage buffer* to achieve a protein concentration of 5.5 mg/mL. Transfer to an HPLC vial and keep at 5°. Prepare in duplicate and inject each duplicate once.

Collagenase II solution: Thaw USP Collagenase II RS at room temperature shortly before use and mix. Store on ice or at 5°. Dilute with *Storage buffer* to achieve a protein concentration of 5.5 mg/mL. Transfer to an HPLC vial and keep at 5°. Prepare in duplicate, and inject each duplicate once.

Sample solution: Dilute Collagenase I with *Storage buffer* to achieve a protein concentration of 5.5 mg/mL and keep at 5°.

Blank: *Storage buffer*

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 280 nm

Column: 5-mm × 5-cm; 10-µm packing L91

Temperatures

Column: 25°

Autosampler: 5°

Flow rate: 1.5 mL/min

Injection volume: 20 µL

System suitability

Sample: *Standard solution*

Suitability requirement: The chromatogram from the *Standard solution* corresponds to the typical chromatogram provided with USP Collagenase I RS.

Analysis

Sample: *Sample solution*

The *Blank* should be considered for integration. Identify the peak corresponding to collagenase II by comparing its retention time to the main peak from the *Collagenase II solution*. Evaluate the purity of Collagenase I using the area-% method but excluding peaks associated with the *Blank*. All shoulders in the fronting and tailing are separated by dropping a perpendicular line at the main peak. The time of integration is approximately 25 min.

Acceptance criteria: NLT 90% for the main peak of collagenase I and NMT 3% of collagenase II

IMPURITIES

- **Clostripain Activity**

Potassium phosphate buffer: 0.1 M pH 7.6, prepared as follows. Dissolve 1.36 g of monobasic potassium phosphate in water, and dilute to 100 mL. Dissolve 2.28 g of dibasic potassium phosphate trihydrate in water, and dilute to 100 mL. Adjust the pH of the second solution to 7.6 with the first solution.

Dithiothreitol solution: 0.194 M, prepared as follows. Dissolve 60 mg of dithiothreitol (DTT) in 2 mL of *Potassium phosphate buffer*.

Calcium chloride solution: 0.01 M, prepared as follows. Dissolve 147 mg of calcium chloride dihydrate in 100 mL of water.

Substrate stock solution: 38 mM, prepared as follows. Dissolve 13 mg of benzoyl-L-arginine ethyl ester hydrochloride (BAEE·HCl) in 1 mL of *Potassium phosphate buffer*.

Substrate solution: 0.73 mM BAEE·HCl, 7.8 mM DTT, and 0.4 mM calcium chloride, prepared as follows. Transfer 0.5 mL of *Substrate stock solution*, 1.0 mL of *Dithiothreitol solution*, and 1.0 mL of *Calcium chloride solution* to a 25-mL volumetric flask, and dilute with *Potassium phosphate buffer* to volume.

Sample solution: Prepare in such a way that $\Delta A/\text{min}$ lies in the 0.02–0.06 range. Dilute with ice-cold *Potassium phosphate buffer* if necessary.

Instrumental conditions

(See *Ultraviolet-Visible Spectroscopy* (857).)

Mode: UV

Pathlength: 1 cm

Analytical wavelength: 255 nm

Temperature: 25°

Analysis

Sample: *Sample solution*

Transfer 3.0 mL of *Substrate solution* into a cuvette, and equilibrate the cuvette to 25°. Start the reaction by adding 0.05 mL of *Sample solution*. Prepare a blank by replacing the *Sample solution* with 0.05 mL of *Potassium phosphate buffer*. Mix well. Determine the change in absorbance ($\Delta A/\text{min}$) from the linear range of the reaction. Assay the *Sample solution* in triplicate.

System suitability

Sample: *Sample solution*

Suitability requirement: 0.02–0.06 for $\Delta A/\text{min}$

Calculate the activity of clostripain in Units/mL in the portion of collagenase I taken:

$$\text{Result} = [V_T / (\epsilon \times V_U \times B)] \times \Delta A/\text{min} \times D$$

V_T = volume of the reaction mixture, 3.05 mL

ϵ = extinction coefficient for 255 nm, $0.81(\text{L} \cdot \text{mmol}^{-1} \cdot \text{cm}^{-1})$

V_U = volume of the *Sample solution*, 0.05 mL

B = absorption pathlength, 1 cm

$\Delta A/\text{min}$ = change in absorbance from the linear range of the reaction

D = dilution factor

Calculate the specific activity in Units/mg of protein:

$$\text{Result} = \text{Activity}/C$$

Activity = activity of clostripain (Units/mL)

C = protein concentration (mg/mL)

Acceptance criteria: NMT 0.5 Units of clostripain activity per mg of protein

• Trypsin Activity

Buffer: 0.1 M Tris and 0.02 M calcium chloride pH 8.0, prepared as follows. Dissolve 6.05 g of Tris and 1.45 g of calcium chloride dihydrate in 400 mL of water. Adjust with 2 N hydrochloric acid to a pH of 8.0 (at $25 \pm 1^\circ$). Dilute with water to a final volume of 500 mL.

Substrate stock solution: Dissolve 10 mg of carbobenzoxy-valyl-glycyl-arginine-4-nitril-anilide acetate,¹ accurately weighed, in 1.5 mL of water. Store on ice. [Note—Use freshly prepared solution only.]

Substrate solution: Prepare a solution by mixing 9.2 mL of *Buffer* and 1.0 mL of *Substrate stock solution*. Store on ice. [Note—Use freshly prepared solution only.]

Sample solution: Undiluted Collagenase I solution

Instrumental conditions

(See *Ultraviolet-Visible Spectroscopy* (857).)

Mode: Visible

Analytical wavelength: 405 nm

Pathlength: 1 cm

Temperature: 25°

Analysis

Sample: *Sample solution*

Transfer 1.02 mL of *Substrate solution* into a polystyrene, semi-micro cuvette, allow the temperature to stabilize, equilibrate the cuvette to 25° , and wait for 10 min. Start the reaction by adding 0.10 mL of *Sample solution*. Start recording the absorbance and continue for at least 5 min after the addition of the *Sample solution*. Determine the change in absorbance ($\Delta A/\text{min}$) from the linear range of the reaction. Assay the *Sample solution* in triplicate. [Note—Use polyethylene pipette tips to transfer the *Sample solution*. The pipette tip should not be wet before transfer, and each pipette tip should be used only for transferring one sample. After withdrawing the *Sample solution*, wipe off the outside of the tip to remove any residual solution. After adding the *Sample solution* to the *Substrate solution*, rinse the tip by pipetting the solution up and down 2–3 times, discard the tip, and mix.]

System suitability

Sample: *Sample solution*

Suitability requirement: >0.01 for $\Delta A/\text{min}$

Calculate the activity of trypsin in Units/mL in the portion of Collagenase I taken:

$$\text{Result} = [V_T / (\epsilon \times V_U \times B)] \times \Delta A/\text{min} \times D$$

V_T = volume of the reaction mixture, 1.12 mL

ϵ = extinction coefficient for 405 nm, $10.4 \text{ (mmol}^{-1} \cdot \text{l cm}^{-1}\text{)}$

V_U = volume of the *Sample solution*, 0.10 mL

B = absorption pathlength, 1 cm

$\Delta A/\text{min}$ = change in absorbance from the linear range of the reaction

D = dilution factor

Calculate the specific activity in Units/mg of protein

$$\text{Result} = \text{Activity}/C$$

Activity = activity of trypsin (Units/mL)

C = protein concentration (mg/mL)

Acceptance criteria: NMT 0.5 Units of trypsin activity per mg of protein

SPECIFIC TESTS

• Protein Content

Sample solutions: Dilute Collagenase I in water. Prepare at least in triplicate.

[Note—Prepare the dilution using plastic pipette tips and not glass pipettes. Carefully wipe off the outside of the tip to remove any residual solution.]

Blank solution: Water

Instrumental conditions

(See *Ultraviolet-Visible Spectroscopy* (857).)

Mode: UV

Analytical wavelength: 280 nm

Pathlength: 1 cm

System suitability

Samples: *Sample solutions*

Suitability requirement: Absorbance is in the range of 0.10–1.00.

Analysis

Samples: *Sample solutions* and *Blank solution*

Determine the net absorbance of *Sample solutions* by subtracting the absorbance of the *Blank solution* from the absorbance of the *Sample solution*. Determine the average net absorbance of *Sample solutions*.

Calculate the protein concentration in mg/mL:

$$\text{Result} = A_U \times D / \epsilon$$

A_U = average net absorbance of the *Sample solutions*
 D = dilution factor
 ϵ = extinction coefficient ($A_{280}1\%/cm$) for collagenase, 1.4

- **Bacterial Endotoxins Test** (85): NMT 50 USP Endotoxin Units/mg of protein
- **Microbial Enumeration Tests** (61): The total bacterial count is NMT 100 cfu/mL.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Store in closed containers at -15° to -25° .
 - **Labeling:** The labeling states that the material is derived from *Clostridium histolyticum* along with the lot number, product or catalog number, and storage conditions.
 - **USP Reference Standards** (11)
 - USP Collagenase I RS
 - USP Collagenase II RS
 - USP Endotoxin RS
- 2S (USP39)

¹ A suitable carbobenzoxy-valyl-glycyl-arginine-4-nitril-anilide acetate is Chromozym TRY from Roche Applied Science (catalog number 10378496103) or equivalent.

BRIEFING

(89.2) **Collagenase II.** This new proposed general chapter is to provide analytical procedures to aid in the assessment of quality for collagenase II isolated from *Clostridium histolyticum*. This chapter, *Collagenase II* (89.2), is part of a series of general chapters that are under development to address the qualities of the enzymes used as ancillary material in pharmaceutical manufacturing. Another proposed chapter in the series, *Collagenase I* (89.1), also appears in this issue of *PF*. Recombinant trypsin is the first enzyme to be introduced in this manner, and was published in *Enzymes Used As Ancillary Material in Pharmaceutical Manufacturing* (89).

This chapter does not discuss the applications of collagenase II but rather focuses on tests to assess the qualities as a process material. Furthermore, this chapter does not provide ways to limit the application of collagenase II in the final medicinal product. The activity of collagenase II is determined by using the chromogenic peptide substrate 4-phenylazobenzyloxycarbonyl-Pro-Leu-Gly-Pro-d-Arg. The liquid chromatographic procedure in the test for *Purity* is based on analyses performed with the GE Healthcare Mono Q 5/50 GL brand of L91 column. A new Reference Standard, USP Collagenase II RS, is proposed for use during assessment of the system suitability for the proposed *Assay* and test for *Purity*.

C₅₀₂₈H₇₆₆₆N₁₃₀₀O₁₅₆₄S₂₁ 112,023 (for ζ subtype)
[[9001-12-1]].

DEFINITION

Collagenase II (EC 3.4.24.3), isolated from *Clostridium histolyticum* and encoded by colH gene (GenBank accession number BAA06251.1), is a key raw material used in the dissociation or destruction of a broad range of tissue types. Collagenase II is a metallo protease that acts as an endoprotease and also exhibits a tripeptidylcarboxypeptidase activity. It shows endopeptidic activity with the main cleavage site found in front of the human collagen duplex amino acids glycine–proline. Hydrolysis takes place in the interior of the triple helical domains of collagen.

Collagenase II is also known as class II collagenase and consists of three subtypes: Δ, ε, and ζ. Collagenase II ζ is the full-length enzyme while collagenase II Δ (100,000 Da) and II ε (110,000 Da) are thought to be proteolytic degradation products of collagenase II ζ caused by other proteases present in *C. histolyticum* (mainly a trypsin-like enzyme and clostripain/endoproteinase Arg C).

Collagenase II can be provided in a liquid formulation consisting of 5 mM *N*-2-hydroxyethylpiperazine-*N'*-2-ethanesulfonic acid (HEPES) and 1 mM calcium chloride pH 7.5, and stored as a frozen liquid. The specific activity of collagenase II is 10–16 Units/mg of protein using 4-phenylazobenzoyloxycarbonyl-Pro-Leu-Gly-Pro-d-Arg as the substrate described in the Assay. The peak area for collagenase II is NLT 90% as determined by HPLC described in the test for Purity. The test for Clostripain Activity is used to assess the activity of the clostripain impurity and the acceptance criterion is NMT 0.5 Units/mg of protein. The test for Trypsin Activity is used to assess the activity of the trypsin-like enzyme impurity and the acceptance criterion is NMT 0.5 Units/mg of protein.

IDENTIFICATION

- **A.** It meets the requirements in the Assay.
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the test for Purity.

ASSAY

• Procedure

Tris buffer: 0.1 M Tris pH 7.1, prepared as follows. Dissolve 6.05 g of tris(hydroxymethyl)aminomethane (Tris) in 400 mL of water, and adjust with 2 N hydrochloric acid to a pH of 7.1 (at 25 ± 1°). Dilute with water to a final volume of 500

mL.

Substrate solution: Dissolve 10 mg of 4-phenylazobenzoyloxycarbonyl (PZ)-Pro-Leu-Gly-Pro-d-Arg in 0.2 mL of methanol, and dilute this solution with *Tris buffer* to a final volume of 10 mL. [Note—Use a freshly prepared solution only.]

Calcium chloride solution: 0.1 M, prepared as follows. Weigh 1.47 g of calcium chloride dihydrate in a volumetric flask, and dilute with water to a final volume of 100 mL.

Citric acid solution: 0.025 M, prepared as follows. Weigh 525 mg of citric acid monohydrate in a volumetric flask, and dilute with water to a final volume of 100 mL.

Extraction mixture: To one test tube per sample to be assayed, pipet 5.0 mL of ethyl acetate, and 1.0 mL of *Citric acid solution*. [Note—Use a freshly prepared mixture only.]

Drying tube: Into one test tube per sample to be assayed, add 0.35–0.40 g of sodium sulfate anhydrous. Seal the test tube with parafilm.

Standard solution: Dilute USP Collagenase II RS with *Tris buffer* in the range of 1:2000 to 1:4000 (v/v). [Note—Avoid freezing and thawing USP Collagenase II RS. After withdrawing USP Collagenase II RS, wipe off the outside of the plastic pipette tips to remove any residual solution.]

Sample solution: Dilute Collagenase II with *Tris buffer* to an appropriate dilution to achieve the absorbance range of 0.3–0.9 from the *Analysis*. Prepare in triplicate. [Note—Avoid freezing and thawing the collagenase II sample. After withdrawing the collagenase II sample, wipe off the outside of the tip to remove any residual solution.]

Instrumental conditions

(See *Ultraviolet-Visible Spectroscopy* (857).)

Mode: UV

Analytical wavelength: 320 nm

Pathlength: 1 cm

Temperature: 25°

Analysis

Samples: *Standard solution* and *Sample solution*

Transfer 1.0 mL of *Substrate solution* and 0.2 mL of *Calcium chloride solution* into a test tube, and equilibrate the test tube to 25°. Start the reaction by adding 0.05 mL of *Standard solution* or *Sample solution*. Prepare a blank by replacing the *Standard solution* or *Sample solution* with 0.05 mL of *Tris buffer*. Mix and incubate for exactly 15 min at 25°. Transfer 0.5 mL of the reaction to the test tube containing 6.0 mL of *Extraction mixture*. Vortex immediately for 20 s. Transfer 3 mL of the ethyl acetate phase (upper layer) into a *Drying tube* using a glass pipette, and vortex thoroughly. Transfer the supernatant to a disposable, semi-micro cuvette suitable for UV absorbance with a Pasteur pipette. Record the absorbance.

Calculate the activity of collagenase II in Units/mL:

$$\text{Result} = (A - A_B) \times [V_T \times V_E / (\epsilon \times V \times V_R \times B \times T)] \times D$$

A = absorbance of the *Standard solution* or *Sample solution*

A_B = absorbance of the blank

V_T = volume of the reaction mixture, 1.25 mL

V_E = volume of ethyl acetate in the *Extraction mixture*, 5.0 mL

ϵ = extinction coefficient for 320 nm, 21 ($\mu\text{mol}^{-1}\cdot\text{cm}^{-1}$)

V = volume of the *Standard solution* or *Sample solution*, 0.05 mL

V_R = volume of the reaction transferred to *Extraction mixture*, 0.5 mL

B = absorption pathlength, 1 cm

T = incubation time, 15 min

D = dilution factor

[Note—One Unit will release the equivalent of 1 μmol of PZ-Pro-Leu from PZ-Pro-Leu-Gly-Pro-d-Arg per min under the conditions of the Assay.]

Calculate the specific activity of collagenase II in Units/mg of protein:

$$\text{Result} = \text{Activity}/C$$

Activity = activity of collagenase II (Units/mL)

C = protein concentration (mg/mL)

System suitability

Samples: *Standard solution* and *Sample solution*

Suitability requirements

Average calculated activity: 90%–110% of the value on the label, *Standard solution*

Absorbance: 0.3–0.9, *Standard solution* and *Sample solution*

Acceptance criteria: 10–16 Units/mg of protein

PURITY

• Procedure

Solution A: 20 mM Tris and 1 mM calcium chloride pH 7.5, prepared as follows. Dissolve 2.42 g of Tris and 147 mg of calcium chloride dihydrate in 900 mL of water. Adjust with 2 N hydrochloric acid to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

Solution B: 20 mM Tris, 1 mM calcium chloride, and 1 M sodium chloride pH 7.5, prepared as follows. Dissolve 2.42 g of Tris, 147 mg of calcium chloride dihydrate, and 58.44 g of sodium chloride in 900 mL of water. Adjust with 2 N hydrochloric acid to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

Mobile phase: See *Table 1*.

Table 1

Time (min)	Solution A (%)	Solution B (%)
0	100	0
2	100	0
22	85	15
32	0	100
34	100	0
40	100	0

Storage buffer: 5 mM HEPES and 1 mM calcium chloride pH 7.5, prepared as follows. Dissolve 1.19 g of HEPES and 147 mg of calcium chloride dihydrate in 900 mL of water. Adjust with 4 N sodium hydroxide solution to a pH of 7.5. Dilute with water to a final volume of 1000 mL.

Standard solution: Thaw USP Collagenase II RS at room temperature shortly before use and mix. Store on ice or at 5°. Dilute with *Storage buffer* to achieve a protein concentration of 5.5 mg/mL. Transfer to an HPLC vial and keep at 5°. Prepare in duplicate and inject each duplicate once.

Sample solution: Dilute Collagenase II with *Storage buffer* to achieve a protein concentration of 5.5 mg/mL and keep at 5°.

Blank: *Storage buffer*

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 280 nm

Column: 5-mm × 5-cm; 10-µm packing L91

Temperatures

Column: 25°

Autosampler: 5°

Flow rate: 1.5 mL/min

Injection volume: 20 µL

System suitability

Sample: *Standard solution*

Suitability requirement: The chromatogram from the *Standard solution* corresponds to the typical chromatogram provided with USP Collagenase II RS.

Analysis

Sample: *Sample solution*

The *Blank* should be considered for integration. Evaluate the purity of Collagenase II using the area-% method but excluding peaks associated with the *Blank*. All shoulders in the fronting and tailing are separated by dropping a perpendicular line at the main peak. The time of integration is approximately 25 min.

Acceptance criteria: NLT 90% for the main peak of collagenase II

IMPURITIES

• Clostripain Activity

Potassium phosphate buffer: 0.1 M pH 7.6, prepared as follows. Dissolve 1.36 g of monobasic potassium phosphate in water, and dilute to 100 mL. Dissolve 2.28 g of dibasic potassium phosphate trihydrate in water, and dilute to 100 mL. Adjust the pH of the second solution to 7.6 with the first solution.

Dithiothreitol solution: 0.194 M, prepared as follows. Dissolve 60 mg of dithiothreitol (DTT) in 2 mL of *Potassium phosphate* buffer.

Calcium chloride solution: 0.01 M, prepared as follows. Dissolve 147 mg of calcium chloride dihydrate in 100 mL of water.

Substrate stock solution: 38 mM, prepared as follows. Dissolve 13 mg of benzoyl-L-arginine ethyl ester hydrochloride (BAEE·HCl) in 1 mL of *Potassium phosphate buffer*.

Substrate solution: 0.73 mM BAEE·HCl, 7.8 mM DTT, and 0.4 mM calcium chloride, prepared as follows. Transfer 0.5 mL of *Substrate stock solution*, 1.0 mL of *Dithiothreitol solution*, and 1.0 mL of *Calcium chloride solution* to a 25-mL volumetric flask, and dilute with *Potassium phosphate buffer* to volume.

Sample solution: Prepare in such a way that $\Delta A/\text{min}$ lies in the 0.02–0.06 range. Dilute with ice-cold *Potassium phosphate buffer* if necessary.

Instrumental conditions

(See *Ultraviolet-Visible Spectroscopy* (857).)

Mode: UV

Pathlength: 1 cm

Analytical wavelength: 255 nm

Temperature: 25°

Analysis

Sample: *Sample solution*

Transfer 3.0 mL of *Substrate solution* into a cuvette, and equilibrate the cuvette to 25°. Start the reaction by adding 0.05 mL of *Sample solution*. Prepare a blank by replacing the *Sample solution* with 0.05 mL of *Potassium phosphate buffer*. Mix well. Determine the change in absorbance ($\Delta A/\text{min}$) from the linear range of the reaction. Assay the *Sample solution* in triplicate.

System suitability

Sample: *Sample solution*

Suitability requirement: 0.02–0.06 for $\Delta A/\text{min}$

Calculate the activity of clostripain in Units/mL in the portion of collagenase II taken:

$$\text{Result} = [V_T / (\epsilon \times V_U \times B)] \times \Delta A/\text{min} \times D$$

V_T = volume of the reaction mixture, 3.05 mL

ϵ = extinction coefficient for 255 nm, $0.81(\text{L} \cdot \text{mmol}^{-1} \cdot \text{cm}^{-1})$

V_U = volume of the *Sample solution*, 0.05 mL

B = absorption pathlength, 1 cm

$\Delta A/\text{min}$ = change in absorbance from the linear range of the reaction

D = dilution factor

Calculate the specific activity in Units/mg of protein:

$$\text{Result} = \text{Activity}/C$$

Activity = activity of clostripain (Units/mL)

C = protein concentration (mg/mL)

Acceptance criteria: NMT 0.5 Units of clostripain activity per mg of protein

● **Trypsin Activity**

Buffer: 0.1 M Tris and 0.02 M calcium chloride pH 8.0, prepared as follows. Dissolve 6.05 g of Tris and 1.45 g of calcium chloride dihydrate in 400 mL of water. Adjust with 2 N hydrochloric acid to a pH of 8.0 (at $25 \pm 1^\circ$). Dilute with water to a final volume of 500 mL.

Substrate stock solution: Dissolve 10 mg of carbobenzoxy-valyl-glycyl-arginine-4-nitril-anilide acetate,¹ accurately weighed, in 1.5 mL of water. Store on ice. [Note—Use freshly prepared solution only.]

Substrate solution: Prepare a solution by mixing 9.2 mL of *Buffer* and 1.0 mL of *Substrate stock solution*. Store on ice. [Note—Use freshly prepared solution only.]

Sample solution: Undiluted Collagenase II solution

Instrumental conditions

(See *Ultraviolet-Visible Spectroscopy* (857).)

Mode: Visible

Analytical wavelength: 405 nm

Pathlength: 1 cm

Temperature: 25°

Analysis

Sample: *Sample solution*

Transfer 1.02 mL of *Substrate solution* into a polystyrene semi-micro cuvette, allow the temperature to stabilize, equilibrate the cuvette to 25°, and wait for 10 min. Start the reaction by adding 0.10 mL of *Sample solution*. Start recording the absorbance and continue for at least 5 min after the addition of the *Sample solution*. Determine the change in absorbance ($\Delta A/\text{min}$) from the linear range of the reaction. Assay the *Sample solution* in triplicate. [Note—Use polyethylene pipette tips to transfer the *Sample solution*. The pipette tip should not be wet before transfer, and each pipette tip should be used only for transferring one sample. After withdrawing the *Sample solution*, wipe off the outside of the tip to remove any residual solution. After adding the *Sample solution* to the *Substrate solution*, rinse the tip by pipetting the solution up and down 2–3 times, discard the tip, and mix.]

System suitability

Sample: *Sample solution*

Suitability requirement: >0.01 for $\Delta A/\text{min}$

Calculate the activity of trypsin in Units/mL in the portion of Collagenase II taken:

$$\text{Result} = [V_T / (\epsilon \times V_U \times B)] \times \Delta A/\text{min} \times D$$

V_T = volume of the reaction mixture, 1.12 mL

ϵ = extinction coefficient for 405 nm, $10.4 \text{ (mmol}^{-1} \cdot \text{l cm}^{-1}\text{)}$

V_U = volume of the *Sample solution*, 0.10 mL

B = absorption pathlength, 1 cm
 $\Delta A/\text{min}$ = change in absorbance from the linear range of the reaction
 D = dilution factor

Calculate the specific activity in Units/mg of protein:

$$\text{Result} = \text{Activity}/C$$

Activity = activity of trypsin (Units/mL)
 C = protein concentration (mg/mL)

Acceptance criteria: NMT 0.5 Units of trypsin activity per mg of protein

SPECIFIC TESTS

• Protein Content

Sample solutions: Dilute Collagenase II in water. Prepare at least in triplicate.

[Note—Prepare the dilution using plastic pipette tips and not glass pipettes. Carefully wipe off the outside of the tip to remove any residual solution.]

Blank solution: Water

Instrumental conditions

(See *Ultraviolet-Visible Spectroscopy* (857).)

Mode: UV

Analytical wavelength: 280 nm

Pathlength: 1 cm

System suitability

Samples: *Sample solutions*

Suitability requirement: Absorbance is in the range of 0.10–1.00.

Analysis

Samples: *Sample solutions* and *Blank solution*

Determine the net absorbance of *Sample solutions* by subtracting the absorbance of the *Blank solution* from the absorbance of the *Sample solution*. Determine the average net absorbance of *Sample solutions*.

Calculate the protein concentration in mg/mL:

$$\text{Result} = A_U \times D / \epsilon$$

A_U = average net absorbance of the *Sample solutions*

D = dilution factor

ϵ = extinction coefficient ($A_{280}1\%/cm$) for collagenase, 1.4

- **Bacterial Endotoxins Test** (85): NMT 50 USP Endotoxin Units/mg of protein
- **Microbial Enumeration Tests** (61): The total bacterial count is NMT 100 cfu/mL.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Store in closed containers at -60° to -90° .

- **Labeling:** The labeling states that the material is derived from *Clostridium histolyticum* along with the lot number, product or catalog number, and storage conditions.
- **USP Reference Standards** (11)
 - USP Collagenase II RS
 - USP Endotoxin RS
- 2S (USP39)

¹ A suitable carbobenzoxy-valyl-glycyl-arginine-4-nitril-anilide acetate is Chromozym TRY from Roche Applied Science (catalog number 10378496103) or equivalent.

BRIEFING

(121.1) **Physicochemical Analytical Procedures for Insulins**, *USP 38* page 195. On the basis of comments received, it is proposed to revise the chapter as follows:

1. Incorporate animal derived insulins prepared from bovine and porcine pancreas into the chapter.
2. In *Peptide Mapping*, clarify the *Tailing factor* requirements, and better define the activity units of *Staphylococcus aureus* strain V8 (*S. aureus* V8) protease.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

Correspondence Number—C157594

Comment deadline: November 30, 2015

(121.1) PHYSICOCHEMICAL ANALYTICAL PROCEDURES FOR INSULINS

INTRODUCTION

Change to read:

Several physicochemical procedures are used for the assessment of the quality attributes of Insulin Human, and

■ ■ 2S (USP39)

various insulin analogues,

■ and animal derived insulins, ■ 2S (USP39)

hereafter called insulins. Of these procedures, peptide mapping and determination of high molecular weight proteins are similar for the various insulin drug substances and drug products. This chapter describes the tests for peptide mapping and for quantitative analysis of high molecular weight proteins that can be used for the various insulins.

Specific instructions that deviate from the general procedures outlined here are given in the respective drug substance or drug product monographs for the different insulins.

Change to read:

PEPTIDE MAPPING

Insulin digestion is performed using *Staphylococcus aureus* strain V8 (*S. aureus* V8) protease

■ (also referred to as Endoproteinase Glu-C), ■ 2S (USP39)

a serine endoproteinase that cleaves at the C-terminal side of glutamyl and aspartyl residues

in phosphate buffer at pH 7.8. This protease is specific for Glu-C digestion in ammonium bicarbonate or other non-phosphate-containing buffers at pH 7.8. The presence of proline on the carboxy side of the peptide bond inhibits cleavage. The buffer system used should cleave all glutamyl bonds in insulin without cleavage of the aspartyl bonds. In general, insulin is digested into four peptides in the buffer system described in the *Sample solution* below. The following show the amino acid differences of the insulin analogues compared to Insulin Human and the *in silico* differences in the fragments obtained upon digestion with *S. aureus* V8 protease.

Figure 1 shows the four fragments of Insulin Human following digestion with *S. aureus* V8 protease.

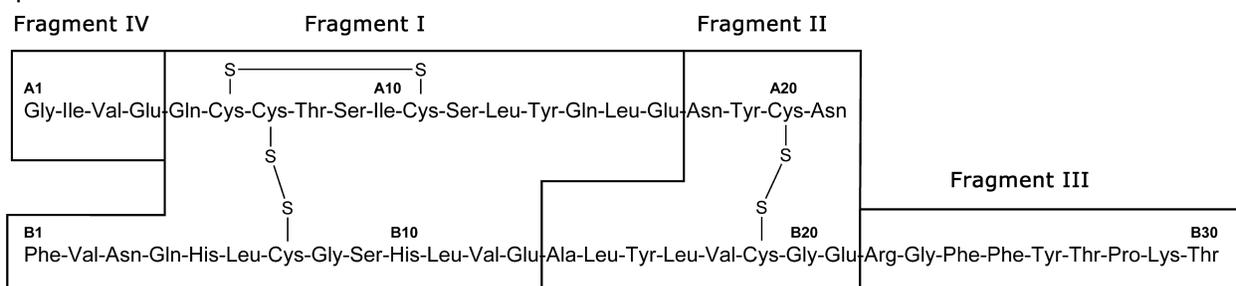

Figure 1. Insulin Human: *S. aureus* V8 protease digest fragments.

Table 1 shows the amino acid differences between insulin analogues,

■ animal derived insulins, ■ 2S (USP39) and Insulin Human.

Table 1. Amino Acid Differences between Insulin Analogues, ■ Animal Derived Insulins, ■ 2S (USP39) and Insulin Human

Insulin Analogue ■ 2S (USP39)	Amino Acid Differences from Insulin Human
Insulin aspart	B28 Asp
Insulin glargine	A21 Gly, two Arg added to C-terminus of B chain
Insulin glulisine	B3 Lys, B29 Glu
Insulin lispro	B28 Lys, B29 Pro
■ Insulin porcine	B30 Ala
Insulin bovine	A8 Ala, A10 Val, B30 Ala ■ 2S (USP39)

Table 2 shows specific *S. aureus* V8 protease digest fragments of insulin analogues

■ and animal derived insulins. ■ 2S (USP39)

Amino acid differences compared to Insulin Human are highlighted.

Table 2. Amino Acid Differences: Insulin Human, and ■ Insulin ■ 2S (USP39) Analogues, ■ and Animal Derived Insulins ■ 2S (USP39) (Differences with Insulin Human Are Shown in Boldface)

Insulin Analogue ■ ■ 2S (USP39)	Amino Acid Differences Compared to Insulin Human^a	
Insulin aspart	Fragment III	(B22) Arg-Gly-Phe-Phe-Tyr-Thr- Asp -Lys-Thr (B30)
Insulin glargine	Fragment II	(A18) Asn-Tyr-Cys- Gly (A21)
	Fragment III	(B22) Arg-Gly-Phe-Phe-Tyr-Thr-Pro-Lys-Thr- Arg-Arg (B32)

	Fragment III	(B22) Arg-Gly-Phe-Phe-Tyr-Thr-Pro- Glu -Thr (B30)
Insulin lispro	Fragment III	(B22) Arg-Gly-Phe-Phe-Tyr-Thr- Lys-Pro -Thr (B30)
■ Insulin porcine	Fragment III	(B22) Arg-Gly-Phe-Phe-Tyr-Thr-Pro-Lys- Ala (B30)
Insulin bovine	Fragment I	(A5) Gln-Cys-Cys- Ala -Ser- Val -Cys-Ser-Leu-Tyr-Gln-Leu-Glu (A17)
	Fragment III	(B22) Arg-Gly-Phe-Phe-Tyr-Thr-Pro-Lys- Ala (B30) ■ 2S (USP39)
^a A and B denote the A and B chains of insulin, respectively; numbers denote amino acid position in the chain.		

● Peptide Mapping Procedure

The following procedure is applicable for preparing peptide maps of Insulin Human, and

■ ■ 2S (USP39)

insulin analogues,

■ and animal derived insulins. ■ 2S (USP39)

HEPES buffer: Dissolve 2.38 g of HEPES (*N*-2-hydroxyethylpiperazine-*N'*-2-ethanesulfonic acid) in about 90 mL of water in a 100-mL volumetric flask. Adjust with 5 M sodium hydroxide to a pH of 7.5, dilute with water to volume, and mix.

Sulfate buffer: 2.0 M ammonium sulfate and 0.5 M sulfuric acid (1:1). Mix, and filter.

● Insulin Digestion

The following procedure provides efficient cleavage of the glutamyl bonds of insulin. [Note—Volumes up to 20-fold higher can be used as long as the ratio of the solutions remains the same. If interfering autolysis byproducts are observed in the chromatogram when a digest of the enzyme alone is run, the enzyme-to-insulin ratio must be decreased and digestion time must be increased.]

Enzyme solution: Prepare a 1-mg/mL solution of *S. aureus* V8 protease in water (approximately 500 units/mg

■ using casein as the substrate). ■ 2S (USP39)

Sample solution: Prepare a 2.0-mg/mL solution of the insulin to be examined in 0.01 N hydrochloric acid. To a clean vial add 25 μ L of the 2.0-mg/mL insulin solution, 100 μ L of HEPES buffer, and 20 μ L of Enzyme solution (final ratio is 25:100:20). Cap the vial, and

incubate at 25° for 6 h. Stop the reaction by adding an equal volume of *Sulfate buffer*. Longer incubation times may be needed for analogues with poor solubility at pH 7.5.

Standard solution: Prepare at the same time and in the same manner a solution of the appropriate USP Insulin Reference Standard as directed in the *Sample solution*.

- **Peptide Fragment Determination**

Determine the peptide fragments using the following peptide mapping procedure (see *Biotechnology-Derived Articles—Peptide Mapping* (1055)).

Solution A: Acetonitrile, water, and *Sulfate buffer* (100:700:200). Filter, and degas.

Solution B: Acetonitrile, water, and *Sulfate buffer* (400:400:200). Filter, and degas.

Mobile phase: See *Table 3*.

Table 3

Time (min)	Solution A (%)	Solution B (%)
0	95	5
3	95	5
30	41	59
35	20	80
40	95	5
50	95	5

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 214 nm

Column: 4.6-mm × 10-cm; 5-µm packing *L1*

Column temperature: 40°

Flow rate: 1 mL/min

Injection volume: 50–100 µL

System suitability

Sample: *Standard solution*

Suitability requirements

Chromatogram comparability: In the chromatogram obtained from the *Standard solution*, identify the peaks due to digest fragments I, II, III, and IV. The chromatogram of the *Standard solution* corresponds to that of the typical chromatogram provided with the appropriate USP Insulin Reference Standard.

Resolution: There should be complete separation of the peaks due to fragments II and III. The resolution is defined in the applicable insulin monograph.

Tailing factor: NMT 1.5

■ for digest fragments II and III ■_{2S} (USP39)

Analysis

Samples: *Sample solution* and *Standard solution*

Condition the *Chromatographic system* by running at initial conditions, $t = 0$ min, for at least 15 min. Carry out a blank gradient program before injecting the digests. Separately inject equal volumes of the *Standard solution* and the *Sample solution*, and record the responses of each peak.

Acceptance criteria: The chromatographic profile of the *Sample solution* corresponds to that of the *Standard solution*.

LIMIT OF HIGH MOLECULAR WEIGHT PROTEINS

- **Procedure**

Solution A: 1 mg/mL of L-arginine in water

Mobile phase: *Solution A*, acetonitrile, and glacial acetic acid (65:20:15). Filter, and degas.

Resolution solution: Store a suitable amount of insulin drug substance at room temperature for a sufficient period of time (5–10 days, or as needed) to obtain insulin with more than 0.4% high molecular weight proteins. Prepare a 4-mg/mL solution in 0.01 N hydrochloric acid. Store the solution in a refrigerator, and use within 7 days. Alternatively, dissolve about 4 mg of USP High Molecular Weight Insulin Human RS in 1 mL of 0.01 N hydrochloric acid.

Sample solution: In a small vial, prepare a 4-mg/mL solution of insulin in 0.01 N hydrochloric acid, and mix to dissolve. Store in a refrigerator, and use within 7 days.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 276 nm

Column: 7.8-mm × 30-cm; 5- to 10- μ m packing L20

Temperatures

Autosampler: It is advisable to use a refrigerated autosampler.

Column: Ambient

Flow rate: 0.5 mL/min

Injection volume: 100 μ L

System suitability

Sample: *Resolution solution*

Suitability requirements

Retention times: Between 13 and 17 min for the polymeric insulin complexes, about 17.5 min for the covalent insulin dimer, and between 18 and 22 min for the insulin monomer, with salts eluting after the insulin monomer

Peak-to-valley ratio: The ratio of the height of the covalent insulin dimer peak to the height of the valley between the covalent insulin dimer peak and the insulin monomer peak is NLT 2.0.

Analysis

Sample: *Sample solution*

Disregard any peaks with retention times greater than that of the insulin monomer.

Calculate the percentage of high molecular weight proteins in the portion of Insulin taken:

$$\text{Result} = \frac{\sum r_H}{(\sum r_H + r_M)} \times 100$$

$\sum r_H$ = sum of the responses of all peaks with retention times less than that of the insulin monomer

r_M = peak response of the insulin monomer

Acceptance criteria: As stated in the applicable insulin monograph

ADDITIONAL REQUIREMENTS

- **USP Reference Standards** <11>
USP High Molecular Weight Insulin Human RS (alternative, optional)

BRIEFING

<127> **Flow Cytometric Enumeration of CD34+ Cells.** The CD34+ Cells Expert Panel recommends and the Biologics and Biotechnology Monographs 3 Expert Committee proposes this new general chapter to provide a test method to enumerate CD34+ cells in samples of peripheral blood, leukapheresis products, bone marrow, and cord blood. CD34+ cell enumeration by flow cytometry is a rare event analysis; therefore, specific gating instructions are provided in the single-platform, flow cytometric method for CD34+ cell enumeration described in this chapter. A new Reference Standard (RS), USP CD34+ Cells RS, is proposed for use during assessment of the *System suitability requirements* for the method.

Comment deadline: November 30, 2015

Add the following:

▪ <127> **FLOW CYTOMETRIC ENUMERATION OF CD34+ CELLS**

INTRODUCTION

The CD34 antigen is expressed on the surface of almost all human hematopoietic stem and progenitor cells. The absolute number of CD34+ hematopoietic stem cells (HSCs) has been shown to correlate with in vitro colony-forming unit (CFU) assay activity and with clinical engraftment in hematopoietic grafts prepared from peripheral blood, bone marrow, and cord blood sources. The single-platform, flow cytometric CD34+ cell enumeration method described here is based on a clinical laboratory protocol,¹ established by the International Society of Hematotherapy and Graft Engineering (ISHAGE), now known as the International Society for Cellular Therapy (ISCT). This protocol can be used to enumerate CD34+ cells in samples of peripheral blood, leukapheresis products, bone marrow, and cord blood. CD34+ cell enumeration by flow cytometry is a rare event analysis, which requires specific gating instructions that are provided in this chapter. Furthermore, the USP CD34+ Cells RS has been developed to assess the reagents and ensure the correct gating during data acquisition and analysis.

IDENTIFICATION OF CD34+ HEMATOPOIETIC STEM CELLS

CD34+ cell enumeration by flow cytometry is a rare event analysis. For the analysis of CD34+ HSCs, cell samples are stained with fluorescently labeled antibodies against both the HSC antigen CD34 and the pan-leukocyte antigen CD45. Five parameters—forward light scatter (FSC), side light scatter (SSC), CD34 staining, CD45 staining, and viability dye staining are combined in a sequential, or Boolean, gating strategy to identify viable CD34+ cells. CD34+ HSCs have FSC and SSC characteristics similar to lymphocytes; expressing both CD45 and CD34, and exhibiting dim CD45 expression and low SSC characteristics. Viability dye does not stain live cells, allowing the exclusion of dead cells from the analysis of viable cell preparations. For analysis of nonviable, fixed (preserved) cell preparations such as the USP CD34+ Cells Reference Standard (RS), either the flow cytometer viable cell analysis gate is fully opened to include all cells, or the *Viability dye* is omitted from the analysis.

ENUMERATION CONSIDERATIONS

The CD34+ cell enumeration method described here relies on the use of synthetic fluorescent microspheres (counting beads) as internal enumeration controls. Homogeneous counting beads are added to the cell sample at a known concentration and volume, or the counting beads may be procured, pre-aliquoted, and lyophilized in special sample tubes, in which all subsequent cell staining and processing steps are conducted. To avoid the loss of counting beads, the wash steps are omitted, and protein-containing sample buffers are used. An ammonium chloride-based, red blood cell (RBC)-lysing protocol is used for fresh cell preparations; no lysing is necessary for frozen, thawed, or fixed cell preparations.

After the cells are stained and processed, the counting beads and cells are simultaneously analyzed on a flow cytometer. The number of CD34+ cells/ μL in the cell sample can be directly calculated by comparing the absolute number of target CD34+ cells and the number of counting beads detected in the same data file. The USP CD34+ Cells RS is used to verify that the correct reagents and flow cytometer gating parameters were used.

EQUIPMENT SPECIFICATIONS

The following equipment is needed:

- A pipettor capable of accurately reverse-pipetting microliter volumes

A flow cytometer with the following minimum specifications (see *Flow Cytometry* (1027)):

- Detection capabilities for FSC; SSC; "green" fluorescence emission (range, 510–550 nm); "yellow" fluorescence emission (range, 560–590 nm); and "red" fluorescence emission (>600 nm)
- Light-scatter and fluorescence measurements that are correlated to time
- Light-scatter resolution allowing for the identification of lymphocytes, monocytes, granulocytes, and fluorescent counting beads
- Detection and data acquisition rates of at least 5000 cells/s
- A 488-nm laser excitation source

- Fluorescence intensity sensitivity allowing for the detection of cellular autofluorescence
- Analysis software, including a data file structure in the Flow Cytometry Standard (FCS) or equivalent, with spectral overlap correction capability

FLOW CYTOMETER INSTRUMENT SETUP AND CONSIDERATIONS

Note—For general information, see <1027> and the flow cytometer manufacture's recommendations.

Ensure that the sheath fluid receptacle is filled, the waste fluid receptacle is empty, and all caps are tightly closed. Verify that the laser power, system vacuum, and pressure are properly set.

Using fluorochrome-conjugated calibration microspheres, verify proper system alignment by measuring the average detection rate, mean fluorescence, mean FSC, mean SSC, and the respective calculated coefficient of variance (CV) values as measured by each detector. All values should fall within the ranges recommended by the manufacturer of the flow cytometer instrument. Adjust the detector threshold to ensure that all counting bead events are included. Use either antibody-binding microspheres or preserved cells, such as the USP CD34+ Cells RS, to establish a matrix of detector values while adjusting for spectral overlap (compensation). Note that although either microspheres or cells can be stained with anti-CD34 phycoerythrin (PE) and anti-CD45 fluorescein isothiocyanate (FITC) antibodies, only fresh cells can be stained with *Viability dye*.

REAGENTS

Phosphate-buffered saline (PBS): 138 mM sodium chloride, 2.7 mM potassium chloride, 8 mM dibasic sodium phosphate, and 1.47 mM monobasic potassium phosphate. [Note—pH 7.0–7.4. If needed, adjust pH with hydrochloric acid.]

Dilution buffer: 1% (w/v) Bovine serum albumin or human serum albumin in *PBS*

10X Stock ammonium chloride RBC lysis buffer: 1.5 M ammonium chloride, 0.01 M sodium bicarbonate, and 0.01 M ethylenediaminetetraacetic acid (EDTA)²

Diluted (1X) RBC lysis buffer: 10X Stock ammonium chloride RBC lysis buffer diluted 1:10 with water

Anti-CD34 PE: Phycoerythrin (PE)-conjugated mouse IgG1 anti-human CD34 antibody (clones QBEnd10, 8G12, 581, Birma K3, or equivalent class II or class III PE-conjugated anti-CD34 antibodies), appropriately titrated

Anti-CD45 FITC: Fluorescein isothiocyanate (FITC) conjugated mouse IgG1 anti-human CD45 antibody (clones J33, T29/33, or HLE-1 or equivalent FITC-conjugated anti-CD45 antibodies), appropriately titrated

Viability dye: 1 µg/mL 7-Aminoactinomycin D (7-AAD) or equivalent, freshly diluted from a stock solution of 100 µg/mL³

Instrument calibration beads: Fluorochrome-conjugated instrument calibration microspheres⁴

Suspended counting beads: Fluorochrome-conjugated counting beads, formulated in liquid

suspension⁵

Lyophilized counting bead tube: Fluorochrome-conjugated counting beads, formulated and lyophilized in a counting tube⁶

System suitability standard USP CD34+ Cells RS: Reconstitute the entire vial of USP CD34+ Cells RS with 0.5 mL of distilled water.

Cell samples: Fresh, fixed, or cryopreserved and thawed cell suspensions containing CD34+ cells, with a minimum of 100,000 nucleated cells/sample. Cell samples may include peripheral blood, leukapheresis product, cord blood, or bone marrow.

SAMPLE PREPARATION

Use reverse-pipetting techniques for all sample dilutions and transfers. Dilute *Cell samples* with *Dilution buffer* to obtain a total nucleated cell concentration of $10\text{--}30 \times 10^6$ cells/mL. Add *Anti-CD45 FITC* and *Anti-CD34 PE* to a 12-mm \times 75-mm polystyrene tube (or a *Lyophilized counting bead tube*), followed by *Viability dye* to a final concentration of 1 $\mu\text{g/mL}$. Add 100 μL of well-mixed *Cell samples* to the bottom of the tube, and mix. Incubate for 20 min protected from light. Add 2 mL of *Diluted (1X) RBC lysis buffer* to fresh samples or add 2 mL of *Dilution buffer* to a fixed or frozen and thawed sample; vortex to mix. For fresh *Cell samples*, incubate for 10 min protected from light; for fixed or frozen then thawed *Cell samples*, no incubation time is needed. Place samples on ice. Samples should be analyzed within 1 h of lysis.

Immediately before acquiring data on the flow cytometer, pipet 100 μL of well-mixed *Suspended counting beads* (if not using *Lyophilized counting bead tubes*) to the prepared *Cell samples* described above. Cap the tube, and gently mix by inversion. Do not add counting beads to *Cell samples* intended to be used for adjustment of the instrumentation compensation matrix.

Immediately proceed to flow acquisition to collect a minimum of 75,000 CD45+ events and a minimum of 100 CD34+ cells. Acquire and analyze data by creating regions and logical gates (manually, or by using software appropriate for the flow cytometer), as described in *Table 1*.

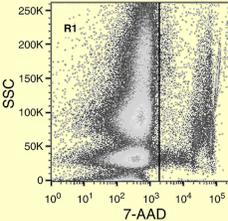

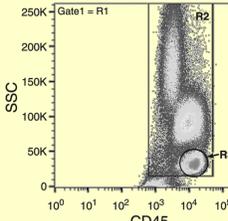

System suitability requirements: Use the USP CD34+ Cells RS to verify that the gating strategy described below allows the detection and quantitation of CD34+ HSCs. Note that for fixed *Cell samples*, the viability gate (*R1* in *Table 1*) must be opened to include all events; alternatively, the *Viability dye* can be omitted. Calculate the number of CD34+ HSCs/ μL in the USP CD34+ Cells RS.

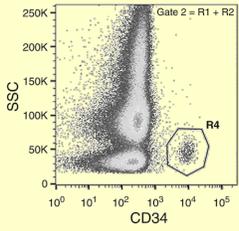

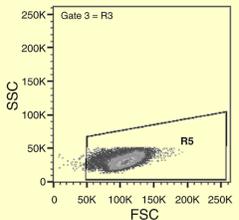

Acceptance criteria: The results should fall within the range provided in the USP CD34+ Cells RS certificate.

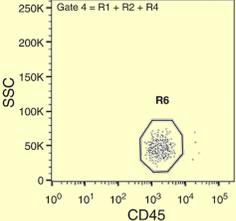

DATA ACQUISITION AND ANALYSIS

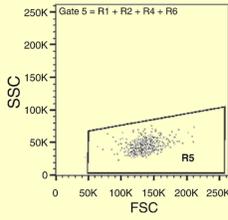

For flow acquisition, collect a minimum of 75,000 CD45+ events and a minimum of 100 CD34+ cells. Acquire and analyze data by creating regions and logical gates (manually, or using software appropriate for the flow cytometer) as described in *Table 1*. The best results are obtained when cell and bead data (events) are displayed as bivariate dot plots. *Table 1* contains representative dot plots and gating strategies for fresh cell samples. Dot plot displays may vary slightly, depending on the cell sample, flow cytometer, and software used.

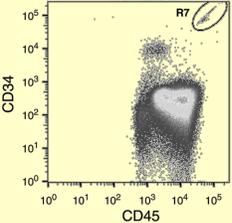

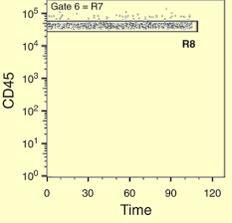

Table 1. Dot Plot Descriptions and Gating Instructions

Step	Format	Purpose	Gating Instructions	Representative Dot Plots and Gating Strategies
1	SSC (linear) vs. Viability dye fluorescence (log)	Define viable cells	<ul style="list-style-type: none"> • Display all unselected events. Create region <i>R1</i> around events with little-to-no fluorescence. • Included in the region: <i>R1</i>, viable cells, debris • Excluded from the region: Dead and dying cells, counting beads 	 <p>A dot plot showing SSC (y-axis, 0 to 250K) versus 7-AAD (x-axis, log scale from 10⁰ to 10⁵). A vertical gate labeled 'R1' is positioned at approximately 10¹ on the x-axis, selecting the population with low 7-AAD fluorescence.</p>
2	SSC (linear) vs. CD45 fluorescence (log)	Define viable CD45+ leukocytes and lymphocytes	<ul style="list-style-type: none"> • Display <i>R1</i>-selected events. Create region <i>R2</i> around events with CD45+ fluorescence, excluding debris (i.e., events with very low SSC). Within <i>R1</i>, create region <i>R3</i> around events with high CD45+ fluorescence and low SSC. • Included in the region: <i>R2</i> is viable CD45+ leukocytes; <i>R3</i> is viable lymphocytes. • Excluded from the region: <i>R2</i> is cell debris, platelets, and unlysed RBCs; <i>R3</i> is granulocytes, monocytes, and other non-lymphocytes. 	 <p>A dot plot showing SSC (y-axis, 0 to 250K) versus CD45 (x-axis, log scale from 10⁰ to 10⁵). A vertical gate labeled 'Gate1 = R1' is shown at the far left. Within this gate, two regions are defined: 'R2' is a large population of CD45+ cells, and 'R3' is a small population of CD45+ cells with low SSC.</p>

Step	Format	Purpose	Gating Instructions	Representative Dot Plots and Gating Strategies
3	SSC (linear) vs. CD34 fluorescence (log)	Define viable CD34+ cells	<ul style="list-style-type: none"> • Display <i>R2</i>-selected events. Create region <i>R4</i> around events with CD34+ fluorescence and low SSC. • Included in the region: <i>R4</i> is viable CD34+ cells. • Excluded from the region: CD34- cells 	
4	SSC (linear) vs. FSC (linear)	Define lymphocytes and blasts	<ul style="list-style-type: none"> • Display <i>R3</i>-selected events. Create region <i>R5</i> to exclude debris (low SSC and low FSC). • Included in the region: <i>R5</i> is viable lymphocytes and blasts. • Excluded from the region: Small debris and events with high SSC values 	

Step	Format	Purpose	Gating Instructions	Representative Dot Plots and Gating Strategies
5	SSC (linear) vs. CD45 fluorescence (log)	Define CD45 dim CD34+ cells	<ul style="list-style-type: none"> • Display <i>R4</i>-selected events. Create region <i>R6</i> around events with low-to-intermediate SSC and intermediate CD45 expression. • Included in the region: <i>R6</i> is viable CD34+ HSCs. • Excluded from the region: Cells that express high levels of CD45 	

Step	Format	Purpose	Gating Instructions	Representative Dot Plots and Gating Strategies
6	SSC (linear) vs. FSC (linear)	Confirm CD34+ HSCs	<ul style="list-style-type: none"> • Display R6-selected events, and paste a copy of the R5 gate parameters into the plot. Events in R5 have light scatter characteristics similar to lymphocytes and blasts, confirming the identity of the events as CD34+ HSCs. • Included in the region: R5 is confirmed viable CD34+ HSCs. • Excluded from the region: Debris and other irrelevant events 	

Step	Format	Purpose	Gating Instructions	Representative Dot Plots and Gating Strategies
7	CD34 fluorescence (log) vs. CD45 fluorescence (log)	Quantify total counting beads	<ul style="list-style-type: none"> • Display all ungated events. Create region <i>R7</i> around events with both high CD34+ and high CD45+ fluorescence. Included in the region: <i>R7</i> is total counting beads. <i>R5</i> have light scatter characteristics similar to lymphocytes and blasts, confirming the identity of the events as CD34+ HSCs. • Included in the region: <i>R7</i> is total counting beads. • Excluded from the region: Cells and debris 	 <p>A dot plot showing CD34 fluorescence (log scale, 10⁰ to 10⁵) on the y-axis versus CD45 fluorescence (log scale, 10⁰ to 10⁵) on the x-axis. A gate labeled 'R7' is drawn around a cluster of events in the upper right quadrant, representing high CD34+ and high CD45+ events.</p>
8	CD45 fluorescence (log) vs. time (linear)	Quantify "singlet" (e.g., unaggregated) counting beads	<ul style="list-style-type: none"> • When recommended by the counting bead manufacturer, display <i>R7</i>-selected events. Create <i>R8</i> around events with lower fluorescence intensity. <i>R8</i> is singlet counting beads. • Included in the region: <i>R8</i> is singlet counting beads. • Excluded from the region: Counting bead aggregates 	 <p>A dot plot showing CD45 fluorescence (log scale, 10⁰ to 10⁵) on the y-axis versus Time (linear scale, 0 to 120) on the x-axis. A gate labeled 'R8' is drawn around a horizontal band of events at a lower CD45 intensity, representing singlet counting beads.</p>

CALCULATION OF ABSOLUTE CD34 NUMBER

The absolute number of viable CD34+ cells/ μ L is calculated as follows:

$$\text{Viable CD34+ cells}/\mu\text{L} = (\text{number of CD34+ cells})/(\text{number of counting beads}) \times (\text{bead concentration} \times DF)$$

DF = sample dilution factor

The number of CD34+ cells is determined from the viable CD34+ cells (region *R5* from *Table 1*, Step 6). Depending on the recommendations of the counting bead manufacturer, the number of counting beads is determined from either the total counting beads (region *R7* from *Table 1*, graph 7) or the singlet counting beads (region *R8* from *Table 1*, graph 8). The bead concentration is specified by the counting bead manufacturer.

Table 2. Troubleshooting Guidelines (see also (1027))

Problems	Possible Reasons	Solutions	Comments
Unable to clearly define the bead gate (<i>R7</i>) in <i>Table 1</i> , graph 7 due to fluorescent debris	Degraded fresh cell sample; fixed sample; too many platelets; incomplete RBC lysis; nucleated RBCs (e.g., in cord blood)	Use a far-red fluorescence channel (>600 nm), instead of FITC, to gate counting beads.	Counting beads are highly fluorescent in all channels. Autofluorescence interference decreases dramatically at longer wavelengths (>600 nm).
Unable to find CD34+ population in, graph 3	Incorrect compensation settings for PE and <i>Viability dye</i>	Repeat the spectral compensation setup procedure, and adjust settings accordingly.	Make sure that counting beads are not in the compensation matrix sample, because they can interfere with compensation settings.
Unsure of gating for singlet or total beads	High levels of counting bead aggregates	Follow the counting bead manufacturer's recommendation for including or excluding aggregates.	Counting bead concentration calculations will vary by manufacturer.
Want to use a different CD34 antibody clone	Multi-parametric flow cytometry considerations	Alternative antibody clones must be carefully validated against the specified CD34 antibodies. Choose a class II or class III antibody that detects all CD34 isoforms and glycoforms.	Class I antibodies do not detect all CD34 glycoforms.
Want to use a different CD45 antibody clone	Multi-parametric flow cytometry considerations	Alternative antibody clones must be carefully validated against the specified CD45 antibodies. Choose an antibody that detects all isoforms and all glycoforms of CD45.

BRIEFING

(212) **Oligosaccharide Analysis**, page 7582 of the *Second Supplement to USP 38*. On the basis of requests for a revision, it is proposed to add a procedure of *High-Performance Anion Exchange Chromatography with Fluorometric Detection* for analysis of *N*-linked oligosaccharides containing multi-sialylated, multi-antennary complex type chains. To support this proposed analytical procedure, two USP Reference Standards (RS) have been added to this chapter: USP Oligosaccharide System Suitability Mixture C RS and USP Oligosaccharide System Suitability Mixture D RS:

- USP Oligosaccharide System Suitability Mixture C RS is a mixture of bi-, tri-, and tetra-antennary *N*-linked oligosaccharides with variable sialylation with or without fucose [also containing sialyl Lewis x (Le^x) type structures]; the mixture was released from human α 1 acid-glycoprotein by peptide *N*-glycosidase F (PNGase F).
- USP Oligosaccharide System Suitability Mixture D RS is a mixture of sialylated bi- and tri-antennary complex type structures with an additional sialic acid on one of the tri-antennary structure; the mixture was released from bovine fetuin by PNGase F.

This new liquid chromatographic procedure for the *High-Performance Anion Exchange Liquid Chromatography with Fluorometric Detection* test was based on analyses performed with the Dionex CarboPac PA1 4.0-mm \times 5-cm, 10- μ m packing brand of guard column and the 4.0-mm \times 25-cm, 10- μ m packing brand of L46 column.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

Add the following:**■ (212) OLIGOSACCHARIDE ANALYSIS****INTRODUCTION**

Change to read:

Analysis of the asparagine (Asn-) linked oligosaccharide (also known as the *N*-linked oligosaccharide or *N*-glycan) composition of selected recombinant therapeutic proteins has become necessary for product characterization or release specifications of these proteins. For information on the characterization and assessment of protein glycosylation, see *Glycoprotein and Glycan Analysis—General Considerations* (1084), which may be a helpful, but not mandatory, resource. Chapter (1084) covers general analytical strategies and also highlights criteria for selecting appropriate methods for specific analytical challenges, thereby providing the context for this chapter. This chapter focuses on the analysis of *N*-linked oligosaccharides that are released from glycosylated recombinant therapeutic proteins. ~~that contain relatively simple biantennary and high mannose chains, with no or low levels of sialylated, phosphorylated, or sulfated structures~~

- ~~2S~~ (USP39)

Therefore, the chapter provides 1) a generic procedure for enzymatic release of *N*-glycans using peptide *N*-glycosidase F (PNGase F), 2) two different approaches for fluorophore labeling of the released *N*-linked oligosaccharides, and 3) ~~four~~

- ~~five~~ ~~2S~~ (USP39)

analytical procedures based on chromatographic and electrophoretic separation, as well as performance criteria for the separation. Alternative analytical strategies are discussed in (1084). Although the procedures in this chapter are validated, the procedures must be verified with the individual specific product (see *Verification of Compendial Procedures* (1226), which may be a helpful but not mandatory resource). Furthermore, validation is required when the procedure is optimized for a specific product (see *Validation of Compendial Procedures* (1225), which may be a helpful but not mandatory resource). Data analysis, quantitation, and lot release specifications, which are expected to be product specific, will be found in individual product monographs; therefore, these aspects are not covered in this chapter.

Labeling oligosaccharides with a fluorophore before analysis provides an important advantage of enhanced detection of oligosaccharides during separation, because oligosaccharides have no or low absorptivity of either ultraviolet (UV) or visible light and no significant fluorophore groups. This chapter describes two different methods for fluorophore labeling of oligosaccharides: derivatization of oligosaccharides using 2-aminobenzamide (2-AB) for liquid chromatographic separation, and labeling of oligosaccharides with 8-aminopyrene-1,3,6-trisulfonic acid (APTS) for capillary electrophoresis (CE) separation. Although electrochemical detection (pulsed amperometric detection or pulsed electrochemical detection) is also used in oligosaccharide analysis by using a strong base elution, the electrochemical detection method is less sensitive and has a higher noise to signal ratio. Therefore, this detection method is not addressed in this chapter.

Many different chromatography and electrophoresis methods have been developed to analyze oligosaccharides, and the procedures described in this chapter have been used successfully for this purpose. The choice of procedures discussed is meant to reflect the most commonly and broadly used approaches for supporting current recombinant glycosylated biological medicines in commerce. These analytical procedures include normal phase or hydrophilic interaction liquid chromatography (HILIC), high-performance anion exchange liquid chromatography (HPAEC), and CE. Several other chromatographic modes that separate oligosaccharides by size, shape, and polarity are also commonly used for oligosaccharide separation, but those other chromatographic modes are not discussed in this chapter. The general principles of

chromatography are covered in *Chromatography* (621), and therefore (621) should be considered within that context.

USP Reference Standards (RS) have been developed to assess system suitability for these analytical procedures:

- USP Oligosaccharide System Suitability Mixture A RS consists of a mixture of partially sialylated, partially galactosylated, and partially fucosylated biantennary *N*-linked oligosaccharides that were released from human polyclonal immunoglobulin G (IgG) by PNGase F.
- USP Oligosaccharide System Suitability Mixture B RS consists of a mixture of high-mannose *N*-linked oligosaccharides with traces of hybrid chains that were released from bovine ribonuclease B (RNase B) by PNGase F.
-
- USP Oligosaccharide System Suitability Mixture C RS is a mixture of bi-, tri-, and tetra-antennary *N*-linked oligosaccharides with variable sialylation with or without fucose (Fuc; also containing Le^x type structures); the mixture was released from human α1 acid-glycoprotein by PNGase F.
- USP Oligosaccharide System Suitability Mixture D RS is a mixture of sialylated bi- and tri-antennary complex type structures with an additional sialic acid on one of the tri-antennary structure; the mixture was released from bovine fetuin by PNGase F.

Change to read:**SAMPLE PREPARATION**

See *Appendix (Table 17)* for abbreviations and structures of glycans.

Ideally, the samples should be free of salts, excipients, and other carrier materials that may interfere with the analysis. This can be achieved by either 1) dialysis against water, a suitable buffer, or a volatile buffer using an appropriate membrane, 2) sample trapping on a solid-phase extraction (SPE) cartridge followed by washing away of salts and excipients and elution of the required sample, or 3) ultrafiltration using an appropriate membrane.

[Note—A control sample with a known glycan profile should be included in the overall procedure to confirm correct performance of the analysis. A reaction blank control only containing the buffer matrix of the glycoprotein sample can also be included in the overall procedure.]

- **Enzymatic Release of *N*-Glycans**

[Note—The following is a generic method that should be optimized for individual products depending on the amount of glycoprotein to be digested and the glycan structures, especially on the basis of the protein to glycan ratio in the molecule and the accessibility of the sugars.]

Procedure 1 for chromatographic separation

Enzyme reaction buffer: 50 mM sodium phosphate pH 7.5 or 15 mM tris(hydroxymethyl)-aminomethane, and adjust with hydrochloric acid to a pH of 7.0.

Digestion with PNGase F: Transfer 0.1–2.25 mg of glycoprotein to a vial, and adjust with *Enzyme reaction buffer* to a final volume of 30–100 μL . Add PNGase F to the glycoprotein sample in a ratio of 0.5–15 units of PNGase F to 0.1 mg of glycoprotein. Incubate at 37° for 12–24 h. Cool at room temperature for about 5 min. Vortex gently and centrifuge briefly. [Note—One unit of PNGase F is defined as the amount of enzyme required to catalyze the release of *N*-linked oligosaccharides from 1.0 nmol of denatured ribonuclease B per min at a pH of 7.5 at 37°, and is equal to 1 IUB milliunit. Complete digestion by PNGase F can be assessed by observing a mobility shift of the deglycosylated proteins on sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), followed by Coomassie Blue staining or on SDS-capillary gel electrophoresis (SDS-CGE), as shown by reduction in mass of approximately 2 kDa per glycan chain cleaved.]

Two methods are described below for performing the separation of released glycans from glycoprotein.

Method 1, using an ultrafiltration membrane with a molecular weight cutoff of 30

kDa:¹ [Note—Ultrafiltration membranes with a lower molecular weight cutoff may be used

for proteins < 150 kDa.] Remove trace amounts of glycerin by centrifuging at 11,000 $\times g$ and rinsing the membrane with 0.5 mL of water. Discard the permeate. Add 0.1 mL of water into the sample reservoir and then add the digested glycoprotein sample to the reservoir. Rinse the reaction vial with 0.1 mL of water and add to the sample reservoir. Centrifuge at 11,000 $\times g$ and collect the permeate. Rinse the sample reservoir twice using 0.1 mL of water for each wash and collect the permeate. Combine the permeates (approximately 0.5 mL) and bring the samples to complete dryness using a centrifugal evaporator without heat.

Method 2, using a reversed-phase SPE cartridge:² Add 2.0 mL of methanol into a syringe, attach the syringe to the cartridge, and use the syringe plunger to pass methanol through to waste. Add into a syringe 6.0 mL of 5% (v/v) acetic acid prepared in water. Attach the syringe to the cartridge and use the syringe plunger to pass the acetic acid solution through to waste. Gently apply the digested sample onto an individual cartridge. Into a 1-mL syringe add 0.5 mL of 5% (v/v) acetic acid, attach the syringe to the cartridge, and use the syringe plunger to pass the acetic acid through to waste. To a 2- to 3-mL syringe add 1.5 mL of 5% (v/v) acetic acid. Attach the syringe to the cartridge, and use the syringe plunger to pass the acetic acid solution through, collecting the eluting solution into a 1.5-mL tube. Bring the samples to complete dryness using a centrifugal evaporator without heat.

Procedure 2 for capillary electrophoresis separation

Enzyme reaction buffer: 50 mM sodium phosphate, pH 7.5

Digestion with PNGase F: Add 2 μL of PNGase F (5 units/ μL) to 50 μg of glycoprotein sample, and adjust with *Enzyme reaction buffer* to a final volume of 50 μL . Incubate at 37° for 18 h. Separate released oligosaccharides by centrifugation using a centrifugal filter with a 10,000 molecular weight cut-off.³ In a centrifugal vacuum evaporator, dry the released oligosaccharides to dryness.

[Note—Follow the guidelines listed in *Table 1* to select the appropriate USP RS and label.]

• **2-AB Labeling⁴ for Liquid Chromatographic Separation**

Solution A: Mix glacial acetic acid and dimethyl sulfoxide (3:7, v/v).

Solution B: Add 1.5 mL of *Solution A* to 75 mg of 2-AB. Mix well by gentle vortexing to completely dissolve 2-AB.

Labeling solution: Add 1 mL of *Solution B* to 63 mg of sodium cyanoborohydride. Mix well by gentle vortexing. Cap the mixture tightly and incubate at 70° for 1–2 min for complete dissolution. Cool at room temperature for 10 min. Use this *Labeling solution* within 1 h of its preparation. Use this solution within 1 h after its preparation, and protect the solution from light.

2-AB labeled standard solution: Add 5–15 μL of *Labeling solution* to 1 vial of USP Oligosaccharide System Suitability Mixture A RS, USP Oligosaccharide System Suitability Mixture B RS,

■ USP Oligosaccharide System Suitability Mixture C RS, or USP Oligosaccharide System Suitability Mixture D RS, ■_{2S} (USP39) and mix well.

2-AB labeled sample solution: Add 5–15 μL of *Labeling solution* to the dried glycan sample after enzymatic release and separation steps, and mix well.

Procedure: Immediately incubate the *2-AB labeled standard solution* and the *2-AB labeled*

sample solution at 37° for 16–18 h or at 65° for 2 h. Allow to cool at room temperature for 10 min. Centrifuge briefly.

■ **Dried 2-AB labeled standard or Dried 2-AB labeled sample:** ■_{2S} (USP39)

Two methods for the removal of free 2-AB are described below.

Method 1, using a gel filtration spin column: Prepare suitable G-10 microcentrifuge spin columns⁵ by tapping the column gently to ensure that the dry resin is settled at the bottom. Remove the caps, and place the column in a 2-mL collection tube. Add 0.5 mL of water to the resin, and let it swell for at least 15 min. A longer swelling time (up to 24 h) is acceptable if maintained at 2°–8°. Centrifuge the column at maximum speed for 5–10 s. Remove the water from the collection tube. Wash the resin by adding 0.5 mL of water, and centrifuge the column. Repeat the washing step one more time. After removing the water from the final wash step, spin at maximum speed for 10 s to remove residual water from the resin. Residual water is sufficiently removed if the resin appears white. Place the column in a new, labeled collection tube. Add 100 µL of water to the *2-AB labeled standard solution* and the *2-AB labeled sample solution*, and then apply the entire solution to the center of each washed G-10 column, respectively. Place the G-10 columns in the microcentrifuge and spin at approximately 200 ×g for 1 min. Apply the flow-through (approximately 90–120 µL) to the center of the second unused but previously washed G-10 column and spin at approximately 200 ×g for 1 min. Transfer the repeat flow-through (approximately 60–100 µL) to a 0.5-mL microcentrifuge tube. Dry the eluates by centrifugal evaporation with no heat.

Method 2, using an SPE cartridge: Prepare suitable SPE cartridges⁶ by washing with 1.0 mL of water, followed by 5 × 1.0 mL of 30% (v/v) acetic acid, and then 1.0 mL of acetonitrile. Apply the *2-AB labeled standard solution* and the *2-AB labeled sample solution* to the center surface of the cartridge discs, and allow the solution to incubate on the disc for 15–20 min. Wash each disc with 1 mL of acetonitrile, followed by 6 × 1.0 mL of 96% (v/v) acetonitrile, allowing each aliquot to drain before the next is applied. Elute the *2-AB labeled standard solution* and the *2-AB labeled sample solution* with 3 × 0.5 mL of water, allowing each aliquot to drain before the next is applied. Dry the eluates by centrifugal evaporation with no heat. [Note—Very small hydrophobic glycans may be lost during this procedure. During method verification, it should be confirmed that no oligosaccharide species are lost during the 2-AB removal step by comparing the chromatographic profiles of an unextracted reaction blank, an un-extracted sample, and an extracted sample.]

● **APTS Labeling for Capillary Electrophoresis Separation**

APTS labeling reagent: Dissolve 5 mg of trisodium APTS in 48 µL of 15% (v/v) acetic acid.

1 M sodium cyanoborohydride: 1 M sodium cyanoborohydride in tetrahydrofuran

Run buffer: Dissolve 1.492 g of triethanolamine (TEA) and 10 g of glycerol, accurately weighed, in 80 mL of water. Adjust with 1 N hydrochloric acid to a pH of 7.5, and dilute with water to a final volume of 100 mL.

Sample buffer: Dilute 1.0 mL of *Run buffer* with 9.0 mL of water.

APTS-labeled standard solution: Add 2 µL of the *APTS labeling reagent* and 2 µL of 1 M *sodium cyanoborohydride* to a vial of USP Oligosaccharide System Suitability Mixture A RS or USP Oligosaccharide System Suitability Mixture B RS. Incubate at 55° for 90 min. Add 46 µL of water to quench the reaction and mix. Transfer 5 µL of the APTS-labeled USP RS

to 1.995 mL of *Sample buffer* before separation. [Note—The volume of *Sample buffer* may need to be adjusted so that the fluorescence signals of the oligosaccharides are similar to those from the *APTS-labeled sample solution*.]

APTS-labeled sample solution: Add 2 μL of *APTS labeling reagent* and 2 μL of 1 M sodium cyanoborohydride to the dried glycan sample after enzymatic release and separation steps. Incubate at 55° for 90 min. Add 46 μL of water to quench the reaction and mix. Transfer 5 μL of the APTS-labeled glycan solution to 95 μL of *Sample buffer* before separation.

[Note—Follow the guidelines listed in *Table 1* to select the appropriate USP RS and label.]

A3 (G3S3)	1.00

Table 14. Standard Solution using USP Oligosaccharide System Suitability Mixture D RS

<i>N</i> -Glycan	Approximate Relative Retention Time
A1 (G1S1), peak 1	0.23
A2 (G2S2)	0.57
A3 (G3S3)	0.78
A3G3S4 (S4NA3, or A3 + Sa)	1.00

Analysis [Note—Equilibrate the column with initial mobile phase conditions for a minimum of 15 min.]

Sample: *Sample solution*

Inject 25 μ L of water, and run the gradient program at least once to equilibrate the column and system. Integrate peaks in the resulting chromatogram, and report the relative peak areas of glycan structures relevant to the product. For general information on chromatographic peak integration, see (621).

■ 2S (USP39)

● **Capillary Electrophoresis**

Run buffer: Dissolve 1.492 g of TEA and 10 g of glycerol in 80 mL of water. Adjust with 1 N hydrochloric acid to a pH of 7.5 and dilute with water to a final volume of 100 mL.

Standard solution: *APTS-labeled standard solution* prepared as directed in the test for 8-Aminopyrene-1,3,6-trisulfonic Acid (APTS) Labeling for CE Separation

Sample solution: *APTS-labeled sample solution* prepared as directed in the test for 8-

Aminopyrene-1,3,6-trisulfonic Acid (APTS) Labeling for CE Separation

Blank solution: Buffer matrix of glycoprotein sample carried through the *Sample Preparation* procedure

Instrumental conditions

Mode: CE

Detector: Laser-induced fluorescence (488-nm excitation wavelength and 520-nm emission wavelength)

Capillary: 50- μ m inner diameter bare fused-silica with 50 cm total length and 40 cm separation length

Preconditioning of the capillary: Between each run, rinse for 5 min at 40 psi with 0.5 N sodium hydroxide, followed by water for 1 min at 40 psi. [Note—Precondition a new capillary or as needed: Rinse for 5 min at 20 psi with methanol, followed by water for 1 min at 50 psi, 1 N hydrochloric acid for 5 min at 20 psi, water for 1 min at 50 psi, 0.5 N sodium hydroxide for 25 min at 20 psi, and water for 5 min at 50 psi.]

Prefilling of the capillary: Rinse for 5 min at 40 psi with *Run buffer*.

Sample injection: 10 s hydrodynamic (pressure) injection

Voltage: 22 kV for 60 min

Temperatures

Capillary cartridge: 18°

Sample storage: 20°

System suitability

Sample: *Standard solution*

Suitability requirements

Electropherogram similarity: If USP Oligosaccharide System Suitability Mixture A RS is used, the electropherogram obtained from the *Standard solution* corresponds to that of the reference electropherogram provided with the USP Certificate for USP Oligosaccharide System Suitability Mixture A RS. If USP Oligosaccharide System Suitability Mixture B RS is used, the electropherogram obtained from the *Standard solution* corresponds to that of the reference electropherogram provided with the USP Certificate for USP Oligosaccharide System Suitability Mixture B RS.

- The electropherogram obtained from the *Standard solution* corresponds to that of the reference electropherogram provided with the Certificate for either USP Oligosaccharide System Suitability Mixture A RS or USP Oligosaccharide System Suitability Mixture B RS. ■_{2S} (USP39)

Presence of N-glycan species: If USP Oligosaccharide System Suitability Mixture A RS is used, identify peaks corresponding to *G2F*, *G2*, *G1Fa*, *G1Fb*, *G0F*, *MAN-5*, *G0*, and *A1F* (see *Table 15*; see also *Appendix*) in the electropherogram obtained from the *Standard solution* by comparing the reference electropherogram provided with the USP Certificate for USP Oligosaccharide System Suitability Mixture A RS. If USP Oligosaccharide System Suitability Mixture B RS is used, identify peaks corresponding to *MAN-5*, *MAN-6*, *MAN-7*, *MAN-8*, and *MAN-9* (see *Table 16*; see also *Appendix*) in the electropherogram obtained from the *Standard solution* by comparing the reference electropherogram provided with the USP Certificate for USP Oligosaccharide System

Suitability Mixture B RS.

Relative migration times: Corresponding to relative migration times listed in *Table 15* or *Table 16*

Table 15. Standard Solution using USP Oligosaccharide System Suitability Mixture A RS

BRIEFING

⟨467⟩ **Residual Solvents**, *USP 38* page 309. This revised version of general chapter *Residual Solvents* ⟨467⟩ represents the result of deliberations of the Residual Solvents Expert Panel, created under the umbrella of the Chemical Analysis Expert Committee. The proposed revisions also reflect the results of a survey conducted in the pharmaceutical industry during 2013. The following main changes are proposed:

1. A section titled *Control Strategy* has been added to better explain the different approaches that can be used to control the quantities of residual solvents in pharmacopeial articles.
2. Under the *Identification, Control, and Quantification of Residual Solvents* section, a more detailed decision tree has been added.
3. The *Analytical Procedures* section has been modernized to align with current format.
4. Under *Analytical Procedures*, text is added to indicate that, when the solvents likely to be present are known, system suitability requirements are based only on the solvents under investigation.
5. A new section titled *Verification and Validation* has been added to provide guidance on the verification process, when the procedures are being implemented in the laboratory, or the validation of alternative procedures.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

⟨467⟩ RESIDUAL SOLVENTS

Change to read:

INTRODUCTION

~~This general chapter applies to existing drug substances, excipients, and products. All substances and products are subject to relevant control of solvents likely to be present in a substance or product.~~

~~Where the limits to be applied comply with those given below, tests for residual solvents are not generally mentioned in specific monographs, because the solvents employed may vary from~~

one manufacturer to another.

The objective of this general chapter is to provide acceptable amounts of residual solvents in pharmaceuticals for the safety of the patient. The chapter recommends the use of less toxic solvents and describes levels considered to be toxicologically acceptable for some residual solvents.

For pharmacopeial purposes, residual solvents in pharmaceuticals are defined as organic volatile chemicals that are used or produced in the manufacture of drug substances or excipients, or in the preparation of drug products. The residual solvents are not completely removed by practical manufacturing techniques. Appropriate selection of the solvent for the synthesis of a drug substance or an excipient may enhance the yield, or determine characteristics such as crystal form, purity, and solubility. Therefore, the solvent may sometimes be a critical element in the synthetic process. This general chapter does not address solvents deliberately used as excipients, nor does it address solvates. However, the content of solvents in such products should be evaluated and justified.

Because residual solvents do not provide therapeutic benefit, they should be removed, to the extent possible, to meet ingredient and product specifications, good manufacturing practices, or other quality-based requirements. Drug products should contain no higher levels of residual solvents than can be supported by safety data. Solvents that are known to cause unacceptable toxicities (Class 1, *Table 1*) should be avoided in the production of drug substances, excipients, or drug products unless their use can be strongly justified in a risk-benefit assessment. Solvents associated with less severe toxicity (Class 2, *Table 2*) should be limited in order to protect patients from potential adverse effects. Ideally, less toxic solvents (Class 3, *Table 3*) should be used where practical. The complete list of solvents included in this general chapter is given in *Appendix 1*. These tables and the list are not exhaustive. For the purposes of this Pharmacopeia, when a manufacturer has received approval from a competent regulatory authority for the use of a new solvent not currently listed in this general chapter, it is the responsibility of that manufacturer to notify the USP regarding the identity of this solvent, the approved residual solvent limit in the article, and the appropriate test procedure for this residual solvent in the article. The USP will then address this topic in the individual monograph. When a new solvent has been approved through the ICH process, it will be added to the appropriate list in this general chapter. At that time, consideration will be given for removal of the specific solvent test requirement in the individual monograph.

Testing of drug substances, excipients, and drug products for residual solvents should be performed when production or purification processes are known to result in the presence of such residual solvents. It is only necessary to test for residual solvents that are used or produced in the manufacture or purification of drug substances, excipients, or products.

Although manufacturers may choose to test the drug product, a cumulative procedure may be used to calculate the residual solvent levels in the drug product from the levels in the ingredients used to produce the drug product. If the calculation results in a level equal to or below that provided in this general chapter, no testing of the drug product for residual solvents need be considered. If, however, the calculated level is above the recommended level, the drug product should be tested to ascertain whether the formulation process has reduced the relevant solvent level to within the acceptable amount. A drug product should also be tested if a residual solvent is used during its manufacture.

For the purposes of this Pharmacopeia, when a manufacturer has received approval from a competent regulatory authority for a higher level of residual solvent, it is the responsibility of that manufacturer to notify the USP regarding the identity of this solvent and the approved residual solvent limit in the article. The USP will then address this topic in the individual monograph.

See *Appendix 2* for additional background information related to residual solvents.

CLASSIFICATION OF RESIDUAL SOLVENTS BY RISK ASSESSMENT

The term *tolerable daily intake* (TDI) is used by the International Program on Chemical Safety (IPCS) to describe exposure limits of toxic chemicals, and the term *acceptable daily intake* (ADI) is used by the World Health Organization (WHO) and other national and international health authorities and institutes. The term *permitted daily exposure* (PDE) is defined as a pharmaceutically acceptable intake of residual solvents to avoid confusion of differing values for ADIs of the same substance.

Residual solvents assessed in this general chapter are listed in *Appendix 1* by common names and structures. They were evaluated for their possible risk to human health and placed into one of three classes as follows:

Residual Solvent Class	Assessment
Class 1	Solvents to be avoided
	Known human carcinogens
	Strongly suspected human carcinogens
	Environmental hazards
Class 2	Solvents to be limited
	Nongenotoxic animal carcinogens or possible causative agents of other irreversible toxicity, such as neurotoxicity or teratogenicity
Class 3	Solvents suspected of other significant but reversible toxicities
	Solvents with low toxic potential
	Solvents with low toxic potential to humans; no health-based exposure limit is needed [Note—Class 3 residual solvents have PDEs of 50 mg or more per day.*]
* For residual solvents with PDEs of more than 50 mg per day, see the discussion in the section <i>Class 3</i> under <i>Limits of Residual Solvents</i> .	

METHODS FOR ESTABLISHING EXPOSURE LIMITS

The method used to establish PDEs for residual solvents is presented in *Appendix 3*.

For articles that are designated "for veterinary use only", higher levels for the PDE and concentration limit may be justified in exceptional cases based upon the actual daily dose, actual target species, and relevant toxicological data and considering consumer safety impact. For the purpose of this Pharmacopeia, when a manufacturer has received approval from a competent regulatory authority for a higher limit, it is the responsibility of that manufacturer to

notify the USP regarding the approved residual solvent limit in the article and the justification. The USP will then address this topic in the individual monograph.

OPTIONS FOR DESCRIBING LIMITS OF CLASS 2 RESIDUAL SOLVENTS

Two options are available when setting limits for Class 2 residual solvents.

Option 1

The concentration limits in ppm stated in *Table 2* are used. They were calculated using the equation below by assuming a product weight of 10 g administered daily.

$$\text{Concentration (ppm)} = (1000 \mu\text{g}/\text{mg} \times \text{PDE})/\text{dose}$$

Here, PDE is given in terms of mg per day, and dose is given in g per day.

These limits are considered acceptable for all drug substances, excipients, and drug products. Therefore, this option may be applied if the daily dose is not known or fixed. If all drug substances and excipients in a formulation meet the limits given in *Option 1*, these components may be used in any proportion. No further calculation is necessary, provided that the daily dose does not exceed 10 g. Products that are administered in doses greater than 10 g per day are to be considered under *Option 2*.

Option 2

It is not necessary for each component of the drug product to comply with the limits given in *Option 1*. The PDE in terms of mg per day as stated in *Table 2* can be used with the known maximum daily dose and the equation above to determine the concentration of residual solvent allowed in a drug product. Such limits are considered acceptable, provided that it has been demonstrated that the residual solvent has been reduced to the practical minimum. The limits should be realistic in relation to analytical precision, manufacturing capability, and reasonable variation in the manufacturing process. The limits should also reflect contemporary manufacturing standards.

Option 2 may be applied by adding the amounts of a residual solvent present in each of the components of the drug product. The sum of the amounts of solvent per day should be less than that given by the PDE.

Consider an example of the application of *Option 1* and *Option 2* to acetonitrile concentration in a drug product. The permitted daily exposure to acetonitrile is 4.1 mg per day; thus, the *Option 1* limit is 410 ppm. The maximum administered daily weight of a drug product is 5.0 g, and the drug product contains two excipients. The composition of the drug product and the calculated maximum content of residual acetonitrile are given in the following table.

Component	Amount in Formulation (g)	Acetonitrile Content (ppm)	Daily Exposure (mg)
Drug substance	0.3	800	0.24
Excipient 1	0.9	400	0.36
Excipient 2	3.8	800	3.04
Drug product	5.0	728	3.64

Excipient 1 meets the *Option 1* limit, but the drug substance, excipient 2, and drug product do

not meet the *Option 1* limit. Nevertheless, the drug product meets the *Option 2* limit of 4.1 mg per day and thus conforms to the acceptance criteria in this general chapter.

Consider another example, using acetonitrile as the residual solvent. The maximum administered daily weight of a drug product is 5.0 g, and the drug product contains two excipients. The composition of the drug product and the calculated maximum content of residual acetonitrile are given in the following table.

Component	Amount in Formulation (g)	Acetonitrile Content (ppm)	Daily Exposure (mg)
Drug substance	0.3	800	0.24
Excipient 1	0.9	2000	1.80
Excipient 2	3.8	800	3.04
Drug product	5.0	1016	5.08

In this example, the drug product meets neither the *Option 1* nor the *Option 2* limit according to this summation. The manufacturer could test the drug product to determine whether the formulation process reduced the level of acetonitrile. If the level of acetonitrile was not reduced to the allowed limit during formulation, the product fails to meet the solvent limits as described in this chapter, and the manufacturer of the drug product should take other steps to reduce the amount of acetonitrile in the drug product. In some instances, the manufacturer may have received approval from a competent regulatory authority for such a higher level of residual solvent. If this is the case, it is the responsibility of that manufacturer to notify the USP regarding the identity of this solvent and the approved residual solvent limit in the article. The USP will then address this topic in the individual monograph.

ANALYTICAL PROCEDURES

Residual solvents are typically determined using chromatographic techniques such as gas chromatography. Compendial methods for testing for residual solvent content are described under the section *Identification, Control, and Quantification of Residual Solvents* in this general chapter. The *General Notices* discuss the use of other methods in special circumstances (see 6.30. *Alternative and Harmonized Methods and Procedures*). If Class 3 solvents are present, a nonspecific method such as loss on drying may be used.

REPORTING LEVELS OF RESIDUAL SOLVENTS

Manufacturers of pharmaceutical products need certain information about the content of residual solvents in drug substances or excipients in order to meet the criteria of this general chapter. The following statements are given as acceptable examples of the information that could be provided from a supplier of drug substances or excipients to a pharmaceutical manufacturer. The supplier might choose one of the following as appropriate:

- Only Class 3 solvents are likely to be present. Loss on drying is less than 0.5%.
- Only Class 2 solvents X, Y,... are likely to be present. All are below the *Option 1* limit. (Here the supplier would name the Class 2 solvents represented by X, Y,...)
- Only Class 2 solvents X, Y,... and Class 3 solvents are likely to be present. Residual Class 2 solvents are below the *Option 1* limit, and residual Class 3 solvents are below 0.5%.

The phrase "likely to be present", as used in the above examples, refers to the solvent used or produced in the final manufacturing step and to solvents that are used or produced in earlier manufacturing steps and not removed consistently by a validated process.

If Class 1 solvents are likely to be present, they should be identified and quantified. If solvents of Class 2 or 3 are present at greater than their *Option 1* limits or 0.5%, respectively, they should be identified and quantified.

LIMITS OF RESIDUAL SOLVENTS

Class 1 (solvents to be avoided)

Class 1 residual solvents (*Table 1*) should not be employed in the manufacture of drug substances, excipients, and drug products because of the unacceptable toxicities or deleterious environmental effects of these residual solvents. However, if their use in order to produce a medicinal product with a significant therapeutic advance is unavoidable, their levels should be restricted as shown in *Table 1*, unless otherwise stated in the individual monograph. The solvent 1,1,1-trichloroethane is included in *Table 1* because it is an environmental hazard. The stated limit of 1500 ppm is based on a review of safety data.

When Class 1 residual solvents are used or produced in the manufacture or purification of a drug substance, excipient, or drug product and are not removed by the process, these solvents should be identified and quantified. The procedures described in the section *Identification, Control, and Quantification of Residual Solvents* in this general chapter are to be applied wherever possible. Otherwise, an appropriate validated procedure is to be employed.

Table 1. Class 1 Residual Solvents
(Solvents that should be avoided)

Solvent	Concentration Limit (ppm)	Concern
Benzene	2	Carcinogen
Carbon tetrachloride	4	Toxic and environmental hazard
1,2-Dichloroethane	5	Toxic
1,1-Dichloroethene	8	Toxic
1,1,1-Trichloroethane	1500	Environmental hazard

Class 2

Class 2 residual solvents (*Table 2*) should be limited in drug substances, excipients, and drug products because of the inherent toxicities of the residual solvents. PDEs are given to the nearest 0.1 mg per day, and concentrations are given to the nearest 10 ppm. The stated values do not reflect the necessary analytical precision of the determination procedure. Precision should be determined as part of the procedure validation.

If Class 2 residual solvents are present at greater than their *Option 1* limits, they should be identified and quantified. The procedures described in the section *Identification, Control, and Quantification of Residual Solvents* in this general chapter are to be applied wherever possible. Otherwise an appropriate validated procedure is to be employed. [Note—The following Class 2 residual solvents are not readily detected by the headspace injection conditions described in the section *Identification, Control, and Quantification of Residual Solvents* in this general

chapter: formamide, 2-ethoxyethanol, 2-methoxyethanol, ethylene glycol, *N*-methylpyrrolidone, and sulfolane. Other appropriate validated procedures are to be employed for the quantification of these residual solvents. Such procedures shall be submitted to the USP for review and possible inclusion in the relevant individual monograph. In addition, USP Residual Solvent Class 2—Mixture C RS can be used to develop an alternative procedure.]

Table 2. Class 2 Residual Solvents

Solvent	PDE (mg/day)	Concentration Limit (ppm)
Acetonitrile	4.1	410
Chlorobenzene	3.6	360
Chloroform	0.6	60
Cumene	0.7	70
Cyclohexane	38.8	3880
1,2-Dichloroethene	18.7	1870
1,2-Dimethoxyethane	1.0	100
<i>N,N</i> -Dimethylacetamide	10.9	1090
<i>N,N</i> -Dimethylformamide	8.8	880
1,4-Dioxane	3.8	380
2-Ethoxyethanol	1.6	160
Ethylene glycol	6.2	620
Formamide	2.2	220
Hexane	2.9	290
Methanol	30.0	3000
2-Methoxyethanol	0.5	50
Methylbutylketone	0.5	50
Methylcyclohexane	11.8	1180
Methylene chloride	6.0	600
<i>N</i> -Methylpyrrolidone	5.3	530
Nitromethane	0.5	50
Pyridine	2.0	200
Sulfolane	1.6	160
Tetrahydrofuran	7.2	720
Tetraalin	1.0	100
Toluene	8.9	890
Trichloroethylene	0.8	80
Xylene*	21.7	2170

* Usually 60% *m*-xylene, 14% *p*-xylene, 9% *o*-xylene with 17% ethyl benzene.

Class 3

Class 3 residual solvents (Table 3) may be regarded as less toxic and of lower risk to human health than Class 1 and Class 2 residual solvents. Class 3 includes no solvent known as a human health hazard at levels normally accepted in pharmaceuticals. However, there are no

long-term toxicity or carcinogenicity studies for many of the residual solvents in Class 3. Available data indicate that they are less toxic in acute or short-term studies and negative in genotoxicity studies.

It is considered that amounts of these residual solvents of 50 mg per day or less (corresponding to 5000 ppm or 0.5% under *Option 1*) would be acceptable without justification. Higher amounts may also be acceptable, provided that they are realistic in relation to manufacturing capability and good manufacturing practice. For the purposes of this Pharmacopeia, when a manufacturer has received approval from a competent regulatory authority for such a higher level of residual solvent, it is the responsibility of that manufacturer to notify the USP regarding the identity of this solvent and the approved residual solvent limit in the article. The USP will then address this topic in the individual monograph. If a Class 3 solvent limit in an individual monograph is greater than 50 mg per day, that residual solvent should be identified and quantified. The procedures described in the section *Identification, Control, and Quantification of Residual Solvents* in this general chapter, with appropriate modifications to the standard solutions, are to be applied wherever possible. Otherwise, an appropriate validated procedure is to be employed.

Table 3. Class 3 Residual Solvents

(Limited by GMP or other quality-based requirements in drug substances, excipients, and drug products)

Acetic acid	Heptane
Acetone	Isobutyl acetate
Anisole	Isopropyl acetate
1-Butanol	Methyl acetate
2-Butanol	3-Methyl-1-butanol
Butyl acetate	Methylethylketone
<i>tert</i> -Butylmethyl ether	Methylisobutylketone
-	2-Methyl-1-propanol
Dimethyl sulfoxide	Pentane
Ethanol	1-Pentanol
Ethyl acetate	1-Propanol
Ethyl ether	2-Propanol
Ethyl formate	Propyl acetate
Formic acid	-

Other Residual Solvents

The residual solvents listed in *Table 4* may also be of interest to manufacturers of drug substances, excipients, or drug products. However, no adequate toxicological data on which to base a PDE was found.

Table 4. Other Residual Solvents

(For which no adequate toxicological data was found)

1,1-Diethoxypropane	Methyl isopropyl ketone
1,1-Dimethoxymethane	Methyltetrahydrofuran
2,2-Dimethoxypropane	Solvent hexane
Isooctane	Trichloroacetic acid
Isopropyl ether	Trifluoroacetic acid

IDENTIFICATION, CONTROL, AND QUANTIFICATION OF RESIDUAL SOLVENTS

Whenever possible, the substance under test needs to be dissolved to release the residual solvent. Because the USP deals with drug products, as well as active ingredients and excipients, it may be acceptable that in some cases, some of the components of the formulation will not dissolve completely. In those cases, the drug product may first need to be pulverized into a fine powder so that any residual solvent that may be present can be released. This operation should be performed as fast as possible to prevent the loss of volatile solvents during the procedure.

[Note—The organic-free water specified in the following procedures produces no significantly interfering peaks when chromatographed.]

Class 1 and Class 2 Residual Solvents

The following procedures are useful to identify and quantify residual solvents when the information regarding which solvents are likely to be present in the material is not available. When the information about the presence of specific residual solvents is available, only *Procedure C* is needed to quantify the amount of residual solvents present. A flow diagram for the application of the residual solvent limit tests is shown in *Figure 1*.

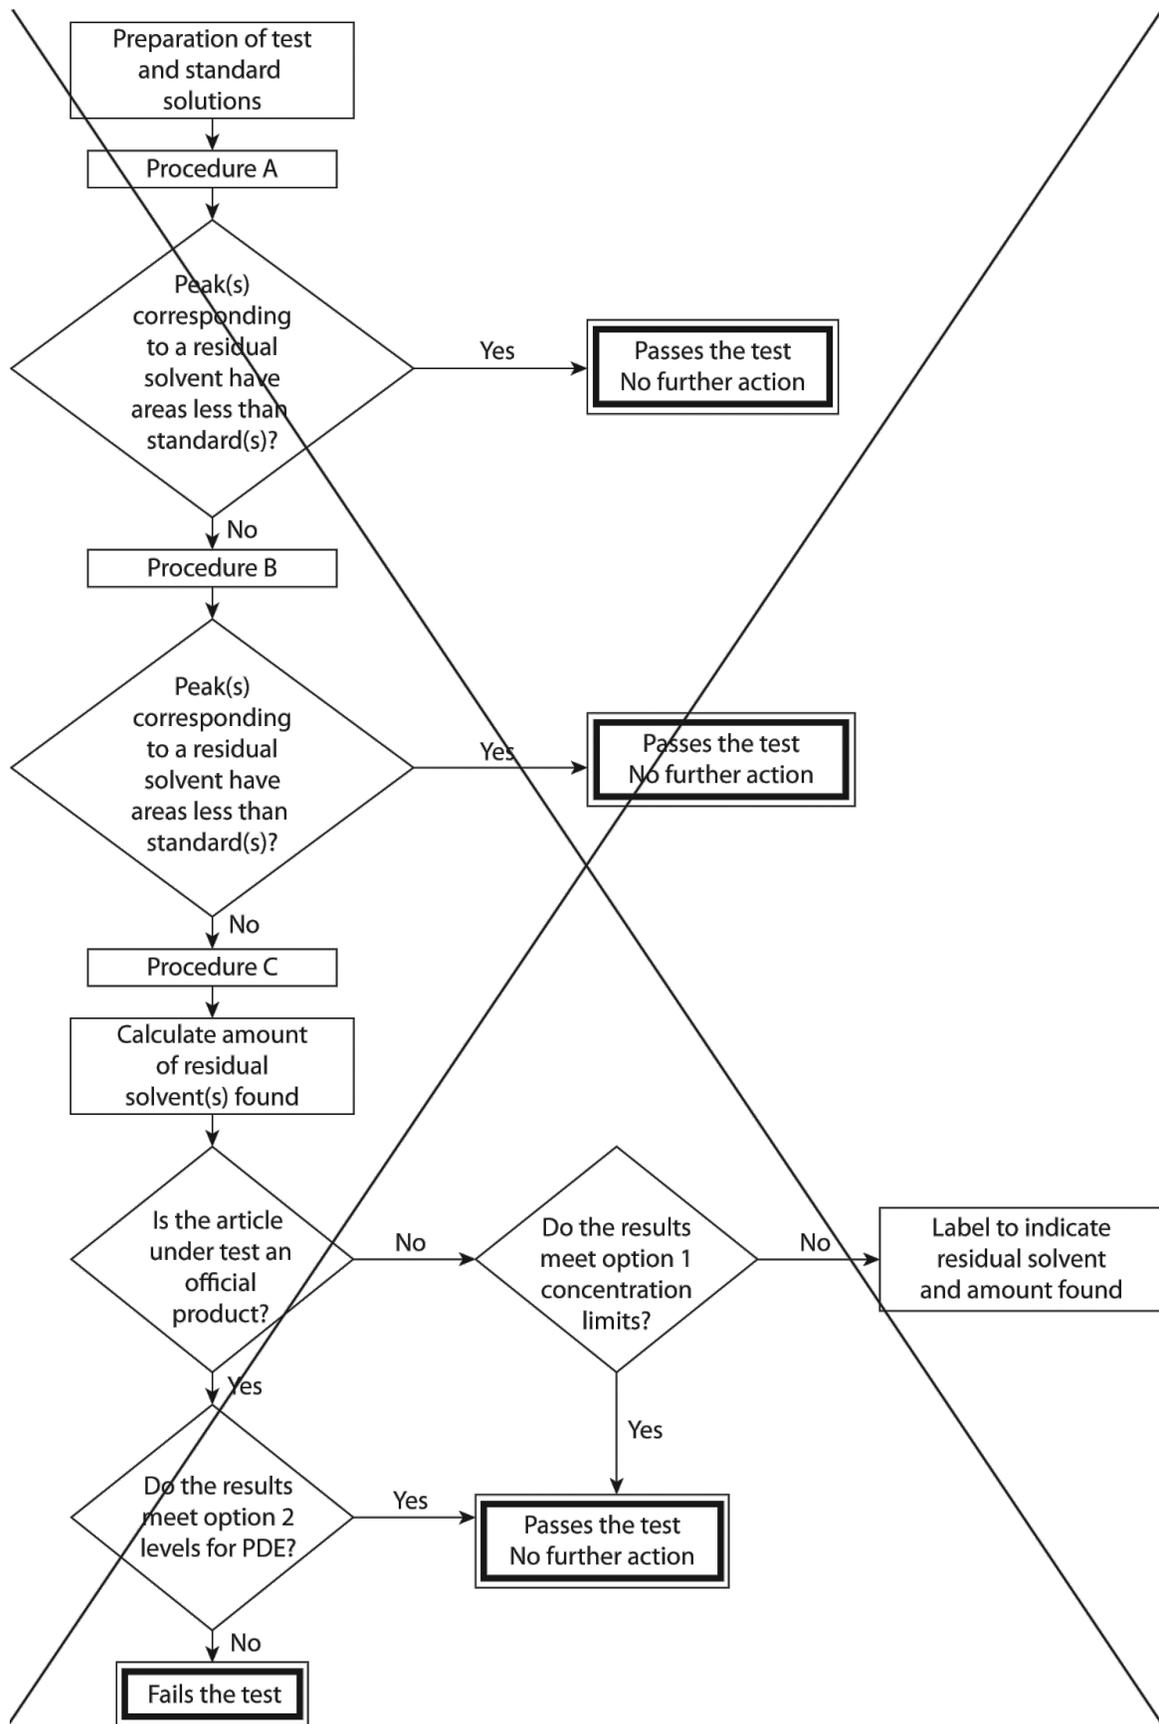

Figure 1. Diagram relating to the identification of residual solvents and the application of limit tests.

WATER-SOLUBLE ARTICLES

Procedure A—

~~*Class 1 Standard Stock Solution*—[Note—When transferring solutions, place the tip of the pipet just below the surface of the liquid, and mix.] Transfer 1.0 mL of USP Class 1 Residual Solvents Mixture RS to a 100-mL volumetric flask, previously filled with about 9 mL of dimethyl sulfoxide, dilute with water to volume, and mix. Transfer 1.0 mL of this solution to a 100-mL volumetric flask, previously filled with about 50 mL of water, dilute with water to volume, and mix. Transfer 10 mL of this solution to a 100-mL volumetric flask, previously filled with about 50 mL of water, dilute with water to volume, and mix.~~

~~*Class 1 Standard Solution*—Transfer 1.0 mL of *Class 1 Standard Stock Solution* to an appropriate headspace vial containing 5.0 mL of water (place the tip of the pipet just below the surface of the liquid for dispensing), apply the stopper, cap, and mix.~~

~~*Class 2 Standard Stock Solutions*—Transfer 1.0 mL of USP Residual Solvents Class 2 Mixture A RS to a 100-mL volumetric flask, dilute with water to volume, and mix. This is *Class 2 Standard Stock Solution A*. Transfer 1.0 mL of USP Residual Solvents Class 2 Mixture B RS to a 100-mL volumetric flask, dilute with water to volume, and mix. This is *Class 2 Standard Stock Solution B*.~~

~~*Class 2 Mixture A Standard Solution*—Transfer 1.0 mL of *Class 2 Standard Stock Solution A* to an appropriate headspace vial, add 5.0 mL of water, apply the stopper, cap, and mix.~~

~~*Class 2 Mixture B Standard Solution*—Transfer 5.0 mL of *Class 2 Standard Stock Solution B* to an appropriate headspace vial, add 1.0 mL of water, apply the stopper, cap, and mix.~~

~~*Test Stock Solution*—Transfer about 250 mg of the article under test, accurately weighed, to a 25-mL volumetric flask, dissolve in and dilute with water to volume, and mix.~~

~~*Test Solution*—Transfer 5.0 mL of *Test Stock Solution* to an appropriate headspace vial, add 1.0 mL of water, apply the stopper, cap, and mix.~~

~~*Class 1 System Suitability Solution*—Transfer 1.0 mL of *Class 1 Standard Stock Solution* to an appropriate headspace vial, add 5.0 mL of *Test Stock Solution*, apply the stopper, cap, and mix.~~

~~*Chromatographic System* (see *Chromatography* (621))—The gas chromatograph is equipped with a flame ionization detector and a 0.32-mm × 30-m fused silica column coated with a 1.8- μ m layer of phase G43 or a 0.53-mm × 30-m wide-bore column coated with a 3.0- μ m layer of phase G43. The carrier gas is nitrogen or helium with a linear velocity of about 35 cm/s, and a split ratio of 1:5. [Note—The split ratio can be modified in order to optimize sensitivity.] The column temperature is maintained at 40° for 20 min, then raised at a rate of 10° per min to 240°, and maintained at 240° for 20 min. The injection port and detector temperatures are maintained at 140° and 250°, respectively. Chromatograph the *Class 1 Standard Solution*, *Class 1 System Suitability Solution*, and *Class 2 Mixture A Standard Solution*, and record the peak responses as directed for *Procedure*: the signal-to-noise ratio of 1,1,1-trichloroethane in the *Class 1 Standard Solution* is NLT 5; the signal-to-noise ratio of each peak in the *Class 1 System Suitability Solution* is NLT 3; and the resolution, *R*, between acetonitrile and methylene chloride in the *Class 2 Mixture A Standard Solution* is NLT 1.0.~~

~~*Procedure*—[Note—It is recommended to increase the temperature of the transfer line between runs to eliminate any potential condensation of solvents.] Separately inject (following one of~~

the headspace operating parameter sets described in *Table 5*) equal volumes of headspace (about 1.0 mL) of the *Class 1 Standard Solution*, *Class 2 Mixture A Standard Solution*, *Class 2 Mixture B Standard Solution*, and *Test Solution* into the chromatograph, record the chromatograms, and measure the responses for the major peaks. If a peak response of any peak, other than a peak for 1,1,1-trichloroethane, in the *Test Solution* is greater than or equal to a corresponding peak in either the *Class 1 Standard Solution* or either of the two *Class 2 Mixture Standard Solutions*, or a peak response of 1,1,1-trichloroethane is greater than or equal to 150 times the peak response corresponding to 1,1,1-trichloroethane in the *Class 1 Standard Solution*, proceed to *Procedure B* to verify the identity of the peak; otherwise the article meets the requirements of this test.

Table 5. Headspace Operating Parameters

-	Headspace Operating Parameter Sets		
	1	2	3ntry>
Equilibration temperature (°)	80	105	80
Equilibration time (min)	60	45	45
Transfer line temperature (°) (if appropriate)	85	110	105
Syringe temperature (°) (if appropriate)	80–90	105–115	80–90
Carrier gas: nitrogen or helium at an appropriate pressure			
Pressurization time(s) (if appropriate)	≥60	≥60	≥60
Injection volume (mL)*	±	±	±
* Or follow the instrument manufacturer's recommendations, as long as the method criteria are met. Injecting less than this amount is allowed as long as adequate sensitivity is achieved.			

Procedure B—

Class 1 Standard Stock Solution, *Class 1 Standard Solution*, *Class 2 Standard Stock Solutions*, *Class 2 Mixture A Standard Solution*, *Class 2 Mixture B Standard Solution*, *Test Stock Solution*, *Test Solution*, and *Class 1 System Suitability Solution*—Prepare as directed for *Procedure A*.

Chromatographic System (see *Chromatography* (621))—The gas chromatograph is equipped with a flame ionization detector and a 0.32-mm × 30-m fused-silica column coated with a 0.25-µm layer of phase G16 or a 0.53-mm × 30-m wide-bore column coated with a 0.25-µm layer of phase G16. The carrier gas is nitrogen or helium with a linear velocity of about 35 cm/s and a split ratio of 1:5. [Note—The split ratio can be modified in order to optimize sensitivity.] The column temperature is maintained at 50° for 20 min, then raised at a rate of 6° per min to 165°, and maintained at 165° for 20 min. The injection port and detector temperatures are maintained at 140° and 250°, respectively. Chromatograph the *Class 1 Standard Solution* and the *Class 1 System Suitability Solution*, and record the peak responses as directed for *Procedure*: the signal-to-noise ratio of benzene in the *Class 1 Standard Solution* is NLT 5; the signal-to-noise ratio of each peak in the *Class 1 System Suitability Solution* is NLT 3; and the resolution, *R*, between acetonitrile and *cis*-dichloroethene in the *Class 2 Mixture A Standard Solution* is NLT 1.0.

Procedure—[Note—It is recommended to increase the temperature of the transfer line between runs to eliminate any potential condensation of solvents.] Separately inject (following one of

the headspace operating parameter sets described in *Table 5*) equal volumes of headspace (about 1.0 mL) of the *Class 1 Standard Solution*, *Class 2 Mixture A Standard Solution*, *Class 2 Mixture B Standard Solution*, and the *Test Solution* into the chromatograph, record the chromatograms, and measure the responses for the major peaks. If the peak response(s) in the *Test Solution* of the peak(s) identified in *Procedure A* is/are greater than or equal to a corresponding peak(s) in either the *Class 1 Standard Solution* or either of the two *Class 2 Mixture Standard Solutions*, proceed to *Procedure C* to quantify the peak(s); otherwise the article meets the requirements of this test.

Procedure C

Class 1 Standard Stock Solution, *Class 1 Standard Solution*, *Class 2 Standard Stock Solution A*, *Class 2 Mixture A Standard Solution*, *Test Stock Solution*, *Test Solution*, and *Class 1 System Suitability Solution*—Prepare as directed for *Procedure A*.

Standard Stock Solution—[Note—Prepare a separate *Standard Stock Solution* for each peak identified and verified by *Procedures A* and *B*. For the *Class 1* solvents other than 1,1,1-trichloroethane, prepare the first dilution as directed for the first dilution under *Class 1 Standard Stock Solution* in *Procedure A*.] Transfer an accurately measured volume of each individual USP Reference Standard corresponding to each residual solvent peak identified and verified by *Procedures A* and *B* to a suitable container, and dilute quantitatively, and stepwise if necessary, with water to obtain a solution having a final concentration of 1/20 of the value stated in *Table 1* or *Table 2* (under *Concentration Limit*).

Standard Solution—Transfer 1.0 mL of this solution to an appropriate headspace vial, add 5.0 mL of water, apply the stopper, cap, and mix.

Spiked Test Solution—[Note—Prepare a separate *Spiked Test Solution* for each peak identified and verified by *Procedures A* and *B*.] Transfer 5.0 mL of *Test Stock Solution* to an appropriate headspace vial, add 1.0 mL of the *Standard Stock Solution*, apply the stopper, cap, and mix.

Chromatographic System (see *Chromatography* (621))—[Note—If the results of the chromatography from *Procedure A* are found to be inferior to those found with *Procedure B*, the *Chromatographic System* from *Procedure B* may be substituted.] The gas chromatograph is equipped with a flame ionization detector and a 0.32-mm × 30-m fused-silica column coated with a 1.8- μ m layer of phase G43 or a 0.53-mm × 30-m wide-bore column coated with a 3.0- μ m layer of phase G43. The carrier gas is nitrogen or helium with a linear velocity of about 35 cm/s, and a split ratio of 1:5. [Note—The split ratio can be modified in order to optimize sensitivity.] The column temperature is maintained at 40° for 20 min, then raised at a rate of 10° per min to 240°, and maintained at 240° for 20 min. The injection port and detector temperatures are maintained at 140° and 250°, respectively. Chromatograph the *Class 1 Standard Solution*, the *Class 1 System Suitability Solution*, and the *Class 2 Mixture A Standard Solution*, and record the peak responses as directed for *Procedure*: the signal to noise ratio of 1,1,1-trichloroethane in the *Class 1 Standard Solution* is NLT 5; the signal to noise ratio of each peak in the *Class 1 System Suitability Solution* is NLT 3; and the resolution, *R*, between acetonitrile and methylene chloride in the *Class 2 Mixture A Standard Solution* is NLT 1.0.

Procedure—[Note—It is recommended to increase the temperature of the transfer line between runs to eliminate any potential condensation of solvents.] Separately inject (following one of the headspace operating parameters described in *Table 5*) equal volumes of headspace (about 1.0 mL) of the *Standard Solution*, *Test Solution*, and the *Spiked Test Solution* into the

chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the amount, in ppm, of each residual solvent found in the article under test by the formula:

$$5(C/W)[r_U/(r_{ST}-r_U)]$$

in which C is the concentration, in μg per mL, of the appropriate USP Reference Standard in the *Standard Stock Solution*; W is the weight, in g, of the article under test taken to prepare the *Test Stock Solution*; and r_U and r_{ST} are the peak responses of each residual solvent obtained from the *Test Solution* and the *Spiked Test Solution*, respectively.

WATER-INSOLUBLE ARTICLES

Procedure A—[Note—Dimethyl sulfoxide may be substituted as an alternative solvent to dimethylformamide.]

Class 1 Standard Stock Solution—Transfer 1.0 mL of USP Class 1 Residual Solvents Mixture RS to a 100-mL volumetric flask previously filled with about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix. Transfer 1.0 mL of this solution to a 100-mL volumetric flask, previously filled with about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix (reserve a portion of this solution for the *Class 1 System Suitability Solution*). Transfer 1.0 mL of this solution to a 10-mL volumetric flask, dilute with dimethylformamide to volume, and mix.

Class 1 Standard Solution—Transfer 1.0 mL of *Class 1 Standard Stock Solution* to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.

Class 2 Standard Stock Solutions—Transfer 1.0 mL of USP Residual Solvents Class 2 Mixture A RS to a 100-mL volumetric flask, previously filled with about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix. This is *Class 2 Standard Stock Solution A*. Transfer 0.5 mL of USP Residual Solvents Class 2 Mixture B RS to a 10-mL volumetric flask, dilute with dimethylformamide to volume, and mix. This is *Class 2 Standard Stock Solution B*.

Class 2 Mixture A Standard Solution—Transfer 1.0 mL of *Class 2 Standard Stock Solution A* to an appropriate headspace vial containing 5.0 mL of water, apply the stopper, cap, and mix.

Class 2 Mixture B Standard Solution—Transfer 1.0 mL of *Class 2 Standard Stock Solution B* to an appropriate headspace vial containing 5.0 mL of water, apply the stopper, cap, and mix.

Test Stock Solution—Transfer about 500 mg of the article under test, accurately weighed, to a 10-mL volumetric flask, dissolve in and dilute with dimethylformamide to volume, and mix.

Test Solution—Transfer 1.0 mL of *Test Stock Solution* to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.

Class 1 System Suitability Solution—Mix 5 mL of *Test Stock Solution* with 0.5 mL of the intermediate dilution reserved from *Class 1 Standard Stock Solution*. Transfer 1.0 mL of this solution to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.

Chromatographic System (see *Chromatography* (621))—The gas chromatograph is equipped with a flame ionization detector and a 0.53-mm \times 30-m wide-bore column coated with a 3.0- μm layer of phase G43. The carrier gas is helium with a linear velocity of about 35 cm/s and a split ratio of 1:3. [Note—The split ratio can be modified in order to optimize sensitivity.] The

column temperature is maintained at 40° for 20 min, then raised at a rate of 10° per min to 240°, and maintained at 240° for 20 min. The injection port and detector temperatures are maintained at 140° and 250°, respectively. Chromatograph the *Class 1 Standard Solution*, *Class 1 System Suitability Solution*, and *Class 2 Mixture A Standard Solution*, and record the peak responses as directed for *Procedure*: the signal-to-noise ratio of 1,1,1-trichloroethane in the *Class 1 Standard Solution* is NLT 5; the signal-to-noise ratio of each peak in the *Class 1 System Suitability Solution* is NLT 3; and the resolution, *R*, between acetonitrile and methylene chloride in the *Class 2 Mixture A Standard Solution* is NLT 1.0.

Procedure—[Note—It is recommended to increase the temperature of the transfer line between runs to eliminate any potential condensation of solvents.] Separately inject (use headspace operating parameters in column 3 of *Table 5* with a vial pressure of 10 psi) equal volumes of headspace (about 1.0 mL) of the *Class 1 Standard Solution*, *Class 2 Mixture A Standard Solution*, *Class 2 Mixture B Standard Solution*, and *Test Solution* into the chromatograph, record the chromatograms, and measure the responses for the major peaks. If a peak response of any peak, other than a peak for 1,1,1-trichloroethane, in the *Test Solution* is greater than or equal to a corresponding peak in either the *Class 1 Standard Solution* or either of the two *Class 2 Mixture Standard Solutions*, or a peak response of 1,1,1-trichloroethane is greater than or equal to 150 times the peak response corresponding to 1,1,1-trichloroethane in the *Class 1 Standard Solution*, proceed to *Procedure B* to verify the identity of the peak; otherwise, the article meets the requirements of this test.

Procedure B—

Class 1 Standard Stock Solution, *Class 1 Standard Solution*, *Class 1 System Suitability Solution*, *Class 2 Standard Stock Solutions*, *Class 2 Mixture A Standard Solution*, and *Class 2 Mixture B Standard Solution*, *Test Stock Solution*, and *Test Solution*—Proceed as directed for *Procedure A*.

Chromatographic System—Proceed as directed for *Procedure B* under *Water-Soluble Articles* with a split ratio of 1:3.[Note—The split ratio can be modified in order to optimize sensitivity.]

Procedure—[Note—It is recommended to increase the temperature of the transfer line between runs to eliminate any potential condensation of solvents.] Separately inject (use headspace operating parameters in column 3 of *Table 5* with a vial pressure of 10 psi) equal volumes of headspace (about 1.0 mL) of the *Class 1 Standard Solution*, *Class 2 Mixture A Standard Solution*, *Class 2 Mixture B Standard Solution*, and *Test Solution* into the chromatograph, record the chromatograms, and measure the responses for the major peaks. If the peak response(s) in *Test Solution* of the peak(s) identified in *Procedure A* is/are greater than or equal to a corresponding peak(s) in either the *Class 1 Standard Solution* or any of the two *Class 2 Mixture Standard Solutions*, proceed to *Procedure C* to quantify the peak(s); otherwise, the article meets the requirements of this test.

Procedure C—

Class 1 Standard Stock Solution, *Class 1 Standard Solution*, *Class 1 System Suitability Solution*, *Class 2 Standard Stock Solution A*, and *Class 2 Mixture A Standard Solution*—Proceed as directed for *Procedure A*.

Standard Stock Solution—[Note—Prepare a separate *Standard Stock Solution* for each peak identified and verified by *Procedures A* and *B*. For the *Class 1* solvents other than 1,1,1-

~~trichloroethane, prepare the first dilution as directed for the first dilution under *Class 1 Standard Stock Solution* in *Procedure A*.] Transfer an accurately measured volume of each individual USP Reference Standard corresponding to each residual solvent peak identified and verified by *Procedures A* and *B* to a suitable container, and dilute quantitatively, and stepwise if necessary, with water to obtain a solution having a final concentration of 1/20 of the value stated in *Table 1* or *Table 2* (under *Concentration Limit*).~~

~~*Standard Solution*—Transfer 1.0 mL of the *Standard Stock Solution* to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.~~

~~*Test Stock Solution*—Proceed as directed for *Procedure A*.~~

~~*Test Solution*—Transfer 1.0 mL of the *Test Stock Solution* to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.~~

~~*Spiked Test Solution*—[Note—Prepare a separate *Spiked Test Solution* for each peak identified and verified by *Procedures A* and *B*.] Transfer 1.0 mL of *Test Stock Solution* to an appropriate headspace vial, add 1 mL of *Standard Stock Solution* and 4.0 mL of water, apply the stopper, cap, and mix.~~

~~*Chromatographic System*—Proceed as directed for *Procedure C* under *Water-Soluble Articles*.~~

~~*Procedure*—[Note—It is recommended to increase the temperature of the transfer line between runs to eliminate any potential condensation of solvents.] Separately inject (use headspace operating parameters in column 3 of *Table 5* with a vial pressure of 10 psi) equal volumes of headspace (about 1.0 mL) of the *Standard Solution*, *Test Solution*, and *Spiked Test Solution* into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the amount, in ppm, of each residual solvent found in the article under test by the formula:~~

$$10 \times (C/W)[r_U/(r_{ST}-r_U)]$$

~~in which *C* is the concentration, in μg per mL, of the appropriate USP Reference Standard in the *Standard Stock Solution*; *W* is the weight, in g, of the article under test taken to prepare the *Test Stock Solution*; and r_U and r_{ST} are the peak responses of each residual solvent obtained from *Test Solution* and *Spiked Test Solution*, respectively.~~

Class 3 Residual Solvents

~~If Class 3 solvents are present, the level of residual solvents may be determined as directed under *Loss on Drying* (731) when the monograph for the article under test contains a loss on drying procedure specifying an upper limit of no more than 0.5% (per *Option 1* in this general chapter), or a specific determination of the solvent may be made. If there is no loss on drying procedure in the monograph for the article under test or if a Class 3 solvent limit in an individual monograph is greater than 50 mg per day (corresponding to 5000 ppm or 0.5% under *Option 1*), the individual Class 3 residual solvent or solvents present in the article under test should be identified and quantified, and the procedures as described above, with appropriate modifications to the standard solutions, are to be applied wherever possible. Otherwise, an appropriate validated procedure is to be employed. USP Reference Standards, where available, should be used in these procedures.~~

~~Acceptable daily intake (ADI): The maximum acceptable intake of toxic chemicals per day. This term is used by the World Health Organization (WHO).~~

~~Genotoxic carcinogens: Carcinogens that produce cancer by affecting genes or chromosomes.~~

~~Lowest observed effect level (LOEL): The lowest dose of a substance in a study or group of studies that produces biologically significant increases in frequency or severity of any effects in exposed humans or animals.~~

~~Modifying factor: A factor determined by professional judgment of a toxicologist and applied to bioassay data so that the data can be safely related to humans.~~

~~Neurotoxicity: The ability of a substance to cause adverse effects on the nervous system.~~

~~No observed effect level (NOEL): The highest dose of a substance at which there are no biologically significant increases in frequency or severity of any effects in exposed humans or animals.~~

~~Permitted daily exposure (PDE): The maximum acceptable intake per day of a residual solvent in pharmaceutical products.~~

~~Reversible toxicity: The occurrence of harmful effects that are caused by a substance and that disappear after exposure to the substance ends.~~

~~Strongly suspected human carcinogen: A substance for which there is no epidemiological evidence of carcinogenesis but for which there are positive genotoxicity data and clear evidence of carcinogenesis in rodents.~~

~~Teratogenicity: The occurrence of structural malformations in a developing fetus when a substance is administered during pregnancy.~~

~~Tolerable daily intake (TDI): Tolerable daily exposure to toxic chemicals. Term used by the International Program on Chemical Safety (IPCS).~~

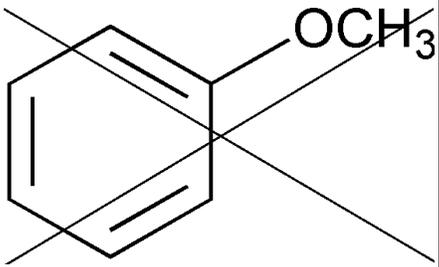

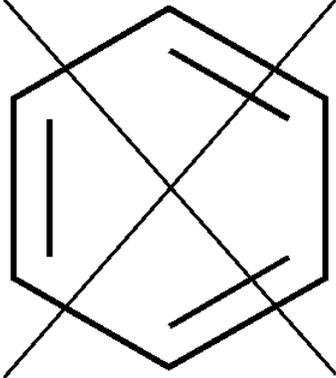

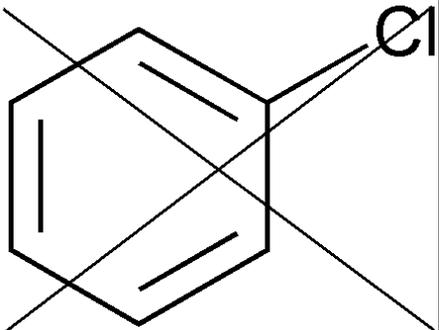

APPENDIX 1. LIST

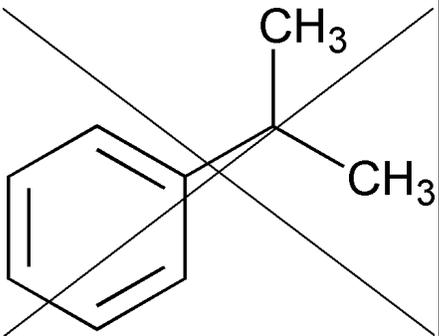

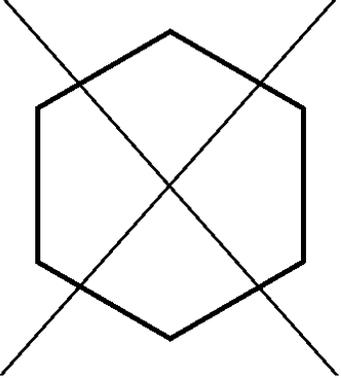

See the table *Appendix 1. List of Residual Solvents Included in This General Chapter.*

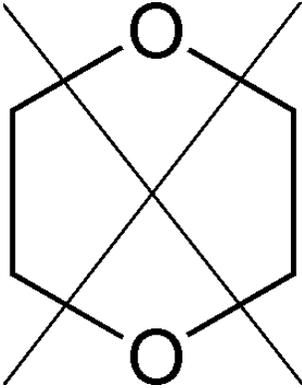

APPENDIX 1. LIST OF RESIDUAL SOLVENTS INCLUDED IN THIS GENERAL CHAPTER

Solvent	Other Names	Structure	Class
Acetic acid	Ethanoic acid	CH_3COOH	Class-3
Acetone	2-Propanone Propan-2-one	CH_3COCH_3	Class-3
Acetonitrile	-	CH_3CN	Class-2

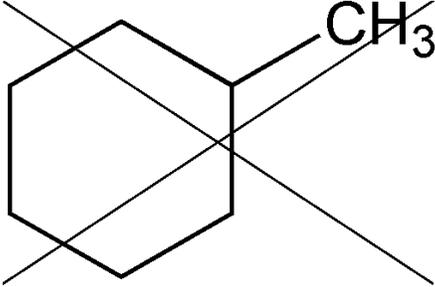

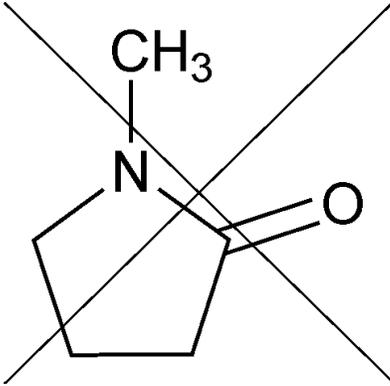

* Usually 60% *m*-xylene, 14% *p*-xylene, 9% *o*-xylene with 17% ethyl benzene.

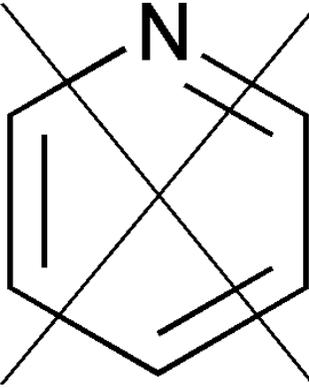

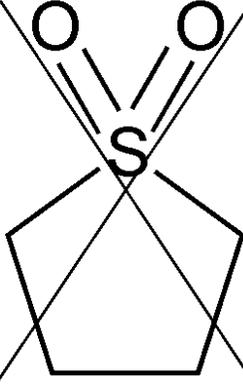

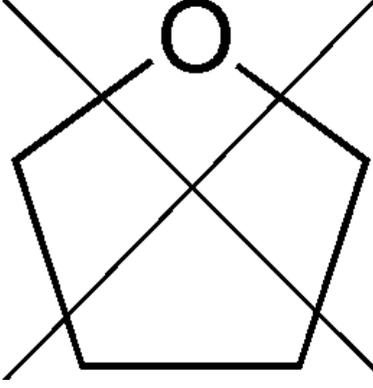

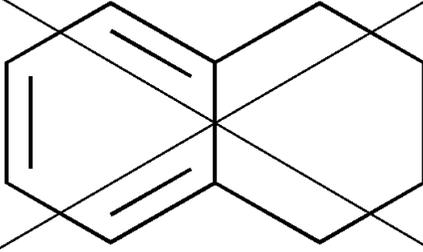

Solvent	Other Names	Structure	Class
Anisole	Methoxybenzene		Class-3
Benzene	Benzol		Class-1
1-Butanol	<i>n</i> -Butyl alcohol Butan-1-ol	$\text{CH}_3(\text{CH}_2)_3\text{OH}$	Class-3
2-Butanol	<i>sec</i> -Butyl alcohol Butan-2-ol	$\text{CH}_3\text{CH}_2\text{CH}(\text{OH})\text{CH}_3$	Class-3
Butyl acetate	Acetic acid butyl ester	$\text{CH}_3\text{COO}(\text{CH}_2)_3\text{CH}_3$	Class-3
<i>tert</i> -Butylmethyl ether	2-Methoxy-2-methylpropane	$(\text{CH}_3)_3\text{COCH}_3$	Class-3
Carbon tetrachloride	Tetrachloromethane	CCl_4	Class-1
Chlorobenzene	-		Class-2
Chloroform	Trichloromethane	CHCl_3	Class-2
* Usually 60% <i>m</i> -xylene, 14% <i>p</i> -xylene, 9% <i>o</i> -xylene with 17% ethyl benzene.			

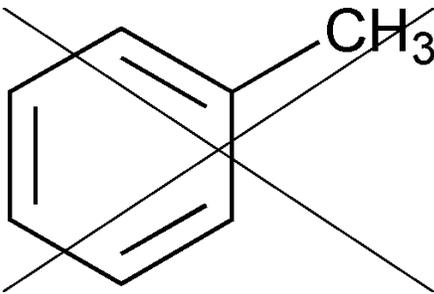

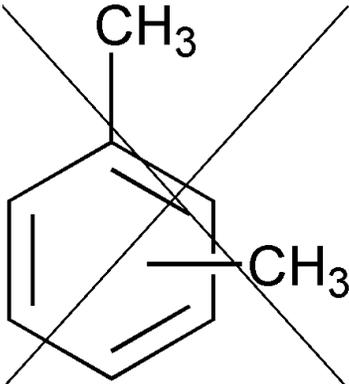

Solvent	Other Names	Structure	Class
Cumene	Isopropylbenzene (1-Methylethyl)benzene		Class-2
Cyclohexane	Hexamethylene		Class-2
1,2-Dichloroethane	<i>sym</i> -Dichloroethane Ethylene dichloride Ethylene chloride	$\text{CH}_2\text{ClCH}_2\text{Cl}$	Class-1
1,1-Dichloroethene	1,1-Dichloroethylene Vinylidene chloride	$\text{H}_2\text{C}=\text{CCl}_2$	Class-1
1,2-Dichloroethene	1,2-Dichloroethylene Acetylene dichloride	$\text{ClHC}=\text{CHCl}$	Class-2
1,2-Dimethoxyethane	Ethyleneglycol dimethyl ether Monoglyme Dimethyl cellosolve	$\text{H}_3\text{COCH}_2\text{CH}_2\text{OCH}_3$	Class-2
<i>N,N</i> -Dimethylacetamide	DMA	$\text{CH}_3\text{CON}(\text{CH}_3)_2$	Class-2
<i>N,N</i> -Dimethylformamide	dimethylformamide	$\text{HCON}(\text{CH}_3)_2$	Class-2
* Usually 60% <i>m</i> -xylene, 14% <i>p</i> -xylene, 9% <i>o</i> -xylene with 17% ethyl benzene.			

Solvent	Other Names	Structure	Class
Dimethyl sulfoxide	Methylsulfinylmethane Methyl sulfoxide dimethyl sulfoxide	$(\text{CH}_3)_2\text{SO}$	Class-3
1,4-Dioxane	<i>p</i> -Dioxane [1,4]Dioxane		Class-2
Ethanol	Ethyl alcohol	$\text{CH}_3\text{CH}_2\text{OH}$	Class-3
2-Ethoxyethanol	Cellosolve	$\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_2\text{OH}$	Class-2
Ethyl acetate	Acetic acid ethyl ester	$\text{CH}_3\text{COOCH}_2\text{CH}_3$	Class-3
Ethylene glycol	1,2-Dihydroxyethane 1,2-Ethanediol	$\text{HOCH}_2\text{CH}_2\text{OH}$	Class-2
Ethyl ether	Diethyl ether Ethoxyethane 1,1'-Oxybisethane	$\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3$	Class-3
Ethyl formate	Formic acid ethyl ester	$\text{HCOOCH}_2\text{CH}_3$	Class-3
Formamide	Methanamide	HCONH_2	Class-2
Formic acid	-	HCOOH	Class-3
Heptane	<i>n</i> -Heptane	$\text{CH}_3(\text{CH}_2)_5\text{CH}_3$	Class-3
Hexane	<i>n</i> -Hexane	$\text{CH}_3(\text{CH}_2)_4\text{CH}_3$	Class-2
Isobutyl acetate	Acetic acid isobutyl ester	$\text{CH}_3\text{COOCH}_2\text{CH}(\text{CH}_3)_2$	Class-3
Isopropyl acetate	Acetic acid isopropyl ester	$\text{CH}_3\text{COOCH}(\text{CH}_3)_2$	Class-3
Methanol	Methyl alcohol	CH_3OH	Class-2
2-Methoxyethanol	Methyl cellosolve	$\text{CH}_3\text{OCH}_2\text{CH}_2\text{OH}$	Class-2
Methyl acetate	Acetic acid methyl ester	$\text{CH}_3\text{COOCH}_3$	Class-3
3-Methyl-1-butanol	Isoamyl alcohol Isopentyl alcohol 3-Methylbutan-1-ol	$(\text{CH}_3)_2\text{CHCH}_2\text{CH}_2\text{OH}$	Class-3
Methylbutylketone	2-Hexanone Hexan-2-one	$\text{CH}_3(\text{CH}_2)_3\text{COCH}_3$	Class-2

* Usually 60% *m*-xylene, 14% *p*-xylene, 9% *o*-xylene with 17% ethyl benzene.

Solvent	Other Names	Structure	Class
Methylcyclohexane	Cyclohexylmethane		Class-2
Methylene chloride	Dichloromethane	CH_2Cl_2	Class-2
Methylethylketone	2-Butanone MEK Butan-2-one	$\text{CH}_3\text{CH}_2\text{COCH}_3$	Class-3
Methyl isobutyl ketone	4-Methylpentan-2-one 4-Methyl-2-pentanone MIBK	$\text{CH}_3\text{COCH}_2\text{CH}(\text{CH}_3)_2$	Class-3
2-Methyl-1-propanol	Isobutyl alcohol 2-Methylpropan-1-ol	$(\text{CH}_3)_2\text{CHCH}_2\text{OH}$	Class-3
<i>N</i> -Methylpyrrolidone	1-Methylpyrrolidin-2-one 1-Methyl-2-pyrrolidinone		Class-2
Nitromethane	-	CH_3NO_2	Class-2
Pentane	<i>n</i> -Pentane	$\text{CH}_3(\text{CH}_2)_3\text{CH}_3$	Class-3
1-Pentanol	Amyl alcohol Pentan-1-ol Pentyl alcohol	$\text{CH}_3(\text{CH}_2)_3\text{CH}_2\text{OH}$	Class-3
1-Propanol	Propan-1-ol Propyl alcohol	$\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$	Class-3
2-Propanol	Propan-2-ol Isopropyl alcohol	$(\text{CH}_3)_2\text{CHOH}$	Class-3
Propyl acetate	Acetic acid propyl ester	$\text{CH}_3\text{COOCH}_2\text{CH}_2\text{CH}_3$	Class-3
* Usually 60% <i>m</i> -xylene, 14% <i>p</i> -xylene, 9% <i>o</i> -xylene with 17% ethyl benzene.			

Solvent	Other Names	Structure	Class
Pyridine	-		Class-2
Sulfolane	Tetrahydrothiophene 1,1-dioxide		Class-2
Tetrahydrofuran	Tetramethylene oxide Oxacyclopentane		Class-2
Tetralin	1,2,3,4- Tetrahydronaphthalene		Class-2
<p>* Usually 60% <i>m</i>-xylene, 14% <i>p</i>-xylene, 9% <i>o</i>-xylene with 17% ethyl benzene.</p>			

Solvent	Other Names	Structure	Class
Toluene	Methylbenzene		Class-2
1,1,1-Trichloroethane	Methylchloroform	CH_3CCl_3	Class-1
Trichloroethylene	1,1,2-Trichloroethene	$\text{HC}(\text{Cl})=\text{CCl}_2$	Class-2
Xylene*	Dimethylbenzene Xylol		Class-2
* Usually 60% <i>m</i> -xylene, 14% <i>p</i> -xylene, 9% <i>o</i> -xylene with 17% ethyl benzene.			

APPENDIX 2. ADDITIONAL BACKGROUND

A2.1. Environmental Regulation of Organic Volatile Solvents

Several of the residual solvents frequently used in the production of pharmaceuticals are listed as toxic chemicals in *Environmental Health Criteria* (EHC) monographs and in the Integrated Risk Information System (IRIS). The objectives of such groups as the International Programme on Chemical Safety (IPCS), the United States Environmental Protection Agency (EPA), and the United States Food and Drug Administration (FDA) include the determination of acceptable exposure levels. The goal is maintenance of environmental integrity and protection of human health against the possible deleterious effects of chemicals resulting from long-term environmental exposure. The procedures involved in the estimation of maximum safe exposure limits are usually based on long-term studies. When long-term study data are unavailable, shorter-term study data can be used with modification of the approach, such as use of larger safety factors. The approach described therein relates primarily to long-term or lifetime exposure of the general population in the ambient environment (i.e., ambient air, food, drinking water, and other media).

A2.2. Residual Solvents in Pharmaceuticals

Exposure limits in this general chapter are established by referring to methodologies and toxicity data described in EHC and IRIS monographs. However, the following specific assumptions about residual solvents to be used in the synthesis and formulation of pharmaceutical products should be taken into account in establishing exposure limits.

1. Patients (not the general population) use pharmaceuticals to treat their diseases or for prophylaxis to prevent infection or disease.
2. The assumption of lifetime patient exposure is not necessary for most pharmaceutical products but may be appropriate as a working hypothesis to reduce risk to human health.
3. Residual solvents are unavoidable components in pharmaceutical production and will often be a part of medicinal products.
4. Residual solvents should not exceed recommended levels except in exceptional circumstances.
5. Data from toxicological studies that are used to determine acceptable levels for residual solvents should have been generated using appropriate protocols such as those described, for example, by the Organization for Economic Cooperation and Development (OECD), EPA, and the FDA *Red Book*.

APPENDIX 3. PROCEDURES FOR ESTABLISHING EXPOSURE LIMITS

The Gaylor-Kodell method of risk assessment (Gaylor, D.W., and Kodell, R.L. Linear Interpolation Algorithm for Low Dose Assessment of Toxic Substance. *Journal of Environmental Pathology and Toxicology*, 4:305, 1980) is appropriate for Class 1 carcinogenic solvents. Only in cases where reliable carcinogenicity data are available should extrapolation by the use of mathematical models be applied to setting exposure limits. Exposure limits for Class 1 residual solvents could be determined with the use of a large safety factor (i.e., 10,000 to 100,000) with respect to the no-observed-effect level (NOEL). Detection and quantification of these residual solvents should be performed by state-of-the-art analytical techniques.

Acceptable exposure levels in this general chapter for Class 2 residual solvents were established by calculation of PDE values according to the procedures for setting exposure limits in pharmaceuticals (page 5748 of *PF 15(6)* [Nov.-Dec. 1989]), and the method adopted by IPCS for Assessing Human Health Risk of Chemicals (*Environmental Health Criteria 170*, WHO, 1994). These procedures are similar to those used by the U.S. EPA (IRIS) and the U.S. FDA (*Red Book*) and others. The method is outlined here to give a better understanding of the origin of the PDE values. It is not necessary to perform these calculations in order to use the PDE values presented in *Table 2* of this document.

PDE is derived from the no-observed-effect level (NOEL), or the lowest-observed-effect level (LOEL), in the most relevant animal study as follows:

$$\text{PDE} = (\text{NOEL} \times \text{Weight Adjustment}) / (\text{F1} \times \text{F2} \times \text{F3} \times \text{F4} \times \text{F5}) \quad (1)$$

The PDE is derived preferably from a NOEL. If no NOEL is obtained, the LOEL may be used. Modifying factors proposed here, for relating the data to humans, are the same kind of "uncertainty factors" used in *Environmental Health Criteria* (*Environmental Health Criteria 170*, WHO, Geneva, 1994) and "modifying factors" or "safety factors" in *Pharmacopoeial Forum*. The assumption of 100 percent systemic exposure is used in all calculations regardless of route

of administration.

The modifying factors are as follows:

F1 =	A factor to account for extrapolation between species	
-	F1 =	2 for extrapolation from dogs to humans
-	F1 =	2.5 for extrapolation from rabbits to humans
-	F1 =	3 for extrapolation from monkeys to humans
-	F1 =	5 for extrapolation from rats to humans
-	F1 =	10 for extrapolation from other animals to humans
-	F1 =	12 for extrapolation from mice to humans

F1 takes into account the comparative surface area to body weight ratios for the species concerned and for man. Surface area (S) is calculated as:

$$S = kM^{0.67} \text{---} (2)$$

in which M = body weight, and the constant k has been taken to be 10. The body weights used in the equation are those shown below in Table A3.1.

F2 =	A factor of 10 to account for variability between individuals. A factor of 10 is generally given for all organic solvents, and 10 is used consistently in this general chapter.
------	---

F3 =	A variable factor to account for toxicity studies of short-term exposure	
-	F3 =	1 for studies that last at least one half-lifetime (1 year for rodents or rabbits; 7 years for cats, dogs, and monkeys)
-	F3 =	1 for reproductive studies in which the whole period of organogenesis is covered
-	F3 =	2 for a 6-month study in rodents, or a 3.5-year study in nonrodents
-	F3 =	5 for a 3-month study in rodents, or a 2-year study in nonrodents
-	F3 =	10 for studies of a shorter duration

In all cases, the higher factor has been used for study durations between the time points (e.g., a factor of 2 for a 9-month rodent study).

F4 =	A factor that may be applied in cases of severe toxicity, e.g., nongenotoxic carcinogenicity, neurotoxicity, or teratogenicity. In studies of reproductive toxicity, the following factors are used:	
-	F4 =	1 for fetal toxicity associated with maternal toxicity
-	F4 =	5 for fetal toxicity without maternal toxicity
-	F4 =	5 for a teratogenic effect with maternal toxicity
-	F4 =	10 for a teratogenic effect without maternal toxicity

F5 =	A variable factor that may be applied if the no-effect level was not established
------	--

When only a LOEL is available, a factor of up to 10 can be used, depending on the severity of

the toxicity. The weight adjustment assumes an arbitrary adult human body weight for either sex of 50 kilograms (kg). This relatively low weight provides an additional safety factor against the standard weights of 60 kg or 70 kg that are often used in this type of calculation. It is recognized that some adult patients weigh less than 50 kg; these patients are considered to be accommodated by the built-in safety factors used to determine a PDE. If the solvent was present in a formulation specifically intended for pediatric use, an adjustment for a lower body weight would be appropriate.

As an example of the application of this equation, consider a toxicity study of acetonitrile in mice that is summarized in *Pharmeuropa*, Vol. 9, No. 1, Supplement, April 1997, page S24. The NOEL is calculated to be $50.7 \text{ mg kg}^{-1} \text{ day}^{-1}$. The PDE for acetonitrile in this study is calculated as follows:

$$\text{PDE} = (50.7 \text{ mg kg}^{-1} \text{ day}^{-1} \times 50 \text{ kg}) / (12 \times 10 \times 5 \times 1 \times 1) = 4.22 \text{ mg day}^{-1}$$

In this example,

F1 =	12 to account for the extrapolation from mice to humans
F2 =	10 to account for differences between individual humans
F3 =	5 because the duration of the study was only 13 weeks
F4 =	1 because no severe toxicity was encountered
F5 =	1 because the no-effect level was determined

A3.1. Values Used in the Calculations in This Document

Rat body weight	425 g
Pregnant rat body weight	330 g
Mouse body weight	28 g
Pregnant mouse body weight	30 g
Guinea pig body weight	500 g
Rhesus monkey body weight	2.5 kg
Rabbit body weight (pregnant or not)	4 kg
Beagle dog body weight	11.5 kg
Rat respiratory volume	290 L/day
Mouse respiratory volume	43 L/day
Rabbit respiratory volume	1440 L/day
Guinea pig respiratory volume	430 L/day
Human respiratory volume	28,800 L/day
Dog respiratory volume	9000 L/day
Monkey respiratory volume	1150 L/day
Mouse water consumption	5 mL/day
Rat water consumption	30 mL/day
Rat food consumption	30 g/day

The equation for an ideal gas, $PV = nRT$, is used to convert concentrations of gases used in inhalation studies from units of ppm to units of mg/L or mg/m^3 . Consider as an example the rat reproductive toxicity study by inhalation of carbon tetrachloride (molecular weight 153.84)

summarized in *Pharmeuropa*, Vol. 9, No. 1, Supplement, April 1997, page S9.

$$\frac{n}{V} = \frac{P}{RT} = \frac{300 \times 10^{-6} \text{ atm} \times 153\,840 \text{ mg mol}^{-1}}{0.082 \text{ L at mK}^{-1} \text{ mol}^{-1} \times 298 \text{ K}} = \frac{46.15 \text{ mg}}{24.45 \text{ L}} = 1.89 \text{ mg/L}$$

The relationship $1000 \text{ L} = 1 \text{ m}^3$ is used to convert to mg/m^3 .

INTRODUCTION

For pharmacopeial purposes, residual solvents in pharmaceuticals are defined as organic volatile chemicals that are used or produced in the manufacturing of drug substances, excipients, or dietary supplement ingredients, or in the preparation of drug products or dietary supplement products. Appropriate selection of the solvent for the synthesis of a drug substance or an excipient may enhance the yield or determine characteristics such as crystal form, purity, and solubility. Therefore, the solvent may sometimes be a critical element in the synthetic process and may not be completely removed by the manufacturing process. Because residual solvents do not provide therapeutic benefit, they should be removed, to the extent possible, to meet safety-based limits, ingredient and product specifications, good manufacturing practices, or other quality-based requirements.

The objective of this general chapter is to define acceptable amounts of residual solvents in pharmaceutical drug products and dietary supplement products for the safety of the patient. Tests for residual solvents are not generally mentioned in specific monographs because the solvents used may vary from one manufacturer to another; however, the limits to be applied must comply with those specified in this general chapter.

This general chapter provides procedures for the analysis of residual solvents, although alternative validated methodologies may also be used to demonstrate compliance with the defined limits. The general chapter also defines requirements for the verification of USP procedures and validation requirements for alternative test methodologies.

This general chapter does not address solvents deliberately used as excipients, nor does it address solvates. However, the content of solvents in such products should be evaluated and justified. The limits specified in this general chapter do not apply directly to excipients and drug substances, except where specified in the individual monographs. However, residual solvent levels present in drug substances and excipients may be used to demonstrate compliance as an integral part of the control strategy, thereby reducing or eliminating the need for analysis in the product (see *Control Strategy*).

Throughout this general chapter, the term "likely to be present" (LTBP) refers to 1) solvents used or produced in the final manufacturing step; 2) solvents used or produced in earlier manufacturing steps that are not consistently removed by a validated process; and 3) solvents properly declared by a validated supplier of a drug substance or excipient.

CLASSIFICATION OF RESIDUAL SOLVENTS BY RISK ASSESSMENT

Residual solvents assessed in this general chapter are listed in *Appendix 1* by common names and structures. These solvents were evaluated for their possible risk to human health and placed into one of three classes based on their toxicity data and their environmental impact.

The USP is aligned with the ICH Q3C approach for the classification of residual solvents (see *Appendix 2* for additional details). The three classes of residual solvents are as follows.

Residual Solvent Class	Assessment
Class 1 (Solvents to be avoided)	Known human carcinogens
	Strongly suspected human carcinogens
	Solvents particularly known to have ozone-depleting properties
Class 2 (Solvents to be limited)	Nongenotoxic animal carcinogens or possible causative agents of other irreversible toxicity, such as neurotoxicity or teratogenicity
	Solvents suspected of other significant but reversible toxicities
Class 3 (Solvents with low toxic potential)	Solvents with low toxic potential to humans; no health-based exposure limit is needed

The limits for Class 2 solvents are based on the toxicological permitted daily exposure (PDE), calculated as defined in *Appendix 3*, whereas Class 3 solvents are considered less toxic, and control to 50 mg/day or less for each of these solvents is acceptable without justification. The lists in this chapter are not exhaustive and subject to revision. For solvents not listed, *Appendix 3* may be used to define PDE limits if sufficient toxicological data are available.

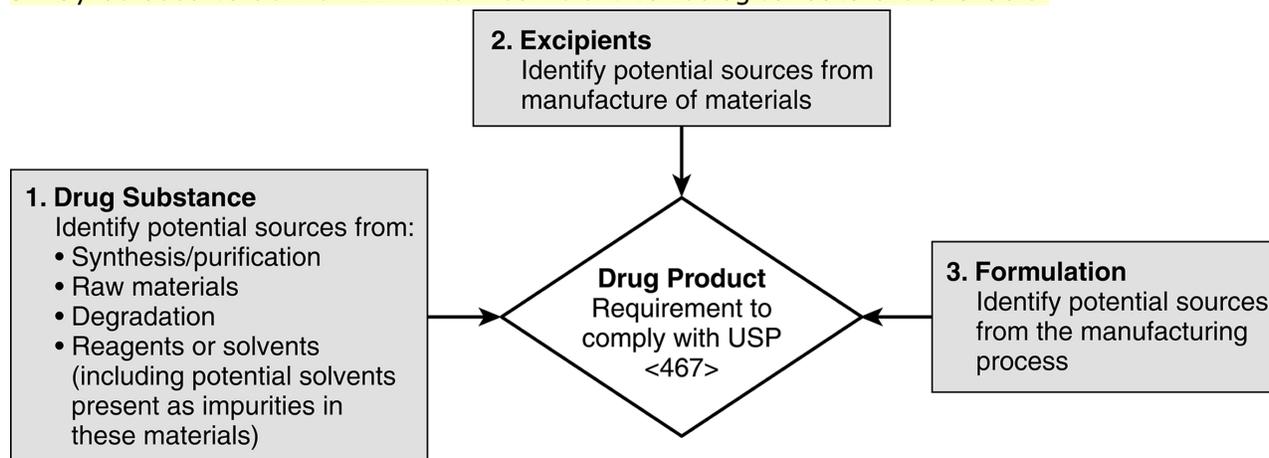

Figure 1. Potential sources of residual solvents in pharmaceutical drug products and dietary supplements.

There are three potential sources of residual solvents in the pharmaceutical drug product that should be considered (see *Figure 1*):

1. Drug substance

Potential sources of solvents include their use or formation during the synthesis or purification of the drug substance; their presence in raw materials or reagents used in their synthesis; or degradation of the drug substance.

2. Excipients

Potential solvent sources include their use or formation during the manufacture or

purification of excipients.

3. Formulation

Potential solvent sources are associated with their use or formation during the drug product manufacturing process.

If solvents are used during production, they must be of suitable quality. In addition, the potential presence of other solvents as impurities must be taken into consideration in the assessment of solvents LTBP. Because of the high toxicity of benzene and other Class 1 solvents, all likely sources of these solvents must be considered. For example, potential sources of benzene may include its presence as an impurity in a solvent used in the manufacturing process; its use in the manufacture of starting material; or its production as a reaction by-product. In the event that the user has insufficient information to complete a thorough assessment of the potential sources of residual solvents or as an alternative to performing this assessment, solvent screening may be used (see *Analytical Procedures*).

Pharmaceutical drug products and dietary supplement products should contain no higher levels of residual solvents than can be supported by safety data. All solvents included in this general chapter are listed in *Appendix 1*. Those solvents that show toxicity of special concern or carcinogenicity, and/or atmospheric ozone-depletion (Class 1, *Table 1*), should be avoided in the production of drug substances, dietary supplement ingredients, excipients, or pharmaceutical drug products/dietary supplement products unless their use can be strongly justified in a risk-benefit assessment. Those solvents associated with less severe but still significant toxicity (Class 2, *Table 2*) should be limited to protect patients from potential adverse effects. Whenever it is practicable, less toxic solvents (Class 3, *Table 3*) should be used. For the purposes of this pharmacopeia, when a manufacturer has received approval from a regulatory authority for the use of a solvent not currently listed in this general chapter, or for a level of a listed solvent higher than the limit currently given in the chapter, it is the responsibility of that manufacturer to notify USP of the identity and level of the solvent, and the appropriate test procedure. USP will then address the information in the individual monograph. A new solvent or revised limit that has been approved through the ICH process will be added to the appropriate list in this general chapter. See *Appendix 2* for additional background information related to residual solvents.

CONTROL STRATEGY

The user may choose to demonstrate compliance with this general chapter by analysis for residual solvents in the drug product or by analysis of the drug product components. These control strategy options are presented in *Figure 2*.

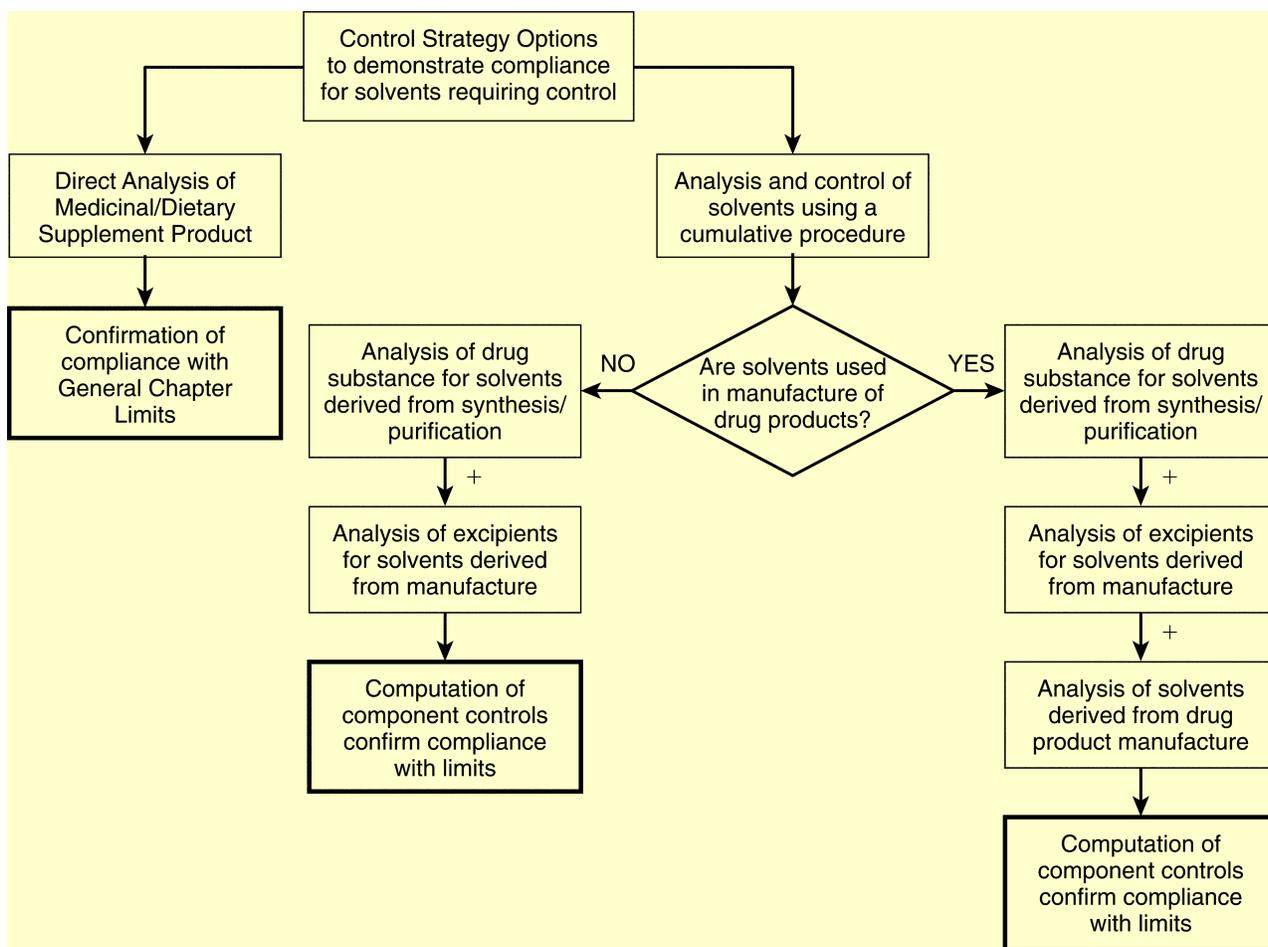

Figure 2. Control strategy options. If analysis of the drug product is needed because solvents are used in the manufacturing process, then analysis of the drug substance and excipients is not needed, provided the solvents LTBP in the drug substance and excipients are included in the test for the drug product.

The following options are to be considered when designing the control strategy.

1. **Testing the drug product:** This approach is acceptable in all cases.
2. **Analysis of the drug product components and using a cumulative approach to determine the solvent content in the drug product:**
 - a. **If no solvents are used during the manufacture of the drug product,** use the cumulative approach to determine the solvent content in API and excipients to calculate solvent levels in the drug product.
 - b. **If solvent(s) are used during the manufacture of the drug product,** use a cumulative approach by analyzing product components [API, intermediate(s), excipients] with the understanding that the solvent content in the product or product intermediate(s) will be determined at the point of use via suitable in-process testing.

In all cases the solvent levels in the final drug product must not exceed the limits defined in the general chapter.

LIMITS OF RESIDUAL SOLVENTS

Class 1: Solvents to Be Avoided

Class 1 residual solvents (*Table 1*) should not be used in the manufacture of drug substances, excipients, or drug products because of their unacceptable toxicities or deleterious environmental effects. However, if their use in order to produce a pharmaceutical drug product with a significant therapeutic advance is unavoidable, their levels should be restricted as shown in *Table 1*, unless otherwise stated in the individual monograph. The solvent 1,1,1-trichloroethane is included in *Table 1* because it is a severe environmental hazard. The stated limit of 1500 ppm is based on a review of safety data.

The procedures described in *Identification, Control, and Quantification of Residual Solvents* in this general chapter are to be applied wherever possible. Otherwise an appropriate validated procedure is to be used.

**Table 1. Control Limits for Class 1 Residual Solvents in Pharmaceutical Products:
Solvents to Be Avoided**

Solvent	Concentration Limit (ppm)	Concern
Benzene	2	Carcinogen
Carbon tetrachloride	4	Toxic and environmental hazard
1,2-Dichloroethane	5	Toxic
1,1-Dichloroethene	8	Toxic
1,1,1-Trichloroethane	1500	Environmental hazard

Class 2: Solvents to Be Limited

Class 2 residual solvents (*Table 2*) should be limited in drug substances, excipients, and drug products because of the inherent toxicities of these residual solvents. PDEs are given to the nearest 0.1 mg/day, and concentrations are given to the nearest 10 ppm. The method used to establish PDEs for residual solvents is presented in *Appendix 3*.

Table 2. Class 2 Residual Solvents

Solvent	PDE (mg/day)	Concentration Limit (ppm)
Acetonitrile	4.1	410
Chlorobenzene	3.6	360
Chloroform	0.6	60
Cumene	0.7	70
Cyclohexane	38.8	3880
1,2-Dichloroethene	18.7	1870
1,2-Dimethoxyethane	1.0	100
<i>N,N</i> -Dimethylacetamide	10.9	1090
<i>N,N</i> -Dimethylformamide	8.8	880
1,4-Dioxane	3.8	380
2-Ethoxyethanol	1.6	160
Ethylene glycol	6.2	620
Formamide	2.2	220
Hexane	2.9	290
Methanol	30.0	3000
2-Methoxyethanol	0.5	50
Methylbutylketone	0.5	50
Methylcyclohexane	11.8	1180
Methylene chloride	6.0	600
<i>N</i> -Methylpyrrolidone	5.3	530
Nitromethane	0.5	50
Pyridine	2.0	200
Sulfolane	1.6	160
Tetrahydrofuran	7.2	720
Tetralin	1.0	100
Toluene	8.9	890
Trichloroethylene	0.8	80
Xylene ^a	21.7	2170

^a Usually 60% *m*-xylene, 14% *p*-xylene, and 9% *o*-xylene with 17% ethyl benzene.

Class 3: Solvents with Low Toxic Potential

Class 3 solvents (*Table 3*) are regarded as less toxic and of lower risk to human health than Class 1 and Class 2 residual solvents. Class 3 includes no solvent known to be a human health hazard at levels normally accepted in pharmaceuticals. However, there are no long-term toxicity or carcinogenicity studies for many of the residual solvents in Class 3. Available data indicate that they are less toxic in acute or short-term studies and negative in genotoxicity studies.

It is considered that amounts of these residual solvents of 50 mg/day or less (corresponding to 5000 ppm or 0.5% in *Option 1* which is described below) would be acceptable for each solvent without justification. Higher amounts may also be acceptable, provided that they are realistic in

relation to manufacturing capability and good manufacturing practice. If a Class 3 solvent limit in an individual monograph is greater than 0.5%, that residual solvent should be identified and quantified. The procedures described in *Identification, Control, and Quantification of Residual Solvents* in this general chapter, with appropriate modifications to the standard solutions, are to be applied wherever possible. Otherwise, an appropriate validated procedure is to be used.

Table 3. Class 3 Residual Solvents

Acetic acid	Heptane
Acetone	Isobutyl acetate
Anisole	Isopropyl acetate
1-Butanol	Methyl acetate
2-Butanol	3-Methyl-1-butanol
Butyl acetate	Methylethylketone
<i>tert</i> -Butylmethyl ether	Methylisobutylketone
Dimethyl sulfoxide	2-Methyl-1-propanol
Ethanol	Pentane
Ethyl acetate	1-Pentanol
Ethyl ether	1-Propanol
Ethyl formate	2-Propanol
Formic acid	Propyl acetate

OPTIONS FOR DESCRIBING LIMITS FOR RESIDUAL SOLVENTS

Class 1 Solvents

All drug products must meet the concentration limits described in *Table 1*. If there are no other sources of Class 1 solvents during the drug product manufacturing process, compliance with the general chapter may be demonstrated by using a cumulative approach or by confirmation that the drug substance and excipients meet the concentration limit and no testing for these solvents in the drug product is necessary.

Class 2 and Class 3 Solvents

This general chapter provides two options for establishing compliance. Both *Option 1* and *Option 2* are based on the PDE.

Option 1

The concentration limits in ppm stated in *Table 2* for Class 2 solvents and the general requirement for Class 3 (5000 ppm) are used. They were calculated using the equation below by assuming a product weight of 10 g administered daily.

$$\text{Concentration (ppm)} = (1000 \mu\text{g/mg} \times \text{PDE})/\text{dose}$$

Here, PDE is given in terms of mg/day, and dose is given in g/day. These limits are considered acceptable for all drug substances, excipients, and drug products. Therefore, *Option 1* may be applied if the daily dose is not known or does not exceed 10 g. If all drug substances and excipients in a formulation meet the limits given in *Option 1*, these components may be used in any proportions. No further calculation is necessary, provided that the daily dose does not exceed 10 g. Products that are administered in doses greater than 10 g/day are to be

considered under *Option 2*.

Option 2

Option 2 uses the PDE and the actual maximum daily dose of the product to calculate solvent exposure and assess compliance.

Option 2 must be used to demonstrate compliance with the general chapter where the maximum daily dose of the drug product exceeds 10 g/day or where at least one component in the formulation exceeds the *Option 1* limits.

These limits are applied by adding the amounts of a residual solvent present in each of the components of the drug product. The contribution of each solvent per day should result in a total amount that does not exceed the PDE.

Consider the example of the application of *Option 1* and *Option 2* limits to acetonitrile concentration in a drug product. The PDE for acetonitrile is 4.1 mg/day, thus the *Option 1* limit is 410 ppm. The maximum administered daily mass of a drug product is 5.0 g, and the drug product contains two excipients. Assuming that there is no other source of acetonitrile in the manufacturing process, the calculated drug product content of acetonitrile and the daily exposure are given in *Table 4*.

Table 4

Component	Amount in Formulation (g)	Acetonitrile Content (ppm)	Daily Exposure (mg)
Drug substance	0.3	800	0.24
Excipient 1	0.9	400	0.36
Excipient 2	3.8	800	3.04
Drug product	5.0	728	3.64

Excipient 1 meets the *Option 1* limit, but the *Drug substance*, *Excipient 2*, and *Drug product* do not meet the *Option 1* limit. Nevertheless, the product meets the *Option 2* limit of 4.1 mg/day and thus conforms to the recommendations in this general chapter.

Consider another example using acetonitrile as a residual solvent. The maximum administered daily mass of a drug product is 5.0 g, and the drug product contains two excipients. Assuming no other source of acetonitrile in the manufacturing process, the *Drug product* content of acetonitrile and the maximum content of residual acetonitrile are given in *Table 5*.

Table 5

Component	Amount in Formulation (g)	Acetonitrile Content (ppm)	Daily Exposure (mg)
Drug substance	0.3	800	0.24
Excipient 1	0.9	2000	1.8
Excipient 2	3.8	800	3.04
Drug product	5.0	1016	5.08

In this example, the product meets neither the *Option 1* nor the *Option 2* limit according to the summation. Compliance with the general chapter may still be demonstrated via analysis of the *Drug product* as it is possible that the formulation process may have reduced the level of acetonitrile below the calculated content. If the level of acetonitrile was not reduced during

formulation to the allowed limit, then the manufacturer of the *Drug product* should take other steps to reduce the amount of acetonitrile in the drug product. If all of these steps fail to reduce the level of residual solvent, in exceptional cases the manufacturer could provide a summary of efforts made to reduce the solvent level to meet the guideline value and provide a risk benefit analysis to support allowing the product to be used with the residual solvent at a higher level.

REPORTING LEVELS OF RESIDUAL SOLVENTS

Manufacturers of pharmaceutical products need certain information about the content of residual solvents in drug substances and excipients to meet the criteria of this general chapter. The following statements are given as acceptable examples of the information that could be provided from a supplier of drug substances or excipients to a pharmaceutical manufacturer. The supplier might choose one of the following as appropriate:

- If Class 1 solvents are present, they should be identified and quantified.
- Only Class 3 solvents are LTBP. Loss on drying is less than 0.5%.
- Only Class 2 solvents X, Y,... are likely to be present. All are below the *Option 1* limit. (Here the supplier would name the Class 2 solvents represented by X, Y,...)
- Only Class 2 solvents X, Y,..., and Class 3 solvents are LTBP. Residual Class 2 solvents are below the *Option 1* limit and residual Class 3 solvents are below 0.5%.
- If other non-listed solvents are present, they should be identified and quantified.

The term LTBP as used in the above examples refers to the solvent used or produced in the final manufacturing step and to solvents used or produced in earlier manufacturing steps and not removed consistently by a validated process.

IDENTIFICATION, CONTROL, AND QUANTIFICATION OF RESIDUAL SOLVENTS

Whenever possible, the substance under test needs to be dissolved to release the residual solvent. The control strategy may involve analysis of drug products, active ingredients, and excipients and in some cases the sample does not dissolve completely. In these cases it may be acceptable to pulverize that sample into a fine powder carefully, avoiding the generation of frictional heat and in a manner to prevent the loss of volatile solvents. This operation assures that any residual solvent that may be present can be released. It should be performed as fast as possible immediately prior to dispersion in the sample solvent to prevent the loss of volatile solvents during the procedure.

[Note—The organic-free water specified in the following procedures produces no significantly interfering peaks when chromatographed.]

Class 1 and Class 2 Residual Solvents

The following procedures are recommended to identify and quantify the residual solvents that are listed in this chapter as Class 1 and Class 2 solvents and that may be present in drug substances, excipients, and drug products, with some exceptions disclosed below.

For each test matrix, verification is needed to demonstrate reliability of the compendial procedure, as described later in this chapter.

When the solvents that are present or potentially present in the sample are known, they may be determined using a limit test such as *Procedure A* and *Procedure B*, or by a quantitative test

such as *Procedure C*.

When the solvents LTBP are not known, use of the screening test of *Procedure A* and *Procedure B* is required. The combination of *Procedure A* and *Procedure B* can separate most of the solvents listed in this chapter. Additionally, *Figure 3* can be used as a decision tree to demonstrate compliance.

In a screening test, and in the case that the article does not meet the acceptance criteria of *Procedure A*, *Procedure B* is to be used to demonstrate compliance. If the article does not meet the criteria using *Procedure A* and *Procedure B*, then *Procedure C* must be used to quantify the residual solvent(s) present in the article.

When the information about solvents LTBP in the material is known through the knowledge of the process, previous testing, or the information provided from a validated vendor, only testing of those solvents is required. System suitability requirements only need to be demonstrated for the solvents expected to be present.

Several residual solvents listed in this chapter are not detected at the limit concentration using the analytical procedure described below. Those solvents include formamide, 2-ethoxyethanol, 2-methoxyethanol, ethylene glycol, *N*-methylpyrrolidone, sulfolane, *N,N*-dimethylacetamide, and *N,N*-dimethylformamide from Class 2, as well as dimethyl sulfoxide, acetic acid, and formic acid from Class 3.

Those solvents should be determined using an alternative method validated according to the procedures described in the *Verification and Validation* section of this chapter.

Class 3 Residual Solvents

These procedures can separate most solvents in Classes 1, 2, and 3. However, the procedures have not been validated for Class 3 solvents and validation will be required in accordance with the procedures described in *Figure 3* before implementation.

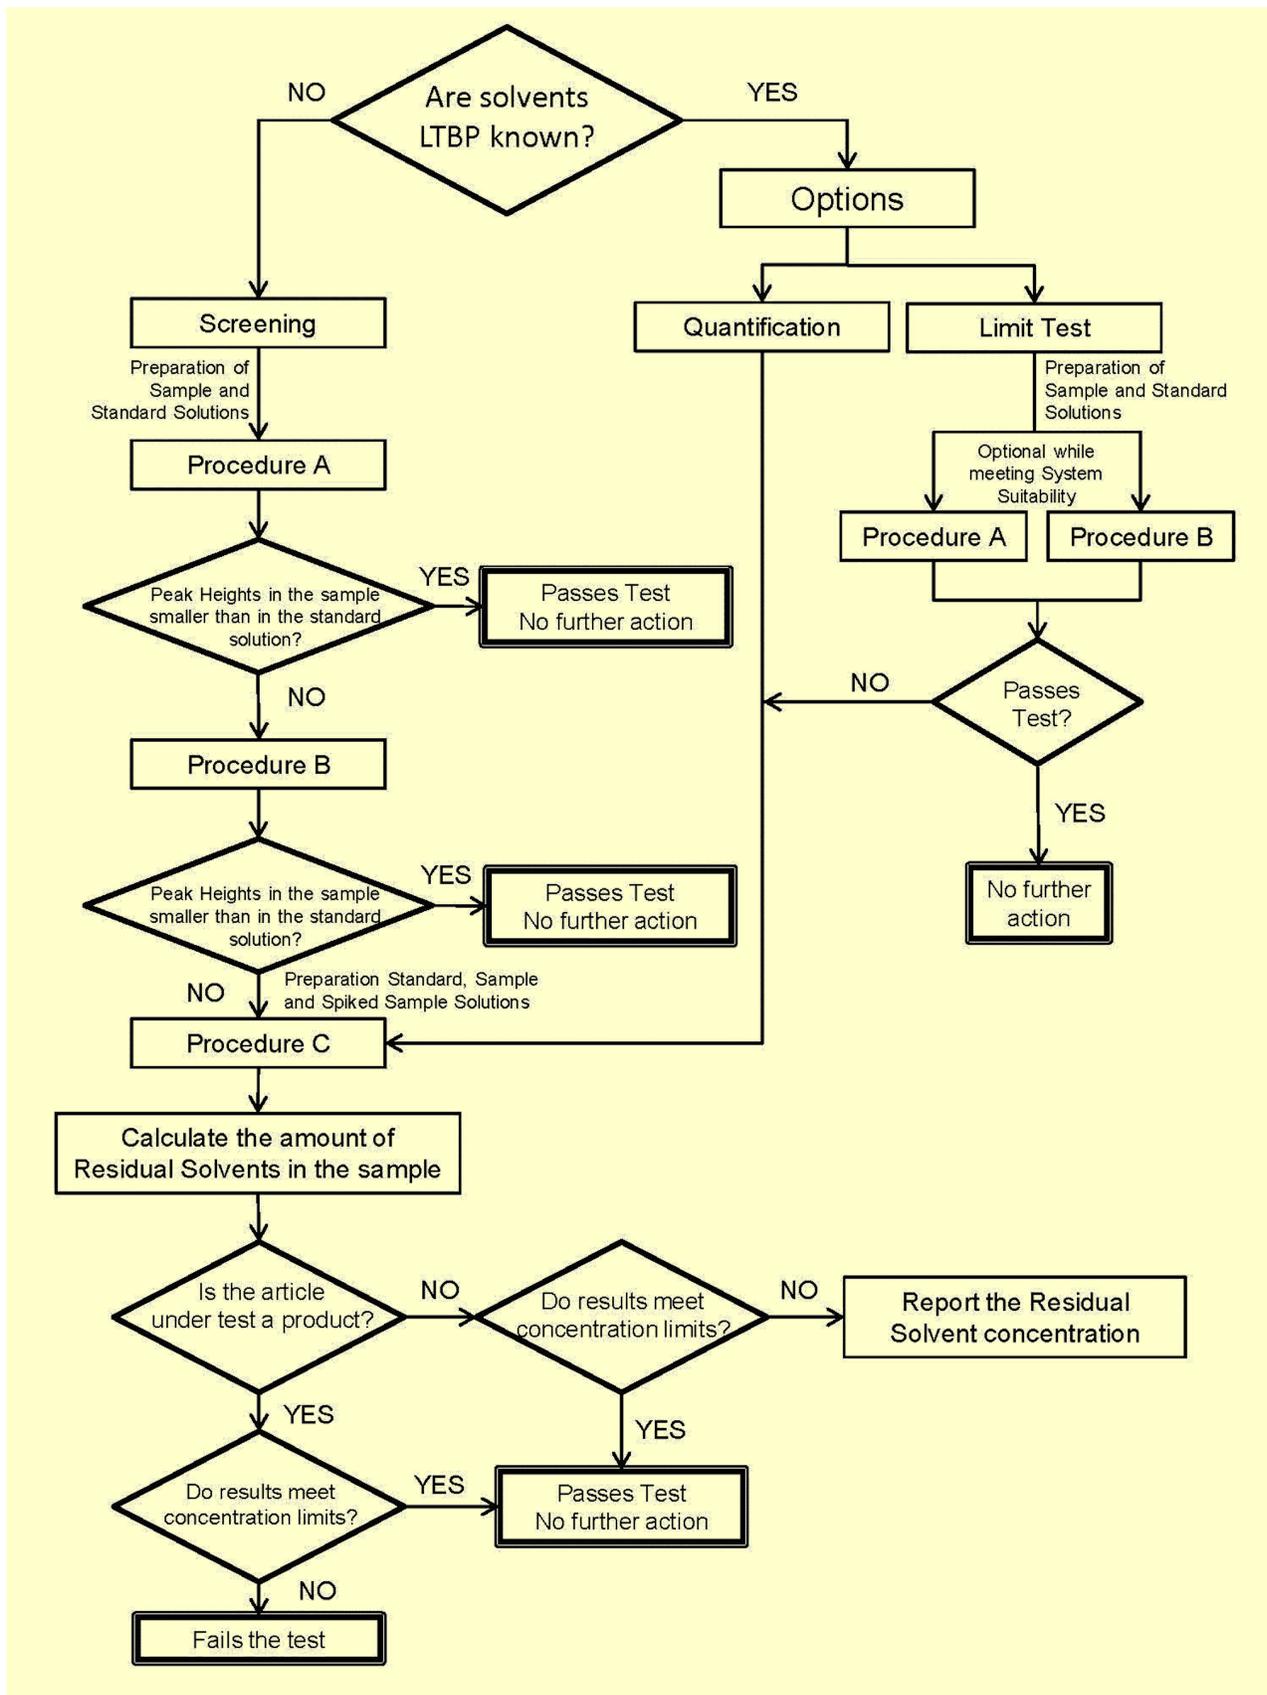

Figure 3. Determination of residual solvents and decision tree using Procedures A, B, and C.

ANALYTICAL PROCEDURES**Chromatographic systems**

(See *Chromatography (621), System Suitability.*)

Procedure A

Mode: GC

Injector: Headspace (see *Table 8* for headspace settings)

Injection type: Split

Split ratio: 1:5. [Note—Split ratio can be modified to optimize sensitivity.]

Detector: Flame ionization

Column: 0.32-mm × 30-m capillary fused silica coated with 1.8- μ m layer of phase *G43* or 0.53-mm × 30-m wide-bore coated with a 3.0- μ m layer of phase *G43*

Column temperature: See *Table 6*.

Table 6

Initial Temperature (°)	Temperature Ramp (°/min)	Final Temperature (°)	Hold Time at Final Temperature (min)
40	0	40	20
40	10	240	—
240	0	240	20

Temperatures

Injection port: 140°

Detector: 250°

Carrier gas: Helium, nitrogen, or hydrogen

Linear velocity: About 35 cm/s for helium (adjustment and verification are necessary for other carrier gases)

Procedure B

Mode: GC

Injector: Headspace (see *Table 8* for headspace settings)

Injection type: Split

Split ratio: 1:5. [Note—Split ratio can be modified to optimize sensitivity.]

Detector: Flame ionization

Column: 0.32-mm × 30-m fused-silica coated with a 0.25- μ m layer of phase *G16* or a 0.53-mm × 30-m wide-bore coated with a 0.25- μ m layer of phase *G16*

Column temperature: See *Table 7*.

Table 7

Initial Temperature (°)	Temperature Ramp (°/min)	Final Temperature (°)	Hold Time at Final Temperature (min)
50	0	50	20
50	6	165	—
165	0	165	20

Temperatures

Injection port: 140°

Detector: 250°

Carrier gas: Helium, nitrogen, or hydrogen

Linear velocity: About 35 cm/s for helium (adjustment and verification are necessary for other carrier gases)

Procedure C

Use the chromatographic conditions, either A or B that provide the best performance for the solvent(s) being tested.

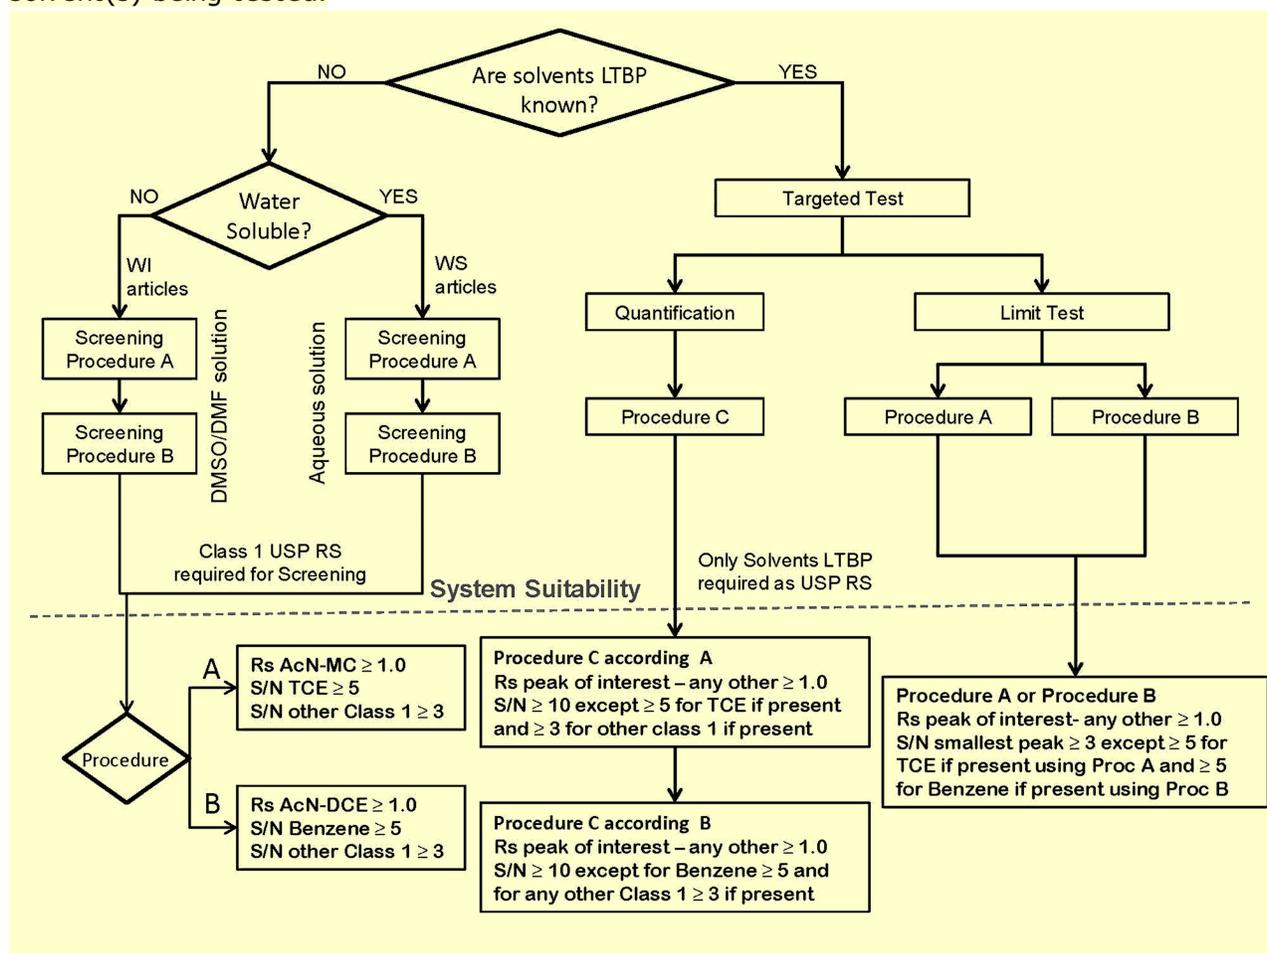

Figure 4. System suitability requirements based on the method of choice and previous

knowledge about solvents LTBP. The acceptance criteria are based on the solvents LTBP (AcN: acetonitrile, TCE: 1,1,1-trichloroethane, DCE: *cis*-dichloroethene, MC: methylene chloride).

SCREENING FOR WATER-SOLUBLE ARTICLES

Class 1 and Class 2 Residual Solvents

Stock solutions

Class 1 standard stock solution: [Note—When transferring solutions, place the tip of the pipet just below the surface of the liquid and mix.] Transfer 1.0 mL of USP Class 1 Residual Solvents Mixture RS to a 100-mL volumetric flask containing about 9 mL of dimethylsulfoxide, dilute with water to volume, and mix. Transfer 1.0 mL of this solution to a 100-mL volumetric flask containing about 50 mL of water, dilute with water to volume, and mix. Transfer 10 mL of this solution to a 100-mL volumetric flask containing about 50 mL of water, dilute with water to volume, and mix.

Class 2 mixture A standard stock solution: Transfer 1.0 mL of USP Residual Solvents Class 2–Mixture A RS to a 100-mL volumetric flask, dilute with water to volume, and mix.

Class 2 mixture B standard stock solution: Transfer 1.0 mL of USP Residual Solvents Class 2–Mixture B RS to a 100-mL volumetric flask, dilute with water to volume, and mix.

Sample stock solution: Transfer about 250 mg of the article under test, accurately weighed, to a 25-mL volumetric flask, dissolve in and dilute with water to volume, and mix.

Standard solutions

Class 1 standard solution: [Note—When transferring solutions, place the tip of the pipet just below the surface of the liquid and mix.] Transfer 1.0 mL of *Class 1 standard stock solution* to an appropriate headspace vial containing 5.0 mL of water. Apply the stopper, cap, and mix.

Class 2 mixture A standard solution: Transfer 1.0 mL of *Class 2 mixture A standard stock solution* to an appropriate headspace vial, add 5.0 mL of water, apply the stopper, cap, and mix.

Class 2 mixture B standard solution: Transfer 5.0 mL of *Class 2 mixture B standard stock solution* to an appropriate headspace vial, add 1.0 mL of water, apply the stopper, cap, and mix.

Sample solution: Transfer 5.0 mL of *Sample stock solution* to an appropriate headspace vial, add 1.0 mL of water, apply the stopper, cap, and mix.

Class 1 system suitability solution: Transfer 1.0 mL of *Class 1 standard stock solution* to an appropriate headspace vial, add 5.0 mL of *Sample stock solution*, apply the stopper, cap, and mix.

PROCEDURE A

Table 8. Headspace Operating Parameters

	Headspace Operating Parameter Sets		
	1	2	3
Equilibration temperature (°)	80	105	80
Equilibration time (min)	60	45	45
Transfer-line temperature (°) (if appropriate) ^a	85	110	105
Syringe temperature (°) (if appropriate)	80–90	105–115	80–90
Carrier gas: helium, nitrogen ^b or hydrogen ^b at an appropriate pressure			
Pressurization time (sec) (if appropriate)	≥60	≥60	≥60
Injection volume (mL) ^c	1	1	1
<p>^a It is recommended to increase the temperature of the transfer line between runs to eliminate any potential condensation of solvents.</p> <p>^b The use of nitrogen or hydrogen as the carrier gas requires adjustment and verification.</p> <p>^c Injection volume may be expressed in terms of the injection time.</p>			

Analysis: Separately inject (following one of the headspace operating parameter sets described in *Table 8*) equal volumes of headspace of the *Class 1 standard solution*, *Class 1 system suitability solution*, *Class 2 mixture A standard solution*, *Class 2 mixture B standard solution*, and *Sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.

System suitability requirements (see *Figure 4*): The signal-to-noise ratio (S/N) for 1,1,1-trichloroethane in the *Class 1 standard solution* is NLT 5. The S/N ratio of each peak in the *Class 1 system suitability solution* is NLT 3, and the resolution between acetonitrile and methylene chloride in the *Class 2 mixture A standard solution* is NLT 1.0.

Acceptance criteria: If a peak response of any peak, other than a peak for 1,1,1-trichloroethane, in the *Sample solution* is greater than or equal to a corresponding peak in either the *Class 1 standard solution* or either of the two *Class 2 mixture standard solutions*, or a peak response of 1,1,1-trichloroethane is greater than or equal to 150 times the peak response corresponding to 1,1,1-trichloroethane in the *Class 1 standard solution*, proceed to *Procedure B* to verify the identity of the peak; otherwise the article meets the requirements of this test.

PROCEDURE B

Analysis: Separately inject (following one of the headspace operating parameter sets described in *Table 8*) equal volumes of headspace of the *Class 1 standard solution*, *Class 1 system suitability solution*, *Class 2 mixture A standard solution*, *Class 2 mixture B standard solution*, and *Sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.

System suitability requirements (see *Figure 4*): The S/N ratio for benzene in the *Class 1 standard solution* is NLT 5. The S/N ratio of each peak in the *Class 1 system suitability solution* is NLT 3, and the resolution between acetonitrile and *cis*-dichloroethene in the *Class 2 mixture A standard solution* is NLT 1.0.

Acceptance criteria: If the peak response(s) in the *Sample solution* of the peak(s) identified in *Procedure A* is/are greater than or equal to corresponding peak(s) in either the *Class 1 standard solution* or either of the two *Class 2 mixture standard solutions*, proceed to *Procedure C* to quantify the peak(s); otherwise the article meets the requirements of this test.

SCREENING FOR WATER-INSOLUBLE ARTICLES

Stock solutions

[Note—Dimethyl sulfoxide may be substituted as an alternative solvent to dimethylformamide. When transferring solutions, place the tip of the pipet just below the surface of the liquid and mix.]

Class 1 standard stock solution: Transfer 1.0 mL of USP Class 1 Residual Solvents Mixture RS to a 100-mL volumetric flask previously filled with about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix. Transfer 1.0 mL of this solution to a 100-mL volumetric flask, previously filled with about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix (reserve a portion of this solution for the *Class 1 system suitability solution*). Transfer 1.0 mL of this solution to a 10-mL volumetric flask, dilute with dimethylformamide to volume, and mix.

Class 2 mixture A standard stock solution: Transfer 1.0 mL of USP Residual Solvents Class 2–Mixture A RS to a 100-mL volumetric flask containing about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix.

Class 2 mixture B standard stock solution: Transfer 0.5 mL of USP Residual Solvents Class 2–Mixture B RS to a 10-mL volumetric flask, dilute with dimethylformamide to volume, and mix.

Sample stock solution: Transfer about 500 mg of the article under test, accurately weighed, to a 10-mL volumetric flask, dissolve in and dilute to volume with dimethylformamide, and mix.

Class 1 system suitability solution: Mix 5 mL of *Sample stock solution* with 0.5 mL of the intermediate dilution reserved from *Class 1 standard stock solution*. Transfer 1 mL of this solution to an appropriate headspace vial containing 5 mL of water, apply the stopper, cap and mix.

Standard solutions

Class 1 standard solution: Transfer 1.0 mL of *Class 1 standard stock solution* to an appropriate headspace vial containing 5.0 mL of water; apply the stopper, cap, and mix.

Class 2 mixture A standard solution: Transfer 1.0 mL of *Class 2 mixture A standard stock solution* to an appropriate headspace vial containing 5.0 mL of water and 1.0 mL of dimethyl sulfoxide, apply the stopper, cap, and mix.

Class 2 mixture B standard solution: Transfer 1.0 mL of *Class 2 mixture B standard stock solution* to an appropriate headspace vial containing 5.0 mL of water, apply the stopper, cap, and mix.

Sample solution: Transfer 1.0 mL of *Sample stock solution* to an appropriate headspace vial containing 5.0 mL of water, apply the stopper, cap, and mix.

PROCEDURE A

Proceed as directed for *Procedure A* in *Screening for Water-Soluble Articles* with a split ratio of 1:3. [Note—The split ratio can be modified in order to optimize sensitivity.] Separately inject (following one of the headspace operating parameter sets described in *Table 8*) equal volumes of headspace of the *Class 1 standard solution*, *Class 2 mixture A standard solution*, *Class 2 mixture B standard solution*, and *Sample solution* into the chromatograph, record the chromatograms, and measure the responses for the major peaks.

System suitability requirements (see *Figure 4*): The S/N ratio for 1,1,1-trichloroethane in the *Class 1 standard solution* is NLT 5. The S/N ratio of each peak in the *Class 1 system suitability solution* is NLT 3; and the resolution between acetonitrile and methylene chloride in the *Class 2 mixture A standard solution* is NLT 1.0.

Acceptance criteria: If a peak response of any peak, other than a peak for TCE in the *Sample solution* is greater than or equal to a corresponding peak in either the *Class 1 standard solution* or either of the two *Class 2 mixture standard solutions*, or a peak response of 1,1,1-trichloroethane is greater than or equal to 150 times the peak response corresponding to 1,1,1-trichloroethane in the *Class 1 standard solution*, proceed to *Procedure B* to verify the identity of the peak; otherwise the article meets the requirements of this test.

PROCEDURE B

Proceed as directed for *Procedure B* in *Screening for Water-Soluble Articles* with a split ratio of 1:3. Separately inject (use headspace operating parameters in column 3 of *Table 8* with a vial pressure of 10 psi) equal volumes of headspace of the *Class 1 standard solution*, *Class 2 mixture A standard solution*, *Class 2 mixture B standard solution*, *Sample solution*, and *Class 1 system suitability solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.

System suitability requirements (see *Figure 4*): The S/N ratio for benzene in *Class 1 standard solution* is NLT 5. The S/N ratio of each peak in the *Class 1 system suitability solution* is NLT 3; and the resolution between acetonitrile and *cis*-dichloroethene in the *Class 2 mixture A standard solution* is NLT 1.0.

Acceptance criteria: If the peak response(s) in the *Sample solution* of the peak(s) identified in *Procedure A* is/are greater than or equal to corresponding peak(s) in either the *Class 1 standard solution* or either of the two *Class 2 mixture standard solutions*, proceed to *Procedure C* to quantify the peak(s); otherwise the article meets the requirements of this test.

CLASS 3 RESIDUAL SOLVENTS

If only Class 3 solvents are present and the monograph for the article under test contains a loss on drying procedure specifying an upper limit of NMT 0.5% (per *Option 1* in this general chapter), then the level of residual solvent can be determined as directed in *Loss on Drying* (731). Otherwise, the chromatographic procedure described previously or other properly validated procedure should be used. If Class 3 solvents are present with other solvents, e.g., Class 1 or Class 2 solvents, or if there is no loss on drying procedure in the monograph for the article under test, or if the limit for Class 3 solvent(s) in an individual monograph is greater than

50 mg/day (corresponding to 5000 ppm or 0.5% under *Option 1*), then the Class 3 residual solvent or solvents present in the article under test should be identified and quantified. In that case, the procedures described in this chapter, with appropriate adjustments, are to be applied wherever possible and USP Reference Standards, where available, should be used in these procedures. Such procedures should be properly validated as disclosed in the *Verification and Validation* section of this chapter. If Class 1 or Class 2 solvents are present and loss on drying is less than 0.5%, then identification of Class 3 solvents is not required and only Class 1 and Class 2 solvents should be identified and quantified.

LIMIT TESTS WHEN SOLVENTS LTBP ARE KNOWN

Prepare the *Standard solution* and the *Sample solution* as directed in *Procedure A* or *Procedure B*, in *Screening for Water-Soluble Articles* or *Screening for Water-Insoluble Articles* according to the procedure chosen based on the sample solubility. Use the USP Reference Standards of those solvents LTBP to prepare the *Standard solution*.

When solvents LTBP are known, only the standards of those solvents LTBP are needed, and determination may be done using a limit test or a quantitative test. Only quantitative tests can be used for *Option 2*.

System suitability solution: Prepare the *System suitability solution* for *Screening for Water-Soluble Articles* or for *Screening for Water-Insoluble Articles* according to the solubility of the sample, at the solvent concentration of the *Standard solution* in the screening test, using only those solvents LTBP.

PROCEDURE A

Analysis (limit test): Separately inject (following one of the headspace operating parameter sets described in *Table 8*) equal volumes of headspace of the *System suitability solution*, *Standard solution* and *Sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.

System suitability requirements (see *Figure 4*): The S/N ratio for 1,1,1-trichloroethane, if present, is NLT 5. The S/N ratio is NLT 3 for any other solvent. If there is more than one solvent LTBP, the resolution between a peak of interest and any adjacent peak is NLT 1.0.

Acceptance criteria: If the peak response of every peak of interest in the *Sample solution* is smaller than the corresponding peak in the *Standard solution*, the article meets the requirements of this test.

PROCEDURE B

Analysis (limit test): Separately inject (following one of the headspace operating parameter sets described in *Table 8*) equal volumes of headspace of the *Standard solution* and *Sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.

System suitability requirements (see *Figure 4*): The S/N ratio for benzene, if present, is NLT 5. The S/N ratio is NLT 3 for any other solvent. If there is more than one solvent LTBP, the resolution between a peak of interest and any other peak is NLT 1.0.

Acceptance criteria: If the peak response of every peak of interest in the *Sample solution* is smaller than the corresponding peak in the *Standard solution*, the article meets the requirements of this test.

QUANTITATIVE TESTS

Quantification for Water-Soluble Articles

Stock solutions

Prepare a *Sample stock solution* as directed in *Procedure A* for water-soluble articles. Only the Reference Standard for those solvents identified by *Procedure A* or *Procedure B* or LTBP need to be used.

Standard stock solution: [Note—Prepare a separate *Standard stock solution* for each solvent LTBP or potentially LTBP, or identified and verified by *Procedure A* and *Procedure B*. For the Class 1 solvents other than 1,1,1-trichloroethane, prepare the first dilution as directed for the first dilution under *Class 1 standard stock solution*.] Transfer an accurately measured volume of each individual USP Reference Standard corresponding to each residual solvent peak LTBP or identified and verified by *Procedure A* and *Procedure B* to a suitable container, and dilute quantitatively and stepwise if necessary, with water to obtain a solution with a final concentration of 1/20 of the value stated in *Table 1* or *Table 2* under *Concentration Limit*.

Standard solution: Transfer 1.0 mL of *Standard stock solution* to an appropriate headspace vial, add 5.0 mL of water, apply the stopper, cap, and mix.

Sample solution: Proceed as directed in *Procedure A*.

Spiked sample solution: [Note—Prepare a separate *Spiked sample solution* for each peak LTBP or potentially LTBP or identified and verified by *Procedure A* and *Procedure B*.] The use of vial containing the sample spiked with multiple standards is permitted, provided that the procedure is validated. Transfer 5.0 mL of each *Sample stock solution* to an appropriate headspace vial, add 1.0 mL of the *Standard stock solution*, apply the stopper, cap, and mix.

Analysis

Proceed as directed for *Procedure A*. [Note—If the performance of *Procedure B* is better than that shown by *Procedure A*, then *Procedure B* may be used for quantification.] Separately inject equal volumes of headspace of the *Standard solution*, *Sample solution*, and *Spiked sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest.

System suitability requirements (see *Figure 4*): The S/N ratio for 1,1,1-trichloroethane, if present, is NLT 5. The S/N ratio is NLT 3 for any other solvent. If there are more than one solvent LTBP, the resolution between a peak of interest and any adjacent peak is NLT 1.0.

Calculate the amount, in ppm, of each residual solvent found in the article under test:

$$\text{Result} = 5(C/W)[r_U/(r_{ST}-r_U)]$$

- C = concentration of the appropriate USP Reference Standard in the *Standard stock solution* ($\mu\text{g}/\text{mL}$)
- W = weight of the article under test taken to prepare the *Sample stock solution* (g)
- r_U = peak responses of each residual solvent obtained from the *Sample solution*

r_{ST} = peak responses of each residual solvent obtained from the *Spiked sample solution*

Quantification for Water-Insoluble Articles

Stock solutions

Prepare a *Sample stock solution* as directed in *Procedure A* for water-insoluble articles. Only the Reference Standard for those solvents LTBP need to be used.

Standard stock solution: [Note—Prepare a separate *Standard stock solution* for each solvent LTBP or potentially LTBP, or identified and verified by *Procedure A* and *Procedure B*. For the Class 1 solvents other than 1,1,1-trichloroethane, prepare the first dilution as directed for the first dilution under *Class 1 standard stock solution*.] Transfer an accurately measured volume of each individual USP Reference Standard corresponding to each residual solvent peak LTBP or identified and verified by *Procedure A* and *Procedure B* to a suitable container, and dilute quantitatively and stepwise if necessary, with water to obtain a solution with a final concentration of 1/20 of the value stated in *Table 1* or *Table 2* under *Concentration Limit*.

Standard solution: Transfer 1.0 mL of *Standard stock solution* to an appropriate headspace vial, add 5.0 mL of water, apply the stopper, cap, and mix.

Sample solution: Transfer 1.0 mL of *Standard stock solution* to an appropriate headspace vial containing 5.0 mL of water, apply the stopper, cap, and mix.

Spiked sample solution: [Note—Prepare a separate *Spiked sample solution* for each peak LTBP or potentially LTBP, or identified and verified by *Procedure A* and *Procedure B*.] Transfer 1.0 mL of *Sample stock solution* to an appropriate headspace vial, add 1.0 mL of *Standard stock solution* and 4.0 mL of water, apply the stopper, cap, and mix. The use of vial containing the sample spiked with multiple standards is permitted, provided that the procedure is validated.

PROCEDURE C

Proceed as directed in *Procedure A*. [Note—If the performance of *Procedure B* is better than that shown by *Procedure A*, then *Procedure B* may be used for quantification.] Separately inject (use headspace operating parameters in column 3 of *Table 8* with a vial pressure of 10 psi) equal volumes of headspace of the *Standard solution*, *Sample solution*, and *Spiked sample solution* into the chromatograph, record the chromatograms, and measure the responses for the peaks of interest. If Class 1 solvents are LTBP, also inject the *Class 1 system suitability solution*.

System suitability requirements (see *Figure 4*): The S/N ratio for 1,1,1-trichloroethane, if present, is NLT 5. The S/N ratio is NLT 3 for any other solvent. If there are more than one solvent LTBP, the resolution between a peak of interest and any adjacent peak is NLT 1.0.

Calculate the amount, in ppm, of each residual solvent found in the article under test:

$$\text{Result} = 10(C/W)[r_U/(r_{ST}-r_U)]$$

- C = concentration of the appropriate USP Reference Standard in the *Standard stock solution* ($\mu\text{g/mL}$)
- W = weight of the article under test taken to prepare the *Sample stock solution* (g)
- r_U = peak responses of each residual solvent obtained from the *Sample solution*
- r_{ST} = peak responses of each residual solvent obtained from the *Spiked sample solution*

VERIFICATION AND VALIDATION

Table 9. Summary of Verification and Validation: Requirements for Class 1 and 2 Solvents

Validation Characteristics	Verification of Compendial Procedure		Validation of Alternative Procedures	
	Limit Test Methods	Quantitative Methods	Limit Test Methods	Quantitative Methods
Specificity	Yes	Yes	Yes	Yes
Detectability	Yes	No	Yes	No
Ability to quantitate	No	Demonstrated by accuracy	No	Demonstrated by accuracy
Accuracy	No	Yes	No	Yes
Precision/repeatability	No	Yes	No	Yes
Linearity	No	Not required (implied by compendial Procedure)	No	Yes
Range	No	Demonstrated by accuracy	No	Demonstrated by accuracy
Ruggedness	No	No	No	Yes
Solution stability	Yes	Yes	Yes	Yes

Users of compendial analytical procedures should establish documented evidence that the method is suitable for its intended purpose under conditions of actual use. When using the procedures described in this chapter, verification can be accomplished using the recommendations below. There are separate recommendations for limit procedures (*Procedure A* and *Procedure B*) and quantitative procedures (*Procedure C*). These procedures have been validated for Class 1 and 2 solvents over the range of 50%–150% of the concentrations described in the standard preparation for *Procedure A*.

Alternative procedures are permitted (see *General Notices 6.30*). Alternative procedures include different analytical procedures from those described in this chapter and modifications to the procedures described herein that go beyond the stated validation of the method (e.g., different concentrations, other analytes or variations to chromatographic conditions beyond those permitted by *Chromatography* (621)). Alternative procedures must be validated. Recommendations for validation of alternative procedures (limit and quantitative) are described in *Validation of Alternative Procedures*.

VERIFICATION OF COMPENDIAL PROCEDURES

For Limit Procedures: Procedure A and Procedure B

Analytical characteristics to be verified: specificity, detectability, and solution stability.

When solvents LTBP are not known

Prepare a reagent blank.

Prepare *Standard solution(s)* as described in *Procedure A*.

Prepare the *Spiked sample solution* as described for *System suitability solution* in *Procedure A*.

Specificity: acceptance criteria

The procedure must be able to separate acetonitrile and methylene chloride (*Procedure A*), or acetonitrile and cis-dichloroethene (*Procedure B*) with a resolution of NLT 1.0.

Detectability: acceptance criteria

The mean S/N ratio for each solvent in the *Standard solution* and *Spiked sample solution* from at least three determinations from a single preparation is NLT 3.

Solution stability: acceptance criteria

Detectability should meet the requirements through the testing period (protect against significant changes across testing period).

When solvents LTBP are known

(These statements only apply to solvents LTBP.)

Prepare a reagent blank.

Prepare *Standard solution(s)* and *Sample solution(s)* as described in *Procedure A* for solvents LTBP.

Prepare *Spiked sample solution(s)* as described in *Procedure C* for solvents LTBP (corrected for native solvent content).

Prepare *75% Spiked sample solution(s)* as described in *Spiked sample solution(s)* in *Procedure C*, except at 75% of the specified concentration (corrected for native solvent content).

Specificity: acceptance criteria

The reagent blank does not produce any significant interference with any of the peaks from solvents LTBP.

The procedure must be able to separate each of the solvents in the standard solution(s) from each other and from other peaks in the *Spiked sample solution* with a resolution of NLT 1.0. If the resolution between any pair of peaks is less than 1.5, then verification must demonstrate that the method is suitable for its intended use, and appropriate resolution criteria must be incorporated in the *System suitability* test for routine use.

If the solvents present in the *Standard solution(s)* are not separated with a resolution of NLT 1.0, then *Procedure B* should be used as confirmatory.

Detectability: acceptance criteria

The mean S/N ratio for each solvent in the *Standard solution* and the *Spiked sample solution* from at least three determinations is NLT 3.

The response from the *Spiked sample solution* is within 80%–120% of the response from the *Standard solution* after correction for native solvent content. (If not, it is acceptable to consider the procedure to be verified with the stipulation that all future tests require use of the *Spiked sample solution* as the *Standard solution*.)

The response from the 75% *Spiked sample solution*, for each solvent LTBP, is less than the response from the *Spiked sample solution* (after correction for native solvent content).

Solution stability: acceptance criteria (not required if only running fresh solutions)

Detectability should meet the requirements through the testing period (without significant change across the testing period).

For Quantitative Procedures (Procedure C)

[Note—When performing *Procedure C*, solvents LTBP are typically known, either based on results from *Procedure A* or *Procedure B*, or based on available knowledge.]

Analytical characteristics to be verified are: specificity, accuracy (informs ability to quantitate, linearity, and range), precision/repeatability, and solution stability.

Specificity

See *Specificity* in *Limit Procedures (Procedure A and Procedure B)*.

Accuracy

Standard stock solution: Prepare a solution containing (at least) each Class 1 or 2 solvent LTBP or each peak identified and verified by *Procedure A* and *Procedure B*, with a concentration as described in *Procedure C* for water-soluble articles or water-insoluble articles, as appropriate.

Sample stock solution: Prepare as described in *Procedure A*.

Spiked sample solution 1: Prepare as described in *Procedure C*, using the *Standard stock solution* described here.

Spiked sample solutions A, B, C, etc.: Prepare *Spiked sample solutions* with the sample matrix and spiked with each Class 1 or 2 solvent LTBP or each peak identified and verified by *Procedure A* and *Procedure B*, in triplicate, at NLT 3 levels covering the range of interest or at least 50%–150% of the corresponding concentration of the *Standard solution* as described in *Procedure A*. [Note—*Spiked sample solution 1* may be used as one of the solutions. Recoveries should be corrected for native content of any solvent under test.]

Acceptance criteria

The mean recovery for each *Spiked sample solution A, B, and C*, when calculated against *Spiked sample solution 1*, is 80%–120%.

The mean recovery for each *Spiked sample solution A, B, and C* is 80%–120%.

Precision/Repeatability

Spiked sample solutions: At least six independent preparations from the same lot, prepared as described for *Spiked sample solution 1* in *Accuracy* or nine independent preparations as described for *Spiked sample solutions A, B, C, etc.*

Acceptance criteria

Relative standard deviation: NMT 20% for each solvent present

Solution stability

Demonstrate acceptable solution stability for the period of time to run the test.

Acceptance criteria: Solutions should exhibit peak responses of 75%–125% throughout the testing period.

VALIDATION OF ALTERNATIVE PROCEDURES

Alternative procedures, in addition to the requirements for verification of compendial procedures, should meet the following criteria. When non-chromatographic alternative procedures are validated, the analytical characteristics listed should be addressed, although it may be appropriate to use other acceptance criteria. For more information, refer to *Validation of Compendial Procedures* (1225).

For concentrations other than the nominal concentrations in this chapter, the acceptance criteria should be determined before the validation protocol is executed.

Limit procedures (*Procedure A* and *Procedure B*)

Analytical characteristics to be validated: None

Quantitative procedures (*Procedure C*)

Analytical characteristics to be validated: Linearity and intermediate precision

Linearity

Spiked sample solutions P, Q, R, etc.: Prepare sample solutions spiked with solvents LTBP, at NLT 5 levels covering the range of interest or at least 50%–150% of the corresponding concentration of the *Standard solution* as described in *Procedure A*.

Prepare *Spiked sample solutions* with the sample matrix and spiked with each Class 1 or 2 solvent LTBP at NLT 5 levels covering the range of interest. [Note—Results should be corrected for native content of any solvent under test.]

Perform linear regression analysis on the results for *Spiked sample solutions P, Q, R, etc.*

Acceptance criteria

The coefficient of determination, r^2 , is NLT 0.90.

Intermediate precision

Perform the *Repeatability* test over two independent events, for example, on different days, and/or using different instruments and/or analysts.

Acceptance criteria

Relative standard deviation: NMT 25% at the nominal concentration level for each solvent present

GLOSSARY

Abbreviations for Solvents Listed in This Chapter

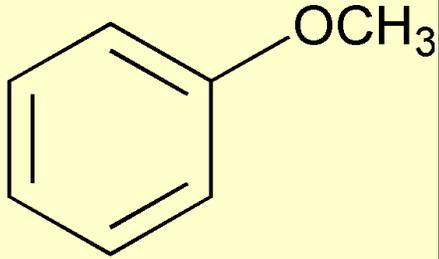

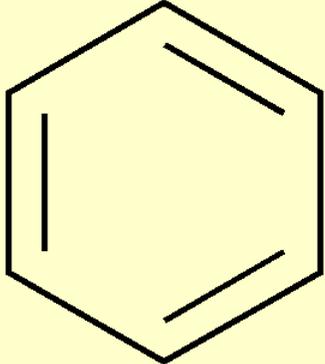

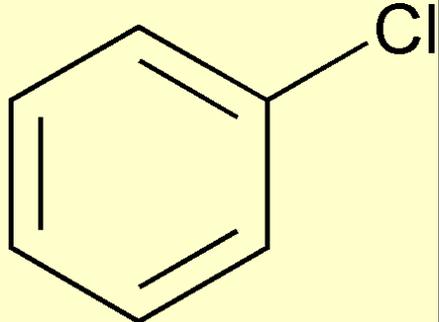

Acceptable daily intake (ADI):	The maximum acceptable intake of toxic chemicals per day. This term is used by the World Health Organization (WHO).
Genotoxic carcinogens:	Carcinogens that produce cancer by affecting genes or chromosomes.
Likely to be present (LTBP):	Those solvents used or produced in the final manufacturing step and solvents that are used or produced in earlier manufacturing steps which are not consistently removed by a validated process, or the solvents properly declared by a validated supplier of a drug substance or excipient.
Lowest-observed-effect level (LOEL):	The lowest dose of a substance in a study or group of studies that produces biologically significant increases in frequency or severity of any effects in exposed humans or animals.
Modifying factor:	A factor determined by professional judgment of a toxicologist and applied to bioassay data so that the data can be safely related to humans.
Neurotoxicity:	The ability of a substance to cause adverse effects on the nervous system.
No-observed-effect level (NOEL):	The highest dose of a substance at which there are no biologically significant increases in frequency or severity of any effects in exposed humans or animals.
Permitted daily exposure (PDE):	The maximum acceptable intake per day of a residual solvent in pharmaceutical products
Reversible toxicity:	The occurrence of harmful effects that are caused by a substance and that disappear after exposure to the substance ends.
Strongly suspected human carcinogen:	A substance for which there is no epidemiological evidence of carcinogenesis but for which there are positive genotoxicity data and clear evidence of carcinogenesis in rodents.
Teratogenicity:	The occurrence of structural malformations in a developing fetus when a substance is administered during pregnancy.
Tolerable daily intake (TDI):	Tolerable daily exposure to toxic chemicals. Term used by the International Program on Chemical Safety (IPCS).

APPENDICES

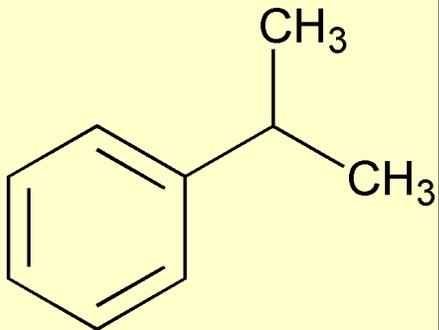

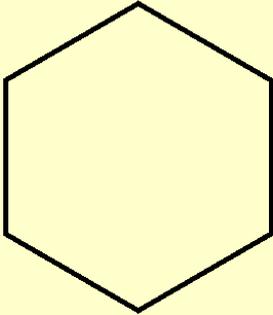

See the table *Appendix 1. List of Residual Solvents Included in This General Chapter.*

APPENDIX 1. LIST OF RESIDUAL SOLVENTS INCLUDED IN THIS GENERAL CHAPTER

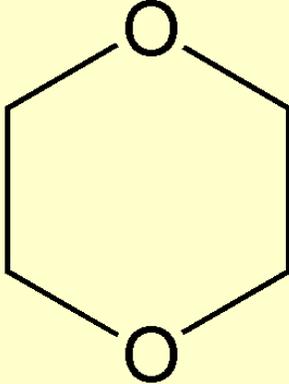

Solvent	Other Names	Structure	Class
Acetic acid	Ethanoic acid	CH ₃ COOH	Class 3
^a Usually 60% <i>m</i> -xylene, 14% <i>p</i> -xylene, and 9% <i>o</i> -xylene with 17% ethyl benzene.			

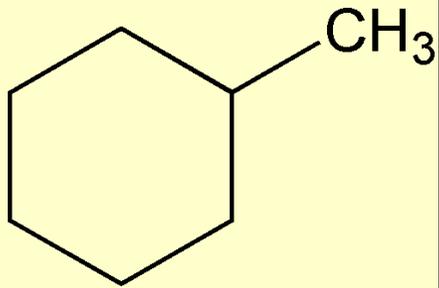

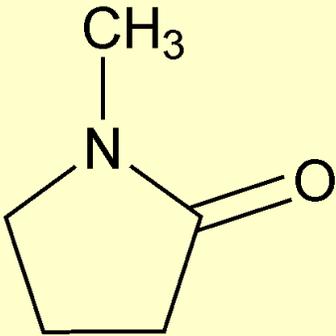

Solvent	Other Names	Structure	Class
Acetone	2-Propanone Propan-2-one	CH_3COCH_3	Class 3
Acetonitrile		CH_3CN	Class 2
Anisole	Methoxybenzene		Class 3
Benzene	Benzol		Class 1
1-Butanol	<i>n</i> -Butyl alcohol Butan-1-ol	$\text{CH}_3(\text{CH}_2)_3\text{OH}$	Class 3
2-Butanol	<i>sec</i> -Butyl alcohol Butan-2-ol	$\text{CH}_3\text{CH}_2\text{CH}(\text{OH})\text{CH}_3$	Class 3
Butyl acetate	Acetic acid butyl ester	$\text{CH}_3\text{COO}(\text{CH}_2)_3\text{CH}_3$	Class 3
<i>tert</i> -Butylmethyl ether	2-Methoxy-2-methylpropane	$(\text{CH}_3)_3\text{COCH}_3$	Class 3
Carbon tetrachloride	Tetrachloromethane	CCl_4	Class 1
Chlorobenzene			Class 2
Chloroform	Trichloromethane	CHCl_3	Class 2

^a Usually 60% *m*-xylene, 14% *p*-xylene, and 9% *o*-xylene with 17% ethyl benzene.

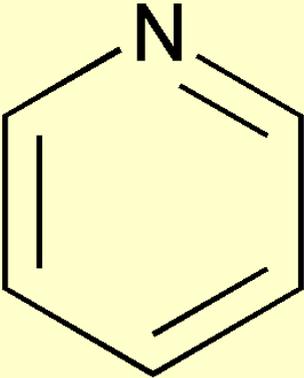

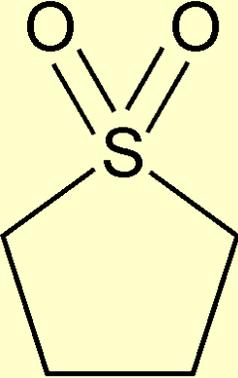

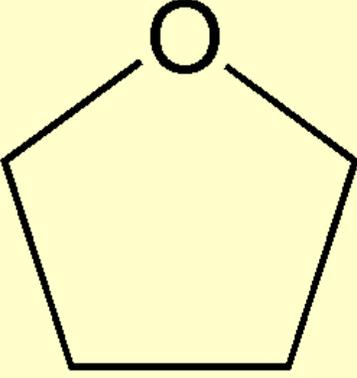

Solvent	Other Names	Structure	Class
Cumene	Isopropylbenzene (1-Methylethyl)benzene		Class 2
Cyclohexane	Hexamethylene		Class 2
1,2-Dichloroethane	<i>sym</i> -Dichloroethane Ethylene dichloride Ethylene chloride	$\text{CH}_2\text{ClCH}_2\text{Cl}$	Class 1
1,1-Dichloroethene	1,1-Dichloroethylene Vinylidene chloride	$\text{H}_2\text{C}=\text{CCl}_2$	Class 1
1,2-Dichloroethene	1,2-Dichloroethylene Acetylene dichloride	$\text{ClHC}=\text{CHCl}$	Class 2
1,2-Dimethoxyethane	Ethyleneglycol dimethyl ether Monoglyme Dimethyl cellosolve	$\text{H}_3\text{COCH}_2\text{CH}_2\text{OCH}_3$	Class 2
<i>N,N</i> -Dimethylacetamide	DMA	$\text{CH}_3\text{CON}(\text{CH}_3)_2$	Class 2
<i>N,N</i> -Dimethylformamide	Dimethylformamide	$\text{HCON}(\text{CH}_3)_2$	Class 2
Dimethyl sulfoxide	Methylsulfinylmethane Methyl sulfoxide Dimethyl sulfoxide	$(\text{CH}_3)_2\text{SO}$	Class 3

^a Usually 60% *m*-xylene, 14% *p*-xylene, and 9% *o*-xylene with 17% ethyl benzene.

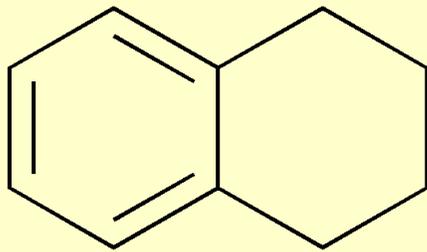

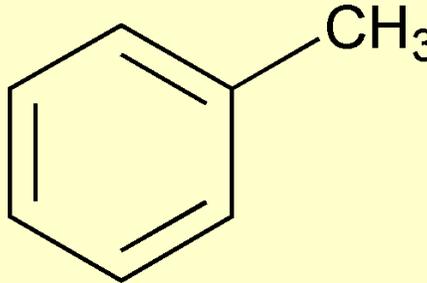

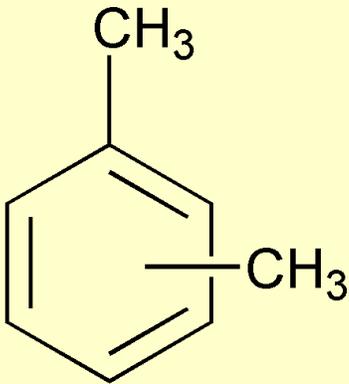

Solvent	Other Names	Structure	Class
1,4-Dioxane	<i>p</i> -Dioxane [1,4]Dioxane		Class 2
Ethanol	Ethyl alcohol	CH ₃ CH ₂ OH	Class 3
2-Ethoxyethanol	Cellosolve	CH ₃ CH ₂ OCH ₂ CH ₂ OH	Class 2
Ethyl acetate	Acetic acid ethyl ester	CH ₃ COOCH ₂ CH ₃	Class 3
Ethylene glycol	1,2-Dihydroxyethane 1,2-Ethanediol	HOCH ₂ CH ₂ OH	Class 2
Ethyl ether	Diethyl ether Ethoxyethane 1,1'-Oxybisethane	CH ₃ CH ₂ OCH ₂ CH ₃	Class 3
Ethyl formate	Formic acid ethyl ester	HCOOCH ₂ CH ₃	Class 3
Formamide	Methanamide	HCONH ₂	Class 2
Formic acid		HCOOH	Class 3
Heptane	<i>n</i> -Heptane	CH ₃ (CH ₂) ₅ CH ₃	Class 3
Hexane	<i>n</i> -Hexane	CH ₃ (CH ₂) ₄ CH ₃	Class 2
Isobutyl acetate	Acetic acid isobutyl ester	CH ₃ COOCH ₂ CH(CH ₃) ₂	Class 3
Isopropyl acetate	Acetic acid isopropyl ester	CH ₃ COOCH(CH ₃) ₂	Class 3
Methanol	Methyl alcohol	CH ₃ OH	Class 2
2-Methoxyethanol	Methyl cellosolve	CH ₃ OCH ₂ CH ₂ OH	Class 2
Methyl acetate	Acetic acid methyl ester	CH ₃ COOCH ₃	Class 3
3-Methyl-1-butanol	Isoamyl alcohol Isopentyl alcohol 3-Methylbutan-1-ol	(CH ₃) ₂ CHCH ₂ CH ₂ OH	Class 3
Methylbutylketone	2-Hexanone Hexan-2-one	CH ₃ (CH ₂) ₃ COCH ₃	Class 2
^a Usually 60% <i>m</i> -xylene, 14% <i>p</i> -xylene, and 9% <i>o</i> -xylene with 17% ethyl benzene.			

Solvent	Other Names	Structure	Class
Methylcyclohexane	Cyclohexylmethane		Class 2
Methylene chloride	Dichloromethane	CH_2Cl_2	Class 2
Methylethylketone	2-Butanone MEK Butan-2-one	$\text{CH}_3\text{CH}_2\text{COCH}_3$	Class 3
Methyl isobutyl ketone	4-Methylpentan-2-one 4-Methyl-2-pentanone MIBK	$\text{CH}_3\text{COCH}_2\text{CH}(\text{CH}_3)_2$	Class 3
2-Methyl-1-propanol	Isobutyl alcohol 2-Methylpropan-1-ol	$(\text{CH}_3)_2\text{CHCH}_2\text{OH}$	Class 3
<i>N</i> -Methylpyrrolidone	1-Methylpyrrolidin-2-one 1-Methyl-2-pyrrolidinone		Class 2
Nitromethane		CH_3NO_2	Class 2
Pentane	<i>n</i> -Pentane	$\text{CH}_3(\text{CH}_2)_3\text{CH}_3$	Class 3
1-Pentanol	Amyl alcohol Pentan-1-ol Pentyl alcohol	$\text{CH}_3(\text{CH}_2)_3\text{CH}_2\text{OH}$	Class 3

^a Usually 60% *m*-xylene, 14% *p*-xylene, and 9% *o*-xylene with 17% ethyl benzene.

Solvent	Other Names	Structure	Class
1-Propanol	Propan-1-ol Propyl alcohol	$\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$	Class 3
2-Propanol	Propan-2-ol Isopropyl alcohol	$(\text{CH}_3)_2\text{CHOH}$	Class 3
Propyl acetate	Acetic acid propyl ester	$\text{CH}_3\text{COOCH}_2\text{CH}_2\text{CH}_3$	Class 3
Pyridine			Class 2
Sulfolane	Tetrahydrothiophene 1,1-dioxide		Class 2
Tetrahydrofuran	Tetramethylene oxide Oxacyclopentane		Class 2

^a Usually 60% *m*-xylene, 14% *p*-xylene, and 9% *o*-xylene with 17% ethyl benzene.

Solvent	Other Names	Structure	Class
Tetralin	1,2,3,4-Tetrahydronaphthalene		Class 2
Toluene	Methylbenzene		Class 2
1,1,1-Trichloroethane	Methylchloroform	CH_3CCl_3	Class 1
Trichloroethylene	1,1,2-Trichloroethene	$\text{HC}(\text{Cl})=\text{CCl}_2$	Class 2
Xylene ^a	Dimethylbenzene Xylol		Class 2
^a Usually 60% <i>m</i> -xylene, 14% <i>p</i> -xylene, and 9% <i>o</i> -xylene with 17% ethyl benzene.			

APPENDIX 2. ADDITIONAL BACKGROUND

A2.1. Environmental Regulation of Organic Volatile Solvents

Several of the residual solvents frequently used in the production of pharmaceuticals are listed as toxic chemicals in *Environmental Health Criteria* (EHC) monographs and in the *Integrated Risk Information System* (IRIS) and other sources. The objectives of such groups as the International Programme on Chemical Safety (IPCS), the U.S. Environmental Protection Agency (EPA), and the U.S. Food and Drug Administration (FDA) include the determination of acceptable exposure levels. The goal is maintenance of environmental integrity and protection

of human health against the possible deleterious effects of chemicals resulting from long-term environmental exposure. The procedures involved in the estimation of maximum safe exposure limits are usually based on long-term studies. When long-term study data are unavailable, shorter-term study data can be used with modification of the approach, such as use of larger safety factors. The approach described therein relates primarily to long-term or lifetime exposure of the general population via the ambient environment (i.e., ambient air, food, drinking water, and other sources).

Residual Solvents in Pharmaceuticals

Exposure limits in this general chapter are established by referring to methodologies and toxicity data described in EHC and IRIS monographs. However, the following specific assumptions about residual solvents to be used in the synthesis and formulation of pharmaceutical products should be taken into account in establishing exposure limits.

1. Patients (not the general population) use pharmaceuticals to treat their diseases or for prophylaxis to prevent infection or disease.
2. The assumption of lifetime patient exposure is not necessary for most pharmaceutical products but may be appropriate as a working hypothesis to reduce risk to human health.
3. Residual solvents are unavoidable components in pharmaceutical production and will often be a part of pharmaceutical drug products.
4. Residual solvents should not exceed recommended levels except in exceptional circumstances.
5. Data from toxicological studies that are used to determine acceptable levels for residual solvents should have been generated using appropriate protocols such as those described by the Organization for Economic Cooperation and Development (OECD), the EPA, and the FDA *Redbook* or derived from alternative sources also considered to be adequate to support PDE limit setting.

APPENDIX 3. PROCEDURES FOR ESTABLISHING EXPOSURE LIMITS

The Gaylor-Kodell method of risk assessment (Gaylor, DW, and Kodell, RL. Linear interpolation algorithm for low dose risk assessment of toxic substances. *J Environ Pathol and Toxycol*, 1980;4:305) is appropriate for Class 1 carcinogenic solvents. Only in cases where reliable carcinogenicity data are available should extrapolation by the use of mathematical models be applied to setting exposure limits. Exposure limits for Class 1 residual solvents could be determined with the use of a large safety factor (i.e., 10,000–100,000) with respect to the no-observed-effect level (NOEL). Detection and quantification of these residual solvents should be performed using state-of-the-art analytical techniques.

Acceptable exposure levels in this general chapter for Class 2 residual solvents were established by calculation of PDE values according to the procedures for setting exposure limits in pharmaceuticals (page 5748 of PF 15(6) [Nov.–Dec. 1989]), and the method adopted by IPCS for *Assessing Human Health Risks of Chemicals (Environmental Health Criteria 170, WHO, 1994)*, detailed calculations are published in *Pharmeuropa*, Vol. 9, No. 1, Supplement, April 1997. These procedures are similar to those used by the U.S. EPA (IRIS) and the U.S. FDA (*Redbook*) and others. The method is outlined here to give a better understanding of the origin of the PDE values. It is not necessary to perform these calculations in order to use the PDE

values presented in *Table 2* of this document.

PDE is derived from the NOEL, or the lowest-observed-effect level (LOEL), in the most relevant animal study as follows:

$$\text{PDE} = (\text{NOEL} \times \text{Weight Adjustment}) / (F1 \times F2 \times F3 \times F4 \times F5)$$

The PDE is derived preferably from a NOEL. If no NOEL is obtained, the LOEL may be used. Modifying factors proposed here, for relating the data to humans, are the same kind of "uncertainty factors" used in *Environmental Health Criteria (Environmental Health Criteria 170, WHO, 1994)* and "modifying factors" or "safety factors" used in *Pharmacopeial Forum*. The assumption of 100% systemic exposure is used in all calculations regardless of the route of administration.

The modifying factors are as follows:

F1 =	A factor to account for extrapolation between species
F1 =	2 for extrapolation from dogs to humans
F1 =	2.5 for extrapolation from rabbits to humans
F1 =	3 for extrapolation from monkeys to humans
F1 =	5 for extrapolation from rats to humans
F1 =	10 for extrapolation from other animals to humans
F1 =	12 for extrapolation from mice to humans

F1 takes into account the comparative surface area to body weight ratios for the species concerned and for humans. Surface area (*S*) is calculated as:

$$S = kM^{0.67}$$

k = a constant that has been taken to be 10

M = body weight

The body weights used in the equation are those shown below in *Table A3.1*.

F2 =	A factor of 10 to account for variability between individuals. A factor of 10 is generally given for all organic solvents, and 10 is used consistently in this general chapter.
F3 =	A variable factor to account for toxicity studies of short-term exposure
F3 =	1 for studies that last at least one half-lifetime (1 year for rodents or rabbits; 7 years for cats, dogs, and monkeys)
F3 =	1 for reproductive studies in which the whole period of organogenesis is covered
F3 =	2 for a 6-month study in rodents, or a 3.5-year study in nonrodents
F3 =	5 for a 3-month study in rodents, or a 2-year study in nonrodents
F3 =	10 for studies of a shorter duration

In all cases, the higher factor has been used for study durations between the time points (e.g., a factor of 2 for a 9-month rodent study).

F4 =	A factor that may be applied in cases of severe toxicity, e.g., nongenotoxic carcinogenicity, neurotoxicity, or teratogenicity. In studies of reproductive toxicity, the following factors are used:	
F4 =	1	for fetal toxicity associated with maternal toxicity
F4 =	5	for fetal toxicity without maternal toxicity
F4 =	5	for a teratogenic effect with maternal toxicity
F4 =	10	for a teratogenic effect without maternal toxicity
F5 =	A variable factor that may be applied if the no-effect level was not established	

When only a LOEL is available, a factor of up to 10 can be used, depending on the severity of the toxicity. The weight adjustment assumes an arbitrary adult human body weight for either sex of 50 kg. This relatively low weight provides an additional safety factor against the standard weights of 60 or 70 kg that are often used in this type of calculation. It is recognized that some adult patients weigh less than 50 kg; these patients are considered to be accommodated by the built-in safety factors used to determine a PDE. If the solvent was present in a formulation specifically intended for pediatric use, an adjustment for a lower body weight would be appropriate.

As an example of the application of this equation, consider a toxicity study of acetonitrile in mice that is summarized in *Pharmeuropa*, 1997;9(1): S24. The NOEL is calculated to be 50.7 mg kg⁻¹ day⁻¹. The PDE for acetonitrile in this study is calculated as follows:

$$\text{PDE} = (50.7 \text{ mg kg}^{-1} \text{ day}^{-1} \times 50 \text{ kg}) / (12 \times 10 \times 5 \times 1 \times 1) = 4.22 \text{ mg day}^{-1}$$

In this example,

F1 =	12	to account for the extrapolation from mice to humans
F2 =	10	to account for differences between individual humans
F3 =	5	because the duration of the study was only 13 weeks
F4 =	1	because no severe toxicity was encountered
F5 =	1	because the no-effect level was determined

A3.1. Values Used in the Calculations in This Document

Rat body weight	425 g
Pregnant rat body weight	330 g
Mouse body weight	28 g
Pregnant mouse body weight	30 g
Guinea-pig body weight	500 g
Rhesus monkey body weight	2.5 kg
Rabbit body weight (pregnant or not)	4 kg
Beagle dog body weight	11.5 kg
Rat respiratory volume	290 L/day
Mouse respiratory volume	43 L/day
Rabbit respiratory volume	1440 L/day
Guinea-pig respiratory volume	430 L/day
Human respiratory volume	28,800 L/day
Dog respiratory volume	9000 L/day
Monkey respiratory volume	1150 L/day
Mouse water consumption	5 mL/day
Rat water consumption	30 mL/day
Rat food consumption	30 g/day

The equation for an ideal gas, $PV = nRT$, is used to convert concentrations of ga

BRIEFING

⟨771⟩ **Ophthalmic Ointments**, *USP 38* page 537 and *PF 40(6)* [Nov.–Dec. 2015]. There are five *USP* general chapters that link with *USP*'s taxonomy for pharmaceutical dosage forms: *Injections and Implanted Drug Products* ⟨1⟩, *Oral Drug Products—Product Quality Tests* ⟨2⟩, *Topical and Transdermal Drug Products—Product Quality Tests* ⟨3⟩, *Mucosal Drug Products—Product Quality Tests* ⟨4⟩, and *Inhalation and Nasal Drug Products—General Information and Product Quality Tests* ⟨5⟩. This taxonomy describes five routes of administration: injection or parenteral; gastrointestinal or oral; topical (dermal and transdermal); mucosal; and lungs or inhalational (for more information, see the *Stimuli* article titled *Product Quality and Product Performance General Chapters* in *PF 39(3)* [May–June 2013]). The five general chapters provide critical product quality attributes for the various dosage forms by the various routes of administration. In addition to these five chapters, *Ophthalmic Ointments* ⟨771⟩ outlines the critical product quality attributes for the various dosage forms that can be applied to the eye. Product quality tests assess physical, chemical, and microbial attributes. Taken together, the tests help ensure identity, strength, quality, and purity of a dosage form. The General Chapters—Dosage Forms Expert Committee is proposing the following revision to ⟨1⟩, ⟨2⟩, ⟨3⟩, ⟨4⟩, ⟨5⟩, and ⟨771⟩ in this issue of *PF* to clarify the applicability of these chapters. On the basis of comments received, it is proposed to make the following revisions to this chapter.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

(771) OPHTHALMIC OINTMENTS ▲ PRODUCTS—QUALITY TESTS ▲^{USP39}

Change to read:

Added Substances—Suitable substances may be added to ophthalmic ointments to increase stability or usefulness, unless proscribed in the individual monograph, provided they are harmless in the amounts administered and do not interfere with the therapeutic efficacy or with the responses to the specified assays and tests. No coloring agent may be added, solely for the purpose of coloring the finished preparation, to an article intended for ophthalmic use (see also *Added Substances* under *General Notices* and under *Antimicrobial Effectiveness Testing* (51)).

A suitable substance or mixture of substances to prevent the growth of microorganisms must be added to ophthalmic ointments that are packaged in multiple-use containers, regardless of the method of sterilization employed, unless otherwise directed in the individual monograph, or unless the formula itself is bacteriostatic. Such substances are used in concentrations that will prevent the growth of or kill microorganisms in the ophthalmic ointments (see also *Antimicrobial Effectiveness Testing* (51) and *Antimicrobial Agents—Content* (341)). Sterilization processes are employed for the finished ointment or for all ingredients, if the ointment is manufactured under rigidly aseptic conditions, even though such substances are used (see also *Parenteral and Topical Preparations* in the section *Added Substances*, under *General Notices*, and *Sterilization and Sterility Assurance of Compendial Articles* (1211)). Ophthalmic ointments that are packaged in single-use containers are not required to contain antibacterial agents; however, they meet the requirements for *Sterility Tests* (71).

Containers—Containers, including the closures, for ophthalmic ointments do not interact physically or chemically with the preparation in any manner to alter the strength, quality, or purity beyond the official requirements under the ordinary or customary conditions of handling, shipment, storage, sale, and use.

Metal Particles—Follow the *Procedure* set forth under *Metal Particles in Ophthalmic Ointments* (751).

Leakage—Select 10 tubes of the Ointment, with seals applied when specified. Thoroughly clean and dry the exterior surfaces of each tube with an absorbent cloth. Place the tubes in a horizontal position on a sheet of absorbent blotting paper in an oven maintained at a temperature of $60 \pm 3^\circ$ for 8 hours. No significant leakage occurs during or at the completion of the test (disregard traces of ointment presumed to originate externally from within the crimp of the tube or from the thread of the cap). If leakage is observed from one, but not more than one, of the tubes, repeat the test with 20 additional tubes of the Ointment. The requirement is met if no leakage is observed from the first 10 tubes tested, or if leakage is observed from not more than one of 30 tubes tested.

INTRODUCTION

Ophthalmic products are sterile products that are intended for application to any ocular

structure, including any space adjacent to an ocular structure and its immediate surrounding spaces.

The routes of administration of ophthalmic products fall into three general categories: topical, intraocular injections, and extraocular injections. Topical drug products are intended to be administered to an ocular surface component, such as the eyelid, conjunctiva, or cornea, and can produce local or systemic effects. Intraocular and extraocular injections are administered through external boundary tissue. The ophthalmic routes of administration include, but are not limited to: topical, subconjunctival, sub-tenons, subretinal, subchoroidal, intracorneal, intrascleral, suprachoroidal, intravitreal, intracameral, juxtasclear, and retrobulbar routes (see *Figure 1*). Ophthalmic products are administered to the eye in a wide variety of dosage forms, including but not restricted to: solutions, suspensions, ointments, gels, emulsions, strips, injections, inserts, and implants.

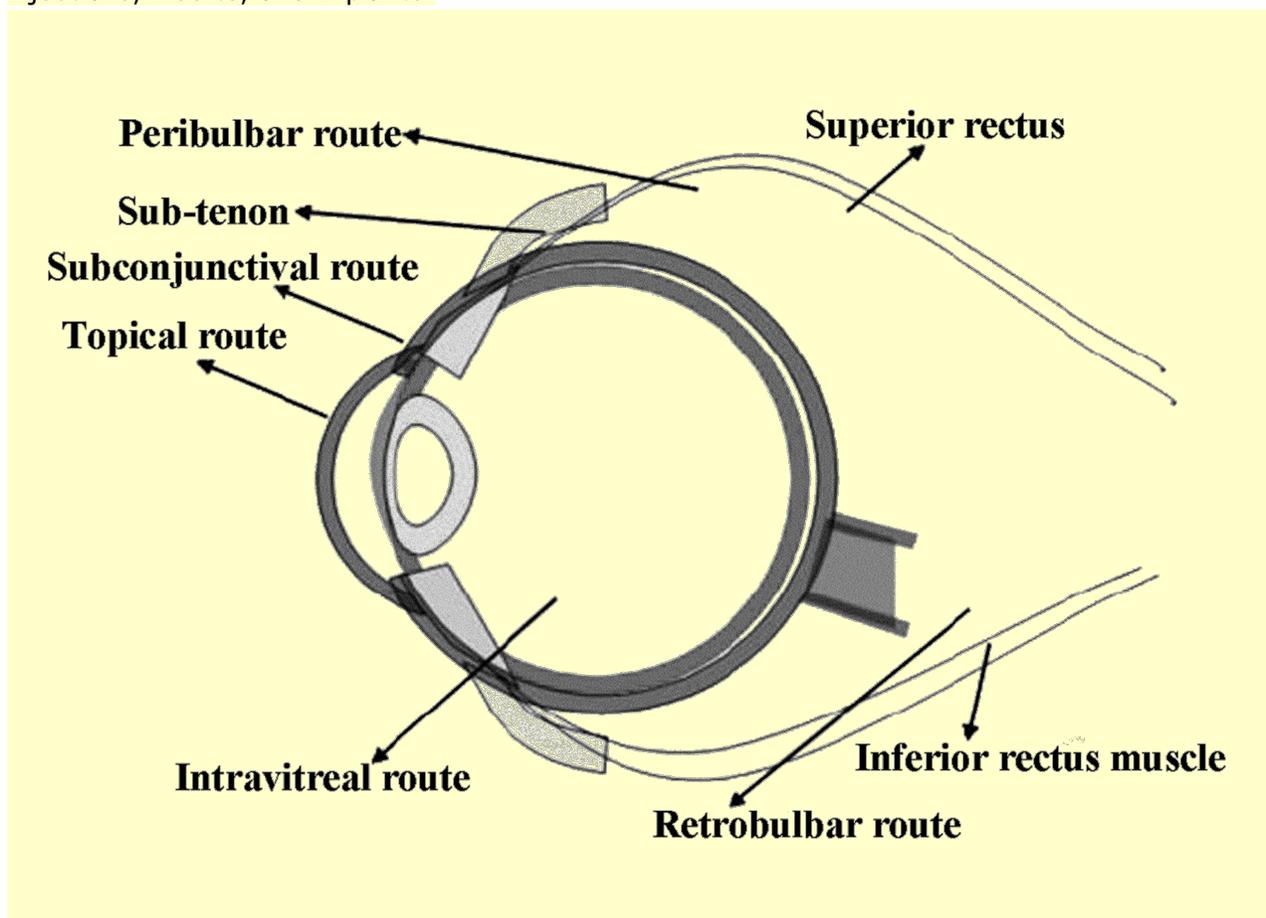

Figure 1. Some of the routes of administration in the eye.

■ General chapter <771> provides lists of consolidated common product quality test requirements in a concise and coherent fashion. This general chapter applies, in part or in its entirety, when referenced in a drug product monograph. The general chapter includes the quality tests for the specific route of administration. The quality tests listed can be used, as appropriate, by manufacturers toward the development of new drug product monographs for submission to the USP.

Note—All references to chapters above 1000 are for information purposes only, for use as a helpful resource. These chapters are not mandatory unless explicitly called out for application.

OPHTHALMIC DOSAGE FORMS

This chapter discusses the specific characteristics of dosage forms that are administered to any structure in the eye. See *Pharmaceutical Dosage Forms* (1151) for additional information pertaining to the description and manufacturing of pharmaceutical dosage forms.

Ophthalmic products have the same or similar requirements as injectables and implants. For more information on the requirements for these dosage forms, see *Injections and Implanted Drug Products* (1).

Depending on the formulation, container–closure system, and sterilization process, degradation and/or morphological changes can occur during the sterilization step of the manufacturing process and should be minimized. Temperatures required for autoclaving can cause irreversible damage to certain dosage forms such as suspensions, semisolids, emulsions, and others, whereas filtration is applicable only to formulations containing particulates with particle sizes $<0.2 \mu\text{m}$. An alternative is to manufacture the product from sterile ingredients in an aseptic environment.

For multidose products, a suitable antimicrobial preservative is required, and its effectiveness over the shelf life of the product must be verified.

Solutions

[Note—Included in this section are those solid products that, when reconstituted according to the label instructions, result in a solution.]

The corneal contact time of topical ophthalmic solutions increases with the viscosity of the formulations. Several synthetic polymers, including but not limited to polyvinylalcohol, polyvinylpyrrolidone, polyethylene glycol, polyacrylic acid, and many cellulose derivatives such as hypromellose and hydroxyethylcellulose, are commonly used as viscosity enhancers because of their physiologic compatibility and satisfactory physicochemical properties.

Another approach to increase the corneal contact time involves the use of polymers that provide the liquid formulation with semisolid consistency only when it is placed in the conjunctival or corneal area. In this way, easy instillation of the solution is followed by prolonged permanence as a result of the viscoelastic properties of the formed hydrogel. "Hydrogel," or "water-based gels," are three-dimensional networks of polymer chains containing water within the network. The network can be either physically or chemically cross-linked (a covalent bonding) structures between polymer chains. The water content of hydrogels can be adjusted by modulating the composition and conformation of polymers, such as the hydrophilic/hydrophobic balance of polymer chains and pendant groups, and the degree of cross-linking. The in situ gelling phenomenon is caused by a change in the conformation of the polymer(s) that can be triggered by external stimuli such as temperature, pH, ionic content, and lacrimal fluid, upon delivery to the eye. Additionally, some polymers can interact, via noncovalent bonds, with conjunctival mucin and maintain the formulation in contact with corneal tissues.

Solutions can be injected not only by the intravitreal route but also by other routes, such as subconjunctival, sub-tenons, retrobulbar, suprachoroidal, and subretinal routes.

Suspensions

[Note—Included in this section are those solid products that, when reconstituted according to

the label instructions, result in a suspension.]

Use of aqueous or oily suspensions may be considered for a number of reasons such as the following: 1) for drugs that are poorly water soluble, 2) for drugs that have poor aqueous stability, and 3) in cases where there is a need to increase contact time with the eye and to increase wetting of the eye. The drug particle size is often reduced to levels $<10\ \mu\text{m}$ in an attempt to avoid excessive lacrimation.

After topical instillation, particles are expected to be retained in the cul-de-sac, and the drug slowly dissolves or is released from the polymeric structures by diffusion, dissolution, polymer degradation, or ion-exchange.

Suspensions can be injected not only by the intravitreal route but also through other routes, such as subconjunctival, sub-tenons, retrobulbar, suprachoroidal, and subretinal.

Ointments

Eye ointments are semisolid products usually intended for application to the conjunctiva, cornea, or eyelid. They have longer contact time when compared to many solutions. A suitable ophthalmic ointment base is nonirritating to the eye and permits diffusion of the drug substance throughout the secretions bathing the eye.

The majority of water-free, oleaginous eye ointment bases are composed of white petrolatum and liquid petrolatum (mineral oil), or the eye ointment base is a modification of the petrolatum-based formula. They are designed to melt at body temperature. Other types of lipophilic ointment bases can also be used. An anhydrous vehicle can be advantageous for moisture-sensitive drugs.

Gels

Semisolid gel-type products are an alternative to traditional ointments and are based on the effect of increasing the viscosity to prolong the retention of the drug in the eye. Several types of gelling agents can be used, such as polyacrylic acid derivatives, carbomer, and hypromellose.

Emulsions

Topical ophthalmic emulsions are generally prepared by dissolving or dispersing the drug substance into an oil phase, adding suitable emulsifying and suspending agents, and mixing with water vigorously to form a uniform oil-in-water emulsion. Each phase is typically sterilized before or during charging into the mixing vessel. High-shear homogenation may be used to reduce oil droplet size to submicron size, which may improve the physical stability of the oil micelles so that they do not coalesce. The resulting dosage form should contain small oil droplets, uniformly suspended.

Limited aqueous solubility of the drug substance(s) is the most common rationale for developing an ophthalmic emulsion. The drug substance(s) can be added to the phase in which it is soluble at the beginning of the manufacturing process, or the drug substance can be added after the emulsion is prepared by a suitable dispersion process.

The physical stability of the emulsion can be measured by light-scattering techniques that characterize oil-phase, globule-size distribution. Suitable surfactants may be added to improve emulsion stability.

Strips

Ophthalmic strips can have different ophthalmic uses including, but not limited to, use as a diagnostic tool to visualize defects or aberrations in the corneal epithelium or to measure the amount of tear production. They are made of filter paper, and they can contain compounds such as fluorescein sodium. They are individually packed to preserve sterility until the moment of use.

Injections

Although injections are considered a dosage form for nomenclature purposes, they are not treated as a dosage form in this chapter. Instead, refer to the appropriate physical form, such as solution, suspension, or others, for general information.

Inserts

Ophthalmic inserts and ocular systems are solid dosage forms of appropriate size and shape that are placed in the conjunctival fornix, in the lacrimal punctum (*Figure 2*), or on the cornea. Inserts can usually be removed, if adverse effects develop, and provide extended release of the drug over a certain period of time. Inserts can be classified as erodible (soluble) or nonerodible (insoluble). Drug release from soluble inserts involves two steps: 1) fast release of a portion of the drug as the tear fluid penetrates into the system, and 2) slow release as a gel layer is formed on the surface of the insert. Collagen shields made from porcine sclera collagen or bovine corium tissue—and devices obtained by molding, extrusion, or compression (minitables) of gelling polymers—belong to this category of soluble inserts. Bioerodible polymers (e.g., cross-linked gelatin derivatives and polyesters) can be used to prepare erodible inserts; these matrices act as reservoirs or interact with the drug molecules through labile bonds.

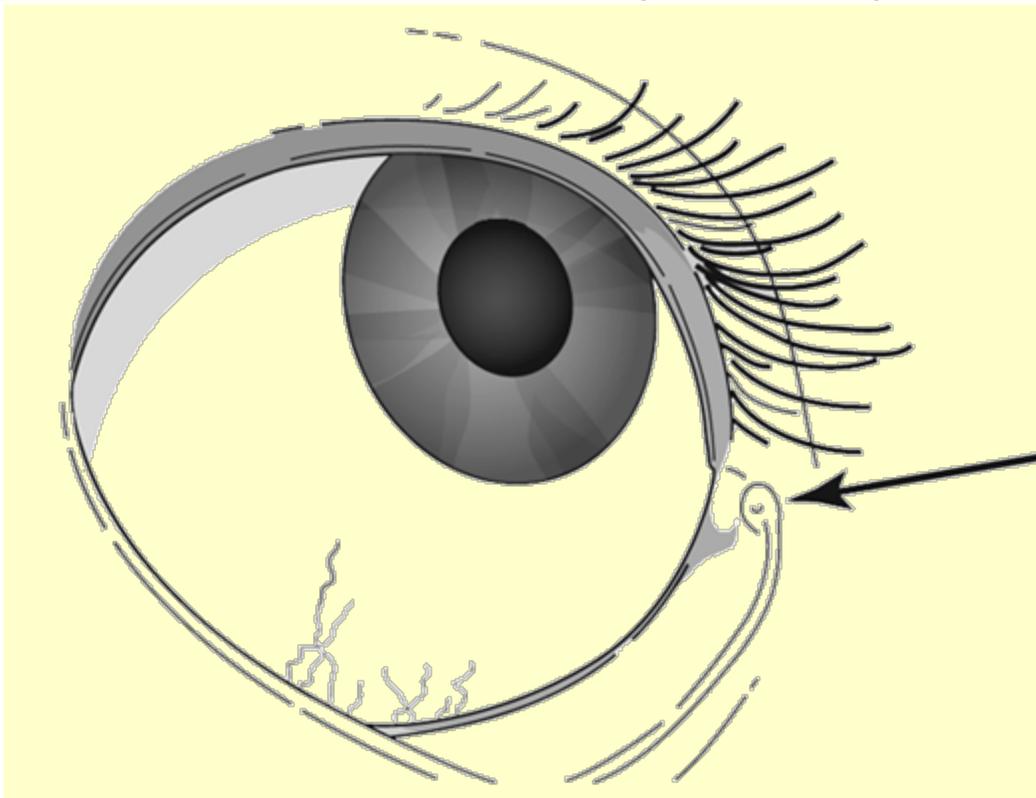

Figure 2. Lacrimal punctum.

Soluble inserts can have the drug incorporated into an erodible matrix, such as hydroxypropyl cellulose, hyaluronic acid, carbomer, or polyacrylic acid. Soluble inserts may be placed in the lower cul-de-sac and generally dissolve within 12–24 h. Erodible polymeric products undergo gradual dissolution while releasing the drug, and the patient does not have to remove the erodible polymeric insert after use.

Insoluble inserts can have a reservoir or matrix structure. Their mechanism of action is based on diffusion of a fluid into the device, dissolving of the drug, and the creation of a saturated solution released to the medium by diffusion out of the insert. These insoluble inserts need to be removed after a certain period of time.

Implants

Implants are injected or implanted into the anterior segment (intracameral, subconjunctival, sub-tenon, or other parts of the anterior segment) or intravitreal cavities, and the implants can be in different shapes, such as a disc or a thin rod. Implants can be made of nonbiodegradable or biodegradable polymers.

Among the types of nonbiodegradable solid (polymer) implants are reservoir-type implants anchored to the sclera, in which the drug is released across a nonbiodegradable, semipermeable polymer. The reservoir-type implants can be made of a variety of materials, including polyvinyl alcohol–ethylene vinyl acetate. Biodegradable polymers can be used to form injectable solid implants.

Drug–Device Combination Products

An ophthalmic drug–device combination product is constituted, in most cases, of two components. One is a pharmaceutical dosage form containing the drug substance(s), and the other is a device that will activate or facilitate the penetration of the drug substance(s) from the dosage form into a particular region of the eye. Some examples of the devices are those that generate waveforms (heat or light).

This chapter is applicable only to the pharmaceutical dosage form component of the ophthalmic drug–device combination product. The appropriate FDA regulations regarding medical devices should be used for the device component.

DRUG PRODUCT QUALITY

Procedures and acceptance criteria for testing ophthalmic products are divided into two categories: 1) those that assess general quality attributes, e.g., identification, potency, purity (and impurities), sterility, and particulate matter; and 2) those that assess in vitro product performance, i.e., dissolution or drug release of the drug substance from the drug product. Quality tests assess the integrity of the dosage form, whereas the performance tests assess drug release and other attributes that relate to in vivo drug performance. Taken together, quality and performance tests ensure the identity, strength, quality, purity, and efficacy of the drug product. This chapter addresses the quality tests for ophthalmic products. The performance tests (dissolution/drug release) are addressed by *Ophthalmic*

Products—Performance Tests (1771).

Universal Tests

In this chapter, the division of the product quality tests into universal and specific tests does not strictly follow the ICH guidance *Q6A Specifications: Test Procedures and Acceptance Criteria for New Drug Substances and New Drug Products: Chemical Substances* (available at www.ich.org). Universal tests in this chapter mean the tests that are applicable to all ophthalmic products, regardless of the dosage form type.

DESCRIPTION

A qualitative description of the drug product should be provided. The acceptance criteria should contain the final acceptable appearance, including clarity and color, of the dosage form and packaging. If the color changes during storage, a quantitative procedure may be appropriate. This is not a compendial test but is part of the manufacturer's specification of the drug product.

IDENTIFICATION

Identification tests are discussed in *General Notices, 5.40 Identity*. Identification tests should establish the identity of the drug or drugs present in the article and should discriminate between compounds of closely related structures that are likely to be present. Identity tests should be specific for the drug substance(s) [e.g., infrared (IR) spectroscopy]. Near-infrared (NIR) or Raman spectrophotometric methods could be acceptable for the identification of the drug product (see *Near-Infrared Spectroscopy—Theory and Practice* (1119) and *Raman Spectroscopy—Theory and Practice* (1120)). The most widely used identification procedures for drug substance(s) contained in pharmaceutical dosage forms are chromatographic procedures with comparison to the appropriate standards (see *Chromatography* (621) and *Thin-Layer Chromatographic Identification Test* (201)). Identification by use of a single chromatographic retention time does not constitute a specific test.

ASSAY

A specific and stability-indicating test should be used to determine the strength (content) of the drug product. In cases where the use of a nonspecific assay test is justified, other supporting analytical procedures should be used to achieve overall specificity. A specific procedure should be used when there is evidence of excipient interference with the nonspecific assay test. Additional information on specific assays may be found in *Antibiotics—Microbial Assays* (81), (621), *Spectrophotometry and Light-Scattering* (851), and *Ion Chromatography* (1065).

IMPURITIES

Process impurities, synthetic byproducts, and other inorganic and organic impurities may be present in the drug substance and excipients used in the manufacture of the drug product. These impurities are controlled by the drug substance and excipient monographs. Organic impurities arising from the degradation of the drug substance in the drug product and those impurities arising during the manufacturing process of the drug product should be monitored. All articles meet the requirements in *Elemental Impurities—Limits* (232) and *Residual Solvents* (467).

See *pH* (791). Normal tears have a pH of about 7.4. The eye can tolerate products over a range of pH values from about 3.0 to about 8.6, depending on the buffering capacity of the formulation. The pH value of the formulation should be the one where the drug product is the most stable. Formulations that target the extremes of the acceptable pH range will have better patient acceptability if the formulations have a low buffering capacity.

OSMOLARITY

See *Osmolality and Osmolarity* (785). Ophthalmic products may be tolerated over a fairly wide range of tonicity (0.5%–5% sodium chloride, equivalent to about 171–1711 mOsm/kg). Hypotonic solutions are better tolerated than hypertonic solutions. Precautions should be taken to ensure that the product maintains its osmolarity during shelf life. Any possible contributions or interferences from the packaging system should be considered.

PARTICULATE AND FOREIGN MATTER

All ophthalmic products should be inspected for package integrity and, to the extent possible, for the presence of observable foreign and particulate matter (visible particulates). These unwanted particles arise from two sources: extrinsic (i.e., foreign matter); and intrinsic, or product-related matter. Extrinsic matter cannot be associated with the product or process. Intrinsic particles are added during assembly of the product or result from a change over time. A third category, inherent matter, describes a physical state or particles that are an expected attribute of the product.

One hundred percent inspection of injectable products in clear packages is required to remove final packages with visible particles. When 100% inspection of the injectable product in the final package is difficult, such as in opaque containers, alternative methods may be used to determine acceptability. *Visible Particulates in Injections* (790) provides further guidance for general inspection methods and a definition of “essentially free of visible particles” for batch compliance.

Two general categories apply for product administration to the tissues in the eye. Intraocular administration includes all ophthalmic products that cross (penetrate) boundary tissue, such as the cornea and sclera. Extraocular administration of ophthalmic products includes all other ocular components and spaces. For subvisible particle content, USP guidance is followed. Products for intraocular use must comply with *Particulate Matter in Ophthalmic Solutions* (789). Products for extraocular use must comply with *Particulate Matter in Injections* (788). Considerations for product evaluation and the background for both subvisible methods are found in *Methods for the Determination of Particulate Matter in Injections and Ophthalmic Solutions* (1788).

STERILITY

Ophthalmic dosage forms must meet the requirements of *Sterility Tests* (71). If the specific ingredients used in the formulation do not lend themselves to routine sterilization techniques, ingredients that meet the sterility requirements described in (71), along with aseptic manufacture, may be used. The immediate container for ophthalmic products shall be sterile at the time of filling and closing. It is mandatory that the immediate containers for ophthalmic products be sealed and tamper proof so that sterility is ensured at the time of first use.

ANTIMICROBIAL PRESERVATIVES

Antimicrobial agents must be added to products that are packaged in containers that allow for the withdrawal or administration of multiple doses, unless one of the following conditions

prevails: 1) there are different directions in the individual monograph; 2) the substance contains a radionuclide with a physical half-life of <24 h; and 3) the drug product, without additional agents, is sufficiently microbicidal to meet the requirements of *Antimicrobial Effectiveness Testing* (51). Substances must meet the requirements of (51) and *Antimicrobial Agents—Content* (341). Acceptance criteria for antimicrobial preservative content in multiple-unit products should be established.

BACTERIAL ENDOTOXINS

All injected ophthalmic drug products shall be prepared in a manner designed to minimize bacterial endotoxins as defined in *Bacterial Endotoxins Test* (85). The limits are NMT 0.5 EU/mL for ophthalmic irrigation products and NMT 2.0 EU/dose/eye for injected or implanted drug products. Typically, this test is not required for topically applied ophthalmic products. This chapter does not address the endotoxin limits for devices that are injected or implanted.

UNIFORMITY OF DOSAGE UNITS

This test is applicable to dosage forms packaged in single-unit containers. It includes both the mass of the dosage form and the content of the drug substance(s) in the dosage form. The test can be performed by either content uniformity or weight variation (see *Uniformity of Dosage Units* (905)).

CONTAINER CONTENTS

Container contents of ophthalmic products should be determined (see *Minimum Fill* (755)).

LEACHABLES AND EXTRACTABLES

The packaging system should not interact physically or chemically with the product in any manner to alter the strength, quality, or purity of the drug product. The packaging system should meet the requirements in *Elastomeric Closures for Injections* (381), *Containers—Glass* (660), *Plastic Materials of Construction* (661.1), and *Plastic Packaging Systems for Pharmaceutical Use* (661.2). Further information regarding packaging systems testing can be found in *Assessment of Extractables Associated with Pharmaceutical Packaging/Delivery Systems* (1663) and *Assessment of Drug Product Leachables Associated with Pharmaceutical Packaging/Delivery Systems* (1664). The assessment of possible leachables and/or extractables and the establishment of any acceptance criteria for these compounds should take into account the risk assessment of the product, its indication, and its packaging system. Furthermore, it should be noted that a risk assessment of extractable/leachable impact on topical or intraocular route of administration is a challenging undertaking. Toxicological or safety assessments of primary or secondary packaging component extractables and leachables are not typically available for ophthalmic routes of administration. A risk assessment may include evaluation of toxicology and safety from other routes of administration and an assessment of the Total Daily Intake of the extractable/leachable being evaluated. The preponderance of such assessments leads to an estimate of extractable/leachable risk via ocular delivery to the patient.

CONTAINER—CLOSURE INTEGRITY

The packaging system should be closed or sealed in such a manner as to prevent contamination or loss of contents and should provide evidence of being tamper proof. Validation of container integrity must demonstrate no penetration of microbial contamination or of chemical or physical impurities (see *Sterile Product Packaging—Integrity Evaluation* (1207)).

Specific Tests

VISCOSITY

An increase in viscosity increases the residence time in the eye. However, drug diffusion out of the formulation into the eye may be inhibited due to high product viscosity. Ophthalmic ointments are designed to be of very high viscosity to prolong the residence time in the eye. The inclusion of viscosity evaluation in the specification of the product should be based on the type of dosage form and if changes in product viscosity will affect its performance. This is not a compendial test but is part of the manufacturer's specification of the drug product. See *Viscosity—Capillary Methods* (911), *Viscosity—Rotational Methods* (912), and *Viscosity—Rolling Ball Method* (913).

ANTIOXIDANT CONTENT

If antioxidants are present in the drug product, tests of their content should be established, unless oxidative degradation can be detected by another test method such as impurity testing. Acceptance criteria for antioxidant content should be established. They should be based on the levels of antioxidant necessary to maintain the product's stability at all stages throughout its proposed usage and shelf life.

RESUSPENDABILITY/REDISPERSIBILITY

Consideration must be given to establishing good physical stability of a suspension. If the particles settle and eventually produce a cake at the bottom of the container, they must redisperse readily at the time of use to achieve dosage uniformity.

PARTICLE SIZE AND PARTICLE SIZE DISTRIBUTION

The potential for any changes in the particle size of ophthalmic suspensions and emulsions needs to be evaluated through stability testing (see *Light Diffraction Measurement of Particle Size* (429)).

DROP SIZE

For ophthalmic drug products dispensed as drops, drop sizes may typically range from 20 to 70 μL . Drop size can be controlled by weight or by volume, and it is typically evaluated during product development.

ADDED SUBSTANCES

Suitable substances may be added to ophthalmic products to increase stability, unless proscribed in the individual monograph, provided they are harmless in the amounts administered and do not interfere with therapeutic efficacy or with responses to the specified assays and tests. Typically, they should be evaluated during product development. The use of ingredients solely to impart a color, odor, or flavor is prohibited.

BRIEFING

(782) **Vibrational Circular Dichroism Spectroscopy.** The General Chapters—Chemical Analysis Expert Committee proposes this new general chapter about vibrational circular dichroism (VCD) spectroscopy. VCD is an extension of electronic circular dichroism (ECD) from the region of electronic transitions in the UV and visible regions of the spectrum to vibrational transitions in the infrared (IR) region. The principal chapter in *USP* that addresses molecular chirality is *Optical Rotation* (781). Optical rotation (OR) and ECD are the traditional forms of chiroptical spectroscopy, whereas VCD is a newer form of chiroptical spectroscopy that contains more molecular structure information and recently has been adopted more broadly for use in the pharmaceutical industry. For discussion of the theory and principles of VCD

measurements, as well as a more detailed discussion of the application of VCD to problems of pharmaceutical interest, see *Vibrational Circular Dichroism Spectroscopy—Theory and Practice* (1782), which also appears in this *PF*. A related *Stimuli* article titled *Vibrational Circular Dichroism as a New Technology for Determining the Absolute Configuration, Conformation, and Enantiomeric Purity of Chiral Pharmaceutical Ingredients* appeared in *PF* 39(4) and provides insight into the rationale for this proposed chapter.

1. INTRODUCTION

Vibrational circular dichroism (VCD) is a form of chiroptical spectroscopy for which chiral molecules have non-zero spectra with intensities that are identical for mirror-image pairs (enantiomers) of chiral molecules but with signs that are opposite with respect to zero intensity. For a chiral molecular substance, two important properties are: 1) absolute configuration (AC), which indicates which of two mirror-image forms of the molecule is present; and 2) enantiomeric excess (EE, also called enantiomeric purity), the fractional excess of one enantiomer of a chiral molecule over its mirror-image enantiomer. The principal chapter in *USP* that addresses molecular chirality is *Optical Rotation* (781). Optical rotation (OR) and electronic circular dichroism (ECD) are the traditional forms of chiroptical spectroscopy, whereas VCD is a newer form of chiroptical spectroscopy that contains more molecular structure information and recently has been adopted more broadly for use in the pharmaceutical industry.

In this chapter, the required methodology for the use of VCD is described in terms of instrument qualification; sign and intensity calibration; procedures, validation, and verification of VCD measurement; calculation; and statistical analysis as needed for the determination of AC and EE of chiral pharmaceutical products. VCD is the extension of ECD from the region of electronic transitions in the UV and visible regions of the spectrum to vibrational transitions in the infrared (IR) region.

VCD is defined as:

$$\Delta A = A_L - A_R$$

ΔA = difference in the IR absorbance

A_L = sample absorbance for left circularly polarized (LCP) radiation

A_R = sample absorbance for right circularly polarized (RCP) radiation

Unpolarized IR intensity is defined as the average of LCP and RCP intensities:

$$A = (A_L + A_R)/2$$

A = IR absorbance

A_L = sample absorbance for left circularly polarized (LCP) radiation

A_R = sample absorbance for right circularly polarized (RCP) radiation

The IR intensities of enantiomers are identical, whereas enantiomers have equal and opposite-signed VCD intensities.

For discussion of the theory and principles of VCD measurements, as well as a more detailed explanation of the application of VCD to problems of pharmaceutical interest, see *Vibrational Circular Dichroism Spectroscopy—Theory and Practice* (1782) in this issue of *PF*.

2. QUALIFICATION OF VCD SPECTROMETERS

This section on qualification is divided into three subsections: 1) Installation Qualification (IQ), 2) Operational Qualification (OQ), and 3) Performance Qualification (PQ) of a Fourier transform (FT)-VCD instrument. Although a VCD instrument can be based on a scanning dispersive spectrometer, no such VCD spectrometers are commercially available, and hence they will not be considered. Additional details on the qualification of instruments can be found in *Analytical Instrument Qualification* (1058).

2.1 Installation Qualification

The IQ requirements provide evidence that the hardware and software are properly installed in the desired location. An FT-VCD instrument is a sensitive, circular-polarization-difference, FT-infrared (FT-IR) spectrometer. Its installation requires a stable bench-top surface, access to dry air or nitrogen for purging of water vapor, and standard electrical outlets. Evidence for IQ involves ensuring that the IR interferometer is scanning, that its photoelastic modulator(s) [PEM(s)] is operating, and that the electronics hardware is interacting with both the FT-IR main bench and the PEM. The final evidence for IQ is that the software display for acquisition of a VCD spectrum is ready for operator use.

2.2 Operational Qualification

In OQ, an instrument's performance is characterized using a qualification standard of known spectral properties to verify that the system operates within target specifications. The purpose of OQ is to demonstrate that instrument performance is suitable. OQ is a check of the key operational parameters and should be performed after installation and after repairs and/or maintenance.

The OQ tests described in the following sections are typical examples only. Other tests and samples can be used to establish specifications for OQ. Instrument vendors often have samples and test parameters available as part of the IQ/OQ package. The acceptance criteria provided in this section are applicable for general use, whereas specifications for particular instruments and applications may vary, depending on analytical methods used and desired accuracy of the final result.

CHARACTERIZING INSTRUMENT PERFORMANCE

FT-VCD spectrometers measure simultaneously the VCD spectrum and the parent IR spectrum. The VCD spectrum is obtained from a VCD interferogram arising from the combined high-frequency PEM polarization modulation and the Fourier frequencies, whereas the parent IR spectrum arises from the conventional FT-IR interferogram based only on the instrument's Fourier frequencies. Part of the instrument performance is from the underlying FT-IR operation, and the remaining part of the instrument performance is from those components that are uniquely associated with the FT-VCD operation. The combined FT-IR and FT-VCD criteria are wavenumber accuracy and absorbance linearity, whereas those uniquely associated with the VCD operation are: VCD sign and intensity calibration, empty-beam baseline accuracy, sample-associated baseline deviations and artifact levels, baseline stability and spectral reproducibility, and signal-to-noise ratio. As described in (1782), two standard samples are commonly used for specifying VCD performance. For sign and intensity calibration, neat α -pinene is used as a validation standard, whereas for baseline characteristics, a solution of camphor in carbon tetrachloride (CCl_4) is used as the qualification standard. VCD spectra presented in (1782) serve as examples of performance characteristics of typical spectra for VCD sign and intensity calibration, baseline stability, and signal-to-noise ratio.

WAVENUMBER ACCURACY

The wavenumber accuracy of FT-VCD instruments is based on the corresponding wavenumber accuracy of the parent FT-IR operation. This accuracy is determined by fringe counting of the visible laser co-operating with the FT-IR interferometer. The frequency calibration is accurate to within the spectral resolution of the instrument and requires no calibration standard. The accuracy of wavenumber frequency should be checked by measuring the IR spectrum of a 35- μm -thick polystyrene film, as described in the *USP* chapters on mid-IR spectroscopy, *Mid-Infrared Spectroscopy* (854) and *Mid-Infrared Spectroscopy—Theory and Practice* (1854). Because the FT-VCD and FT-IR spectra are simultaneously measured by the action of the same interferometer, the wavenumber accuracy of the VCD spectrum is the same as that of the FT-IR operation of the instrument.

LINEARITY AND STABILITY

Commercial FT-IR instruments have excellent linearity, provided that the infrared detector remains unsaturated. FT-IR spectra are particularly prone to detector saturation, because the

intensity of the entire spectrum is present simultaneously at the detector. Detector saturation can be avoided by the use of a long-wavelength pass filter or appropriate adjustment of the gain of the preamplifier to ensure that the maximum of the FT-IR interferogram lies within the range of preamplifier voltage capability. The hallmark of the onset of nonlinearity is distortion of the FT-IR interferogram that can lead to negative FT-IR absorbance values at the endpoint frequency of the spectral coverage, which is clearly incorrect for an absorbing sample. Aperture reduction, insertion of screens, or neutral density filters can be used to avoid detector saturation.

These same considerations apply to the linearity of FT-VCD measurements. The linearity of VCD is more sensitive to the onset of detector saturation than is the parent IR spectrum. VCD spectra are unstable and distorted when the parent FT-IR spectrum has any saturation, and in some cases linearity in the VCD is not restored until the FT-IR intensity is well below saturation. Saturation can be tested by varying the throughput of the instrument by changing the sample path length and making sure that all of the points across the spectrum are changed by the same factor, i.e., there are no relative shape changes in the spectrum. These relative shape changes should be less than the apparent noise level or, at most, 2% (1.00 ± 0.02), depending on the accuracy needed for the VCD measurements.

PHASE CORRECTION, SIGN, AND INTENSITY CALIBRATION

The raw VCD spectrum is measured as the ratio of the FT of the VCD interferogram to that of the FT of the IR interferogram. Both of these interferograms must be phase corrected before performing the FT. The phase correction for the IR is straightforward, but the phase correction of the VCD interferogram requires transfer of a phase file from a VCD interferogram representing only positive intensities. Most commercial FT-VCD instruments provide such phase files for the measurement of VCD.

Next, the measured raw VCD spectrum must be calibrated such that VCD spectra with the correct signs and intensities are produced. The signs can be determined by measuring the qualification standard of (-)-camphor or (+)-camphor in carbon tetrachloride solution and comparing it to a previously published standard VCD spectrum of this molecule, such as that provided in (1782). Either all of the signs agree, in which case the sign is correctly set, or all of the signs are opposite, in which case the phase of the VCD synchronous detection (lock-in amplifier or numerical processing) must be changed by 180° to reverse the signs of all VCD bands, positive-to-negative and negative-to-positive.

Calibration of VCD intensities is performed by dividing the raw VCD by a calibration curve representing the magnitude of unit VCD intensity for the VCD spectrometer. The shape of the calibration curve follows a first-order Bessel function, which in turn depends on the settings of the PEM generating LCP and RCP radiation. The maximum of the calibration curve corresponds to the maximum wavenumber value set on the PEM controller. The calibration curve for a given PEM setting can be obtained from the crossing points of curves generated by placing a multiple-wave plate followed by a polarizer in place of the sample and measuring the VCD spectrum in the usual manner. Commercial VCD instruments provide such curves, and the correct calibration curve must be used for each wavenumber setting of the PEM. For an example of a calibration curve for the PEM setting at 1200 cm^{-1} , see (1782).

After calibration of the intensities of the VCD instrument, a measurement of a 0.9 M solution of (+)-*R*-camphor in carbon tetrachloride measured in a 100- μm path-length cell should be

approximately 2×10^{-4} . After baseline subtraction, described below and in (1782), this difference should be a positive peak ΔA value of $+1 \times 10^{-4}$ absorbance units at 1240 cm^{-1} and a negative ΔA peak value of -1×10^{-4} at 1040 cm^{-1} .

EMPTY BEAM BASELINE CHARACTERISTICS

To avoid significant levels of baseline deviations from the absorbance features of a sample, the empty beam baseline for a VCD instrument should be as close as possible to the true zero of the measurement. A minimum standard for FT-VCD spectrometers is to have empty beam baselines sufficiently close to zero so that deviations from true zero are <25% of the span of maximum positive-to-negative absorbance intensity of a 0.9 M solution of (+)-*R*-camphor in carbon tetrachloride, measured in a 100- μm path-length cell. This magnitude, noted above, is approximately 2×10^{-4} as determined from a positive peak value of $+1 \times 10^{-4}$ at 1240 cm^{-1} and a negative peak value of -1×10^{-4} at 1040 cm^{-1} . The value of 25% of this intensity range is approximately 5×10^{-5} . VCD empty beam baseline deviations (maximum to minimum), over the mid-IR range from 900 to 1800 cm^{-1} , should not exceed $\pm 5 \times 10^{-4}$ and should not deviate more than $+5 \times 10^{-4}$ or -5×10^{-4} from the zero of VCD intensity over this wavenumber range.

SAMPLE BASELINES AND ABSORPTION ARTIFACTS

An important test for a VCD measurement is the VCD spectrum of a racemic sample relative to that of the baseline of the empty instrument or the VCD spectrum of a nonchiral solvent, such as carbon tetrachloride. Because of possible baseline changes due to the sample cell, it is preferable to compare the VCD of the solvent with that of a solution of the racemic sample of the chiral molecule in the same solvent. Both should have zero VCD, but the racemic solution may have baseline artifacts (offsets) at the location of the absorption bands. Absorption bands change the index of refraction of the sample and can cause baseline deviations that are particular to the sample molecule. If such absorption artifacts are present, the only way to recover the artifact-free VCD spectrum is by subtraction of the racemic mixture (equal quantities of both enantiomers) from that of the measured VCD spectrum. Alternatively, subtraction of the VCD spectrum of the opposite enantiomer is divided by 2, because the VCD intensity doubles if the VCD spectrum of one enantiomer is subtracted from that of the other. The qualification standard used for measuring the VCD baseline with an absorbing sample present is racemic camphor in carbon tetrachloride solution versus the VCD spectrum of neat carbon tetrachloride in the range $900\text{--}1800 \text{ cm}^{-1}$, where there are only absorption bands from camphor and none for carbon tetrachloride. Both samples should have zero VCD and a baseline that is featureless with respect to the camphor absorption bands.

SIGNAL-TO-NOISE RATIO

The signal-to-noise ratio of a VCD measurement can be determined from the noise curve generated by subtracting one-half of the FT scans of a measurement from the other half, thus cancelling the signal and exposing the noise level. The noise level varies across the spectrum and increases when the light level reaching the detector decreases, either due to the overall throughput of the instrument in a particular spectral region or directly within the absorption

bands of the sample. The level of noise in the noise curve can be reduced by increasing the measurement time of the spectrum. The noise level is inversely proportional to the square root of the measurement time. This is illustrated with a particular example in *Figures 9 and 10 of (1782)*.

Smoothing a VCD spectrum without increasing the measurement time will reduce the size of the peak-to-peak noise excursions but will not reduce the overall accuracy of a VCD measurement, because the VCD baseline, and hence the VCD intensity relative to the zero baseline, will undergo the same level of variations, although the VCD spectrum appears to have less noise after smoothing. To know the true level of the noise and hence the uncertainty level of a VCD spectrum, all smoothing functions, if any, should be turned off. Noise can legitimately be reduced by lowering the spectral resolution. In evaluating the noise level of the VCD measurement, the resolution and interferogram apodization must be specified.

2.3 Performance Qualification

PQ determines that the instrument is capable of meeting the user's requirements for all the parameters that may affect the quality of the measurement. Depending on typical use, the specifications for PQ may be different from the manufacturer's OQ specifications; however, for general use across a range of typical chiral molecules and sampling conditions, the specifications for OQ will be the same as those needed for PQ. For validated methods, specific PQ tests, also known as system suitability tests, can be used in lieu of PQ requirements. Specific procedures, acceptance criteria, and time intervals for characterizing performance depend on the instrument and intended application. Demonstrating stable instrument performance over extended periods of time provides some assurance that reliable measurements can be taken from test sample spectra.

Particular long-term stability tests that can be carried out for PQ evaluation beyond those carried out for IQ or OQ are as follows. It is recommended that a 60-min measurement of a 0.9 M solution of (+)-*R*-camphor in carbon tetrachloride, measured in a 100- μm path-length cell, be performed between different applications of the VCD spectrometer to ensure that the signs, intensities, and signal-to-noise ratio of the VCD spectrum established as a qualification test during OQ are maintained. This is particularly important if there has been an interruption in power or a long hiatus between measurements.

If averaging over long periods of time, such as overnight, it is important that the stability of both the VCD baseline and the sample VCD spectrum are stable over time and that the signal-to-noise ratio improves as expected with the square-root of measurement time or number of interferometer scans, as illustrated by the example in (1782). In general, stability should be maintained to within the noise level of the VCD measurement. Because VCD intensities are generally three to four orders of magnitude smaller than the parent IR intensity, the instrument stability for the FT-IR performance of the instrument is typically larger over time relative to the noise level of the VCD spectrum.

3. PROCEDURE

The measurement of the VCD spectrum of a sample follows the same general rules as the measurement of an IR spectrum as for mid-IR spectroscopy described in (854).

3.1 Sample

A VCD spectrum can be measured in all types of standard IR transmission cells, either for neat liquids or solutions. For solids, such as in potassium bromide (KBr) pellets, mulls, or thin films, it is recommended that additional steps be taken to ensure that artifacts arising from sample linear birefringence are not present as described in (1782) for advanced instrumentation methods, such as dual PEM modulation or rotating sample cells.

Because of the importance of noise control in a VCD measurement, the absorbance of a sample should not exceed $A = 1.0$ in the region of measurement interest. For absorbance >1.0 , insufficient radiation is present at the detector, and noise dominates the VCD spectrum. The optimum level of absorbance relative to the sample reference (empty beam or solvent) is approximately 0.4. One should adjust the path length and/or concentration of the sample such that the average absorbance is approximately 0.4–0.5 over the region of interest, with limits of 0.1–1.0. For samples with a wide range of absorbance, more than one measurement can be carried out with differing average absorbance values to ensure that a VCD spectrum of adequate quality is obtained over the entire range of interest.

To perform a solution-state VCD measurement, first find a solvent that dissolves an adequate amount of solute to achieve a desired absorbance level. Solvents without CH bonds are the most desirable for this purpose; these include carbon tetrachloride, deuterated chloroform (CDCl_3), or deuterated dimethyl sulfoxide (DMSO-d_6). The IR cell should have windows that are transparent in the mid-IR region, with generally low levels of linear birefringence. Commonly used materials are barium fluoride (BaF_2), which has good transmission to 800 cm^{-1} , and calcium fluoride (CaF_2), which is used if coverage to only $1100\text{--}1200\text{ cm}^{-1}$ is needed, such as for aqueous solutions.

3.2 Standard

To ensure that the analyst can use an IR cell for a transmission measurement of a solution, it is recommended that a standard OQ measurement of a 0.9 M solution of (+)-*R*-camphor in carbon tetrachloride using a 100- μm barium fluoride cell be performed. For different choices of concentration or path length, one can use the linear dependence of these quantities on the measured ΔA to ensure that an accurate measurement with the correct signs and intensities has been achieved.

3.3 Analysis

VCD spectra, once measured, can be analyzed in a variety of ways, depending on the intended application. The principal application of VCD in the pharmaceutical industry is the determination of absolute configuration (AC) in conjunction with a VCD calculation using a quantum chemistry computation software package. A second application is the determination of EE of a sample, either for the purpose of determining the EE of a sample or for monitoring the EE of one or more species during the course of the chemical reaction involving chiral species. Achievement of the highest level of accuracy in the determination of EE requires the use of a chemometric software package that uses the entire range of the VCD spectrum, as opposed to a single band or wavenumber frequency. Other applications of VCD are its use with a standard database of VCD and IR spectra to simultaneously ensure the correct identity, AC, and EE of a chiral substance, for example as a chiral raw material identification. VCD can also be used to specify the AC and EE of a drug product in the presence of either achiral or chiral excipients, such as

carbohydrates. These applications are described in more detail in (1782).

4. VALIDATION AND VERIFICATION

4.1 Validation

The objective of VCD procedure validation, as with the validation of any analytical process, is to demonstrate that the measurement is suitable for its intended purpose. The application of VCD spectroscopy is somewhat different from that of conventional vibrational spectroscopic techniques because it is not a primary technique. Rather, it is the polarization difference spectroscopy of the parent IR spectroscopy that has been used by itself for decades as a primary identification and quantitation technique as described for mid-IR spectroscopy in (854). The differential VCD spectrum supplements the parent IR spectrum with a new set of intensities at each position of an IR absorption band. The new set of intensities then reveals stereospecific properties of the sample molecules that must be chiral to have a non-zero VCD spectrum. There are two primary properties of a sample of a chiral molecule; one is the AC of the dominant chiral species (dominant enantiomer), and the second property is the EE of the dominant enantiomer over its lesser (mirror-image) enantiomer. In addition, the VCD spectrum carries additional information about the solution-state conformation, or conformational distribution, of the molecule that may be available in only lesser detail, if any, using the parent IR spectrum alone. Applications that require validation for the use of VCD spectroscopy also exist for the combined use of the measurement of the VCD of a substance for which there exists a reference spectrum with known AC and EE. Any subsequent measurement of the VCD spectrum, together with the simultaneous measurement of its parent IR spectrum, confirms in one measurement the molecular identity of the sample as well as the AC and EE. Such applications are useful, for example, for chiral raw-material identification of AC and EE, for which there is currently no established methodology for a single measurement. VCD can also confirm, in a single measurement, the AC and EE of a final drug product, including the chirality (if any) of the excipients.

Before validation of VCD for AC determination, an overall instrument validation should be carried out by the measurement of the VCD spectrum of neat (-)-*S*- α -pinene or (+)-*R*- α -pinene using a 75- μ m cell. The calibrated, baseline-corrected VCD spectrum should yield a positive peak maximum of ΔA equal to approximately $+5 \times 10^{-4}$ absorbance units at 1220 cm^{-1} , and a negative peak value of approximately -4×10^{-4} at 1130 cm^{-1} . The noise level should be comparable to that established for the instrument during the OQ phase of instrumental qualification described above. Because the VCD spectrum of α -pinene is relatively large, sufficient signal-to-noise ratio is available with a 20-min collection to verify that the instrument is operating with correct VCD intensities, signs, and noise levels for the applications of VCD described below.

Validation for AC determination by VCD can be achieved by the successful comparison of the measured VCD spectrum of the validation standard, neat (-)-*S*- α -pinene, to its quantum chemistry calculated VCD spectrum. Success is achieved by measuring the baseline-corrected VCD spectrum with sufficient signal-to-noise ratio that the signs, frequencies, and relative intensities of the major VCD bands can be compared clearly to the corresponding VCD signs, frequencies, and relative intensities of the calculated VCD spectrum. If the signs, frequencies, and relative intensities agree, then the AC of the measured sample of (-)- α -pinene is the same

as that for the model of *S*- α -pinene that has been constructed for the calculation of this standard molecule. If the frequencies and relative VCD intensities are opposite after instrument sign calibration, then the AC of the sample is opposite (the mirror image) of the enantiomer used for the calculation. A successful comparison requires pretreatment of the VCD data for baseline subtraction and intensity calibration. It also requires a computational procedure that is known to be accurate in calculating VCD spectra. Finally, a program should be used to impartially assess the degree of agreement between measured and calculated VCD spectra such that one relies on more than an analyst's visual assessment of the agreement, or lack of agreement, between a measured spectrum and a calculated spectrum. An example of this procedure can be found in (1782) as well as in the references cited in (1782).

Validation of VCD spectroscopy for the determination of EE is achieved by plotting the EE predicted by VCD versus the EE for a sample of neat (–)-*S*- α -pinene for a series of samples with differing values of %EE over the range from 100% EE to 0% EE. The EE predicted by VCD involves measurement of the VCD spectra at a chosen spectral resolution and time of collection to achieve a desired level of signal-to-noise ratio, followed by pretreatment of the measured VCD spectra for baseline subtraction. The prediction of EE could be based on a size of a single VCD band for the samples with differing VCD, normalized for constant IR intensity; but more generally and with better accuracy, the entire range of VCD bands across the spectrum is used for each spectrum by means of a chemometrics software package. Validation is accompanied by a measure of the %EE accuracy through a cross-correlation analysis, yielding a root mean square (RMS). An example of such a determination of %EE by VCD for neat (–)-*S*- α -pinene is provided, along with literature references, in (1782).

More generally, validation is required when a method is intended for use as an alternative to the official procedure for testing an official article. The objective is to demonstrate that the measurement of VCD is suitable for its intended purpose as described for various types of measurements in *Validation of Compendial Procedures* (1225). For %EE determination, creation of a linear plot of actual versus VCD-predicted values of %EE establishes that the magnitude of IR-normalized VCD spectra, as evaluated with chemometrics, exhibits sufficient linearity, range, accuracy, specificity, precision, detection limit, quantitation limit, and robustness with respect to the detection of %EE.

Chapter (1225) provides definitions and general guidance on analytical procedures validation without indicating specific validation criteria for each characteristic. The intention of the following sections is to provide the user with specific validation criteria that represent the minimum expectations for VCD technology. For each particular application, tighter criteria may be needed to demonstrate suitability for the intended use.

ACCURACY

Accuracy can be determined by the measurement of a VCD spectrum of the established validation standard of neat (–)- α -pinene or (+)- α -pinene, as presented, for example, in (1782), and verifying that the measured signs and intensities of the VCD spectrum agree with the standard VCD spectrum to within the noise level of the measurement. In particular, the VCD spectrum should yield a positive peak maximum of ΔA equal to approximately $+5 \times 10^{-4}$ absorbance units at 1220 cm^{-1} and a negative peak value of approximately -4×10^{-4} at 1130 cm^{-1} . This validation ensures that the VCD spectrometer is accurately calibrated and has the correct signs for the VCD bands.

4.2 Precision

REPEATABILITY

Validation criteria: Measurement of VCD spectra of the validation standard sample, neat (+)- α -pinene or (-)- α -pinene, in 20-min blocks with variations in the VCD spectra at or less than the noise level of each 20-min block that is approximately ΔA equal to or less than 1×10^{-5} .

INTERMEDIATE PRECISION

The effect of random events on the analytical precision of the validation criteria of VCD measurement should be established. Typical variables include performing the analysis on different days, using different instrumentation, or having the method performed by two or more analysts. As a minimum, any combination of at least two of these factors totaling six experiments will provide an estimation of intermediate precision. (For example, this could be two analysts on each of 3 days, or two analysts on two sets of equipment on 2 days for each analyst–equipment combination.)

Validation criteria: The *Validation criteria* are the same as those for *Repeatability*, above.

SPECIFICITY

Specificity is not a required metric for the determination of AC. For the measurement of EE for more than one chiral species in a single set of measurements, the analytical procedure, including chemometric analysis, must be able to unequivocally assess the EE of chiral species in the presence of components that may be expected to be present, i.e., solvent and other nonchiral species.

Validation criteria: The *Validation criteria* are demonstrated by meeting the *Accuracy* requirement.

QUANTITATION LIMIT

For the determination of AC, there is no quantitation limit (QL). The QL for EE can be determined by carrying out a determination of quantitation of %EE for the VCD validation standard of neat α -pinene for a series of EE values, performing a chemometric analysis of VCD-predicted EE values and performing a determination of RMS error, as illustrated, for example, in (1782).

Validation criteria: The analytical procedure should be capable of determining the analyte precisely and accurately at a level equivalent to approximately 1% EE for neat α -pinene.

LINEARITY

A linear relationship between the analyte concentration and response should be demonstrated by preparing NLT 5 standard solutions at concentrations encompassing the anticipated concentration of the test solution. The standard curve should then be evaluated using appropriate statistical methods, such as a least-squares regression, for the area of peak height of a selected VCD band, or for the entire spectrum, using chemometric analysis such as partial least squares. For experiments that do not yield a linear relationship between analyte concentration and response, appropriate statistical methods must be applied to describe the analytical response.

Validation criteria: The *Validation criteria* find the correlation coefficient above 0.95 for a

linear plot of actual EE versus VCD-predicted EE.

ROBUSTNESS

The reliability of an analytical measurement should be demonstrated by deliberate changes to experimental parameters, such as changes in spectral resolution, concentration, or path length for measurement of VCD.

4.3 Verification

U.S. Current Good Manufacturing Practices regulations [21 CFR 211.194(a)(2)] indicate that users of the analytical procedures, as described in *USP-NF*, are not required to validate these procedures if provided in a monograph. Instead, they must simply verify their suitability under actual conditions of use.

The objective of procedure verification is to demonstrate that the procedure, as prescribed in a specific monograph, can be executed by the analysts with suitable accuracy, specificity, and precision using the instruments, and sample solutions of chiral molecules available. According to *Verification of Compendial Procedures* (1226), if the verification of the compendial procedure by following the monograph is not successful, the procedure may not be suitable for use with the article under test. It may be necessary to develop and validate an alternative procedure as allowed in *General Notices* 6.30.

Verification of compendial methods should, at a minimum, include the execution of the validation parameters for specificity, accuracy, precision, and limit of quantitation, when appropriate, as indicated in *Validation*. ■ 2S (*USP39*)

BRIEFING

(821) **Radioactivity**, *USP 38* page 616. This chapter was introduced in its current form in 1975 and has not undergone any major revision since its first publication. Currently, the chapter contains definitions, special considerations, and procedures with respect to the monographs for radiopharmaceuticals (radioactive drugs). The majority of this chapter is informational. USP has launched an initiative to minimize nonprocedural information in general chapters with numbers below 1000. The USP Council of Experts believes that (821) should be revised as part of this initiative. To achieve this objective, several members of the USP Council of Experts jointly published a *Stimuli* article in *PF 38(4)* [July–Aug. 2012], *Revision of General Chapter Radioactivity* (821). The objectives of this *Stimuli* article were threefold: (1) provide background information about the need for the proposed revision, (2) initiate discussion about this topic, and (3) solicit public comments for review and discussion by the relevant Expert Committee and Expert Panel members and USP staff.

The current chapter is divided into two major sections, *General Considerations* and *Identification and Assay of Radionuclides*, both of which contain several subsections with information about aspects of radioactivity. Because of the nature of the information presented in these subsections, these can be moved to the proposed *Radioactivity—Theory and Practice* (1821). The *Terms and Definitions* section is now listed as *Glossary* and has been revised to reflect current practices. The revised chapter will contain procedures and information about instrumentation used in the identification and assay of the radionuclides, along with appropriate information about calibration and maintenance of instrumentation. To make the chapter more useful, we propose to include quantitative requirements such as minimum resolution for the detector, allowed variation for instrument performance, and appropriate interval for

performance checks, as well as other useful parameters that can ensure the suitability of the equipment for its intended use. Interested parties are invited to submit their comments to the proposed revisions of the chapter.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

The following Briefing list includes monographs and/or chapters that both reference the General Chapter under revision and require revision to keep references to the General Chapter accurate. Other monographs and/or chapters may also be listed, even where the reference to the General Chapter remains unchanged, as additional notice to stakeholders where there is believed to be potential for the change in the general chapter itself to affect pass-fail determinations for particular monograph articles.

(821) RADIOACTIVITY

Change to read:

~~Radioactive pharmaceuticals require specialized techniques in their handling and testing in order that correct results may be obtained and hazards to personnel be minimized. All operations should be carried out or supervised by personnel having had expert training in handling radioactive materials.~~

~~The facilities for the production, use, and storage of radioactive pharmaceuticals are generally subject to licensing by the federal Nuclear Regulatory Commission, although in certain cases this authority has been delegated to state agencies. The federal Department of Transportation regulates the conditions of shipment of radioactive materials. State and local agencies often have additional special regulations. Each producer or user must be thoroughly cognizant of the applicable regulations of the federal Food, Drug, and Cosmetic Act, and any additional requirements of the U. S. Public Health Service and of state and local agencies pertaining to the articles concerned.~~

~~Definitions, special considerations, and procedures with respect to the Pharmacopeial monographs on radioactive drugs are set forth in this chapter.~~

GENERAL CONSIDERATIONS

Fundamental Decay Law

~~The decay of a radioactive source is described by the equation:~~

$$N_t = N_0 e^{-\Lambda t}$$

~~in which N_t is the number of atoms of a radioactive substance at elapsed time t , N_0 is the number of those atoms when $t = 0$, and Λ is the transformation or decay constant, which has a characteristic value for each radionuclide. The *half-life*, $T_{1/2}$, is the time interval required for a given activity of a radionuclide to decay to one-half of its initial value, and is related to the decay constant by the equation:~~

$$T_{1/2} = 0.69315/\Lambda$$

~~The activity of a radioactive source (A) is related to the number of radioactive atoms present by the equation:~~

$$A = \Lambda N$$

~~from which the number of radioactive atoms at time t can be computed, and hence the mass of the radioactive material can be determined.~~

~~The activity of a pure radioactive substance as a function of time can be obtained from the exponential equation or from decay tables, or by graphical means based on the half-life (see *Normalized Decay Chart, Figure 1*).~~

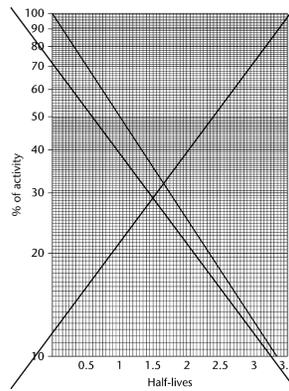

Fig. 1. Normalized Decay Chart.

The activity of a radioactive material is expressed as the number of nuclear transformations per unit time. The fundamental unit of radioactivity, the *curie* (Ci), is defined as 3.700×10^{10} nuclear transformations per second. The *millicurie* (mCi) and *microcurie* (μ Ci) are commonly used subunits. The "number of nuclear transformations per unit time" is the sum of rates of decay from all competing modes of disintegration of the parent nuclide. Before the activity of any given radionuclide in a measured specimen can be expressed in curies, it is often necessary to know the abundance(s) of the emitted radiation(s) measured.

Geometry

The validity of relative calibration and measurement of radionuclides is dependent upon the reproducibility of the relationship of the source to the detector and its surroundings. Appropriate allowance must be made for source configuration.

Background

Cosmic rays, radioactivity present in the detector and shielding materials, and radiation from nearby radioactive sources not properly shielded from the measuring equipment, all contribute to the background count rate. All radioactivity measurements must be corrected by subtracting the background count rate from the gross count rate in the test specimen.

Statistics of Counting

Since the process of radioactive decay is a random phenomenon, the events being counted form a random sequence in time. Therefore, counting for any finite time can yield only an estimate of the true counting rate. The precision of this estimate, being subject to statistical fluctuations, is dependent upon the number of counts accumulated in a given measurement and can be expressed in terms of the standard deviation Σ . An *estimate* for Σ is

$$\sqrt{n}$$

where n is the number of counts accumulated in a given measurement. The probability of a single measurement falling within

$$\pm 100/\sqrt{n}\%$$

of the mean of a great many measurements is 0.68. That is, if many measurements of n counts each were to be made, approximately two thirds of the observations would lie within

$$\pm 100/\sqrt{n}\%$$

of the mean, and the remainder outside.

Because of the statistical nature of radioactive decay, repeated counting of an undisturbed source in a counting assembly will yield count rate values in accordance with the frequency of a normal distribution. Deviations in these values from the normal distribution conform to the χ^2 test. For this reason, the χ^2 test is frequently applied to determine the performance and correct operation of a counting assembly. In the selection of instruments and conditions for assay of radioactive sources, the figure of merit ϵ^2/B should be maximized (where ϵ = counter efficiency = observed count rate/sample disintegration rate, and B = background count rate).

Counting Losses

The minimum time interval that is required for the counter to resolve two consecutive signal pulses is known as the dead time. The dead time varies typically from the order of microseconds for proportional and scintillation counters, to hundreds of microseconds for Geiger-Müller counters. Nuclear events occurring within the dead time of the counter will not be registered. To obtain the corrected count rate, R , from the observed count rate, r , it is necessary to use the formula:

$$R = r / (1 - r\tau)$$

in which τ is the dead time. The foregoing correction formula assumes a nonextendable dead time. Thus, for general validity, the value of $r\tau$ should not exceed 0.1. The observed count rate, r , refers to the gross specimen count rate and is not to be corrected for background before use in the foregoing equation.

Calibration Standards

Perform all radioactivity assays using measurement systems calibrated with appropriately certified radioactivity standards. Such calibration standards may be purchased either direct from the National Institute of Standards and Technology or from other sources that have established traceability to the National Institute of Standards and Technology through participation in a program of inter-comparative measurements. Where such calibration standards are unavailable, the Pharmacopeia provides the nuclear decay data required for calibration. These data, as well as half-life values, are obtained from the Evaluated Nuclear Structure Data File of the Oak Ridge Nuclear Data Project, and reflect the most recent values at the time of publication.

Carrier

The total mass of radioactive atoms or molecules in any given radioactive source is directly proportional to the activity of the radionuclide for a given half-life, and the amount present in radiopharmaceuticals is usually too small to be measured by ordinary chemical or physical methods. For example, the mass of ^{131}I having an activity of 100 mCi is 8×10^{-7} g. Since such small amounts of material behave chemically in an anomalous manner, carriers in the form of nonradioactive isotopes of the same radionuclide may be added during processing to permit ready handling. In many cases, adsorption can be prevented merely by increasing the hydrogen ion concentration of the solution. Amounts of such material, however, must be sufficiently small that undesirable physiological effects are not produced. The term "carrier-free" refers only to radioactive preparations in which nonradioactive isotopes of the radionuclide are absent. This implies that radioactive pharmaceuticals produced by means of (n, f) reactions cannot be considered carrier-free.

The activity per unit volume or weight of a medium or vehicle containing a radionuclide either in the carrier-free state or in the presence of carrier is referred to as the radioactive concentration, whereas the term specific activity is used to express the activity of a radionuclide per gram of its element.

Radiochemical Purity

Radiochemical purity of a radiopharmaceutical preparation refers to the fraction of the stated radionuclide present in the stated chemical form. Radiochemical impurities in radiopharmaceuticals may result from decomposition and from improper preparative procedures. Radiation causes decomposition of water, a main ingredient of most radiopharmaceuticals, leading to the production of reactive hydrogen atoms and hydroxyl radicals, hydrated electrons, hydrogen, hydrogen ions, and hydrogen peroxide. The last mentioned is formed in the presence of oxygen radicals, originating from the radiolytic decomposition of dissolved oxygen. Many radiopharmaceuticals show improved stability if oxygen is excluded. Radiation may also affect the radiopharmaceutical itself, giving rise to ions, radicals, and excited states. These species may combine with one another and/or with the active species formed from water. Radiation decomposition may be minimized by the use of chemical agents that act as electron or radical scavengers. Electrons trapped in solids cause discoloration due to formation of F-centers and the darkening of glass containers for radiopharmaceuticals, a situation that typifies the case. The radiochemical purity of radiopharmaceuticals is determined by column, paper, and thin-layer chromatography or other suitable analytical separation techniques as specified in the individual monograph.

Radionuclidic Purity

Radionuclidic purity of a radiopharmaceutical preparation refers to the proportion of radioactivity due to the desired radionuclide in the total radioactivity measured. Radionuclidic purity is important in the estimation of the radiation dose received by the patient when the preparation is administered. Radionuclidic impurities may arise from impurities in the target materials, differences in the values of various competing production cross-sections, and excitation functions at the energy or energies of the bombarding particles during production.

Terms and Definitions

The *date of manufacture* is the date on which the manufacturing cycle for the finished product is completed.

The *date of assay* is the date (and time, if appropriate) when the actual assay for radioactivity is performed.

The *date of calibration* is an arbitrary assigned date and time to which the radioactivity of the product is calculated for the convenience of the user.

The *expiration date* is the date that establishes a limit for the use of the product. The expiration period (i.e., the period of time between the date of manufacture and the expiration date) is based on a knowledge of the radioactive properties of the product and the results of stability studies on the finished dosage form.

Labeling

Individual radiopharmaceutical monographs indicate the expiration date, the calibration date, and the statement, "Caution—Radioactive Material." The labeling indicates that in making

dosage calculations, correction is to be made for radioactive decay, and also indicates the radioactive half-life of the radionuclide. Articles that are Injections comply with the requirements for *Labeling under Injections* (1), and those that are Biologics comply with the requirements for *Labeling under Biologics* (1041).

IDENTIFICATION AND ASSAY OF RADIONUCLIDES

Instrumentation

IONIZATION CHAMBERS

An ionization chamber is an instrument in which an electric field is applied across a volume of gas for the purpose of collecting ions produced by a radiation field. The positive ions and negative electrons drift along the lines of force of the electric field, and are collected on electrodes, producing an ionization current. In a properly designed well-type ionization chamber, the ionization current should not be too dependent on the position of the radioactive specimen, and the value of the current per unit activity, known as the calibration factor, is characteristic of each gamma-ray emitting radionuclide.

The ionization current produced in an ionization chamber is related to the mean energy of the emitted radiation and is proportional to the intensity of the radiation. If standard sources of known disintegration rates are used for efficiency calibration, the ionization chamber may then be used for activity determinations between several microcuries and several hundred millicuries or more. The upper limit of activity that may be measured in an ionization chamber usually is not sharply defined and may be limited by saturation considerations, range of the amplifier, and design of the chamber itself. The data supplied with or obtained from a particular instrument should be reviewed to ascertain the useful ranges of energies and intensities of the device.

Reproducibility within approximately 5% or less can be readily obtained in about 10 seconds, with a deep re-entrant well-type chamber. The most commonly used form of ionization chamber for measurement of the activities of radiopharmaceuticals is known as a dose calibrator.

Although the calibration factor for a radionuclide may be interpolated from an ionization chamber energy-response curve, there are a number of sources of error possible in such a procedure. It is therefore recommended that all ionization chamber calibrations be performed with the use of authentic reference sources of the individual radionuclides, as described hereinafter.

The calibration of a dose calibrator should be maintained by relating the measured response of a standard to that of a long-lived performance standard, such as radium-226 in equilibrium with its daughters. The instrument must be checked daily with the ^{226}Ra or other source to ascertain the stability over a long period of time. This check should include performance standard readings at all radionuclide settings employed. To obtain the activity (A_x) of the radionuclide being measured, use the relationship:

$$A_x = R_x R / R_n$$

in which R_n is the new reading for the radium or other source, R_c is the reading for the same source obtained during the initial calibration procedure, and R is the observed reading for the radionuclide specimen. Obviously, any necessary corrections for radioactive decay of the reference source must first be applied. Use of this procedure should minimize any effects due to

drift in the response of the instrument. The recommended activity of the ^{226}Ra or other monitor used in the procedure described above is 75 to 150 μCi . It is recommended also that the reproducibility and/or stability of multirange instruments be checked for all ranges with the use of appropriate standards.

The size and shape of a radioactive source may affect the response of a dose calibrator, and it is often necessary to apply a small correction when measuring a bulky specimen.

SCINTILLATION AND SEMICONDUCTOR DETECTORS

When all or part of the energy of beta or gamma radiation is dissipated within scintillators, photons of intensity proportional to the amount of dissipated energy are produced. These pulses are detected by an electron multiplier phototube and converted to electrical pulses, which are subsequently analyzed with a pulse height analyzer to yield a pulse height spectrum related to the energy spectrum of the radiation emitted by the source. In general, a beta-particle scintillation pulse height spectrum approximates the true beta energy spectrum, provided that the beta-particle source is prepared in such a manner that self-absorption is minimized. Beta ray spectra may be obtained by using calcium fluoride or anthracene as the scintillator, whereas gamma ray spectra are usually obtained with a thallium-activated sodium iodide crystal or a large volume lithium-drifted germanium semiconductor detector. The spectra of charged particles also may be obtained using silicon semiconductor detectors and/or gas proportional counters. Semiconductor detectors are in essence solid-state ionization chambers, but the energy required to create an electron-hole pair or to promote an electron from the valence band to the conduction band in the semiconductor is about one-tenth the energy required for creation of an ion pair in a gas-filled ionization chamber or proportional counter and is far less than the energy needed to produce a photon in a NaI(Tl) scintillation crystal. In gamma ray spectrometry, a Ge(Li) detector can yield an energy resolution of 0.33% for 1.33 MeV gamma rays from ^{60}Co , while a 3 × 3 inch NaI(Tl) crystal can give a value of 5.9% for the same gamma ray energy. The energy resolution is a measure of the ability to distinguish the presence of two gamma rays closely spaced in energy and is defined by convention as the full width of the photopeak at its half maximum (FWHM), expressed in percentage of the photopeak energy.

Gamma ray spectra exhibit one or more sharp, characteristic photopeaks, or full-energy peaks, as a result of total absorption in the detector of the full energy of gamma radiations from the source; these photopeaks are useful for identification purposes. Other secondary peaks are observed as a consequence of backscatter, annihilation radiation, coincidence summing, fluorescent X-rays, etc., accompanied by a broad band known as the Compton continuum arising from scattering of the photons in the detector and from surrounding materials. Since the photopeak response varies with gamma ray energy, calibration of a gamma ray spectrometer should be achieved with radionuclide standards having well-known gamma ray energies and emission rates. The shape of the gamma ray spectrum is dependent upon the shape and size of the detector and the types of shielding materials used.

When confirming the identity of a radionuclide by gamma ray spectrometry, it is necessary to make a comparison of the specimen spectrum with that of a specimen of known purity of the same radionuclide obtained under *identical instrument parameters and specimen geometry*. Where the radionuclides emit coincident X- or gamma radiations, the character of the pulse-height distribution often changes quite dramatically because of the summing effect of these coincident radiations in the detector as the efficiency of detection is increased (e.g., by

bringing the source closer to the detector). Such an effect is particularly evident in the case of iodine-125. Among the more useful applications of gamma-ray spectrometry are those for the identification of radionuclides and the determination of radionuclidic impurities.

Where confirmation of the identity of a given radionuclide by means of a direct comparison with the spectrum of a specimen of the same radionuclide of known purity is not possible, the identity of the radionuclide in question must then be established by the following method. Two or more of the following nuclear decay scheme parameters of the radionuclide specimen to be identified shall be measured, and agreement shall be within $\pm 10\%$: (1) half-life, (2) energy of each gamma- or X-ray emitted, (3) the abundance of each emission, and (4) E_{\max} for those radionuclides that decay with beta-particle emissions. Such measurements are to be performed as directed in the *Identification* and *Assay* sections of this chapter. Agreement of two or more of the measured parameters with the corresponding published nuclear decay scheme data constitutes confirmation of the identity of the radionuclide.

LIQUID-SCINTILLATION COUNTERS

Alpha- and beta-emitting radionuclides may be assayed with the use of a liquid-scintillation detector system. In the liquid scintillator, the radiation energy is ultimately converted into light quanta that are usually detected by two multiplier phototubes so arranged as to count only coincidence radiation. The liquid scintillator is a solution consisting of a solvent, primary and secondary solutes, and additives. The charged particle dissipates its energy in the solvent, and a fraction of this energy is converted into fluorescence in the primary solute. The function of the secondary solute is to shift the fluorescence radiation to longer wavelengths that are more efficiently detected by the multiplier phototubes. Frequently used solvents are toluene and *p*-xylene; primary solutes are 2,5-diphenyloxazole (PPO) and 2-(4'-*tert*-butylphenyl)-5-(4-biphenyl)-1,3,4-oxadiazole (butyl-PBD); and secondary solutes are 2,2'-*p*-phenylenebis[4-methyl-5-phenyloxazole] (dimethyl-POPOP) and *p*-bis(*o*-methylstyryl)benzene (bis-MSB). As a means of attaining compatibility and miscibility with aqueous specimens to be assayed, many additives, such as surfactants and solubilizing agents, are also incorporated into the scintillator. For an accurate determination of radioactivity of the specimen, care must be exercised to prepare a specimen that is truly homogeneous. The presence of impurities or color in solution causes a decrease in photon output of the scintillator; such a decrease is known as quenching. Accurate radioactivity measurement requires correcting for count-rate loss due to quenching.

The disintegration rate of a beta-particle source may be determined by a procedure in which the integral count rate of the specimen is measured as a function of the pulse-height discriminator bias, and the emission rate is then obtained by extrapolation to zero bias. Energetic alpha-particle emitters may be similarly measured by this method.

Identification

A radionuclide can be identified by its mode of decay, its half-life, and the energies of its nuclear emissions.

The radioactive half-life is readily determined by successive counting of a given source of the radionuclide over a period of time that is long compared to its half-life. The response of the counting assembly when employed for the decay measurement of long-lived radionuclides should be monitored with an even longer-lived reference source to assess and compensate for errors arising from electronic drift. In the case of short-lived radionuclides, when the counting period constitutes a significant fraction of the half-life of the radionuclide, the recorded count

rate must be corrected to the time when the count is initiated, as follows:

$$R_t = rAt/(1 - e^{-\Lambda t})$$

in which R_t is the count rate at the beginning of a counting period, r is the count rate observed over the entire counting period, t is the duration of the counting period, Λ is the decay constant of the radionuclide, and e is the base of the natural logarithm. When t is small compared to the half-life of the radionuclide under study so that $\Lambda t < 0.05$, then $(1 - e^{-\Lambda t})$ approaches Λt , and no such correction is necessary.

The energy of nuclear emissions is often determined by the maximum range of penetration of the radiation in matter (in the case of alpha and beta particles) and by the full-energy peak or photopeak in the gamma-ray spectrum (in the case of X and gamma rays). Since beta particles are emitted with a continuous energy spectrum, the maximum beta energy, E_{\max} , is a unique index for each beta-emitting radionuclide. In addition to the maximum range and energy spectrum of the beta particles, the absorption coefficient, when obtained under reproducible counting conditions, can serve as a reliable index for identification of a beta emitter. Fortunately, beta particles are absorbed in matter in an approximately exponential manner, and a plot of the logarithm of the beta-particle count rate as a function of the absorber thickness is known as the absorption curve. The initial portion of the absorption curve shows linearity from which the absorption coefficient can be obtained. The maximum range is determined by the use of absorbers of varying thickness, and the energy spectrum is measured by beta-ray scintillation spectrometry.

The absorption of gamma rays in matter is strictly exponential, but the half-value layers of attenuation have not been very useful for the purpose of radionuclide characterization. Gamma rays from each isomeric transition are mono-energetic; their energy can be directly measured by gamma-ray spectrometry. Because of their high energy resolution, solid-state detectors [Ge(Li)] are vastly superior to scintillation detectors [NaI(Tl)] in gamma-ray spectrometry.

The activities of radiopharmaceutical solutions are frequently in the range of millicuries per mL. Such solutions usually must be extensively diluted before they can be accurately assayed. The diluent should be compatible with the radiopharmaceutical with respect to factors such as pH and redox potentials, so that no hydrolysis or change in oxidation state occurs upon dilution, which could lead to adsorption and separation of the radionuclide from solution.

BETA-EMITTING RADIONUCLIDES

Mass Absorption Coefficient Procedure—Deposit and dry an aliquot of the radioactive phosphorus-32 solution on a thin plastic film to minimize backscattering, and place it under a suitable counter. Determine the counting rates successively, using not less than six different "thicknesses" of aluminum each between 20 and 50 mg/cm² and a single absorber thicker than 800 mg/cm², which is used to measure the background. (The absorbers are inserted between the test specimen and the counter but are placed nearer the counter window to minimize scattering.) Net beta-particle count rates are obtained after subtraction of the count rate found with the absorber having a thickness of 800 mg/cm² or greater. Plot the logarithm of the net beta-particle count rate as a function of the total absorber "thickness." The total absorber "thickness" is the "thickness" of the aluminum absorbers plus the "thickness" of the counter window (as stated by the manufacturer) plus the air-equivalent "thickness" (the distance in

centimeters of the specimen from the counter window multiplied by 1.205 mg/cm³ at 20° and 76 cm of mercury), all expressed in mg/cm². An approximately straight line results.

Choose two total absorber "thicknesses" that differ by 20 mg/cm² or more and that fall on the linear plot, and calculate the mass absorption coefficient, μ , by the equation:

$$\mu = 1/(t_2 - t_1) \cdot \ln(N_{t_1}/N_{t_2}) = (2.303/(t_2 - t_1)) \times (\log N_{t_1} - \log N_{t_2})$$

in which t_1 and t_2 represent the total absorber "thicknesses," in mg/cm², t_2 being the thicker absorber, and N_{t_1} and N_{t_2} being the net beta particle rates with the t_1 and t_2 absorbers, respectively.

For characterization of the radionuclide, the mass absorption coefficient should be within $\pm 5\%$ of the value found for a pure specimen of the same radionuclide when determined under identical counting conditions and geometry.

Other Methods of Identification—Other methods for determining the identity of a beta emitter also rely upon the determination of E_{\max} . This may be accomplished in several ways. For example, (1) utilization of the range energy relationships of beta particles in an absorber, or (2) determination of E_{\max} from a beta particle spectrum obtained on an energy calibrated beta spectrometer using a thin source of the radionuclide (see *Scintillation and Semiconductor Detectors* in this chapter).

GAMMA-EMITTING RADIONUCLIDES

The gamma ray spectrum of a radionuclide is a valuable tool for the qualitative identification of gamma ray emitting radionuclides. The full energy peak, or the photopeak, is identified with the gamma ray transition energy that is given in the decay scheme of the radionuclide.

In determining radionuclidic identity and purity, the gamma ray spectrum of a radioactive substance is obtained with either a NaI(Tl) crystal or a semiconductor Ge(Li) detector. The latter has an energy resolution more than an order of magnitude better than the former and is highly preferred for analytical purposes. The spectrum obtained shall be identical in shape to that of a specimen of the pure radionuclide, measured with the same detection system and in the same geometry. The gamma ray spectrum of the radiopharmaceutical shall contain only photopeaks identifiable with the gamma ray transition energies found in the decay scheme of the same radionuclide. For low geometrical efficiencies, the areas under the photopeaks, after correction for the measured detector efficiency, shall be proportional to the abundances or emission rates of the respective gamma rays in the radionuclide.

RADIONUCLIDIC IMPURITIES

Because they are extremely toxic, alpha emitting nuclides must be strictly limited in radiopharmaceutical preparations. Procedures for identifying beta and gamma active radionuclides as given in the foregoing text are applicable to the detection of gamma and usually beta contaminants.

The gross alpha particle activity in radiopharmaceutical preparations can be measured by the use of a windowless proportional counter or a scintillation detector employing a silver activated zinc sulfide phosphor or by the techniques of liquid scintillation counting.

The heavy ionization caused by alpha particles allows the measurement of alpha emitting radionuclides in the presence of large quantities of beta and gamma active nuclides by the

use of appropriate techniques for discriminating the amplitudes of signal pulses. In proportional counting, the operating voltage region for counting alpha particles, referred to as the "alpha plateau," is considerably lower than the "beta plateau" for counting beta and gamma radiations. Typical "alpha plateau" and "beta plateau" voltage settings with P-10 counting gas are 900 to 1300 and 1600 to 2000 volts, respectively.

When silver-activated zinc sulfide phosphor is employed for alpha-particle detection, the alpha particles can be distinguished from other interfering radiation by pulse-height discrimination. Care must be exercised to minimize self-absorption at the source whenever specimens are prepared for alpha-particle counting.

Assay

BETA-EMITTING RADIONUCLIDES

Procedure—The disintegration rate (A) of a beta-particle-emitting specimen is obtained by counting a quantitatively deposited aliquot in a fixed geometry according to the formula:

$$A = R/(\epsilon \times f_r \times f_b \times f_s)$$

in which ϵ is the counting efficiency of the counter; f_r is the correction factor for counter dead time; f_b is the correction factor for backscatter; and f_s is the correction factor for self-absorption. The count rate for zero absorber is obtained by extrapolation of the initial linear portion of the absorption curve to zero absorber "thickness," taking into consideration the mg/cm^2 "thickness" of specimen coverings, counter window, and the intervening air space between specimen and the counter window. The counter efficiency, ϵ , is determined by use of a long-lived secondary standard with similar spectral characteristics. $\text{RaD} + \text{E}$ has frequently been used for efficiency calibration of counters for phosphorus-32. By the use of identical measurement conditions for the specimen and the standard (and extrapolation to zero absorber), the ratio of the values of f_r , f_b , and f_s for the standard and the specimen approaches unity.

The previous relationship is valid also when the counter has been calibrated with a standard of the radionuclide to be assayed. In this case, however, the extrapolations to zero absorber "thickness" for the specimen and standard are not required, as the two absorption corrections cancel for a given geometry.

Another useful and frequently employed method for the determination of the disintegration rate of beta-emitting radionuclides is liquid-scintillation counting, which also utilizes an extrapolation of the specimen count rate to zero pulse-height discriminator bias.

GAMMA-EMITTING RADIONUCLIDES

For the assay of gamma-emitting radionuclides, three methods are provided. The selection of the preferred method is dictated by the availability of a calibration standard of the radionuclide to be assayed and the radionuclidic purity of the article itself.

Direct comparison with a calibration standard is required if a calibration standard of the radionuclide to be assayed is available and if the upper limit of conceivable error in the activity determination arising from the presence of radionuclidic impurities has been determined to be less than 3%. If the required calibration standard is not routinely available, as would probably be the case for a short-lived radionuclide, but was available at some time prior to the performance of the assay for determination of efficiency of the counting system for the

radionuclide to be assayed, use a calibrated counting system, provided the radionuclidic impurity content of the specimen meets the requirements stated for the direct comparison method. If the requirements for either of the first two methods cannot be met, use the method for determination of activity from a calibration curve.

With the exception of the first method, the counting systems used are monitored for stability. This requirement is met by daily checks with a long-lived performance check source and weekly checks with at least three sources covering a broad range of gamma-ray emission energies (e.g., ^{57}Co , ^{137}Cs , and ^{60}Co). If a discrepancy for any of the aforementioned measurements is found, either completely recalibrate or repair and recalibrate the system prior to further use.

Assay by Direct Comparison with a Calibration Standard—An energy selective measurement system (e.g., pulse height analyzer) is not required for this procedure. Use either an ionization chamber or an integral counting system with a NaI(Tl) detector. A consistently reproducible geometrical factor from specimen to specimen is essential for accurate results. With proper precautions, the accuracy of this method approaches the accuracy with which the disintegration rate of the calibration standard is known.

Determine the counting rate of the detector system for a calibration standard of the radionuclide to be assayed (e.g., active enough to give good measurement statistics in a reasonable time, but not so active as to cause serious dead-time problems), selecting such a standard as to provide optimum accuracy with the particular assembly used. Place an accurately measured aliquot of the unknown assay specimen (diluted, if necessary) in a container identical to that used for the standard, and measure this specimen at approximately the same time and under the same geometrical conditions as for the standard. If the elapsed time between the measurements of the calibration standard and the specimen exceeds 12 hours, check the stability of the measurement system within 8 hours of the specimen measurement time with a long-lived performance check source. Record the system response with respect to the same check source at the time of calibration, and if subsequent checks exceed the original recorded response by more than $\pm 3\%$, recalibration is required. Correct both activity determinations for background, and calculate the activity, in $\mu\text{Ci per mL}$, by the formula:

$$SD(g/b)$$

in which S is the μCi strength of the standard, D is the dilution factor, and g and b are the measured values of counting rate for the specimen and the standard, respectively.

Assay with a Calibrated Integral Counting System—The procedure and precautions given for the preceding direct comparison method apply, except that the efficiency of the detector system is determined and recorded for each radionuclide to be assayed, rather than simply recording the counting rate of the standard. Thus, the efficiency for a given radionuclide, x , is determined by $\epsilon_x = b_x/s_x$, in which b_x is the counting rate, corrected for background and dead-time, for the calibration standard of the radionuclide, x , and s_x is the corresponding activity of the certified calibration standard in nuclear transformations per second. For subsequent specimen assays, the activity is given by the formula:

$$A_x = Dg_x/\epsilon_x$$

in which D is the dilution factor, g_x is the specimen counting rate (corrected for background and dead-time), and ϵ_x is the corresponding efficiency for the radionuclide.

Determination of Activity from a Calibration Curve—Versatility in absolute gamma-ray intensity measurements can be achieved by employing multi-channel pulse height analysis. The photopeak efficiency of a detector system can be determined as a function of gamma-ray energy by means of a series of gamma-ray emission rate standard specimens, and the gamma-ray emission rate of any radionuclide for which no standard is available can be determined by interpolation from this efficiency curve. However, exercise care to ensure that the efficiency curve for the detector system is adequately defined over the entire region of interest by using a sufficient number of calibration points along the photopeak-energy axis.

Selection of a Counting Assembly—A gamma-ray spectrometer is used for the identification of radionuclides that emit X-rays or gamma rays in their decay. Requirements for an assembly suitable for identification and assay of the radionuclides used in radiopharmaceuticals are that (a) the resolution of the detector based on the 662-keV photopeak of ^{137}Cs - $^{137\text{m}}\text{Ba}$ must be 8.0% or better, (b) the detector must be equipped with a specimen holder designed to facilitate exact duplication of counting geometry, and (c) the pulse height analyzer must have enough channels to delineate clearly the photopeak being observed.

Procedure—Minimal requirements for the maintenance of instrument calibrations shall consist of weekly performance checks with a suitable reference source and a complete recalibration semi-annually. Should the weekly performance check deviate from the value determined at the time of calibration by more than 4.0%, a complete recalibration of the instrument is required at that time.

This method involves three basic steps, namely photopeak integration, determination of the photopeak efficiency curve, and calculation of the activity of the specimen.

photopeak integration—The method for the determination of the required photopeak area utilizes a Gaussian approximation for fitting the photopeak. A fixed fraction of the total number of photopeak counts can be obtained by taking the peak width, a , at some fraction of the maximum, where the shape has been experimentally found to be very close to Gaussian, and multiplying by the counting rate of the peak channel, P , after correction for any Compton and background contributions to the peak channel count rate. This background usually can be adequately determined by linear interpolation. This is illustrated in *Figure 2*.

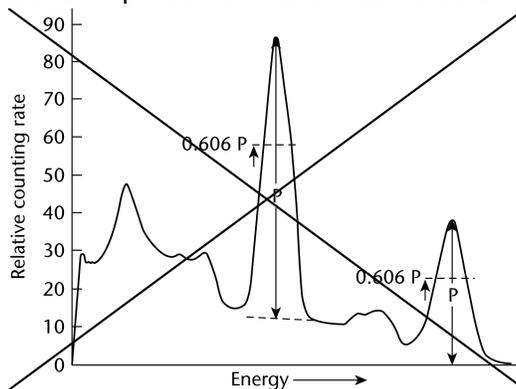

Fig. 2. Typical Gamma-ray Spectrum Showing the Selection of the Peak Channel Counting Rate, P , after the Correction for Compton and Background Contributions.

The photopeak curve shape is closest to a straight line at $0.606P$, and the contribution of the fractional channels to a can be accurately estimated by interpolation. Calculate a by the equation:

$$a = D - D' + \left[\frac{(d - 0.606P)}{(d - c)} \right] + \left[\frac{(d' - 0.606P)}{(d' - c')} \right]$$

in which c and d and also c' and d' are the single channel counting rates on either side of $0.606P$, and D and D' are the channel numbers (locations) of d and d' , respectively. The location of the required variables on the photopeak is illustrated in Figure 3.

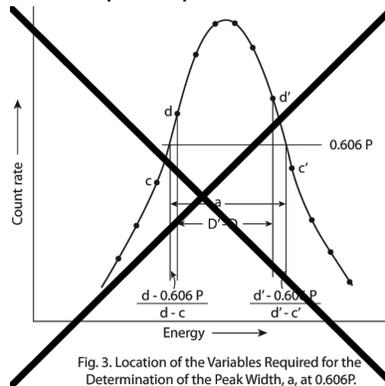

Fig. 3. Location of the Variables Required for the Determination of the Peak Width, a , at $0.606P$.

From the known values for the counting rate in the peak channel of the photopeak, P , and the width of the peak at $0.606P$, a , a calibrated fraction of the photopeak area is then obtained from the product, (aP) .

To summarize the procedures involved in obtaining a calibrated fraction of a photopeak area using this method, the necessary steps or calculations are presented below in a stepwise manner:

- (1) Subtract any Compton and background contributions from the photopeak to be measured.
- (2) Determine the counting rate of the peak channel (maximum channel counting rate after subtracting Compton and background), P .
- (3) Multiply P by 0.606 , and locate the horizontal line corresponding to the peak width, a .
- (4) Obtain the peak width, a , by inserting the values of variables (obtained as shown in the preceding figure) into the equation defining a .
- (5) The desired calibrated fraction of the peak area is then equal to the product of a times P or $F = aP$, where F is a fractional area of the peak proportional to the emission rate of the source.

This method provides a quick and accurate means of determining the gamma-ray emission rate of sources while avoiding, to a large extent, subjective estimates of the detailed shape of the tails of the peaks. The error due to using the maximum channel counting rate, rather than the theoretical maximum or peak channel rate, is of the order of 1.0% if a is 6 or greater.

photopeak efficiency calibration—Radionuclides such as those listed in the accompanying table together with some of their nuclear decay data are available as certified reference standards.* A sufficient number of radioactive standard reference sources should be selected in order to obtain the calibration curve over the desired range. Where possible, standard sources of those radionuclides that are to be assayed should be included.

Nuclear Properties of Selected Calibration Standards^(1,2)

Principal Photon Emissions	Energy (ke V)	Photons per 100 Disintegrations

(5) For this photon intensity to be usable, all emitted positrons must be annihilated in the source material.

(6) Cascade.

Calculate the gamma-ray emission rate from the equation:

$$F = A_s b$$

in which A_s is the activity, in disintegrations per second, of the standard used, and b is the number of gamma rays per disintegration at that energy. Accurately measure quantities of standard solutions of each radionuclide into identical containers, and determine the fractional photopeak area (F) for each of the standards.

Using the equation $\epsilon_p = F/\Gamma$, calculate the photopeak efficiency, ϵ_p , and construct a log-log plot of ϵ_p versus the gamma ray energy as shown in Figure 4.

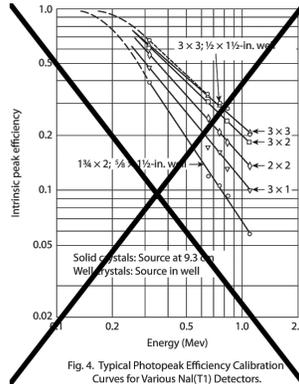

Fig. 4. Typical Photopeak Efficiency Calibration Curves for Various NaI(Tl) Detectors.

determination of specimen activity—In the same manner as in the preparation of the calibration curve, determine the fractional area (F) of the principal photopeak of the specimen under assay or an accurately measured aliquot adjusted to the same volume in an identical container as used for the standards. From the calibration curve, find the value of ϵ_p for this radionuclide.

Using the equation $\Gamma = F/\epsilon_p$, calculate the gamma ray emission rate (Γ). Calculate the activity (A), in disintegrations per second, of the specimen using the equation $A = (\Gamma/b)(D)$, in which b is the number of gamma rays per disintegration and D is the dilution factor. To obtain the activity, in μCi or mCi , divide A by 3.7×10^4 or 3.7×10^7 , respectively. The above relationship is equally valid for obtaining the activity of an undiluted specimen or capsule; in this case, the dilution factor, D , is unity.

1. INTRODUCTION

Radiopharmaceuticals and radioactive devices require specialized techniques in their production, testing, handling, dispensing, and administration in order to ensure optimal effectiveness and maintain safety for workers, patients, and the public. Hence, all operations involving these articles should be carried out by or under the supervision of personnel who have been appropriately trained in the handling of radioactive materials and appropriate instruments.

The facilities for the production, storage, and use of radioactive drugs and radioactive devices are generally subject to licensing by the U.S. Nuclear Regulatory Commission or Agreement State agency, or similar governmental agency outside the United States. Most radioactive drugs and radioactive devices are subject to other regulations relating to transportation, environmental release, and workplace safety.

USP monographs for radioactive articles include specifications for radionuclide identification and assay for radioactivity. Moreover, radioactivity counting assemblies or radiation detectors are required instruments for the determination of radionuclidic purity and radiochemical purity. The purpose of this general chapter is to provide standards for measurement of radioactivity including instrument qualification, performance checks, identification of radionuclides and radionuclidic impurities; and assay of radionuclides.

Information regarding radioactivity is described in *Radioactivity—Theory and Practice* (1821), which includes definitions, types of decay, general considerations relating to radioactive decay, counting, radionuclide production, purity, labeling, and instrumentation for detection and measurement of radioactive emissions; and a glossary.

2. PERSONNEL TRAINING AND DOCUMENTATION

Qualification of instruments and personnel training should be completed in accordance with written policies and/or procedures. Documentation of the qualification of instruments and personnel training should be included in the Quality Assurance Program. The length of time to retain the documentation varies depending on the appropriate regulatory requirements.

3. QUALIFICATION OF INSTRUMENTS

3.1 Installation Qualification

Installation Qualification (IQ) is to be performed upon installation of an instrument and after major repair. There are two categories in an IQ—visual inspection and operating environment. Visual inspection involves a check of the condition of the instrument to determine if it is ready to use. The inspection confirms that all cables are intact, the instrument is intact with no broken pieces/parts, and all components of the equipment are in working order. The operating environment for the device is checked for proper temperature, humidity, and power requirements. The operating environment should also be checked to avoid high background radioactivity. Temperatures are typically 10°–30° C and relative humidity ranges are generally 20%–90%. Shielding may be necessary to ensure that the background radiation has no negative effect on the instrument performance.

3.2 Operational Qualification

Operational Qualification (OQ) is a check of operational specifications for the equipment, including equipment set-up, functional testing of subsystems, and proper overall operation. OQ should describe operational procedures for the equipment and is performed after IQ and after major repair. OQ should include all appropriate tests to show that the instrument is capable of functioning properly. Typical examples of OQ include clock accuracy, high voltage, zero adjust, background response, and contamination check.

3.3 Performance Qualification

Performance Qualification (PQ) demonstrates that the equipment is capable of performing tasks required in the operating environment and provides the intended results. PQ should describe the required performance tasks for the equipment and include all appropriate tests to demonstrate that the instrument is performing within its operating parameters. These PQ tests are done following the OQ tests. Additionally, some or all the PQ tests are performed routinely (e.g., daily, quarterly, semiannually, annually) to demonstrate the instruments continual acceptance for use. Typical PQ tests include constancy and relative response, accuracy, reproducibility (precision), system linearity, determination of “quench” curves in liquid scintillation counters, and supplier equivalence.

3.4 Geometry Testing

The purpose of the geometry test is to demonstrate correct readings of the test sample, accounting for differences in the container, volume, or position of the test sample compared to the radioactive calibration standard. Geometry testing should be performed at installation of the dose calibrator and for each type of vial and syringe used to contain the test sample. Testing should include the test sample holder. Corrections factors may be developed as needed.

4. ONGOING PERFORMANCE TESTS OF INSTRUMENTS

Performance and operational tests are completed periodically to ensure the instrument is capable of meeting specified criteria for accurate assays and that no changes have occurred since initial testing. Tests include physical inspection, measurement of system parameters, and operational tests with radioactive calibration sources. These tests should also be completed

after repair. Regulatory agencies may require specific tests at a regular frequency. The following sections describe the performance tests using a dose calibrator as an example. The same principles will apply to other instruments used for radiation measurements.

4.1 Physical Inspections

Ensure that the dose calibrator and associated accessories, such as source holders and well liners, are undamaged and that foreign objects are not present in the chamber. Prior to use, repair or replace any damaged components as required and remove all foreign objects.

4.2 System Parameters

The system electronics should be tested according to the manufacturer's diagnostic testing procedures. The results should meet the acceptance criteria detailed in the manufacturer's manual. These parameters typically include the high voltage on the chamber, the zero adjustment on the electrometer, verification of communication between components of the system, and the accuracy of the system clock.

If the manufacturer's diagnostic procedures are not available, then at a minimum the user should check, record, and trend the chamber high voltage and the measured value for the electrometer zero check. Small changes in the high voltage will identify system malfunctions that might not be apparent with the use of radioactive calibration sources, but will begin impacting higher activity readings. The system clock should be checked and should be accurate within one min.

4.3 Operational Tests

BACKGROUND AND CONTAMINATION TEST

The purpose of this test is to determine the background radiation level and to ensure the absence of contamination that may affect measurements on the dose calibrator. Background radiation may fluctuate due to movement of sources near the chamber, as well as by contamination in or near the chamber, the liner, or the source holder. For this reason, this test should be performed with the liner and the source holder in the chamber. All radioactive sources should be well shielded or at a sufficient distance from the chamber. The background should be recorded at least once on each day of use, or more frequently if necessary, using the most common radionuclide setting. The background radiation level should be determined and recorded at initial installation, and periodically verified. It is especially important to verify if the minimum assayed quantity of radioactivity decreases.

CONSTANCY TEST

The purpose of this test is to ensure the constancy of the dose calibrator over time. This test should be performed on each day of use, and completed after the system tests outlined above. Typical radioactive calibration sources used in this test are Cesium-137 or Cobalt-60 contained within a solid matrix. Cobalt-57 might not be suitable due to its nominal half-life of less than one year. The radioactive calibration source is not required to have the same geometry as routine test samples. A single radioactive calibration source is sufficient for this check. The source is placed in the source holder and the reading recorded for the dedicated radionuclide setting, as well as for all other commonly used radionuclide settings. This ensures no drift in response for any setting. Results should be recorded and be within the appropriate range of the decay corrected value recorded during IQ. Control charts or other data representations should

be used to identify and document trends.

ACCURACY TEST

The purpose of this test is to demonstrate the stability of the dose calibrator over the energy range used. This test should be performed annually or after the dose calibrator is repaired or moved. If the dose calibrator is used for multiple radionuclides, two or three different radioactive calibration sources should be included to cover the energy range of the radionuclides. These calibration sources are typically contained in a solid matrix and do not necessarily match the geometry of routine test samples. If the dose calibrator is only used for a single radionuclide, or only for position emission tomography (PET) radionuclides, a single calibration source may be adequate. The quantity of radioactivity in the calibration source should be greater than 100 μCi (3.7×10^6 Bq). Sources used for this test should be traceable to a National Metrology Institute (NMI). Measurements of the calibration source activity are recorded and the average measured value is compared to the expected value. The measured value should be within the appropriate range of the expected value.

REPRODUCIBILITY TEST

The purpose of this test is to measure the precision of the dose calibrator and should be performed at least annually. The radioactive calibration source should have a half-life such that decay corrections are not required over the period of the test. The quantity of radioactivity in the calibration source should be greater than 100 μCi (3.7×10^6 Bq). An appropriate number of consecutive readings are recorded using the same geometry. Each of the measurements taken should be within an appropriate range of the mean of all the measurements.

LINEARITY TEST

The purpose of this test is to show that the response of the dose calibrator is linear across the range of radioactivity levels to be measured. This is especially critical at high levels of radioactivity where the measured radioactivity may differ from the true radioactivity due to saturation effects, and at low levels of radioactivity due to variations on the background radiation and changes in the source positioning. This test should be performed annually or after the dose calibrator has been repaired or moved.

The test is considered successful if the ratio of the measured radioactivity to the expected activity is within the appropriate range of the expected values. Three techniques may be employed for this test: decay, graded shield, and graded source. Use of graded shields is acceptable once an initial linearity test using the decay method is successfully completed. Refer to the manufacturer's recommendations on the use of the graded shields. The graded source method requires accurate measurements of volume or mass, and is not generally recommended.

Table 1 is an example of ongoing performance checks for dose calibrators.

Table 1. List of Performance Tests

Parameter	Daily ^a	Annually (at a minimum)
Physical inspection	Yes	NA
System electronics	Yes	NA
Clock accuracy	Yes	NA
High voltage	Yes	NA
Zero adjust	Yes	NA
Background response/contamination check	Yes	NA
Radioactive calibration source (constancy and relative response)	Yes	NA
Accuracy	See footnote ^b	Yes
Reproducibility (precision)	See footnote ^b	Yes
System linearity	See footnote ^b	Yes
Supplier equivalence	See footnote ^b	Yes
^a At the beginning of each day of use. ^b This is required after repair.		

5. IDENTIFICATION OF RADIONUCLIDES

5.1 Half-Life Determination

The half-life is an identifying characteristic of a radionuclide. The half-life is determined by measuring the quantity of radioactivity in the test sample as a function of time. The approximate half-life may be used to confirm the radionuclidic identity. Perform the measurements using an appropriately calibrated instrument, such as a quantitative radioactivity detector, provided the quantity of radioactivity is within the linear range of the instrument throughout the measurements and the geometry of the test sample is not changed during the measurements.

The test sample may be used directly, or diluted and/or dried in a capsule as needed. The test sample is prepared in a manner that avoids losses during handling. If the test sample is a liquid or solution, the sample is held in a closed container. If the test sample is a residue from drying in a capsule, the sample is protected by a cover consisting of a sheet of adhesive cellulose acetate or other material. The quantity of radioactivity in the test sample should be sufficient to allow measurements over the time frame of the test. If necessary, correction for dead-time losses may be applied. The measured half-life should be within the range of the expected half-life as defined in each particular application of this test.

5.2 Gamma Ray Spectrometry

The gamma-ray emission spectrum may be used to identify and quantify gamma-emitting radionuclides. The detector should be calibrated with a radioactive calibration source traceable to a NMI. The calibration source used to determine the efficiency of the detector should have a

sufficient quantity of radioactivity to produce an adequate number of counts for each photopeak used in the calibration. The calibration source and the test sample should be measured with the same geometry and distance from the detector. It is critical that the geometry, including vial type and volume, be the same since these factors affect the amount of incident radiation on the detector. Photopeaks in the test sample should be comparable to those in the calibration source, both in terms of energy and intensity. The presence of unknown peaks or changes in peak abundance is indicative of impurities. Ensure that background radiation levels remain constant during the measurement, as changes may result in unknown peaks. Counting time or shielding should be optimized to achieve the necessary required minimum detectable activity to meet test specifications. It may be necessary to allow the radioactivity in the test sample to decay before it is possible to detect impurities at the required levels. There may also be short-lived impurities present, so an analysis should be completed to identify impurities and their half-lives to ensure the sample is assayed prior to their decay. Positron-emitting radionuclides typically cannot be differentiated since their emitted energy (511 keV) is the same for each radionuclide. Performance tests of the gamma-spectroscopy system should be completed on each day of use to ensure the functionality of the system.

5.3 Beta-Emitter Analysis and Identification

The purpose of the beta-emitter analysis and identification is to determine the maximum energy of the beta particle, which is unique and can be used for identification. Beta-emitting radionuclides can be identified either by evaluation of their spectrum or by measuring their mass attenuation coefficients in a series of absorption foils and constructing an attenuation curve. Performance tests of the beta counting system should be completed on each day of use to ensure the functionality of the system.

5.4 Alpha Spectrometry

The alpha emission spectrum may be used to identify and quantify alpha-emitting radionuclides. Pure alpha emitters present unique challenges due to their low penetration distance and their toxicity, especially if they are volatile compounds that could create airborne radioactivity and therefore internal radiation exposure to the experimenter or operator. Alpha particles can be detected either by the use of proportional counters, scintillation detection using a silver-activated zinc sulfide phosphor, or by the techniques of liquid scintillation counting (LSC). Performance tests of the alpha spectroscopy system should be completed on each day of use to ensure the functionality of the system.

6. ASSAY OF RADIONUCLIDES

6.1 Measurement of Radioactivity Using a Dose Calibrator

Using a holder, the test sample is placed in the chamber of the dose calibrator at a given position. Once the response is stable, the radioactivity reading is taken. Performing measurements on the test sample with the same geometry as the calibration source provides the most accurate results; however, geometry correction factors may be developed and used as necessary. Refer to the manufacturer's recommendations for the maximum radioactivity that can be determined in the dose calibrator.

6.2 Measurement of Radioactivity Using a Solid-State Detector

The test sample is positioned in front of the detector or into the well of a well-type detector. The detector must be adequately shielded and calibrated using a radioactive calibration source traceable to an NMI.

6.3 Measurement of Radioactivity Using Chromatographic Systems

A scintillation detector can be used for dynamic radioactivity measurements, e.g., the eluate of a liquid chromatograph is directed over or through a detector. The quantity of radioactivity in the test sample should provide a count rate that is within the linear range of the detector.

6.4 Measurement of Radioactivity Using a Liquid Scintillation Counter

LSC is the standard laboratory method to quantify radioactivity of particle-emitting radionuclides, mostly beta- and alpha-emitting radionuclides. The sample to be analyzed may require a liquid scintillation fluid (cocktail) depending on the energy of the beta particle. The LSC detection method uses liquid scintillation cocktails to transform emitted radiation into detectable light photons. The sample to be analyzed is placed into a liquid scintillation vial and the cocktail is added in the required amount. While a sample that can be dissolved into the fluid is preferred, other samples can be assayed if the impact on the light output is quantified. The detector should be calibrated using an appropriate radioactive calibration source traceable to an NMI. The absorption of scintillation photons is called quench, and it is necessary to develop a "quench curve" during PQ and additional quench curves may be necessary for different types of samples to correct the counting efficiency. Performance tests of the LSC should be completed on each day of use to ensure the functionality of the system.

7. GLOSSARY

The following definitions apply to commonly encountered words and phrases when dealing with radioactivity.

Alpha particles (α): Positively charged particles emitted from nuclei during radioactive decay. Alpha particles are essentially ^4He nuclei, consisting of two protons and two neutrons, but no electrons.

Beta particles (β^-): Negatively charged particles that are emitted from nuclei during radioactive decay. Beta particles are essentially electrons.

Beyond-use date: Date (and time, if appropriate) that establishes a limit for the use of a compounded preparation. The acceptable use period (i.e., the period of time between the date and time of compounding and the beyond-use date and time) is based on a knowledge of the radioactive properties of the preparation, the results of stability studies on the preparation, and, as appropriate, the assurance of sterility of the compounded sterile preparation.

Bremsstrahlung: Electromagnetic radiation produced by the deceleration of a charged particle through interaction with another charged particle, typically an electron and an atomic nucleus, respectively. The moving particle (e.g., beta particle) loses kinetic energy, which is converted into photons (X-rays). This electromagnetic radiation exhibits a continuous spectrum, with peak intensity a function of the energy of the incident particle.

Calibration factor: The coefficient used to convert the measured ionization chamber current to a nominal radioactivity. This term is often referred to as the "calibration coefficient".

Calibration time: Arbitrary time and date, if appropriate at which the specified amount of radioactivity is present.

Carrier-free: A preparation free from stable isotopes of the same element as the radionuclide.

Counting assembly: Consists of a sensing unit and an electronic scaling device. The sensing unit may be a Geiger-Müller tube, a proportional counter, a scintillation detector in which a photomultiplier tube is employed in conjunction with a scintillator, or a solid-state semiconductor.

Dose calibrator: A well-type ionization chamber commonly used to assay radiopharmaceuticals. Display units are typically in Curies ($\mu\text{Ci}/\text{mCi}/\text{Ci}$) or Becquerels ($\text{kBq}/\text{MBq}/\text{GBq}$).

Expiration date: Date (and time, if appropriate) that establishes a limit for the use of the manufactured product, which is based on the knowledge of the radioactive properties of the product and the results of stability studies on the finished dosage form.

Gamma rays (Γ rays): Electromagnetic radiation emitted from nuclei during radioactive decay. Gamma rays have a wide range of energies. The gamma rays emitted from a given radionuclide are always at the same energy(ies) providing a unique signature that enables the identification of a gamma-emitting radionuclide.

Geiger-Müller counter: Often referred to as G-M counter or Geiger counter. An instrument in which a high voltage potential is applied across a volume of inert gas for the purpose of collecting ions produced by a radiation field. The negative electrons are internally multiplied to produce a readily detectable current pulse. Display units are typically counts per min (cpm) or milliroentgen per h (mR/hr).

Geometry: The characteristics of a radioactive source (i.e., container type, container wall thickness, volume and position of the container in the well chamber) that, along with the physical characteristics of the ionization chamber, affect the magnitude of the calibration coefficient for a specific radionuclide. The principal geometry considerations that may affect the accuracy of a source measurement in a dose calibrator are container configuration, source volume, position of the source in the chamber well and the radionuclide itself. [Note—It is customary to compare a standardized preparation and radiopharmaceutical drug or preparation using identical geometry conditions for assay, identification, and other parameters. The validity of the result is critically dependent upon the reproducibility of the spatial relationships of the source to the detector and its surroundings and upon the accuracy of the standardized preparation.]

Ionization chamber: An instrument in which an electric field is applied across a volume of inert gas for the purpose of collecting ions produced by a radiation field. The positive ions and negative electrons drift along the lines of force of the electric field, and are collected on electrodes, producing an ionization current. The most commonly used form of ionization chambers for measurement of the activities of radiopharmaceuticals is a well-type ionization chamber known as a dose calibrator.

Isobars: Nuclides with the same mass number (protons + neutrons).

Isomers: Atoms with the same number of protons and neutrons, but a different nuclear energy configuration. Short-lived radioactive isomers are generally referred to as metastable. Different

isomers are different nuclides based on their nuclear energy configurations.

Isotones: Nuclides with the same number of neutrons and a different number of protons. Isotones are different elements with different atomic masses.

Isotopes: Nuclides with the same number of protons and a different number of neutrons. Isotopes are the same element with a different atomic mass.

Isotopic carrier: A stable isotope of the element concerned either present in or added to the radioactive preparation in the same chemical form as the radionuclide.

Liquid scintillation counter (LSC): An instrument which detects scintillation light from the absorption of radiation energy in a scintillation liquid. This instrument is used primarily for beta-emitting radionuclides that do not also emit gamma photons. For best results, the radioactive sample should be soluble in the scintillation liquid.

Minimum detectable activity: Smallest quantity of radioactivity that can be detected above the background with a specified level of confidence.

National Metrology Institute (NMI): A measurement standards body, which is a laboratory of metrology that establishes standards for a country or organization. For example, National Institute of Standards and Technology (NIST) is the NMI for the United States.

No-carrier-added: A preparation where no stable isotopes of the same element as the radionuclide being tested are intentionally added in the stated chemical form or at the position of the radionuclide in the molecule being tested.

Nuclide: An atom with a specific number of protons and neutrons in a given nuclear energy state.

Positrons (β^+): Positively charged particles emitted from a nucleus during radioactive decay. Positrons are anti-electrons.

Radioactivity: 1) The spontaneous transformation of nuclei by radioactive decay. Radioactivity is typically described as atoms undergoing radioactive decay per unit time (or disintegrations per unit time). 2) The quantity of radioactive material, as measured in units of Curies (US units) or Becquerels (SI units). The quantity of radioactive material may also be referred to as activity.

Radiochemical identity: The molecular structure of the intended active radiopharmaceutical ingredient, which is present in the radiopharmaceutical preparation.

Radiochemical purity: The ratio, expressed as a percentage, of the radioactivity of the intended active radiopharmaceutical ingredient to the total radioactivity of all radioactive ingredients and impurities present in the radiopharmaceutical preparation.

Radioisotope: A radioactive atom, generally used in the context of an isotope of an element.

Radionuclide: An unstable nuclide that undergoes radioactive decay; a radioactive nucleus. The terms radionuclide and radioisotope are commonly used interchangeably.

Radionuclidic identity: The intended radionuclide in the radiopharmaceutical preparation.

Radionuclidic purity: The ratio, expressed as a percentage, of the radioactivity of the intended radionuclide to the total radioactivity of all radionuclides in the radiopharmaceutical

preparation.

Radiopharmaceutical (Radiopharmaceutical preparation/Radioactive drug): A finished dosage form that contains a radioactive substance in association with one or more other ingredients and that is intended to diagnose, stage a disease, monitor treatment, or provide therapy. A radiopharmaceutical includes any nonradioactive reagent kit or radionuclide generator that is intended to be used in the preparation of any such substance. The terms radiopharmaceutical and radioactive drug are commonly used interchangeably.

Scintillation crystal counter: An instrument consisting of a crystal scintillator, such as NaI (TI), with attached photomultiplier tube and associated electronics. Scintillation light produced from the absorption of gamma and X-rays in the crystal is converted to electrons and amplified in the photomultiplier tube. The resultant current pulse may be further analyzed with regard to photon energy. A commonly used form of this instrument that has a hole in the crystal of sufficient size to allow placement of a test tube or similar container is known as a well counter.

Semiconductor detector: An instrument consisting of a semiconductor material, such as silicon or germanium crystals, that detects ionizing radiation through generation of charge carriers (passage of electrons through holes). The current pulse produced by migration of these charge carriers, under the influence of a voltage potential across the material, can be further amplified and analyzed to determine the quantity and energy of the incident radiation.

Solid-state detector: A crystal-based detector, in contrast to a gas-based detector. Often is used as a synonym for a semiconductor detector.

Specific activity: The radioactivity of a radionuclide per unit mass of the element or compound. The unit of specific activity is radioactivity per mass expressed on a gram or mole basis [e.g., mCi/ μ g (MBq/ μ g), Ci/mmol (GBq/mmol)].

Strength: The radioactivity concentration of the radiopharmaceutical at the calibration time. The unit of strength is the amount of radioactivity on a volume basis (e.g., mCi/mL or MBq/mL).

Total radioactivity: The radioactivity of the radionuclide, expressed per unit (e.g., vial, capsule, ampoule, generator, and others) at the calibration time.

Validation: Establishment of documented evidence that a method, process, or system meets its intended requirements.

Verification: Confirmation that an established method, process, or system meets predetermined acceptance criteria.

X-rays: A type of electromagnetic radiation emitted from the electron orbitals. While they do not arise from the nucleus they are often present immediately following a decay event if there are interactions between the emitted radiation and the orbital electrons.

BRIEFING

⟨1004⟩ **Mucosal Drug Products—Performance Tests.** The General Chapters Dosage Forms Expert Committee proposes *Mucosal Drug Products—Performance Tests* ⟨1004⟩ to provide guidance on in vitro performance tests for drug products delivered by the mucosal route. The information on performance tests in this chapter represents guidance based on the information available.

Well-defined compendial apparatuses are not always available or adaptable to the in vitro performance testing of products administered by the mucosal route. The use of noncompendial apparatus is suggested throughout. Examples include the use of the small-volume apparatus included in this proposal for films, suspensions, sublingual tablets, and buccal tablets. Proper qualification standards for such apparatuses remain to be developed. Information is requested on qualification standards for small-volume dissolution apparatuses or other noncompendial apparatuses mentioned in this proposed general information chapter.

Other related information is available from *Mucosal Drug Products—Product Quality Tests* ⟨4⟩.

Comment deadline: November 30, 2015

Add the following:

■ ⟨1004⟩ MUCOSAL DRUG PRODUCTS—PERFORMANCE TESTS

INTRODUCTION

Mucosal drug products deliver drug substances to the body via the mucosal route. For the purposes of this chapter, the mucosal route of drug administration is divided into seven membrane surfaces characterized as otic, ophthalmic, nasal, oropharyngeal, urethral, vaginal, and rectal. Mucosal drug products include a wide variety of dosage forms such as solutions, suspensions, emulsions, creams, ointments, gels, inserts, strips, aerosols, sprays, films, medicated chewing gums, lozenges, tablets, and suppositories. Some of these dosage forms are also administered by other routes. For example, creams can be administered by the mucosal route (vaginal) and also by the topical route. Two categories of tests—product quality and product performance—are performed on these products. These tests provide assurances of batch-to-batch quality, reproducibility, reliability, and performance of a drug product. Product quality tests are performed to assess attributes such as assay, identification, and content uniformity and are part of the compendial monograph (see *Mucosal Drug Products—Product Quality Tests* ⟨4⟩). Product performance tests are conducted to assess the drug release from the dosage form. For certain mucosal drug products, determination of aerodynamic particle size or globule size may serve as a product performance test.

Where a compendial performance test exists for a dosage form administered by a nonmucosal route, such as a dissolution test for an oral tablet, that test may have application for the

dosage form administered by a mucosal route (e.g., buccal tablets or sublingual tablets).

PERFORMANCE TESTS FOR MUCOSAL DRUG PRODUCTS

The performance tests for the various mucosal drug products can be broadly divided into two categories: 1) test procedures that use or can adopt methodology in existing general chapters, and 2) tests that need additional developmental work before they can be recommended.

The Dissolution Procedure: Development and Validation (1092) should be a reference when developing a drug release test (e.g., selecting the drug release medium, apparatus/procedure, or analytical method). For several mucosal drug products, drug release procedures described in *Dissolution* (711), *Drug Release* (724), and *Semisolid Drug Products—Performance Tests* (1724) may be applicable.

In some instances, mini-basket or mini-paddle apparatuses may be suitable. These apparatuses resemble *Dissolution* (711), *Apparatus 1 (Basket Apparatus)* and *Dissolution* (711), *Apparatus 2 (Paddle Apparatus)*, with dimensions scaled down to accommodate medium volumes of <500 mL (1,2). Several designs are commercially available. However, as of now, these apparatuses are not standardized.

Because of the varied and specific environments characterizing the mucosal route of administration, researchers may be inclined to use “physiological medium” for the drug release of the specific dosage form. It may not be essential to use such a medium for the performance test of the product, and in many instances a simple buffer may suffice. A reference (3) for the composition of such media is provided for additional information.

AEROSOLS AND NASAL SPRAYS

Performance tests for aerosols and nasal sprays are largely concerned with droplet or particle size distribution and aerodynamic size distribution. The procedures in *Aerosols* (601) can be applied to products administered by mucosal routes. When the drug substance is present as a solid with a modified-release mechanism in the administered dose, attempts should be made to determine the dissolution of the particles (4).

CREAMS, GELS, AND OINTMENTS

Drug release tests for creams, gels, and ointments can be performed using a procedure described in (1724).

EMULSIONS

Performance tests for emulsions include globule size determination and dissolution/drug release testing. Globule size can be determined using a procedure described in *Globule Size Distribution in Lipid Injectable Emulsions* (729). The drug release test can be performed using *Dissolution* (711), *Apparatus 2 (Paddle Apparatus)* or a vertical diffusion cell as described in *Semisolid Drug Products—Performance Tests* (1724), *Drug Release Rate Determination Using Vertical Diffusion Cell Apparatus*.

FILMS

Drug Release (724), *Apparatus 5 (Paddle over Disk)* can be used to determine the drug release from film dosage forms. A mini-basket can be used for drug release testing of films.

GUMS

For gum products, the performance test includes drug release from the formulation. A device is described in the *European Pharmacopoeia* (5). The release of drug from the formulation requires masticatory activity that renews the surface exposed to the medium. The rate of release will be a function in part of the frequency of chewing that is simulated by the test apparatus. Gums can require conditioning at the temperature of the mouth to deform plastically under the action of the oscillating platens of the test apparatus.

Important parameters for the apparatus include: dissolution medium volume, distance between upper and lower chewing surfaces, recommended rotation angle, temperature, and chewing frequency. The dissolution medium chosen, the test time(s), and the volume sampled are also important considerations.

INSERTS

Drug release testing for inserts can be performed using *Dissolution* (711), *Apparatus 1 (Basket Apparatus)* or *Dissolution* (711), *Apparatus 2 (Paddle Apparatus)*.

LOZENGES

Drug release testing of lozenges can be performed using either *Dissolution* (711), *Apparatus 2 (Paddle Apparatus)* at high agitation (175 rpm) or *Dissolution* (711), *Apparatus 3 (Reciprocating Cylinder)*.

SUPPOSITORIES

There are two types of suppositories: 1) hydrophilic (water soluble), and 2) lipophilic (oil soluble or melting). Drug release (dissolution) for water-soluble suppositories can be performed using *Dissolution* (711), *Apparatus 1 (Basket Apparatus)*, *Dissolution* (711), *Apparatus 2 (Paddle Apparatus)*, or *Dissolution* (711), *Apparatus 4 (Flow-Through Cell)*. Drug release testing for lipophilic suppositories may need modification of the dissolution procedure to avoid analytical interference from the oil globules. Several alternative methods have been proposed (6–8). The flow-through cell apparatus using the cell for suppositories may be useful (see *Disintegration and Dissolution of Dietary Supplements* (2040), *Figure 2*). The selection of the method will be dependent on the nature of the formulation.

SUSPENSIONS

The dissolution test for suspensions can be performed using *Dissolution* (711), *Apparatus 2 (Paddle Apparatus)*. A small-volume, mini-paddle apparatus may be used.

SUBLINGUAL TABLETS AND BUCCAL TABLETS

Drug release for these dosage forms can be performed using *Dissolution* (711), *Apparatus 1 (Basket Apparatus)* or *Dissolution* (711), *Apparatus 2 (Paddle Apparatus)*. Mini-baskets or the mini-paddles can also be used for drug release testing of buccal and sublingual tablets.

BRIEFING

(1015) **Automated Radiochemical Synthesis Apparatus**, *USP 38* page 717. This chapter is primarily intended for use in providing the information regarding synthesis of Positron Emission Tomography (PET) drugs. A comprehensive informational chapter *Positron Emission Tomography (PET) Drugs—Information* (1823) is being proposed elsewhere in this issue of *Pharmacoepial Forum*. The proposed new chapter captures all the relevant information from

(1015) making the existing chapter redundant. Hence, the General Chapters—Physical Analysis Expert Committee proposes to omit this chapter from *USP-NF*. Interested parties are invited to submit comments to USP on or before January 31, 2016.

■ ~~(1015) AUTOMATED RADIOCHEMICAL SYNTHESIS APPARATUS~~

~~The preparation and quality control of diagnostic radiopharmaceuticals labeled with the very short-lived positron-emitting nuclides (e.g., ^{15}O , ^{13}N , ^{11}C and ^{18}F having half-lives of 2, 10, 20, and 110 minutes, respectively), are subject to constraints different from those applicable to therapeutic drugs: (1) Synthesis must be rapid, yet must be arranged to protect the chemist or pharmacist from excessive radiation exposure. (2) Except to a limited extent for ^{18}F , synthesis must occur at the time of use. (3) With the exception of ^{18}F , each batch of radiopharmaceutical generally leads to only a single administration.~~

~~These factors raise the importance of quality control of the final drug product relative to validation of the synthesis process. Since with few exceptions every dose is individually manufactured, ideally every dose should be subjected to quality control tests for radiochemical purity and other key aspects of quality before administration. Because quality testing of every batch is not possible, batches are selected at regular intervals for examination to establish and completely characterize their radiopharmaceutical purity. This routine and thorough quality testing of selected batches forms the basis of process validation, which is absolutely essential for prospective assessment of batch quality and purity when dealing with such extremely short-lived radiopharmaceuticals. Since radiopharmaceuticals used in positron emission tomography (PET) are administered intravenously or (for radioactive gases) by inhalation, batch-to-batch variability in bioavailability is not an issue. Furthermore, the very small scale of radiopharmaceutical syntheses (almost always less than 1 milligram and often in the microgram range) and the fact that patients generally receive only a single dose of radioactive drug minimize the likelihood of administering harmful amounts of chemical impurities. These statements are not intended to contest the need for quality control in the operation of automated synthesis equipment, but to place the manufacture of positron-emitting radiopharmaceuticals in an appropriate perspective and to reemphasize the overwhelming importance of prospective process validation and finished product quality control.~~

~~The routine synthesis of radiopharmaceuticals can result in unnecessarily high radiation doses to personnel. Automated radiochemical synthesis devices have been developed, partly to comply with the concept of reducing personnel radiation exposures to "as low as reasonably achievable" (ALARA). These automated synthesis devices can be more efficient and precise than existing manual methods. Such automated methods are especially useful where a radiochemical synthesis requires repetitive, uniform manipulations on a daily basis.~~

~~The products from these automated radiosynthesis devices must meet the same quality assurance criteria as the products obtained by conventional manual syntheses. In the case of~~

positron-emitting radiopharmaceuticals, these criteria will include many of the same determinations used for conventional nuclear medicine radiopharmaceuticals, for example, tests for sterility and bacterial endotoxins. Many of the same limitations apply. Typical analytical procedures such as spectroscopy are not generally applicable because the small amount of product is below the minimum detection level of the method. In all cases, the applicable Pharmacopeial method is the conclusive arbiter (see *Procedures* under *Tests and Assays* in the *General Notices*).

Preparation of Fludeoxyglucose F-18 Injection and other positron-emitting radiopharmaceuticals can be adapted readily to automated synthesis. In general, the equipment required for the manual methods is simpler and less expensive than that used in automated methods but is more labor-intensive. Of special concern are the methods involved in validating the correct performance of an automated apparatus. For a manual procedure, human intervention and correction by inspection can nullify many procedural errors. In an automated system, effective feedback also can begin during the synthesis. For example, radiation detectors can monitor activity at various stages of radiosynthesis. Failure to obtain the appropriate activity could activate an alarm system that would lead to human intervention.

Radiochemicals versus Radiopharmaceuticals—It is appropriate to draw a distinction between a radiochemical and a corresponding radiopharmaceutical. In research PET centers, automated equipment is used to prepare labeled compounds for animal experiments. These radiochemicals are not regarded as radiopharmaceuticals if (1) they are not prepared according to a validated process that provides a high degree of assurance that the preparation meets all established requirements for quality and purity; and (2) have not been certified by qualified personnel (licensed pharmacists and approved physicians) in accordance with published Pharmacopeial methods for individual radiopharmaceuticals.

Automated Equipment—The considerations in this chapter apply to synthesis conducted by general purpose robots and by special purpose apparatus. Both are automated devices used in the synthesis of radiochemicals. The exact method of synthesis device control is variable. Both hard-wired and software-controlled synthesis devices fall under the general designation, and there is a spectrum ranging from traditional manual equipment through semi-automated devices to completely automatic devices.

Common Elements of Automated Synthesis Equipment—To manipulate a chemical apparatus to effect the synthesis of a radiochemical, control of parameters such as time, temperature, pressure, volume, and sequencing are needed. These parameters can be monitored and constrained to fall within certain bounds.

Equipment Quality Assurance—The goal of quality assurance is to help ensure that the subsequent radiopharmaceutical meets Pharmacopeial standards. Although the medical device good manufacturing practice regulations (21 CFR 820) are not applicable, they may be helpful in developing a quality assurance program. As a practical matter this involves documented measurement and control of all relevant physical parameters controlled by the synthesis apparatus.

Routine Quality Control Testing—Routine quality control testing of automated equipment implies periodic testing of all parameters initially certified during the quality assurance qualification. Depending on the criticality and the stability of the parameter setting, testing may be as often as daily. This process performance assessment must be augmented by regular end-product testing. For example, variations in the temperature of an oil bath may be

acceptable if the radiochemical (end product) can be shown to meet all relevant testing criteria.

Reagent Audit Trail—Materials and reagents used for the synthesis of radiopharmaceuticals should conform to established quality control specifications and tests. Procedures for the testing, storage, and use of these materials should be established. In this context, a reagent is defined as any chemical used in the procedure leading to the final radiochemical product, whereas materials are defined as ancillary supplies (tubing, glassware, vials, etc.). For example, in some processes compressed nitrogen is used to move liquid reagents. In this case, both the nitrogen and the tubing should meet established specifications.

Documentation of Apparatus Parameters—Key synthesis variables should be identified, monitored, and documented. These characteristics include meaningful physical, chemical, electrical, and performance attributes. A method for specifying, testing, and documenting computer software and hardware is especially important for microprocessor and computer-controlled devices. This program should include periodic generalized testing of the computer hardware. In addition, the software program code should be periodically examined to determine that it has not been modified and that it continues to result in the final product's meeting all specifications. In-process feedback is one means of confirming that the synthesis is under control. Changes to the software code should involve a formal authorization procedure, and changes should be documented.

Each type of radiochemical synthesis device requires a set of specific procedures for testing and monitoring the reliability and reproducibility of the various subsystems that make up the total synthesis system.

It is essential that calibration of each of the components be confirmed according to an established maintenance timetable and that measurements or monitoring be made under actual synthesis conditions.

Delivery times, reagent volumes, temperatures, gas pressures, and rates of flow need to be measured and shown to be stable and reproducible within established limits. Delivery of the reagents and solvents needs to be calibrated periodically. Other components to be routinely calibrated include the radiation detection system and process monitoring sensors and system.

For illustration, elements of system validation of several representative components of an automatic synthetic device are as follows:

Reaction vessels may be cleaned and inspected by an established documented method. The vessels themselves may be numbered and their performance tracked.

Heating and cooling systems (such as oil baths) may be monitored by thermometers or thermocouples. The temperatures may be recorded in a batch sheet, or they may be automatically printed out as part of a computerized log. Maintenance involves periodic calibration.

Gases and gas delivery system performance may be tracked by pressure gauges and flowmeters. Gas purity may be established via supplier certificates of analysis or may be verified by independent testing. Maintenance of gauges and flowmeters involves periodic calibration with standards.

Position-dependent motor performance may be verified by limit switches. Maintenance could involve actual measurement of distance traversed and elapsed time.

~~Solenoid valves may be checked electrically, by flow and pressure tests.~~

~~Heater output is evidenced by proper thermocouple readings. Additional tests could involve resistance measurements.~~

~~Reagents may be accepted on the basis of suppliers' certificates of analysis. Alternatively, the chemical could be tested in-house or sent to an independent testing laboratory. Periodic retesting may be necessary depending on stability.~~

~~Computer programs may be tested by documenting elapsed time of synthesis, with printouts verifying that all appropriate manipulations occurred, including printing of relevant parameters such as times, temperature, pressures, and activities.~~

~~Patterns of activity distribution such as absolute amount of product, percentage yield, and individual impurity activity levels afford the experienced user an opportunity to discern systems failures.~~

~~**Changes in the Synthesis Method**—Some changes in the synthesis apparatus can be considered to be trivial. This category would often include changes not affecting any of the monitored parameters. However, it is important that care be taken to ensure that seemingly innocuous changes do not have an unexpected impact. For example, changes in a comment line of a computer program may result in inadvertently changing or deleting a vital instruction. Any changes in monitored parameters have the potential for changing the process output. If the resultant radiochemical does not meet specifications or if the subsequent radiopharmaceutical does not meet Pharmacopeial criteria, the process change is unacceptable; the fault must be corrected and the process revalidated.~~

BRIEFING

(1029) **Good Documentation Guidelines**, *PF* 40(3) [May–June 2014]. This revision is proposed on the basis of public comments received on its previous publication in *PF*. This proposed new general chapter provides guidelines on how to develop and maintain good documentation practices within Good Manufacturing Practice (GMP) operations. This chapter was created to address a need for descriptions of what constitutes good documentation, for example, records of all types that are clear, accurate, and complete. These records may include protocols, procedures, reports, and raw data. The overarching goal of this chapter is to provide useful information to the GMP-regulated industries, thereby assisting the user in designing procedures that will promote record integrity and control. In turn, record integrity and control are essential for the evaluation and reconstruction of GMP activities, and ultimately for ensuring the quality and safety of regulated ingredients and products.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

Add the following:

■ (1029) GOOD DOCUMENTATION GUIDELINES

INTRODUCTION

Purpose

Documentation can be viewed as the foundation of all quality systems because clear, complete, accurate records are essential to all operations and procedures. This general chapter provides guidelines on good documentation practices for the Good Manufacturing Practice (GMP)-regulated industries, to be used in the production and control of pharmaceutical products, active pharmaceutical ingredients (APIs), excipients, dietary supplements, food ingredients, and medical devices. This chapter describes the underlying principles of proper documentation for GMP operations to assist the user while working with GMP activities. These guidelines should be helpful for building the basic foundation of a quality system that will ensure proper documentation as well as record integrity and control.

Scope

This chapter covers different levels and types of documentation, including paper and electronic records that consist of raw data, reports, protocols, and procedures related to manufacturing controls and analytical data. The chapter also includes recommendations on information that should be recorded for various types of GMP documents. Electronic systems should be developed to meet guidelines described in this chapter.

This chapter does not provide information about all applicable current legal requirements, nor does it affect any applicable current requirements under GMP regulations.

PRINCIPLES OF GOOD DOCUMENTATION

All steps related to the manufacturing, testing, packaging, or holding of pharmaceutical products, APIs, excipients, dietary supplements, food ingredients, and medical devices should be documented.

Good documentation principles for manual or electronic records include the following, as applicable:

- Records should be clear, concise, accurate, and legible.
- Data entries should be recorded promptly when actions are performed.
- Backdating and postdating are not allowed.
- All corrections to the original entries should be initialed and dated, with an explanation included in cases where the reason for the change is not obvious.
- Data entries should be traceable to the person who made the entry.
- Uncommon abbreviations and acronyms should be defined.
- Controls should be in place to protect the integrity of the records.
- In the event that ink may have faded over time (e.g., thermal paper), a copy can be used with verification of its accuracy; the copy should be initialed and dated.
- Notebooks, data sheets, and worksheets should be traceable.
- An adequate documentation system is needed to ensure data integrity and availability

of current and archived records.

- Records should be retained per regulatory requirements and be readable during the retention period.
- All pages should be paginated. Attachments (supporting documents) should be paginated with a reference to the parent document.

DATA COLLECTION AND RECORDING

Formats for data collection and recording include, but are not limited to, the following:

- Paper forms, data sheets, and worksheets
- Notebooks and logbooks
- Instrument printouts
- Electronic data obtained with a system such as an electronic data system, laboratory information management system (LIMS), or electronic laboratory notebook (ELN)

All data should be permanently recorded directly and legibly when the activity is performed. If it is paper record, then it should be recorded in indelible ink. The use of transient records must not be used for documentation of GMP activities. All data entries should be traceable to who made the entry and when. Additionally, electronic records must meet the requirements of the *Code of Federal Regulations Title 21* (21 CFR), Part 11.

Any change to an entry should be made in a way that does not obscure the original entry, with an explanation in cases where the reason for the change is not obvious. Changes should be traceable to who made the change and when the change was made. For clarity, predefined correction codes may be used, for example, WD = wrong date.

Notebook pages and worksheets should be used consecutively, and information should be recorded chronologically. GMP records such as batch records, test methods, and specifications should be given unique identifiers and use version control for the documents.

All data entry fields should be completed. A single line and/or "N/A" should be drawn through portion(s) of a page that are not used. If the record is in an electronic system and the system provides traceability of who filled each field and when, the field can be left blank.

Decimals less than one should be preceded by a zero. Rounding rules and guidelines on significant figures are described in *USP–NF General Notices and Requirements*.

All dates should be expressed in a format that clearly indicates the day, month, and year.

All GMP records should undergo appropriate review and signature by a second person to confirm the accuracy, compliance, and completeness of the entries. Additional signatures may be required on the basis of local Standard Operating Procedures (SOPs) for different levels of review (e.g., performed by, verified by, checked by, reviewed by, approved by) as accountability steps.

An official record of signature and initials should exist for each employee or can be contained within the document. Controls should be in place for assigning signature approval requirements and delegation of signature authority, when needed.

In the event that verified copies of raw data have been prepared, the verified copy may be substituted for the original source as raw data.

All multiple-page data sheets or instrument printouts should be signed/initialed on the first or last page with a note indicating the total number of pages. The first page and all subsequent pages should be uniquely identified to the activity being performed, such as the notebook reference, study number, or worksheet reference.

DIFFERENT TYPES OF GMP DOCUMENTS

The following or similar documents should include the following information, but are not limited to these items.

Laboratory Records

Laboratory records should be organized to ensure that the records are concise, clear, legible, and accurate, and detail the following:

- Description of materials, such as reagents. This information typically includes the material name, manufacturer and lot number, titer or concentration, expiration date, grade (if known), and a reference to the lab notebook if prepared in the lab.
- Identification of equipment used. This information typically includes equipment name, unique control number, and calibration expiration date, as applicable.
- Procedures used.
- Measurements.
- Formulae and calculations.
- Results and conclusions.

Equipment-Related Documentation

All equipment used in manufacturing, testing, packing, or holding of a raw material, component, API, finished product, or other similar item should be maintained and qualified for its intended use. The documentation related to equipment includes:

- Policies and procedures for operation and maintenance
- Use and maintenance logs
- Calibration or qualification records
- Instrument labeling

Deviations and Investigations

All aberrations, anomalies, and exceptions related to manufacturing, testing, packing, or holding of a raw material, component, API, finished product, or other similar item should be documented. Once documented, the deviation should be evaluated and investigated, as appropriate. Procedures should be in place for documenting, evaluating, and investigating such events. Documentation of the investigation should at least include the following:

- Description of the event
- Root-cause investigation and trend data analysis
- Responsibilities of people involved in the investigation or deviations
- Corrective Action and Preventive Action (CAPA) with timelines
- Review and approval

Batch Records

A Master Batch Record (MBR) is created as a template for the manufacture of a specific product. An Executed Batch Record, based on the MBR, is used to document the steps and materials involved in the production of a specific batch of a raw material, component, API,

finished product, or other similar item. Typically, the following sections are included in a Batch Record, and should be approved by an appropriate representative from the manufacturing site or packaging site:

- Header information (e.g., product name, batch number, manufacturing site)
- Unit of operation (e.g., blending, coating, filling)
- Manufacturing process
 - Target weights (raw materials)
 - Conditions (time, temperature)
 - Deviations and investigations
- In-process sampling or testing
- Other critical information, as applicable
- Sampling plan for release, stability, and retention
- Review and approval with approval dates

Certificate of Analysis

The purpose of the Certificate of Analysis ("C of A" or CoA) is to report analytical results for a specific batch of a raw material, component, API, finished product, or other similar item. Typically, the following sections are included on a C of A and should be approved by an appropriate representative from the testing site:

- Vendor, supplier, or manufacturer information (as applicable)
- Product information (name and strength)
- Results for the specific batch, with name of test, acceptance criteria, and result for each test
- Conformance statement or equivalent
- Reference to procedure and specification document
- Reference of data source
- Approval and date
- Expiration date or retest information

Standard Operating Procedures

The purpose of an SOP is to provide directions to trained personnel regarding a given set of activities. SOPs should be clear and concise. The following sections are typically included in an SOP:

- Purpose and scope
- Instructions and procedure
- Responsibilities and roles
- Materials or equipment, as appropriate
- Definitions or references, as needed
- Review and approval
- Revision history

Protocols and Reports

Many tasks and activities are executed on the basis of a predefined, preapproved protocol. The results of these activities are then documented in a final report with conclusions. Examples of such activities are as follows:

- Equipment qualification
- Analytical method validation or verification
- Manufacturing process validation
- Analytical method or manufacturing technology transfer
- Cleaning validation
- Stability study or testing
- Comparability study

Both the protocol and the report should typically include the following sections:

- Purpose
- Plan or instructions
- Predetermined acceptance criteria
- Deviations or investigations, including impact assessment (or a reference to)
- Assessment or evaluation (for report only)
- Data reference (for report only)
- Review and approval
- Revision history

Analytical Procedures

Analytical procedures provide direction to an operator on how to perform a given analytical test. The following sections will typically be included in the analytical procedure:

- Purpose
 - Test information
 - Product information
- Safety information, if applicable
- Materials and equipment
- Procedure, as applicable
 - System suitability
 - Preparation of solutions and reagents
 - Preparation of standards and samples
 - Instrument parameters
 - Calculations and reporting
- Review and approval with approval dates
- Revision history

Training Documentation

Personnel should be trained to perform their assigned tasks. The training should be documented, and the training records should be retained and kept readily accessible. In general, training documentation should include:

- Training description including name of training, version, and mode (self-training or instructor led)
- Completion date
- Information on the trainer, as applicable

RETENTION OF DOCUMENTS

An adequate policy for record retention and archiving should be established for the above records. The required length of time depends on the regulatory requirements or company procedures; however, it should be at least 1 year after the batch expiration date. ■ 2S (USP39)

BRIEFING

⟨1063⟩ **Shear Cell Methodology for Powder Flow Testing.** This proposed new general chapter describes the use of shear cells for testing the powder flow properties of pharmaceutical ingredients and their mixtures. This chapter incorporates responses to a *Stimuli* article published previously in *Pharmacopeial Forum*, and thus it represents a consensus view on the appropriate use of shear cells for the testing of pharmaceutical powders. It is not intended as a prescriptive method, nor as a replacement for a given shear cell user manual or standard method. Instead, the chapter describes best practices for obtaining reliable and accurate powder flow data using a shear cell. A *Stimuli* article included in this *PF* provides responses to the comments received on the previously published *Stimuli* article in *PF* 39(3) [May–June 2013].

 - 4.2 Instrument Preparation
5. SELECTION OF TEST CONDITIONS
6. TEST PROCEDURE
7. DATA ANALYSIS AND CALCULATIONS
8. REFERENCE MATERIALS AND REPRODUCIBILITY
9. APPENDIX

1. INTRODUCTION

A large number of pharmaceutical processes involve powder transfer and feeding, and the ability of powders to flow in a controlled manner during these operations is critical to product quality. For example, drug product attributes such as weight and content uniformity depend on powder flow characteristics. Shear cells are among the most important methods for measuring powder flow properties, and the data from shear cell testing can be used to predict a wide variety of powder flow behaviors during pharmaceutical manufacturing. Shear cells have many

advantages over simpler methods of measuring powder flow (see *Powder Flow* (1174)), but their operation is more complex and the procedures for their use must be carefully controlled to produce accurate and reproducible data. This general chapter describes best practices for obtaining reliable and accurate powder flow data using a shear cell.

This chapter focuses on the three most popular shear cell types used for measuring powder flow properties:

1. Translational (Jenike type)
2. Annular (Schulze type)
3. Rotational (Peschl type)

These three shear cell types are categorized as direct shear tests in which a region of the powder is sheared under a series of controlled normal stresses. From these data, a wide variety of parameters can be obtained, including the yield locus representing the shear-stress to normal-stress relationship at incipient flow, the angle of internal friction, the unconfined yield strength, powder cohesion, and a variety of related parameters such as the flow function. In addition, these three shear cells can be set up with wall coupons (see 9. *Appendix*) to measure the powder wall friction. When the shear cell data are combined with unconfined yield strength, wall friction data, and bulk density data, they can be used for bin and hopper evaluation and design. Other testing approaches, such as triaxial testers and indirect or hybrid testers (e.g., the Johanson Indicizer), are outside the scope of this chapter.

2. THEORY AND PRINCIPLES

The flow behavior of a powder is fundamentally different from the flow of a fluid. First, powder flow properties and shear behaviors are strongly dependent on the consolidation stresses applied to the powder and are minimally dependent on the strain or flow rate (under the assumption of quasi-static conditions such as flow in a bin). Fluid flow, in contrast, is strongly dependent on the strain rate (where viscosity describes the relationship between shear stresses and strain rates) and is minimally dependent on absolute pressure. Second, when shear stresses are applied to powders, they may not immediately fail (that is, they can avoid flow under a sustained shear stress), whereas Newtonian and viscoelastic fluids do not behave this way and always flow under an applied shear stress. Thus, powders have the potential for arching and ratholing, depending on the flow pattern (see 9. *Appendix*).

However, powders can sustain a shear stress without flowing only up to a certain point. The yield locus for a given powder is a function of many variables, including its composition, particle size and shape, moisture content, temperature, time stored at rest, and the state of consolidation. Once a powder is subjected to stresses (whether by gravity or some mechanical means) that reach or exceed the yield locus, the powder flows. Hence, determining the yield locus for a given powder under conditions representative of its manufacturing process is an essential step in evaluating the flow behaviors for that process. In some circumstances, this may involve testing under controlled environmental conditions, as well as holding the powder under load for an extended period before shearing (a "time test").

Because powder properties are highly dependent upon the degree of consolidation, the preparation of a uniform powder bed (consistent bulk density throughout the powder bed) is

the first critical step of shear cell testing. The next stage of testing is the application of a normal stress (Σ) and shear stress (τ) to the powder bed to achieve steady-state shear, resulting in a known state of consolidation. The shear stress then is removed, and a reduced normal stress is applied. A shear stress then is applied and is progressively increased until the powder bed yields and begins to flow. This procedure is repeated at several different normal stress conditions to create a "yield locus" plot. To complete a full flow function analysis, the operator must determine several yield loci, which requires that the unconfined yield strength be determined under several different levels of consolidation.

Although this chapter focuses on the powder (particle-particle) properties, the wall (particle-wall) properties and bulk density are also important. Such properties are used for bin design and also are essential when one compares different wall materials (e.g., different grades and finishes of stainless steel, or the effect of plastic coatings on powder flow behaviors). The most fundamental property of a wall material in this regard is ϕ' , the angle of friction between the bulk powder and the wall material, or, correspondingly, the coefficient of wall friction (μ_w):

$$\mu_w = \tan(\phi') = \tau_w / \Sigma_w$$

ϕ' and μ_w = function of the applied stress (Σ_w)

τ_w = wall shear stress

Σ_w = wall normal stress

3. DESCRIPTION OF SHEAR CELL COMPONENTS AND DESIGNS

Figures 1–3 provide schematics of the different types of shear cells considered in this general chapter. All have the same general operating principle of being able to measure the force required to shear a powder bed to which a normal load has been applied. The applied load or measured force can be expressed as a stress by dividing by the cross-sectional area of the shear plane under consideration.

The translational shear cell (*Figure 1*) has a fixed base with a movable ring above it, and both hold the bulk powder. A cover that fits within the ring is used to contain the powder and to provide a uniform application of the normal load (N). The ring and cover are pushed as a unit while a load cell records the shear forces (F) that are generated. The shear plane forms between the powder that is contained in the base and the powder contained in the ring.

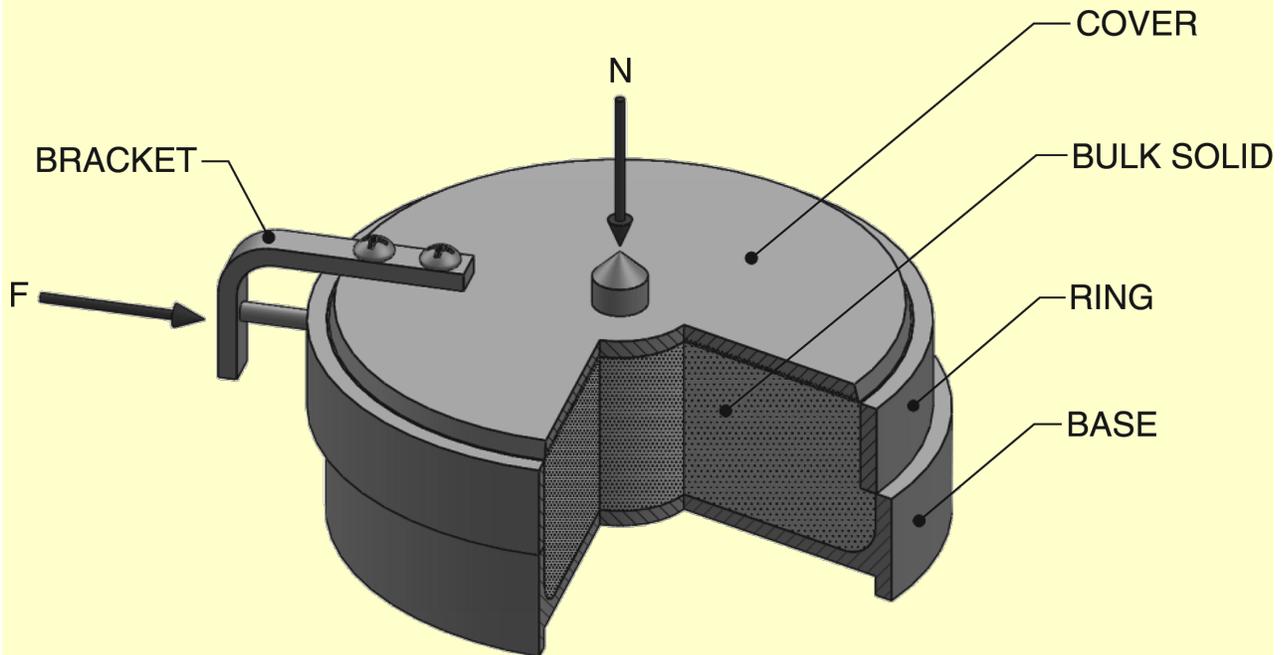

Figure 1. Descriptive schematic of the translational shear cell.

The annular shear cell (*Figure 2*) consists of a shear cell or base that holds the powder. A cover that fits within the cell is used to contain the powder and to provide a uniform application of the normal load (N). The cover is free to move up and down, but otherwise remains fixed in place by a load cell that measures the shear forces (F) that are generated. The shear cell is rotated at a constant angular velocity (Ω) to create a shear plane that forms in the powder bed somewhere between the cell bottom and the cover. The cover and shear cell usually have baffles or other surface features that prevent the powder from sliding or shearing at the interface between the powder and the cover or shear cell base.

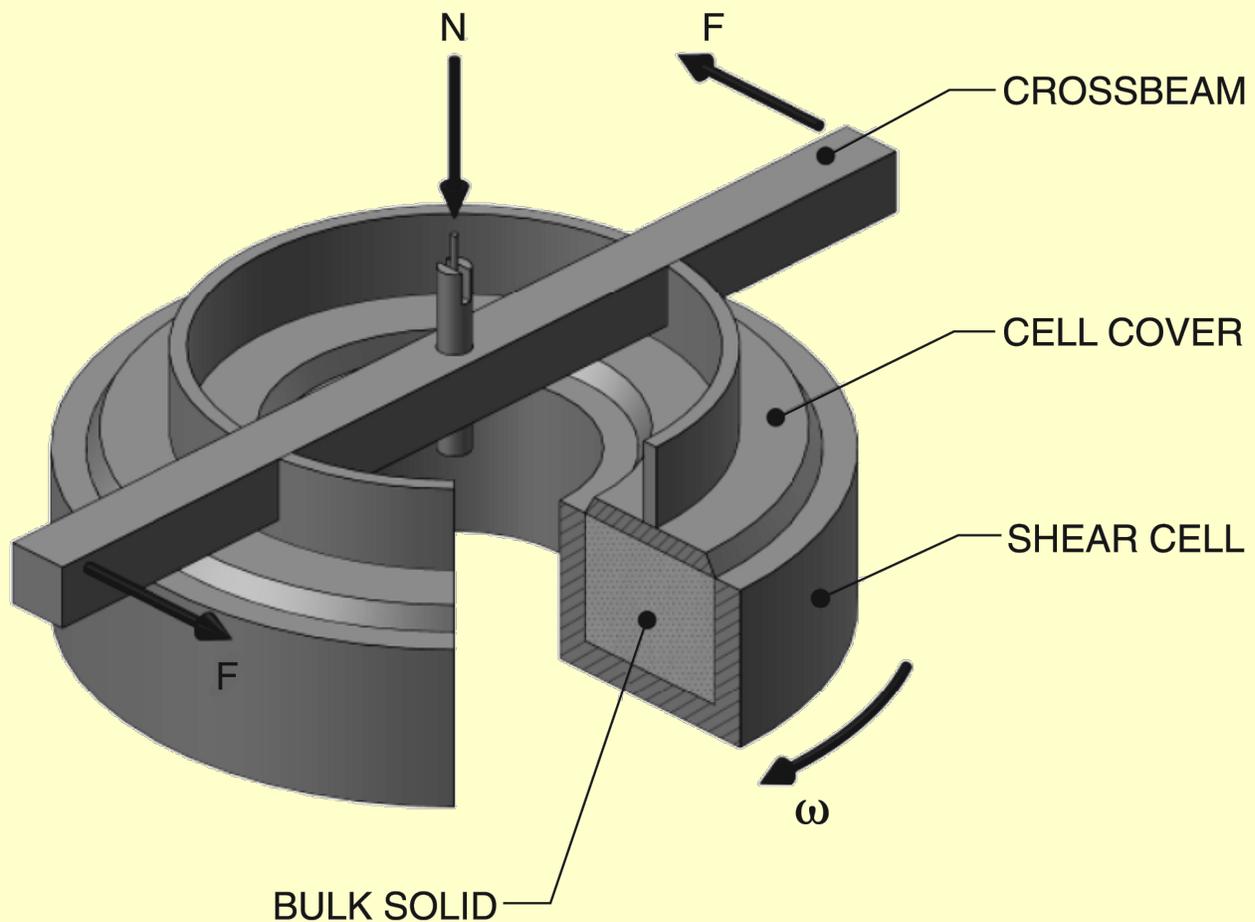

Figure 2. Descriptive schematic of the annular shear cell.

The rotational shear cell (*Figure 3*) has a base and ring that hold the powder. A loading lid that fits within the ring is used to contain the material and to provide a uniform application of the normal load (N). The loading lid is free to move up and down, but otherwise remains fixed in place, connected to a load cell that measures the shear forces (F) that are generated. The shear cell base then is rotated at a constant angular velocity (Ω) to create a shear plane that forms in the powder bed somewhere between the ring and the base. Alternatively, the base can be fixed, and the lid can be rotated to create the shear plane in the powder specimen. The ring and base usually have surface features that prevent the powder from sliding at the powder-surface interface.

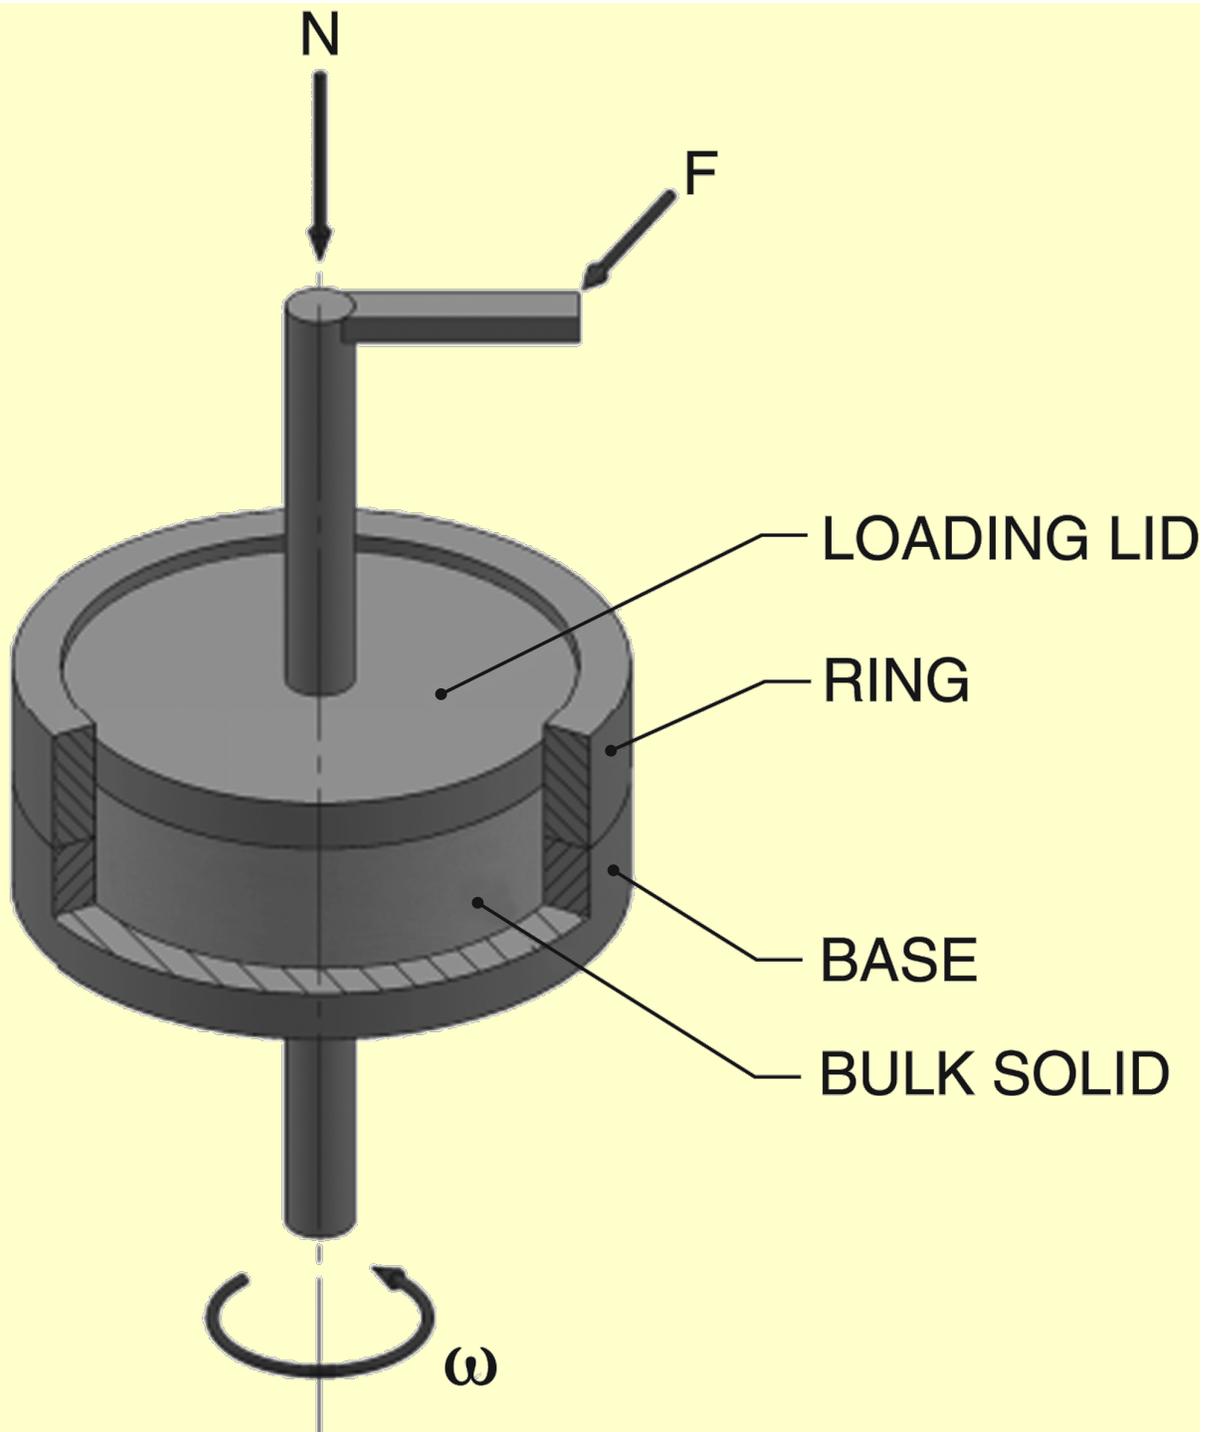

Figure 3. Descriptive schematic of the rotational shear cell.

The choice of one shear cell type over another depends on factors such as the availability of equipment and ease of use for a particular technician. Because of the infinite travel permitted with the annular and rotational shear cell geometry, these types of cells are more suited for powders for which reaching steady state requires large strains. Another advantage of the infinite travel of rotational testers is that a preconsolidation step may not always be required. Wall friction tests can be carried out using all of the shear cells referenced in this chapter with only minor modifications, namely by creating a shear plane in which the powder slides over a suitable wall coupon rather than having the shear plane within the powder bed. This usually is

achieved by replacing the base of the shear cell with a coupon of the wall material and adjusting the amount of powder used to create a shear plane at the powder-coupon interface.

4. SHEAR CELL MEASUREMENTS

4.1 Sample Preparation

The applicability of shear cell data depends strongly on the use of a representative powder sample. Detailed discussion of appropriate sampling procedures can be found in *Bulk Powder Sampling Procedures* (1097).

The cell size (volume and diameter) usually is selected based on the maximum particle size of the powder sample, and the proportion of large particles in the sample. The particle size limit is usually reported by the supplier of commercially available testing equipment. For a translational cell, the maximum particle size is approximately 5% of the diameter of the cell, and for an annular cell the maximum particle size is approximately 10% of the width of the annulus, i.e., the difference between the outer and inner radius of the shear cell trough. Fresh powder is desired for each test, if possible, so the use of a smaller cell may be preferable to reusing the powder. Under some circumstances, a smaller cell may be needed to reach higher consolidation stresses. Smaller cell sizes may have reduced precision and increased bias, depending on the specific tester and the cell size under consideration, because of the larger contribution of non-idealities caused by wall effects.

The shear strength of some powders (such as fibrous or flaky solids) is often caused by interlocking of particles; therefore, such materials may prove to be unsuitable for testing with a conventional shear cell. Likewise, powders with high springback (rubberlike or highly elastic properties) sometimes can fall outside of the practical limits of a shear tester. Poor reproducibility and unexpected results may indicate a problem with testing these types of powders.

Powder samples must be handled and tested under conditions that are relevant from a practical standpoint. For example, many pharmaceutical powders will sorb/desorb moisture from their surroundings according to the ambient relative humidity and temperature. This sorbed moisture can significantly affect the measured powder flow properties. Controlling the environmental conditions during sample handling and testing so that sample behavior is representative of the processing conditions of interest is essential for most powders.

Some pharmaceutical powders "age" quickly after they are produced, and such powders may need to be tested immediately after they are manufactured. The testing of some powders may result in caking or particle attrition that can render a powder unsuitable for retesting. In these circumstances, fresh powder samples should be used for each test.

4.2 Instrument Preparation

The shear cell should be situated in an area that is free of vibrations. Vibrations can affect the instrument readings and also can densify or dilate the powder while it is being tested.

Because shear testers measure forces, their load cells must be calibrated for the forces being measured. Some testers also measure the displacement (linear or angular) of the cell (indicating travel) and/or the vertical displacement of the cover or lid (used to calculate the volume of the cell and hence an average bulk density). In these cases, the displacement transducers must

also be calibrated. The rate of any changes in force and displacement will need to be confirmed as part of this calibration. In addition, the shear cell is operated under the assumption that all of the parts are precisely aligned, and there is a minimal degree of wobble when the cell rotates. For example, if the cover and shear cell trough are not parallel during testing, it will be difficult to get reproducible results.

Thus, the alignment and mechanical operation of the shear cell must be evaluated at regular intervals. No other adjustments with respect to calibration are performed, although the correct performance of the apparatus may be confirmed by the measurement of the yield locus of a reference powder under standardized test conditions.

Wall coupons used for testing must be representative of the surfaces upon which the powder will slide. Directional surfaces can be either oriented in the direction of flow in the application (e.g., grain oriented down the length of a hopper), oriented in the worst-case condition (often, grain oriented perpendicular to the direction of flow in the hopper), or evaluated in both directions.

All shear cell components (including wall coupons) should be carefully cleaned before use with a method that does not abrade the surface or leave any chemical residue behind. In addition, the cleaning method should be capable of removing all of the components of the test sample, including lubricants and other additives.

5. SELECTION OF TEST CONDITIONS

Preshear normal stresses usually are selected based on the powder's density values. Standards, such as ASTM Standard 6128, provide tables of specific initial preshear normal stresses as a function of the sample bulk density.¹ Subsequent preshear normal stresses are given in multiples of the initial preshear value (such as two, four, and eight times the initial level). The number of preshear normal stress levels should be at least four. It is often valuable to match preshear stresses in the test to the stresses expected in the processing situation of interest. Hold times for time tests are selected based on matching the hold time in the practical application. If long hold times are unrealistic, operators may consider several intermediate time points and extrapolation of the data.

Normal stress levels for shear are selected to provide a range of data points on the yield locus. Typically, a range between 25% and 80% of the preshear normal stress is valid, although powders with high unconfined yield strength or internal friction may require a narrower range. The range of normal shear stress levels should be sufficient to allow meaningful fitting and extrapolation of the data to determine the unconfined yield stress and other related parameters.

6. TEST PROCEDURE

Shear cell testing involves a sequence of steps that consolidates the powder to a known extent and then shears it under carefully controlled conditions while recording the applied normal stresses and measuring the shear stresses. In most cases, the essential steps are as follows:

1. Fill the test cell with an appropriate and representative sample of the powder in a manner that provides a uniform bulk density and composition. This sample in the test cell is referred to as the specimen. Detailed procedures vary according to the type of

tester being used, but in all cases it is essential to evenly distribute the powder and avoid pockets of air that can be difficult to remove later.

2. For translational shear cells, perform a preconsolidation step to create the desired density in the cell. This is accomplished by twisting the cover while under a compressive normal load. This step reduces the travel needed to achieve a steady-state preshear value and can limit the total vertical displacement of the cover during the test. A preconsolidation step may be conducted in other cell types, but this is often not conducted, because the unlimited rotation of the annular and rotational cells can generally provide a sufficient state of consolidation. The appropriate level of preconsolidation is critical, and care must be taken not to over- or under-consolidate the specimen.
3. Consolidate the specimen by applying a known normal stress to the powder specimen via the cell cover/lid.
4. Preshear the specimen until a steady-state shear value is reached. Care should be taken to avoid over-consolidating the specimen. The applied shear stress is then reduced to zero.
5. An instantaneous shear test is run by shearing the specimen under a reduced normal stress (with respect to the applied preshear stress) until the shear stress goes through a maximum value and then begins to decrease.

Steps 1–4 are repeated at a series of different reduced normal stress conditions to create a complete set of data (yield locus) and then at a series of different preshear normal stress conditions to create a “flow function”. The test cell is preferably emptied and refilled before generating each point on the yield locus. For annular or rotational shear cell types, it is common that steps 3–5 are repeated a number of times for the same specimen without emptying and refilling the cell. If the same specimen is used for multiple test points, caution must be taken to ensure that the specimen has not changed from test to test. A wall friction test is run in an analogous manner by sliding the specimen over a coupon of wall material and measuring the shear stress as a function of the applied normal stress. In a time test, a normal stress is applied to the specimen for a predetermined period of time before shearing. Both wall-friction and time-consolidation tests can be conducted with the three types of shear cells described in this chapter, as long as directionality (if any) of the wall surface, relative to the cell movement, is taken into account.

7. DATA ANALYSIS AND CALCULATIONS

Illustrative results from the shear cell test procedure are presented in *Figure 4*. For analysis, the applied preshear normal stress (Σ_p) and all valid applied normal stress points (Σ_{si}) for $i = 1, 2, 3, \dots, n$ and their corresponding measured shear stress points $\tau_p, \tau_{s1}, \tau_{s1}, \dots, \tau_{sn}$ are plotted in (Σ, τ) -coordinates. These data are then used to generate a smooth line through all the valid shear points to obtain the yield locus. Typically, the yield locus passes above or through the preshear point. If not, the test results should be analyzed in more detail. In some circumstances, the yield locus can be forced to pass through the preshear point and can be

fitted to all yield points.

The “unconfined yield strength” of the powder is obtained by drawing a Mohr circle through the origin and tangential to the yield locus. The higher point of intersection of this Mohr circle and the Σ -axis is the unconfined yield strength f_c . The “major consolidation stress”, Σ_1 , is found by drawing a second Mohr circle through the preshear point and tangential to the yield locus. The higher point of intersection of this Mohr circle (consolidation locus) and the Σ -axis is the major consolidation stress.

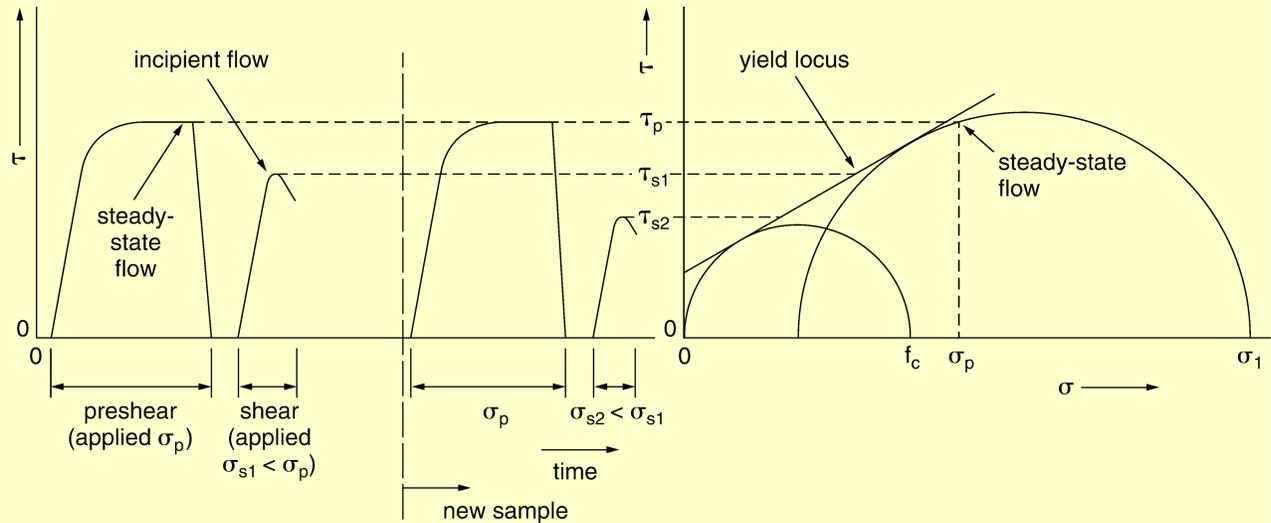

Figure 4. Shear cell testing and data analysis: shear cell raw data (left) and yield locus calculated from raw data (right).

The “angle of internal friction”, ϕ , is defined as the slope of the yield locus, as shown in Figure 5. A line drawn through the origin and tangential to the steady-state Mohr circle has an angle, Δ , that is defined as the “effective angle of friction”. The “cohesion,” C , is the intersection of the yield locus and the τ -axis.

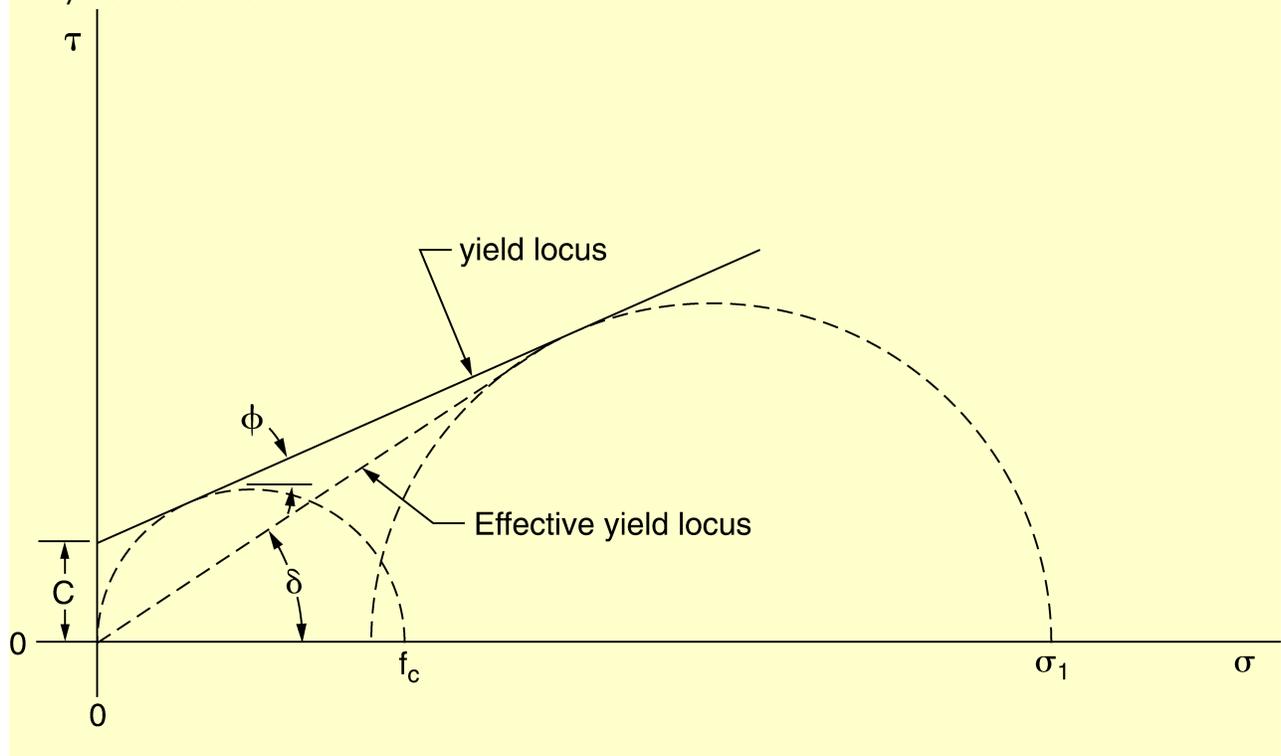

Figure 5. Graphical representation of the angle of internal friction (ϕ), effective angle of friction (Δ), and cohesion (C).

From a family of yield loci generated at different preshear normal stresses, it is possible to plot the unconfined yield strength, f_c , as a function of the major consolidation stress, Σ_1 , as shown in Figure 6. The best-fit curve to these points is called the “flow function” and can be used to calculate the potential for arching and ratholing in a storage bin.

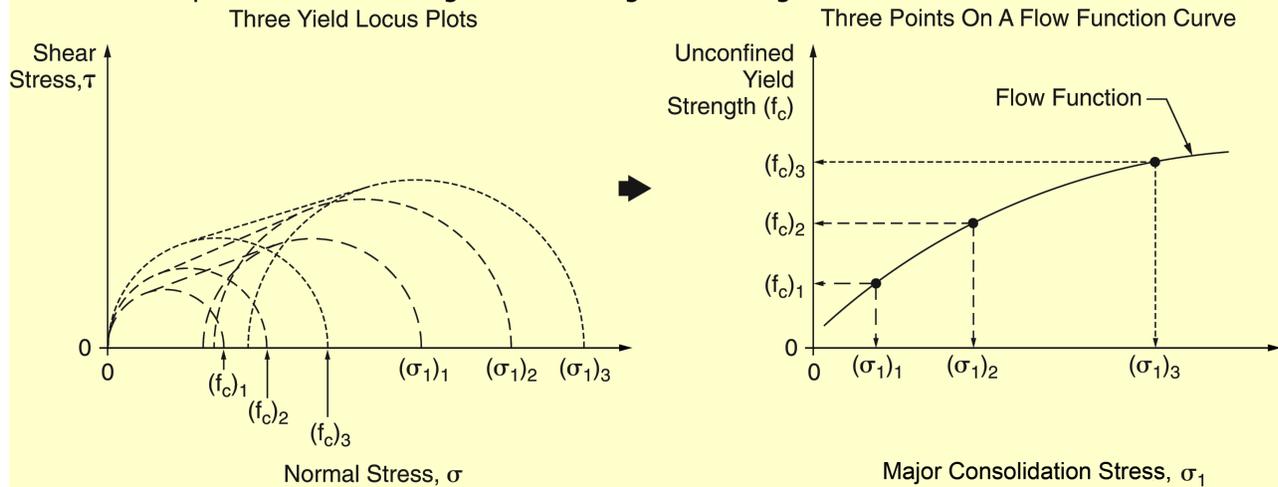

Figure 6. Calculation of the flow function from multiple yield locus plots.

The “kinematic wall yield locus” is developed in a manner similar to the calculation of the yield locus. This is depicted in Figure 7. The “wall friction angle”, ϕ' , is defined as the inclination of a line from the origin to a point on the wall yield locus. In general, low wall friction angles are desirable.

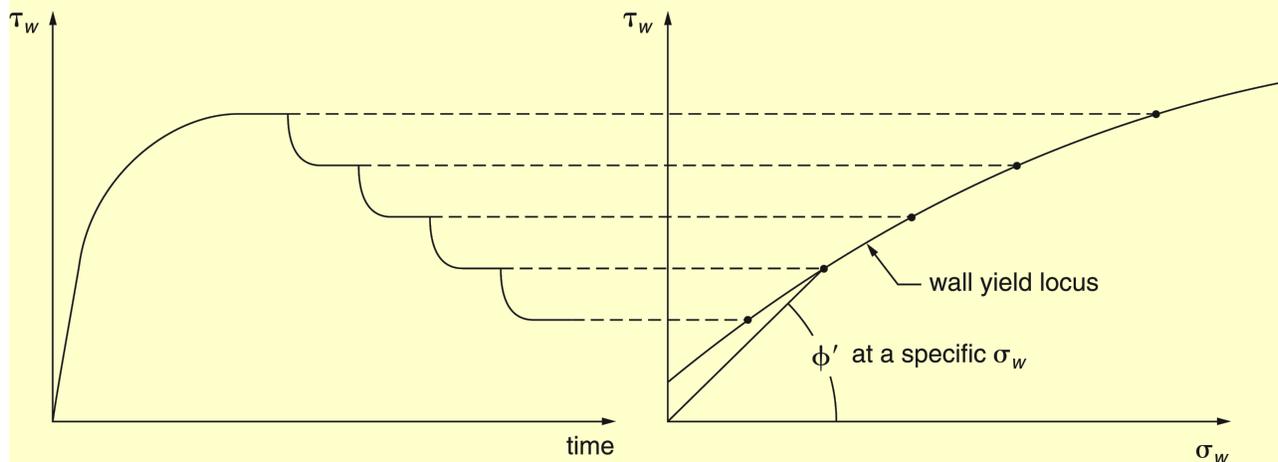

Figure 7. Calculation of the wall yield locus.

Test conditions should be carefully documented for every shear cell analysis to allow for accurate data interpretation and meaningful data comparisons. When analysts compare multiple powders—matching the tester type, specific tester model, test cell size, sample preparation, test procedures, applied normal stresses, and environmental conditions—increased confidence is provided that any differences in the results are attributable to the powder and not to the test. Changes in material sourcing or manufacturing may require the repetition of the initial studies.

Shear cell tests allow the analyst to characterize consolidated powders under quasi-static conditions. The tests are unable to directly measure powder flow properties at very low stress conditions or high shear rates, which may occur in some powder handling situations. Thus, no single parameter can describe powder flowability. Instead, the parameters described in this general chapter should be interpreted together and in the context of the conditions under which the powder will be stored and handled (e.g., equipment dimensions, environmental conditions, and others).

The ratio of the major consolidation stress Σ_1 to the unconfined yield strength f_c at a particular value of the major consolidation stress provides a general, simplified way of assessing powder flowability. As a general case, the flow of powdered materials is classified in *Table 1*:

Table 1. General Classification of Flow Character³

Σ_1/f_c	Flow Character
<2	Very cohesive, nonflowing
2-4	Cohesive
4-10	Easy-flowing
>10	Free-flowing

This approach can be useful for rank ordering the flow character of pharmaceutical powders as part of formulation and process development activities. However, it should be noted that this simplified view may lead to significant errors in interpretation, because this approach does not take into account the flow pattern, or the size or geometry, of the manufacturing equipment being used.

8. REFERENCE MATERIALS AND REPRODUCIBILITY

For a tester that is installed and operated correctly, the performance of the instrument and operator can be assessed by testing a standard material. There is currently no specific pharmaceutical reference material for shear cell test method verification. Limestone powder has been used as a certified reference material.⁴

Figures 8, 9, 10, 11, 12, and 13 show representative yield loci and flow function plots for several common pharmaceutical excipient powders determined at a range of conditions. The plots are provided to illustrate the type of data that can be generated for pharmaceutical powders using a shear cell and the typical reproducibility of the data. The data in *Figures 8, 9, 10, and 11* were collected using a procedure consistent with that described for *Figure 4*. These plots are not intended for use as reference data, and they should not be assumed to be representative of all test conditions and material types.

9. APPENDIX

Notation

Term	Symbol and SI Units	Definition	Comments
Angle of internal friction	ϕ , degrees	The inclination of the yield locus (<i>Figure 5</i>).	
Angular velocity	Ω , degrees per second	The angular velocity at which the shear cell base rotates.	Is usually held constant.
Annular shear cell	NA	A shear cell based on a rotating annulus design (<i>Figure 2</i>).	The Schulze Ring Shear Tester is a common annular shear cell.

Term	Symbol and SI Units	Definition	Comments
Arching	NA	The formation of a bridge of powder across an opening caused by attractive interactions between particles.	Also known as "bridging".
Bulk density	ρ , kg/m ³	The mass of a quantity of a powder divided by its total volume.	Varies with the applied normal stress and history of a sample.
Cohesion	C , Pa, kPa	The failure shear stress at zero normal stress, normally obtained by extrapolation of the yield locus (<i>Figure 5</i>).	An indication of the intrinsic strength of an unconsolidated powder.
Consolidation	NA	The process of increasing the density of a powder, which usually results in increasing its unconfined yield strength. Achieved in a shear cell by applying a preshear normal load and shear load to the specimen.	
Coupon	NA	Flat surface that is in contact with powder specimen during wall friction testing.	The coupon surface finish must be representative of the wall surface of interest.
Effective angle of friction	Σ , degrees	The inclination of the effective yield locus (<i>Figure 5</i>).	Sometimes used as a measure of relative flowability.
Effective yield locus	NA	The straight line passing through the origin of the Σ - τ plot and tangential to the steady-state Mohr's circle, corresponding to steady-state flow conditions of a powder of given bulk density. (<i>Figure 5</i>).	
Flowability	NA	A qualitative estimate of the relative flow properties of a powder.	Often based on measured values of the flow function or effective angle of friction.

Term	Symbol and SI Units	Definition	Comments
Flow function	NA	The plot of unconfined yield strength versus major consolidation stress for one specific powder (<i>Figure 6</i>). Quantified as the ratio of the major consolidation stress to the unconfined yield strength at a particular value of major consolidation stress.	
Funnel flow	NA	A flow pattern where an active flow channel forms through stagnant material.	
Lid	NA	Cover of the cell containing the specimen within a shear cell.	The lid position can be measured to determine displacement, bulk density, and powder dilation.
Major consolidation stress	Σ_1, Pa	The major principal stress given by the steady-state Mohr circle. This circle is tangential to the yield locus and effective yield locus and passes through the preshear point. (<i>Figure 4</i>).	
Mass flow	NA	A flow pattern in a converging hopper where all material is in motion, including material sliding along the hopper walls.	
Mohr's circle	NA	A graphical representation of a state of stress in coordinates of normal and shear stresses (<i>Figure 4</i>).	
Normal stress	Σ, Pa	The stress acting normally (perpendicularly) to the considered plane.	Σ_p is the preshear normal stress. Σ_{Si} for $i = 1, 2, 3, \dots$ the test normal stresses.
Preconsolidation	NA	Normal stress applied to consolidate a powder before testing in some shear cells (<i>Figure 4</i>).	
Preshear	NA	Application of normal stress while shearing to attain steady-state shear conditions (<i>Figure 4</i>).	
Ratholing	NA	Tendency of powder to flow only in the region above an opening, thus forming a narrow rathole in the powder.	Also known as "core flow".

Term	Symbol and SI Units	Definition	Comments
Rotational shear cell	NA	A shear cell operating under rotational shear conditions (that is, rotational shearing perpendicular to the applied normal stress). (<i>Figure 3</i>).	The Peschl and Freeman shear cells are common rotational shear cells.
Shear stress	τ , Pa	The stress required to shear the powder in a direction perpendicular to the normal stress.	
Time consolidated strength	f_{ct} , Pa	The unconfined yield strength of a powder after being held at fixed consolidation conditions for a certain time.	
Time yield locus	NA	The yield locus of a powder that has remained at rest under a given normal stress for a certain time.	
Translational shear cell	NA	A shear cell operating under translational shear conditions (that is, linear shearing perpendicular to the applied normal stress). (<i>Figure 1</i>).	The Jenike shear cell is a common translational shear cell.
Unconfined yield strength	f_c , Pa	The major principal stress of the Mohr stress circle that is tangential to the yield locus when the minor principal stress is zero (<i>Figure 4</i>).	
Wall friction angle	ϕ' , degrees	The arctan of the wall friction coefficient (<i>Figure 7</i>).	
Wall friction coefficient	μ_w	The ratio of the wall shear stress to the wall normal stress at a given normal stress condition.	
Wall yield locus	NA	A plot of the wall shear stress versus wall normal stress. Used to determine the wall friction angle for a powder-wall combination (<i>Figure 7</i>).	
Yield locus	NA	A plot of shear stress versus normal stress at failure. The yield locus sometimes is called the instantaneous yield locus to differentiate it from the time yield locus (<i>Figure 4</i>).	A powder exhibits a series of yield loci for each different level of consolidation (density).

BRIEFING

(1228.3) **Depyrogenation by Filtration.** The General Chapters—Microbiology Expert Committee proposes this new general chapter as an addition to the *Depyrogenation* (1228) family of chapters. Production of parenteral products requires not only sterile manufacturing but also processes that prevent harmful levels of pyrogens. Effective destruction or removal of pyrogens, or depyrogenation, depends on the product that has been manufactured and the proposed method of removal and/or destruction. Liquid products can be depyrogenated through filtration. This chapter provides an overview of that process and the various approaches and technologies used to complete it.

1. INTRODUCTION

Endotoxins are lipopolysaccharides from the cell walls of Gram-negative bacteria. Endotoxins are responsible for making up the majority of pyrogens, which must be removed from pharmaceutical products including injectable biologics. There are many factors to be considered when designing a depyrogenation filtration process for solutions containing proteins and peptides: type of target protein and its concentration; electrolyte concentration; pH and buffer system; protein molecular weight and isoelectric point (pI); filtration parameters (e.g., flow rate); and interactions with other components causing aggregation. In general, a combination of these factors determines the most effective depyrogenation method.

Depyrogenation of liquids may be accomplished by means of filtration through various types of

filter media including microporous membranes, reverse osmosis (RO) membranes, ultrafilters, charge-modified depth filters, activated carbon, and membrane absorbers. Depyrogenation filtration processes are not intended to remove microorganisms from a process stream; however, by their nature, filters selected for use in depyrogenation processes may also be capable of retaining many types of microorganisms.

2. TECHNOLOGIES USED FOR DEPYROGENATION BY FILTRATION

2.1 Microporous Membrane Filtration

Microporous membranes (typically with pore size or retention ratings between 1.0 and 0.1 μm) can be very effective in removing intact bacteria via size exclusion and adsorption within flow pathways. The use of microporous membranes on a freshly prepared solution to be filtered can effectively prevent bacterial proliferation in the solution, along with any potential subsequent endotoxin formation. Endotoxin, however, is composed of fragments of bacterial cell wall, often $<0.025 \mu\text{m}$ (1) that may easily penetrate most bacteria-retentive membrane filters. These negatively charged particles with endotoxin activity can be removed via adsorption by positively charged membranes (2). Adsorption of endotoxin has also been shown by hydrophobic membranes, where it is thought that a hydrophobic interaction occurs between the Lipid A core and hydrophobic sites on the membrane flow path surfaces (3). Reduction or removal of endotoxin activity by adsorption to microporous membranes can be dependent on flow rate, pH, concentration, and fluid and membrane surface properties. Once the effective binding capacity of the membrane approaches saturation under applied conditions, remaining endotoxin will pass through the membrane.

2.2 Reverse Osmosis

RO membranes are the tightest membranes in size separation. They can separate dissolved salts and sugars from water. Pyrogens, and essentially everything else, are removed from water via size exclusion. RO systems are operated most efficiently at high pressure (200–1000 psi) to overcome osmotic pressure. RO membrane rating or tightness is measured and expressed with retention or rejection of marker salts such as sodium chloride or magnesium sulfate.

RO membranes may be composites (thin film coated on top of ultrafiltration membranes) or cast as a single layer (cellulose acetate type). Configuration of RO membrane modules can be flat sheet, tubular, or hollow fiber. All commercially available RO membranes are polymeric, and most are of a spiral-wound, flat-sheet format.

RO systems are not intended to remove all bacteria, and because they are run at ambient temperatures, microbiological contamination is a concern. Ultraviolet (UV) light may be used in the system downstream from the RO units to control microbiological contamination.

2.3 Ultrafiltration

Ultrafiltration (UF) is a process whereby a fluid is passed through membranes with pore sizes nominally between about 1 and 100 nm under pressure. The filters are usually not rated by the pore size but by the molecular weight cut-off (MWCO). The methods to determine the MWCO vary by the manufacturer and usually involve measuring passage of molecules of a certain size, such as a solution of mixed dextrans, polyethylene glycol, or proteins to assign a numerical rating (4).

UF membranes are usually polymeric porous structures, manufactured from a range of materials, most commonly regenerated cellulose or polyether sulfone, but also ceramics. UF membranes may be produced as flat sheet, hollow fibers, or ceramic tubes.

UF is generally operated in tangential/cross flow mode, which separates the starting (feed) solution into two components: permeate (the portion of solution going through the membrane) and retentate (the concentrated solution that is passed over the membrane). UF membranes need to be encased in a suitable integral device to enable practical operation. Heat sealing, over-molding, and resin-potting are all used to assemble membrane devices and ensure integral flow paths. Ceramic tubes are sealed by gaskets within tubular cylinders.

It is generally assumed that the basic subunit of lipopolysaccharide (LPS) is about 10–20 kDa (5). Membranes of 6–10 kDa cut-off are often used for depyrogenation by size exclusion. However, monomeric LPSs are rarely found in solution because of their poor solubility in water. LPS is usually present in aggregated forms, such as vesicles ranging in molecular weight from 300 to 1000 kDa. Thus, endotoxin can be successfully removed by higher flux membranes, with MWCOs of 30–100 kDa (6).

Adsorption, in addition to size exclusion, also can be a mechanism of endotoxin removal by UF. Several hollow-fiber membrane materials have been evaluated, and the best removal was obtained with more hydrophobic membranes. Endotoxin removal was correlated to the degree of endotoxin adsorption on the membranes in an equilibrium experiment (7).

UF has been used successfully to depyrogenate small molecule drugs, buffers, electrolytes, antibiotics, and antifungal agents (8). UF is generally not recommended for endotoxin removal from solutions containing larger molecules such as proteins.

2.4 Charge-Modified Depth Filters

Depth filters exhibit two primary clarification mechanisms because of their structural and chemical composition: size exclusion, either through sieving or entrapment; and adsorption, either through electrokinetic (positive zeta potential) or hydrophobic interactions.

Size exclusion of particles is a function of the tortuous flow path through the media as well as the depth or length of the flow path in relation to the size distribution of the contaminate loading, e.g., cellular debris, including LPS from cell walls and hard particles. Depth filtration efficiency depends on many factors, including the filter media characteristics, materials of construction, e.g., cellulose, filter aids, binding resins—the fluid characteristics, e.g., viscosity, dirt load, cell debris, temperature—as well as the particle characteristics: solid/hard, pleomorphic, proteinaceous, colloidal. Electrokinetic adsorption is attributed to the resin binders and filter aids that impart a net-positive charge, positive zeta potential, to the filter medium. Adsorption is a complex mechanism that will vary based on a combination of parameters including positive zeta potential, hydrophobic adsorption, particle surface charge, pH, and ionic strength of process fluids. This positive zeta potential can remove negatively charged particles smaller than the nominal rating of the depth filter medium. The adsorptive mechanism results in high removal efficiencies for fine particles, colloidal and cellular materials, e.g., bacterial endotoxins, nucleic acids, and removal of negatively charged trace contaminants, whereas the depth medium porosity influences operating parameters such as pressure differentials, flow rates, dirt load capacity, and throughput.

Most cellulose-based depth filters contain a filter aid to enhance particle retention and flow characteristics. Filter aids are available in various particle sizes and levels of purity. Common filter aids include diatomaceous earth, perlite (volcanic origin), carbon (natural sources), and silica- and/or metallic-based materials.

The cartridges and capsule configurations are constructed of primarily polypropylene and other common elastomers and polymers, e.g., nylon, polycarbonate, polysulfone. Depth filters are available in standard filter cartridge/capsule configurations; lab-scale discs (47 mm/90 mm), flat stock sheets, lenticular cartridges (stacked discs), and capsules.

In general, the charge-modified depth filters showed lower endotoxin breakthrough levels at charge exhaustion as compared to charge-modified membrane filters.

Membranes demonstrated total endotoxin breakthrough once the charge capacity of the membrane is saturated. Generally, charge-modified depth filter media demonstrate lower endotoxin unit (EU) levels that increase slowly at the point of first endotoxin detection as compared to membranes that exhibit complete breakthrough.

Benefits of charge-modified depth filters include removal of bacterial endotoxin [4–5 log reduction value (LRV)] (9–11), DNA fragments, host cell protein, reduction of viruses, and economical throughput with low extractable levels. System flow rate determinations are necessary to optimize residence time to maximize adsorptive capture. This parameter is especially important for the removal of colloids and endotoxins.

Cellulosic depth filters commonly contain extractable *Limulus* amoebocyte lysate (LAL)-reactive materials that are often determined to be β -1,3-glucans. β -1,3-Glucans activate an alternative LAL pathway, Factor G. The activation of Factor G by β -1,3-glucans will induce the proclotting enzyme, causing a non-endotoxin-positive LAL result (or enhanced result). To reduce the risk of β -1,3-glucan extractables from cellulosic depth filters, it is important to follow the recommended rinse conditions of the specific depth filter. An alternative to reduce the effects of β -1,3-glucans is to select LAL reagents tolerant of β -glucans or to add a β -glucan blocking buffer to LAL samples.

To some users, the most important attribute of charge-modified depth filters is their effectiveness as prefilters. In more difficult filtrations, such as those containing colloids, bacteria, or endotoxins, the user can realize substantial cost savings.

2.5 Activated Carbon Depth Filters

Depth filtration, using activated carbon as a filter aid adsorbent, removes color, odor, and bacterial endotoxins and nucleic acids. Activated carbon is derived from organic materials, e.g., peat, wood, coconut, bone, lignite coal. The microstructure of the carbon contains millions of pores that create a highly adsorptive material with a vast internal effective surface area as compared to polymeric microporous structures. These carbon filter aids are typically activated by steam or chemical treatment such as acid. Although highly effective in reducing endotoxin (4–5 log reduction) and other undesirable contaminants, active carbon may, because of this highly adsorptive characteristic, remove other process components and target molecules due to this nonspecific adsorption property. The high loading capacity and strong adsorptive attributes make activated carbon depth filtration an attractive alternative to conventional filtration methods or addition of bulk carbon, where care must be taken to remove fine carbon particulates in the effluent.

2.6 Membrane Adsorbers

When the target protein in the solution is in the same molecular weight range as that of the endotoxins (10–20 kDa for endotoxin monomers), the target proteins cannot be separated by UF. Ion exchange chromatography is the most common depyrogenation method for proteins; however, it has some drawbacks, which limit its usefulness as a depyrogenation step. This

includes handling and usage problems such as packing, channeling, low flow rates, long regeneration times, compressibility, and limited chemical stability. Charge-modified membrane adsorbers with ion exchange ligands functionalized on the membrane surface can provide the required performance needed for depyrogenation from the laboratory up to process scale. Generally, two strategies can be used for removal of endotoxin from solutions with such membrane adsorber devices. Using the strong basic anion exchanger of quaternary amine (Q) type in a buffer with pH lower than the pI of the protein, endotoxin will bind to the charged membrane substrate, and protein will pass through the membrane (negative chromatography). Alternatively, a strong acidic ion exchanger type S also can be used with a buffer pH lower than the pI of the protein. In this case, the endotoxin will pass through, and the protein will be bound to the charged membrane substrate, which can be subsequently eluted using appropriate buffers in the next step.

Such membrane adsorbers have been used as validated endotoxin clearance steps in downstream processing of monoclonal antibody (mAb) or recombinant protein manufacturing. Typical log reduction values (LRVs) reported are >4 (12) based on lab scale testing.

Another solution is to use mixed-mode membrane adsorbers exhibiting both anionic and hydrophobic chemistries. Endotoxins (hydrophobic and negatively charged) tightly bind onto the membrane surfaces. By adjusting the concentration of salt or pH appropriately, proteins flow through the mixed-mode membrane adsorber by charge repulsion, while endotoxins remain bound. Mixed-mode membrane adsorbers allow the depyrogenation of protein solution or buffers with higher concentrations of salt (e.g., 100–500 mM) than with the Q adsorber. Such membrane adsorbers have been used as validated endotoxin clearance steps in downstream processing of mAb or recombinant protein manufacturing. Typical LRVs reported are in the 3–4 range based on lab scale testing.

3. VALIDATION

See *Depyrogenation* (1228) for a comprehensive discussion of depyrogenation process validation and the use of endotoxin standards.

BRIEFING

{1228.5} **Endotoxin Indicators for Depyrogenation.** The General Chapters—Microbiology Expert Committee proposes this new general chapter as an addition to the *Depyrogenation* {1228} family of chapters. The effectiveness of the depyrogenation process can be measured biologically by conducting a challenge study using a known quantity of endotoxin that is attached to, or contained in a carrier, in a manner that is representative of the articles intended to be depyrogenated. In this chapter the biological tool used to challenge the depyrogenating capabilities of a process will be defined as an endotoxin indicator. The following topics will be discussed in this chapter: endotoxin and lipopolysaccharide, applications of endotoxin indicators, preparation and use of endotoxin indicators, and analysis of test results.

1. INTRODUCTION

Depyrogenation is defined as destruction or removal of pyrogens (see *Depyrogenation* (1228)). For the purposes of this chapter, the terms "bacterial endotoxin or endotoxin" refer to a component of the outer cell membrane of Gram-negative bacteria, which is known to induce a febrile response in humans and other mammals. The endotoxin complex contains many cell wall components including, but not limited to, phospholipids, lipoproteins, and lipopolysaccharides. Lipopolysaccharide (LPS) is the biologically active portion of both naturally occurring and laboratory-prepared endotoxin complexes. The USP Endotoxin Reference Standard (which, by convention, is abbreviated as RSE) and Control Standard Endotoxin (CSE) preparations purchased from lysate manufacturers and other third-party vendors are not endotoxins but rather are preparations of purified LPS.

"Endotoxin indicators" (EIs) are tools that are used (where required) in conjunction with physical measurements to analyze the effectiveness of a depyrogenation process. EIs used to determine the effectiveness of dry heat depyrogenation processes are commonly purchased as glass vials that are inoculated with a known level of LPS activity. This chapter expands the definition of EI to include any carrier, including glass vials, inoculated with endotoxin or LPS that is used to challenge a depyrogenation process. EIs can be used to analyze the effectiveness of endotoxin removal by washing, rinsing, cleaning, or by using separation technologies, such as filtration or chromatography. Carriers can be a variety of materials, including rubber stoppers to assess stopper washing processes, bulk product to assess and validate processing steps, and stainless steel coupons to assess the cleaning of production vessels.

Purified LPS, such as CSE obtained from lysate manufacturers or other third-party vendors, has historically been a convenient choice for use as the analyte used in the preparation of EIs. However, EIs prepared in-house using laboratory-derived endotoxin more closely mimic product contamination, and as a result can provide a more realistic assessment of the depyrogenating capability of various production processes than does highly purified LPS. This chapter provides information on the preparation and use of these more specialized indicators to assure both consistency and comparability of data among method development and validation studies.

2. ENDOTOXIN AND LPS

A bacterial endotoxin is defined in the *Introduction*. LPS is the biologically active portion of the naturally occurring and laboratory-prepared endotoxin complex. Highly purified LPS, extracted from the natural endotoxin complex, is used to prepare the primary compendial endotoxin Reference Standard (RSE) or secondary Control Standard Endotoxin (CSE) preparations, such as those purchased from *Limulus* amoebocyte lysate (LAL) reagent manufacturers. LPS consists of three distinct regions:

1. The structure of the hydrophobic lipid A portion of the molecule is the most highly conserved among Gram-negative species and is responsible for most, if not all, of the biological activity of endotoxins.
2. A core oligosaccharide links the lipid A to the hydrophilic O-specific side chain or O-antigen.
3. The hydrophilic O-antigen is a highly variable region that confers serological specificity to the organism and is often used to distinguish strains of Gram-negative bacteria.

When drug products and devices are contaminated with endotoxin, the contaminant is not purified LPS but rather whole Gram-negative cells and/or cell wall fragments containing LPS. LPS and endotoxin are therefore dissimilar in many respects.

The amphipathic nature of the LPS molecule [i.e., having both a polar (hydrophilic) end and a nonpolar (hydrophobic) end] enables it to form complicated, three-dimensional, aggregated structures in solution. The aggregated forms of LPS have the capacity to adsorb, or "stick", to surfaces, and depending on the LPS formulation and the surface, extraction and detection may prove difficult using conventional extraction methods (see below). The degree of aggregation of the purified molecule is also affected by the conditions to which the LPS is exposed. Factors such as temperature, pH, salt concentration, divalent cation concentration, chelating agents, and detergents can have a profound effect on the biological activity and stability of LPS in solution. Purified LPS preparations used for depyrogenation studies should not contain any "fillers" or excipients. The excipients that are commonly used in the formulation of CSE have been shown to reduce the heat resistance of LPS (1) and may interfere in the recovery of LPS because of a caramelized excipient that has been post-processed by dry heat.

Endotoxins contaminating parenteral products may exhibit greater stability of activity in solution and less surface adsorption than purified LPS. As well, the detection of endotoxin may be less influenced than LPS by aggregation, disaggregation, or other conformations induced by some product matrices. Information on principles to consider when preparing endotoxin in the laboratory can be found below.

3. APPLICATION OF ENDOTOXIN INDICATORS

The choice of an EI should be relevant to the process being validated. For physical depyrogenation, such as dry heat, the carrier material for the EI may be a surface such as a glass vial or appropriate coupon material onto which a known quantity of LPS or of endotoxin has been inoculated. For stopper washing/depyrogenation studies, stopper carriers are inoculated with known levels of LPS or endotoxin. For raw materials or process intermediates that are inherently contaminated with assayable levels of endotoxin activity, there may not be a need to add LPS or endotoxin to validate endotoxin reduction in the manufacturing process, as the level of contamination may be sufficient to accurately measure activity upstream and downstream of the depyrogenating step(s).

For processes using raw materials or for upstream intermediates that are not contaminated with endotoxins, the use of either the USP RSE or CSE, which are both highly purified preparations, may not reflect the actual removal or reduction potential of the product stream depyrogenation step(s) under challenge. For these purposes, endotoxins harvested from Gram-negative cultures may be more suitable for depyrogenation processes typically found in

biopharmaceutical product streams. The cell wall fragments and outer membrane constituents associated with these endotoxins represent realistic challenges to process operations such as ultrafiltration, affinity chromatography, and the use of charged media membranes or columns. Challenge studies for LPS or endotoxin removal in process streams should be conducted at the laboratory or pilot scale so as not to introduce high levels of endotoxin or LPS into the actual production environment.

4. PREPARATION AND USE OF ENDOTOXIN INDICATORS

4.1 Methodology to Create a Laboratory-Prepared Endotoxin: Principles to Consider

Glass vial EIs purchased from third-party vendors do not need further preparation before use. These indicators are labeled with a nominal value of inoculated LPS, and the label claim should be confirmed upon receipt to assure that there is sufficient activity (endotoxin unit, or EU) available for the study.

- There is not one “best” or “standard” method for preparing endotoxin in the laboratory, but one example of a published method for the preparation of laboratory-prepared endotoxin may be found in Bowers and Tran (2). Regardless of the methodology for preparation, the following recommendations should be considered to properly and consistently produce, identify, and maintain laboratory-prepared endotoxin for use as a tool for depyrogenation studies. An appropriate Gram-negative bacterial strain from a recognized culture collection is a good choice for preparing a laboratory-derived endotoxin. Alternatively, a Gram-negative organism isolated from a facility, water system, raw material, or product that is identified to the species level, that has been shown to be genetically stable and that is properly maintained, may also be considered. Establishing the identity and baseline genetic fingerprint of an environmental organism will assure that subsequent preparations are consistent.
- The laboratory should create detailed procedures or laboratory work instructions for culture maintenance and endotoxin preparation to assure consistency between batches of endotoxin. For example, endotoxin may be isolated from a live culture or a culture that has been subjected to autoclaving by filtration through a filter of 0.22- μm pore size into a sterile container. Whatever the methodology for growth and endotoxin isolation that is developed by the laboratory, the methodology should be documented and used consistently.
- Consistent with good microbiological practice, the culture and maintenance of the cells used to produce a laboratory-prepared endotoxin should be consistent with *Microbiological Best Laboratory Practices* (1117). Instructions on: 1) the proper maintenance of the organism; 2) growth conditions, including any requirements to prepare media, nutrient requirements, and time/temperature of incubation; 3) methods for cryopreservation or lyophilization for master cell banks and working cell banks; 4) storage of the endotoxin, once prepared including concentration, vessel type, and volume; and 5) master batch production records to assure consistency in subsequent studies should be written, managed via change control, and followed.
 - Once isolated, the relative activity of the endotoxin preparation should be established by comparing its activity to a known LPS standard such as RSE, or a

CSE that has been standardized against the RSE. Determination of activity involves diluting the endotoxin preparation and assaying the dilutions against an LPS standard curve such that the result of the dilution falls within the range of the referenced standard curve. As with the CSE standard used in the bacterial endotoxins test (BET) assay from *Bacterial Endotoxins Test* (85), the activity of the endotoxin may vary, depending on the lot of lysate and lot of LPS used for the analysis. It is recommended, consistent with the assignment of potency for the CSE, that activity of an endotoxin preparation be evaluated for each lysate manufacturer, lysate lot, and test method (gel, kinetic turbidimetric, or kinetic chromogenic) in use in the laboratory.

The activity of the stock endotoxin preparation in EU/mL is reported as:

$$(\text{Test result in EU/mL}) \times (\text{dilution factor}) = \text{EU/mL of the starting endotoxin preparation}$$

- Once activity has been determined, and if applicable to the study design, a standard series of dilutions of the newly prepared endotoxin should demonstrate onset times that result in slope and y-intercept values that are consistent with the standard curve parameters of the RSE/CSE standard using the same lot of lysate. This demonstrates that the activity of endotoxin preparation dilutes and reacts with the lysate in a manner that is similar to LPS.
- Characterization of the endotoxin preparation should also include data on the stability of the preparation, because stability is critical to the comparison of data from one study to the next. If the endotoxin preparation is stored, storage parameters including the concentration of the preparation in EU/mL, the composition of the vessel, the temperature of storage, and the length of storage, should be defined. An expiration date should be assigned based on determined stability.

4.2 Inoculation of EIs

To prepare an EI in house, inoculate endotoxin or LPS onto an article (carrier) that will serve as the substrate for the EI. Carriers for EIs can be anything that is subject to depyrogenation such as: vials (for dry heat depyrogenation), stoppers (for stopper washing), stainless steel coupons (for vessel cleaning), or product (for depyrogenation of process streams).

The simplest way to inoculate these indicators is to add a small volume of a highly concentrated solution of endotoxin or LPS to the carrier. The volume and concentration of added endotoxin or LPS should be calculated to add at least 1000 EU to the carrier, although higher or lower concentrations may be justified. For nonliquid carriers, the endotoxin is "fixed" or dried onto the carrier substrate. This fixing step is most easily accomplished by drying in a unidirectional air flow cabinet or hood, although other drying methods including vacuum drying, lyophilization, and other fixation methods could be used. In depyrogenation challenge studies, once a fixing method is chosen, it should not change in subsequent studies to assure comparability of results. Before using the EIs, a recovery procedure, consisting of a reconstitution or extraction method, should be developed and verified for consistency (3). For liquid carriers such as bulk product, the level of inoculation in EU/mL should be justified based on "worst case" challenge for the depyrogenation step under study, meaning that the

highest concentration of endotoxin that could be in the upstream product, based on process knowledge and historical endotoxin values, should be used. Such justification should take all contributing factors into account, including but not limited to: Gram-negative bioburden in raw materials and bulk; endotoxin content in raw materials including water, contributions by product contact surfaces; and the effect of hold times, particularly for nonsterile bulk.

4.3 Recovery of Endotoxin from EIs

To use EIs, it is necessary to recover and quantify the activity of the endotoxin or LPS from both unprocessed indicators (controls) and from processed indicators (i.e., those that have been through the depyrogenation process). LPS tends to adsorb to surfaces and may aggregate or disaggregate in some product matrices; therefore, recovery of activity from EIs made with LPS is often not 100% of the nominal or measured spike value. This section addresses the methodology for recovery and possible strategies for addressing recoveries that may be observed in challenge testing.

In the case of commercially available EIs prepared with LPS, the manufacturer's directions for extraction and recovery should be followed. With such products, there should be little difficulty in achieving recovery within a factor of 2 of the labelled LPS concentration. If recoveries within the specified range cannot be achieved, the manufacturer should be contacted for technical assistance.

For EIs made in-house using LPS, the composition of carriers, such as plastics, can affect recovery or result in inconsistent recovery because of adsorption. For these carriers, there is no prelabelled concentration to verify. In this case, the expected recovery should be based on the measure of the activity of endotoxin or LPS added to the article and the volume of extraction fluid used to recover it. The actual (measured) activity in the extract should then be compared to the measured activity of the endotoxin or LPS added to determine the percentage of recovery.

For example, consider a stock endotoxin or LPS preparation containing a measured activity of 100,000 EU/mL that is used to prepare in-house EIs. If a volume of 50 μ L of this preparation is dried on the surface of each of a number of 10-mL vials, the known amount of activity added is 5000 EU. If the recovery/extraction is performed in 5 mL of water for BET, and the recovery is 100%, the expected activity in the extract solution is 1000 EU/mL.

$$\frac{5,000 \text{ EU/vial}}{5 \text{ mL extraction solution/vial}} = 1000 \text{ EU/mL}$$

If, however, the measured activity after extraction is 200 EU/mL as opposed to the expected 1000 EU/mL, the efficiency of the extraction method is 20%.

Recovery of endotoxin or LPS from nonliquid EIs prepared in-house can follow recommendations for the extraction of medical devices in preparation for LAL testing. USP general chapter *Medical Devices—Bacterial Endotoxin and Pyrogen Tests* (161) states, "The standard extraction method is to soak or immerse the device or flush the fluid pathway with extracting fluid that has been heated to $37 \pm 1.0^\circ$, keeping the extracting fluid in contact with the relevant surface(s) for NLT 1 h." The volume used for reconstitution or extraction should be appropriate for the material, size, and shape of the EI, recognizing that a volume too low may not efficiently recover the endotoxin or LPS and that excessive volumes will unnecessarily dilute the endotoxin or LPS that has been extracted.

If the recovery of added endotoxin or LPS is variable, an alternate extraction method may be developed and validated. This may include agitation or mixing, sonication or alternative extraction solutions. A combination of extraction in 0.01% sodium laurel sulfate, sonication, and vortex mixing is one such approach that has been reported to be more effective than extraction in water for medical devices (4–6). Other extraction methods are summarized by Bryans et al. (7) and in ANSI/AAMI standard ST72:2011 (8).

Another situation concerns liquid endotoxin or LPS preparations that are used either to validate a depyrogenation process in a process stream or to investigate the destruction or removal of endotoxin or LPS in a manufacturing process. In these cases, the initial concentration of the stock liquid endotoxin or LPS solution should be measured before it is added to the system or process. If some of this preparation is added (“spiked”) to a bulk process solution that is then subject to a particular process or treatment, the activity of endotoxin or LPS in this bulk solution should be measured and recorded as the starting activity. It is important to determine whether changes in the endotoxin or LPS activity of the processed solution are due to effects of the process and not to instability of the LPS or endotoxin in the solution. The stability of the activity of the LPS or endotoxin in these preparations should be verified over a period appropriate to the proposed use of the preparation.

As with the spiking method (choice of endotoxin/LPS and “fixing” process), whichever reconstitution/extraction procedure is chosen should be verified for consistency and should be used for all subsequent studies to assure comparability of results.

4.4 Choice of Test Methodology for the Analysis of EIs

Any of the test methods described in (85) can be used for the analysis of processed and unprocessed EIs. As with the rest of the methodology, it is highly recommended that an assay (kinetic turbidimetric, kinetic chromogenic, or gel clot assay) be chosen during method development and used consistently throughout the initial study and in subsequent studies to assure that data are comparable. The use of alternate assays is permissible, provided that they are validated to assure that they are equivalent to or non-inferior to the standard compendial assays.

5. ANALYSIS OF RESULTS OF DEPYROGENATION STUDIES

To evaluate the effectiveness of a depyrogenation process, the residual activity that is recovered from processed indicators is compared to the endotoxin or LPS activity of unprocessed controls. Typically, the \log_{10} of the endotoxin or LPS activity measured for the processed EI (or solution) is subtracted from the \log_{10} of the measured endotoxin or LPS activity of unprocessed control indicator. The result of the subtraction is the log reduction that is attributable to the depyrogenation process. If there are multiple controls and/or samples of processed material (and there usually are), the most conservative approach is to subtract the highest \log_{10} concentration recovered from the processed EIs (or solution samples) from the lowest \log_{10} unprocessed control endotoxin activity. For example:

- The activities in three unprocessed EIs are 1286, 1000, and 1532 EU/mL.
- The activities in three processed EIs are 0.634, 0.512, and 0.496 EU/mL.

The log reduction is calculated as:

$$\log_{10} (1000) - \log_{10} 0.634 = 3 - (-0.198) = 3.198 \text{ log reduction}$$

Historically, a ≥ 3 -log reduction has been required by regulatory/compliance guidance. However, depending on the process and historical data, a 3-log reduction may be either excessive or inadequate. For example, for glass vials with a low or nonmeasurable endotoxin content upon receipt, the requirement to continually and repeatedly revalidate with an acceptance criterion of a 3-log reduction of the endotoxin spike of >1000 EU is excessive. Alternatively, a fermentation process with an endotoxin content of $>10^7$ EU/mL in the clarified culture supernatant will require more than a 3-log reduction to achieve safe levels of endotoxin in the drug substance or drug product. In any event, an appropriate specification for the log reduction of processed indicators should be established and justified in a preapproved protocol for the study. The total reduction, of course, may be achieved over several steps in a purification process. Thus, the necessary reduction is often achieved additively over the course of multiple purification steps.

(1229.13) **Sterilization-in-Place.** The General Chapters—Microbiology Expert Committee proposes this new general chapter as an addition to the *Sterilization of Compendial Articles* (1229) family of chapters. This chapter discusses sterilization of a system or piece of process equipment in situ (sterilization-in-place; SIP) to reduce the need for post-sterilization handling. This chapter provides information on the common elements of the SIP process, different physical methods used for performing SIP, and routine process control.

Comment deadline: November 30, 2015

Add the following:

■ **(1229.13) STERILIZATION-IN-PLACE**

INTRODUCTION

Sterilization-in-place (SIP) can be defined as the sterilization of a system or piece of process equipment in situ. The purpose of SIP is to eliminate, or greatly reduce, the need for post-sterilization handling, including that necessary to make aseptic connections. Mobile process equipment (e.g., portable tanks, storage vessels, and other equipment), once sterilized in this manner, may be relocated. The SIP process can be carried out by using any of the following physical methods: moist heat, dry heat, gas, liquid, or vapor (described below) according to the approaches described in *Sterilization of Compendial Articles* (1229), as adapted for use with the specific equipment or system.

COMMON ELEMENTS OF STERILIZATION-IN-PLACE PROCESSES

There are a number of considerations appropriate for the design and use of SIP procedures that apply to all of the sterilization methods:

- The use of an SIP method is normally associated with a “closed system.” Closed systems are almost always sterilized in situ, and the design elements of the typical closed system are consistent with many SIP process needs.
- For large systems, it may be necessary to sterilize in portions. The individual sterilization processes should overlap to ensure treatment of all internal surfaces.
- The focus of the SIP procedure is sterilization of the product contact surfaces (the interior of the system). Demonstration of process lethality relies upon physical measurements and biological indicators. This confirmation should extend to the “sterile boundary” of the system, including vessel headspace, connections to other vessels/equipment, and other parts of the system. The interior surfaces of the process equipment, irrespective of their materials of construction, should be exposed to lethal conditions sufficient to sterilize the system and confirmed as lethal with an appropriate biological challenge.

- SIP is accomplished almost exclusively using the overkill approach to sterilization. The components of the physical equipment should be chosen based upon their ability to withstand the sterilizing conditions to be used. Filters, whether membrane or high-efficiency particulate air (HEPA), in the process system are typically the most susceptible to damage during SIP, and care must be taken to preserve the integrity of the filters. Filter manufacturers can provide guidance on acceptable sterilization methods and parameters.
- The absence of specifically designed equipment in which the sterilization process is performed places the bulk of responsibility for design onto the user. SIP systems ordinarily cannot be purchased directly in the way one purchases a steam sterilizer or a dry heat oven. Instead, the system, which was designed for the operating process, may require modification to accommodate the SIP process to be used. The user must assume the role of designer for the process, equipment, and control system.
- The system design and operating procedures must provide for an efficient means of introducing and removing the sterilization agent. Establishment of a reliable process sequence is a critical part of the cycle development exercise. The sterilizing agent is normally introduced through a filter on the system that may also serve as a process, purge gas, or vent filter.
- At the conclusion of the sterilization process sequence and until ready for use, the system should be pressurized with a purge gas (sterile air or nitrogen are the most common) to prevent the introduction of contaminants to the sterilized system.
- The critical process parameters for the SIP process should be recorded as the process is executed. The important parameters may include temperature, pressure, concentration, flow rate, humidity, and time, among others.

CLOSED SYSTEMS

In pharmaceutical manufacturing operations, closed systems are used for various applications including maintenance of large quantities of materials (liquids or powders) in a sterile state; manufacture of biological and synthetic organic active ingredients (especially where microbial absence is essential); and preparation of process equipment for use in sterile drug product manufacturing and filling. The use of closed systems provides superior separation of sterile materials from the surrounding environment. Typically, closed systems are maintained under positive pressure at all times. The characteristics of a closed system that establish its designation as "closed" include the following:¹

- It maintains integrity during all operating periods and under all conditions.
- It is sterilized-in-place or sterilized while closed before use.
- It can be adapted for materials transfer in and/or out while maintaining its sterile state.
- It can be connected to other closed systems while maintaining the integrity of all systems.
- It is subject to scheduled preventive maintenance.

- It uses sterilizing-grade filters for sterilization of liquid and gas process streams.

STERILIZATION-IN-PLACE METHODS

Moist Heat

The use of saturated steam is the most prevalent method for SIP of large systems. The majority of installations use gravity displacement cycles adapted from those originally used in steam sterilizers (the size and complexity of many systems preclude the use of pre-vacuum cycles). Important considerations include the provision for air removal, condensate discharge, and steam removal post-dwell.^{2,3} This method is commonly used for bioreactors, sterile bulk production, holding tank and delivery lines, and other large systems.

Superheated Water

Systems used for *Water for Injection* and *Purified Water* can be sterilized by using superheated water (water that is heated above its boiling point and pressurized to maintain it as a liquid) circulating through the system. This method has the ability to sterilize vessels, filters, and other wetted components at the same time.⁴

Dry Heat

Dry heat has been used for SIP of spray dryers and their associated material collection systems. The air supply for sterilization in these systems is provided through HEPA filters.

Gas

Gas-phase SIP has been used for non- and low-pressure-rated process equipment, such as freeze dryers, pre-freezers, process vessels, and other equipment.

Liquid

Liquid chemical sterilization is best suited for liquid-handling systems and can be used only for fully wetted surfaces.

Vapor

Sterilizing vapors have been used for the in situ sterilization of the same types of process equipment as those treated with sterilizing gases. The precautions associated with vapor sterilization described in *Vapor Phase Sterilization* (1229.11) are required.

ROUTINE PROCESS CONTROL

SIP processes are subject to formal controls that maintain a validated state over time. The practices outlined in (1229) include the general requirements appropriate for all sterilization systems as well as those specific to an individual sterilization method. Sterilization is accomplished by a number of related practices that are essential for continued use of the

process over an extended period of time. The essential practices to maintain validated status include calibration, physical measurements, physical integrators or indicators, ongoing process control, change control, preventive maintenance, periodic re-assessment, and training.

BRIEFING

{1231} **Water for Pharmaceutical Purposes**, *USP 38* page 1492. On the basis of the conclusions of the former Pharmaceutical Waters Expert Committee (from the 2005–2010 volunteer cycle) and public comments received suggesting that the chapter be revised to make it more user-friendly, the Pharmaceutical Waters Expert Panel of the General Chapters Chemical Analysis Expert Committee was tasked to revise chapter {1231} *Water for Pharmaceutical Purposes*.

The overall intent and purpose of the chapter are unchanged. The following list includes a summary of the changes:

1. Updating the chapter to improve the organization and clarity of the information and remove redundant discussion text. This includes the organization into nine specific sections listed below.
2. Removing wording redundant to referenced monograph wording.
3. Adding a detailed *Outline/Table of Contents* to improve user's topic discussion findability (topics will be hyperlinked in future electronic *USP* versions).

Significant revisions have been made or discussion added in several reorganized sections: 1. *Introduction*; 2. *Source Water Considerations*; 3. *Waters Used for Pharmaceutical Manufacturing and Testing Purposes*; 4. *Validation and Qualification of Water Purification, Storage, and Distribution Systems*; 5. *Design and Operation of Purified Water and Water for Injection Systems*; 6. *Sampling*; 8. *Microbial Considerations*; and 9. *Alert and Action Levels and Specifications*. The remaining section 7. *Chemical Evaluations* is not being revised at this time.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

{1231} WATER FOR PHARMACEUTICAL PURPOSES

Change to read:

INTRODUCTION

Water is widely used as a raw material, ingredient, and solvent in the processing, formulation, and manufacture of pharmaceutical products, active pharmaceutical ingredients (APIs) and intermediates, compendial articles, and analytical reagents. This general information chapter provides additional information about water, its quality attributes that are not included within a water monograph, processing techniques that can be used to improve water quality, and a description of minimum water quality standards that should be considered when selecting a water source.

This information chapter is not intended to replace existing regulations or guides that already exist to cover USA and international (ICH or WHO) GMP issues, engineering guides, or other regulatory (FDA, EPA, or WHO) guidances for water. The contents will help users to better understand pharmaceutical water issues and some of the microbiological and chemical concerns unique to water. This chapter is not an all-inclusive writing on pharmaceutical waters. It contains points that are basic information to be considered, when appropriate, for the processing, holding, and use of water. It is the user's responsibility to assure that pharmaceutical water and its production meet applicable governmental regulations, guidances, and the compendial specifications for the types of water used in compendial articles.

Control of the chemical purity of these waters is important and is the main purpose of the monographs in this compendium. Unlike other official articles, the bulk water monographs (*Purified Water* and *Water for Injection*) also limit how the article can be produced because of the belief that the nature and robustness of the purification process is directly related to the resulting purity. The chemical attributes listed in these monographs should be considered as a set of minimum specifications. More stringent specifications may be needed for some applications to ensure suitability for particular uses. Basic guidance on the appropriate applications of these waters is found in the monographs and is further explained in this chapter.

Control of the microbiological quality of water is important for many of its uses. Most packaged forms of water that have monograph standards are required to be sterile because some of their intended uses require this attribute for health and safety reasons. USP has determined that a microbial specification for the bulk monographed waters is inappropriate, and it has not been included within the monographs for these waters. These waters can be used in a variety of applications, some requiring extreme microbiological control and others requiring none. The needed microbial specification for a given bulk water depends upon its use. A single specification for this difficult-to-control attribute would unnecessarily burden some water users with irrelevant specifications and testing. However, some applications may require even more careful microbial control to avoid the proliferation of microorganisms ubiquitous to water during the purification, storage, and distribution of this substance. A microbial specification would also be inappropriate when related to the "utility" or continuous supply nature of this raw material. Microbial specifications are typically assessed by test methods that take at least 48–72 h to generate results. Because pharmaceutical waters are generally produced by continuous processes and used in products and manufacturing processes soon after generation, the water is likely to have been used well before definitive test results are available. Failure to meet a compendial specification would require investigating the impact and making a pass/fail decision on all product lots between the previous sampling's acceptable test result and a subsequent sampling's acceptable test result. The technical and logistical problems created by a delay in the result of such an analysis do not eliminate the user's need for microbial specifications. Therefore, such water systems need to be operated and maintained in a controlled manner that

requires that the system be validated to provide assurance of operational stability and that its microbial attributes be quantitatively monitored against established alert and action levels that would provide an early indication of system control. The issues of water system validation and alert/action levels and specifications are included in this chapter.

SOURCE OR FEED WATER CONSIDERATIONS

To ensure adherence to certain minimal chemical and microbiological quality standards, water used in the production of drug substances or as source or feed water for the preparation of the various types of purified waters must meet the requirements of the National Primary Drinking Water Regulations (NPDWR) (40 CFR 141) issued by the U.S. Environmental Protection Agency (EPA) or the drinking water regulations of the European Union or Japan, or the WHO drinking water guidelines. Limits on the types and quantities of certain organic and inorganic contaminants ensure that the water will contain only small, safe quantities of potentially objectionable chemical species. Therefore, water pretreatment systems will only be challenged to remove small quantities of these potentially difficult to remove chemicals. Also, control of objectionable chemical contaminants at the source water stage eliminates the need to specifically test for some of them (e.g., trihalomethanes and heavy metals) after the water has been further purified.

Microbiological requirements of drinking water ensure the absence of coliforms, which, if determined to be of fecal origin, may indicate the potential presence of other potentially pathogenic microorganisms and viruses of fecal origin. Meeting these microbiological requirements does not rule out the presence of other microorganisms, which could be considered undesirable if found in a drug substance or formulated product.

To accomplish microbial control, municipal water authorities add disinfectants to drinking water. Chlorine-containing and other oxidizing substances have been used for many decades for this purpose and have generally been considered to be relatively innocuous to humans. However, these oxidants can interact with naturally occurring organic matter to produce disinfection by-products (DBPs), such as trihalomethanes (THMs, including chloroform, bromodichloromethane, and dibromochloromethane) and haloacetic acids (HAAs, including dichloroacetic acid and trichloroacetic acid). The levels of DBPs produced vary with the level and type of disinfectant used and the levels and types of organic materials found in the water, which can vary seasonally.

Because high levels of DBPs are considered a health hazard in drinking water, drinking water regulations mandate their control to generally accepted nonhazardous levels. However, depending on the unit operations used for further water purification, a small fraction of the DBPs in the starting water may carry over to the finished water. Therefore, the importance of having minimal levels of DBPs in the starting water, while achieving effective disinfection, is important.

DBP levels in drinking water can be minimized by using disinfectants such as ozone, chloramines, or chlorine dioxide. Like chlorine, their oxidative properties are sufficient to damage some pretreatment unit operations and must be removed early in the pretreatment process. The complete removal of some of these disinfectants can be problematic. For example, chloramines may degrade during the disinfection process or during pretreatment removal, thereby releasing ammonia, which in turn can carry over to the finished water. Pretreatment

~~unit operations must be designed and operated to adequately remove the disinfectant, drinking water DBPs, and objectionable disinfectant degradants. A serious problem can occur if unit operations designed to remove chlorine were, without warning, challenged with chloramine-containing drinking water from a municipality that had been mandated to cease use of chlorine disinfection to comply with ever-tightening EPA Drinking Water THM specifications. The dechlorination process might incompletely remove the chloramine, which could irreparably damage downstream unit operations, but also the release of ammonia during this process might carry through pretreatment and prevent the finished water from passing compendial conductivity specifications. The purification process must be reassessed if the drinking water disinfectant is changed, emphasizing the need for a good working relationship between the pharmaceutical water manufacturer and the drinking water provider.~~

TYPES OF WATER

~~There are many different grades of water used for pharmaceutical purposes. Several are described in *USP* monographs that specify uses, acceptable methods of preparation, and quality attributes. These waters can be divided into two general types: bulk waters, which are typically produced on-site where they are used; and sterile waters, which are produced, packaged, and sterilized to preserve microbial quality throughout their packaged shelf life. There are several specialized types of sterile waters, differing in their designated applications, packaging limitations, and other quality attributes.~~

~~There are also other types of water for which there are no monographs. These are all bulk waters, with names given for descriptive purposes only. Many of these waters are used in specific analytical methods. The associated text may not specify or imply certain quality attributes or modes of preparation. These nonmonographed waters may not necessarily adhere strictly to the stated or implied modes of preparation or attributes. Waters produced by other means or controlled by other test attributes may equally satisfy the intended uses for these waters. It is the user's responsibility to ensure that such waters, even if produced and controlled exactly as stated, be suitable for their intended use. Wherever the term "water" is used within these compendia without other descriptive adjectives or clauses, the intent is that water of no less purity than *Purified Water* be used.~~

~~What follows is a brief description of the various types of pharmaceutical waters and their significant uses or attributes. *Figure 1* may also be helpful in understanding some of the various types of waters.~~

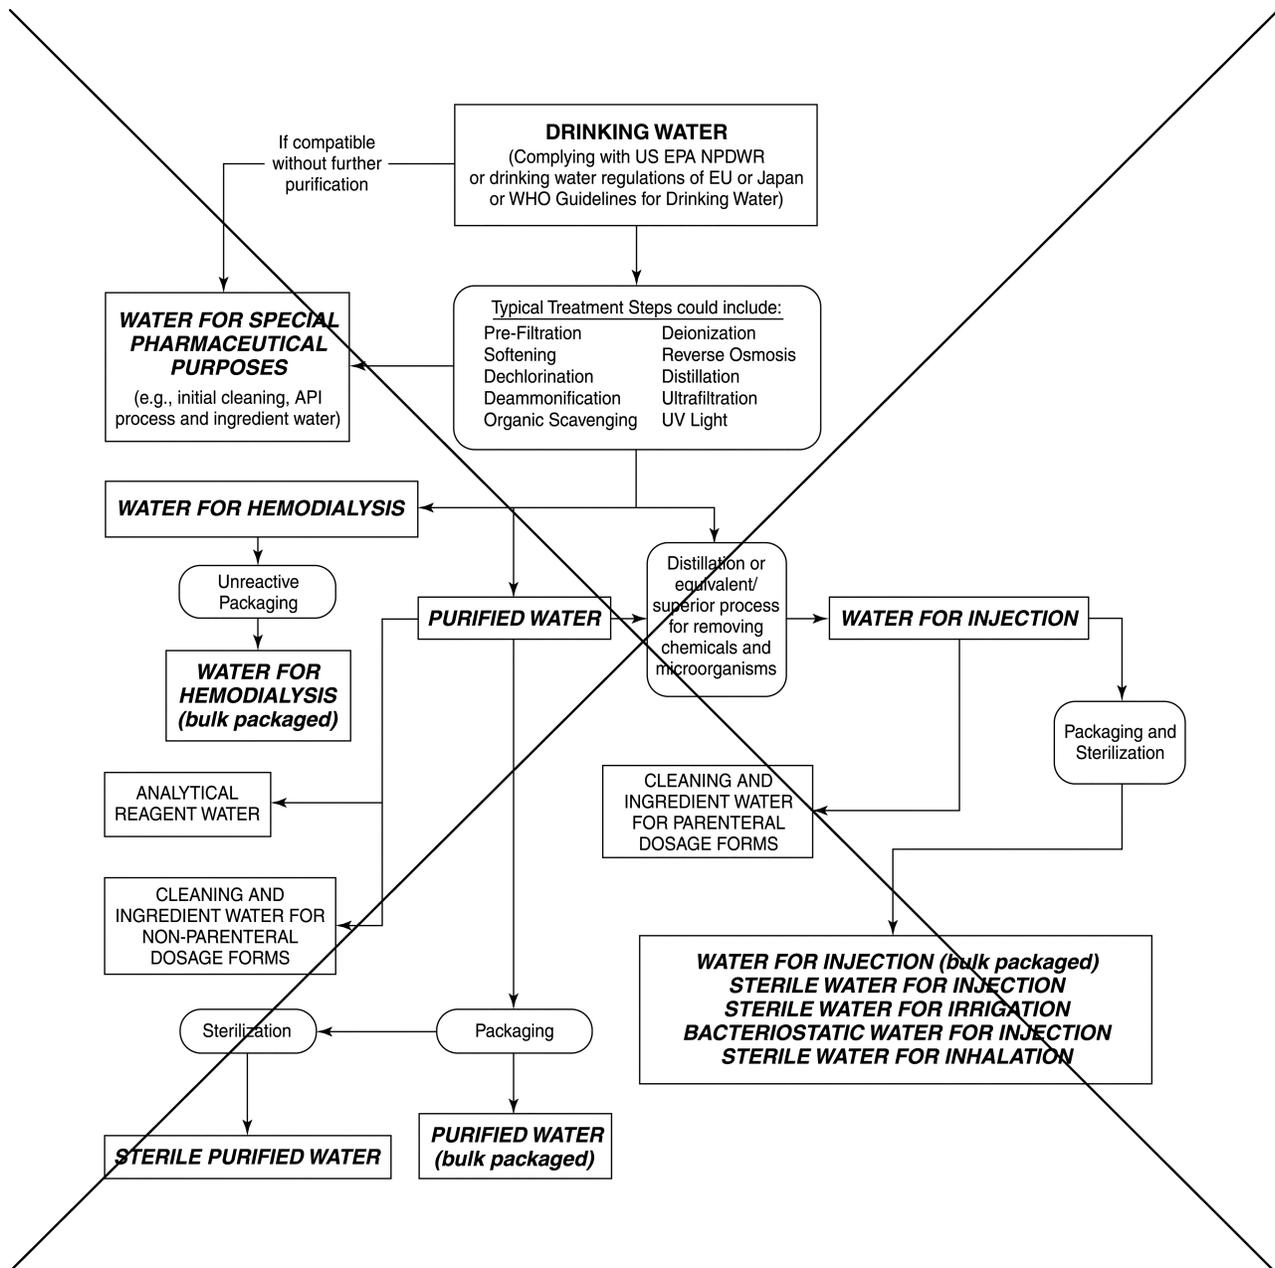

Figure 1. Water for pharmaceutical purposes.

Bulk Monographed Waters and Steam

The following waters are typically produced in large volume by a multiple-unit operation water system and distributed by a piping system for use at the same site. These particular pharmaceutical waters must meet the quality attributes as specified in the related monographs.

Purified Water—*Purified Water* (see the *USP* monograph) is used as an excipient in the production of nonparenteral preparations and in other pharmaceutical applications, such as cleaning of certain equipment and nonparenteral product contact components. Unless otherwise specified, *Purified Water* is also to be used for all tests and assays for which water is indicated (see *General Notices and Requirements*). *Purified Water* is also referenced throughout the *USP-NF*. Regardless of the font and letter case used in its spelling, water complying with the *Purified Water* monograph is intended. *Purified Water* must meet the requirements for ionic and organic chemical purity and must be protected from microbial contamination. The minimal

quality of source or feed water for the production of *Purified Water is Drinking Water*. This source water may be purified using unit operations that include deionization, distillation, ion exchange, reverse osmosis, filtration, or other suitable purification procedures. Purified water systems must be validated to reliably and consistently produce and distribute water of acceptable chemical and microbiological quality. Purified water systems that function under ambient conditions are particularly susceptible to the establishment of tenacious biofilms of microorganisms, which can be the source of undesirable levels of viable microorganisms or endotoxins in the effluent water. These systems require frequent sanitization and microbiological monitoring to ensure water of appropriate microbiological quality at the points of use.

The *Purified Water* monograph also allows bulk packaging for commercial use elsewhere. In contrast to *Sterile Purified Water*, bulk packaged *Purified Water* is not required to be sterile. Because there is potential for microbial contamination and other quality changes in this bulk packaged nonsterile water, this form of *Purified Water* should be prepared and stored in a fashion that limits microbial growth and/or is simply used in a timely fashion before microbial proliferation renders it unsuitable for its intended use. Also depending on the material used for packaging, there could be extractable compounds leaching into the water from the packaging. Although this article is required to meet the same chemical purity limits as the bulk water, packaging extractables will render the packaged water less pure than the bulk water. The nature of these impurities may even render the water an inappropriate choice for some applications. It is the user's responsibility to ensure fitness for use of this packaged article when used in manufacturing, clinical, or analytical applications where the pure bulk form of the water is indicated.

Water for Injection—*Water for Injection* (see the *USP* monograph) is used as an excipient in the production of parenteral and other preparations where product endotoxin content must be controlled, and in other pharmaceutical applications, such as cleaning of certain equipment and parenteral product contact components. The minimum quality of source or feed water for the generation of *Water for Injection* is *Drinking Water* as defined by the U.S. Environmental Protection Agency (EPA), EU, Japan, or WHO. This source water may be pretreated to render it suitable for subsequent distillation (or whatever other validated process is used according to the monograph). The finished water must meet all of the chemical requirements for *Purified Water* as well as an additional bacterial endotoxin specification. Because endotoxins are produced by the kinds of microorganisms that are prone to inhabit water, the equipment and procedures used by the system to purify, store, and distribute *Water for Injection* must be designed to minimize or prevent microbial contamination as well as remove incoming endotoxins from the starting water. *Water for Injection* systems must be validated to reliably and consistently produce and distribute this quality of water.

The *Water for Injection* monograph also allows bulk packaging for commercial use. In contrast to *Sterile Water for Injection*, bulk packaged *Water for Injection* is not required to be sterile. However, to preclude significant changes in its microbial and endotoxins content during storage, this form of *Water for Injection* should be prepared and stored in a fashion that limits microbial growth and/or is simply used in a timely fashion before microbial proliferation renders it unsuitable for its intended use. Also depending on the material used for packaging, there could be extractable compounds leaching into the water from the packaging. Although this article is required to meet the same chemical purity limits as the bulk water, packaging extractables will render the packaged water less pure than the bulk water. The nature of these impurities may

even render the water an inappropriate choice for some applications. It is the user's responsibility to ensure fitness for use of this packaged article when used in manufacturing, clinical, or analytical applications where the purer bulk form of the water is indicated.

Water for Hemodialysis—*Water for Hemodialysis* (see the *USP* monograph) is used for hemodialysis applications, primarily the dilution of hemodialysis concentrate solutions. It is produced and used on site and is made from EPA Drinking Water that has been further purified to reduce chemical and microbiological components. It may be packaged and stored in unreactive containers that preclude bacterial entry. The term "unreactive containers" implies that the container, especially its water contact surfaces, is not changed in any way by the water, such as by leaching of container-related compounds into the water or by any chemical reaction or corrosion caused by the water. The water contains no added antimicrobials and is not intended for injection. Its attributes include specifications for water conductivity, total organic carbon (or oxidizable substances), microbial limits, and bacterial endotoxins. The water conductivity and total organic carbon attributes are identical to those established for *Purified Water* and *Water for Injection*; however, instead of total organic carbon (TOC), the organic content may alternatively be measured by the test for *Oxidizable Substances*. The microbial limits attribute for this water is unique among the "bulk" water monographs, but is justified on the basis of this water's specific application that has microbial content requirements related to its safe use. The bacterial endotoxins attribute is likewise established at a level related to its safe use.

Pure Steam—*Pure Steam* (see the *USP* monograph) is also sometimes referred to as "clean steam". It is used where the steam or its condensate would directly contact official articles or article contact surfaces, such as during their preparation, sterilization, or cleaning where no subsequent processing step is used to remove any codeposited impurity residues. These *Pure Steam* applications include but are not limited to porous load sterilization processes, product or cleaning solutions heated by direct steam injection, or humidification of processes where steam injection is used to control the humidity inside processing vessels where the official articles or their in-process forms are exposed. The primary intent of using this quality of steam is to ensure that official articles or article contact surfaces exposed to it are not contaminated by residues within the steam.

Pure Steam is prepared from suitably pretreated source water analogously to either the pretreatment used for *Purified Water* or *Water for Injection*. The water is vaporized with suitable mist elimination, and distributed under pressure. The sources of undesirable contaminants within *Pure Steam* could arise from entrained source water droplets, anticorrosion steam additives, or residues from the steam production and distribution system itself. The attributes in the *Pure Steam* monograph should detect most of the contaminants that could arise from these sources. If the official article exposed to potential *Pure Steam* residues is intended for parenteral use or other applications where the pyrogenic content must be controlled, the *Pure Steam* must additionally meet the specification for the *Bacterial Endotoxins Test* (85):

These purity attributes are measured on the condensate of the article, rather than the article itself. This, of course, imparts great importance to the cleanliness of the *Pure Steam* condensate generation and collection process because it must not adversely impact the quality of the resulting condensed fluid.

Other steam attributes not detailed in the monograph, in particular, the presence of even small

quantities of noncondensable gases or the existence of a superheated or dry state, may also be important for applications such as sterilization. The large release of energy (latent heat of condensation) as water changes from the gaseous to the liquid state is the key to steam's sterilization efficacy and its efficiency, in general, as a heat transfer agent. If this phase change (condensation) is not allowed to happen because the steam is extremely hot and in a persistent superheated, dry state, then its usefulness could be seriously compromised. Noncondensable gases in steam tend to stratify or collect in certain areas of a steam sterilization chamber or its load. These surfaces would thereby be at least partially insulated from the steam condensation phenomenon, preventing them from experiencing the full energy of the sterilizing conditions. Therefore, control of these kinds of steam attributes, in addition to its chemical purity, may also be important for certain *Pure Steam* applications. However, because these additional attributes are use-specific, they are not mentioned in the *Pure Steam* monograph.

Note that less pure "plant steam" may be used for steam sterilization of nonproduct contact nonporous loads, for general cleaning of nonproduct contact equipment, as a nonproduct contact heat exchange medium, and in all compatible applications involved in bulk pharmaceutical chemical and API manufacture.

Finally, owing to the lethal properties of *Pure Steam*, monitoring of microbial control within a steam system is unnecessary. Therefore, microbial analysis of the steam condensate is unnecessary.

Sterile Monographed Waters

The following monographed waters are packaged forms of either *Purified Water* or *Water for Injection* that have been sterilized to preserve their microbiological properties. These waters may have specific intended uses as indicated by their names and may also have restrictions on packaging configurations related to those uses. In general, these sterile packaged waters may be used in a variety of applications in lieu of the bulk forms of water from which they were derived. However, there is a marked contrast between the quality tests and purities for these bulk versus sterile packaged waters. These quality tests and specifications for sterile packaged waters have diverged from those of bulk waters to accommodate a wide variety of packaging types, properties, volumes, and uses. As a result, the inorganic and organic impurity specifications and levels of the bulk and sterile packaged forms of water are not equivalent as their name similarities imply. The packaging materials and elastomeric closures are the primary sources of these impurities, which tend to increase over these packaged articles' shelf lives. Therefore, due consideration must be given to the chemical purity suitability at the time of use of the sterile packaged forms of water when used in manufacturing, analytical, and cleaning applications in lieu of the bulk waters from which these waters were derived. It is the user's responsibility to ensure fitness for use of these sterile packaged waters in these applications. Nevertheless, for the applications discussed below for each sterile packaged water, their respective purities and packaging restrictions generally render them suitable by definition.

Sterile Purified Water—*Sterile Purified Water* (see the *USP* monograph) is *Purified Water*, packaged and rendered sterile. It is used in the preparation of nonparenteral compendial dosage forms or in analytical applications requiring *Purified Water* where access to a validated *Purified Water* system is not practical, where only a relatively small quantity is needed, where *Sterile Purified Water* is required, or where bulk packaged *Purified Water* is not suitably microbiologically controlled.

Sterile Water for Injection—~~*Sterile Water for Injection* (see the USP monograph) is *Water for Injection* packaged and rendered sterile. It is used for extemporaneous prescription compounding and as a sterile diluent for parenteral products. It may also be used for other applications where bulk *Water for Injection* or *Purified Water* is indicated but where access to a validated water system is either not practical or where only a relatively small quantity is needed. *Sterile Water for Injection* is packaged in single-dose containers not larger than 1 L in size.~~

Bacteriostatic Water for Injection—~~*Bacteriostatic Water for Injection* (see the USP monograph) is sterile *Water for Injection* to which has been added one or more suitable antimicrobial preservatives. It is intended to be used as a diluent in the preparation of parenteral products, most typically for multi-dose products that require repeated content withdrawals. It may be packaged in single-dose or multiple-dose containers not larger than 30 mL.~~

Sterile Water for Irrigation—~~*Sterile Water for Irrigation* (see the USP monograph) is *Water for Injection* packaged and sterilized in single-dose containers of larger than 1 L in size that allows rapid delivery of its contents. It need not meet the requirement under small-volume injections in the general test chapter *Particulate Matter in Injections* (788). It may also be used in other applications that do not have particulate matter specifications, where bulk *Water for Injection* or *Purified Water* is indicated but where access to a validated water system is not practical, or where somewhat larger quantities than are provided as *Sterile Water for Injection* are needed.~~

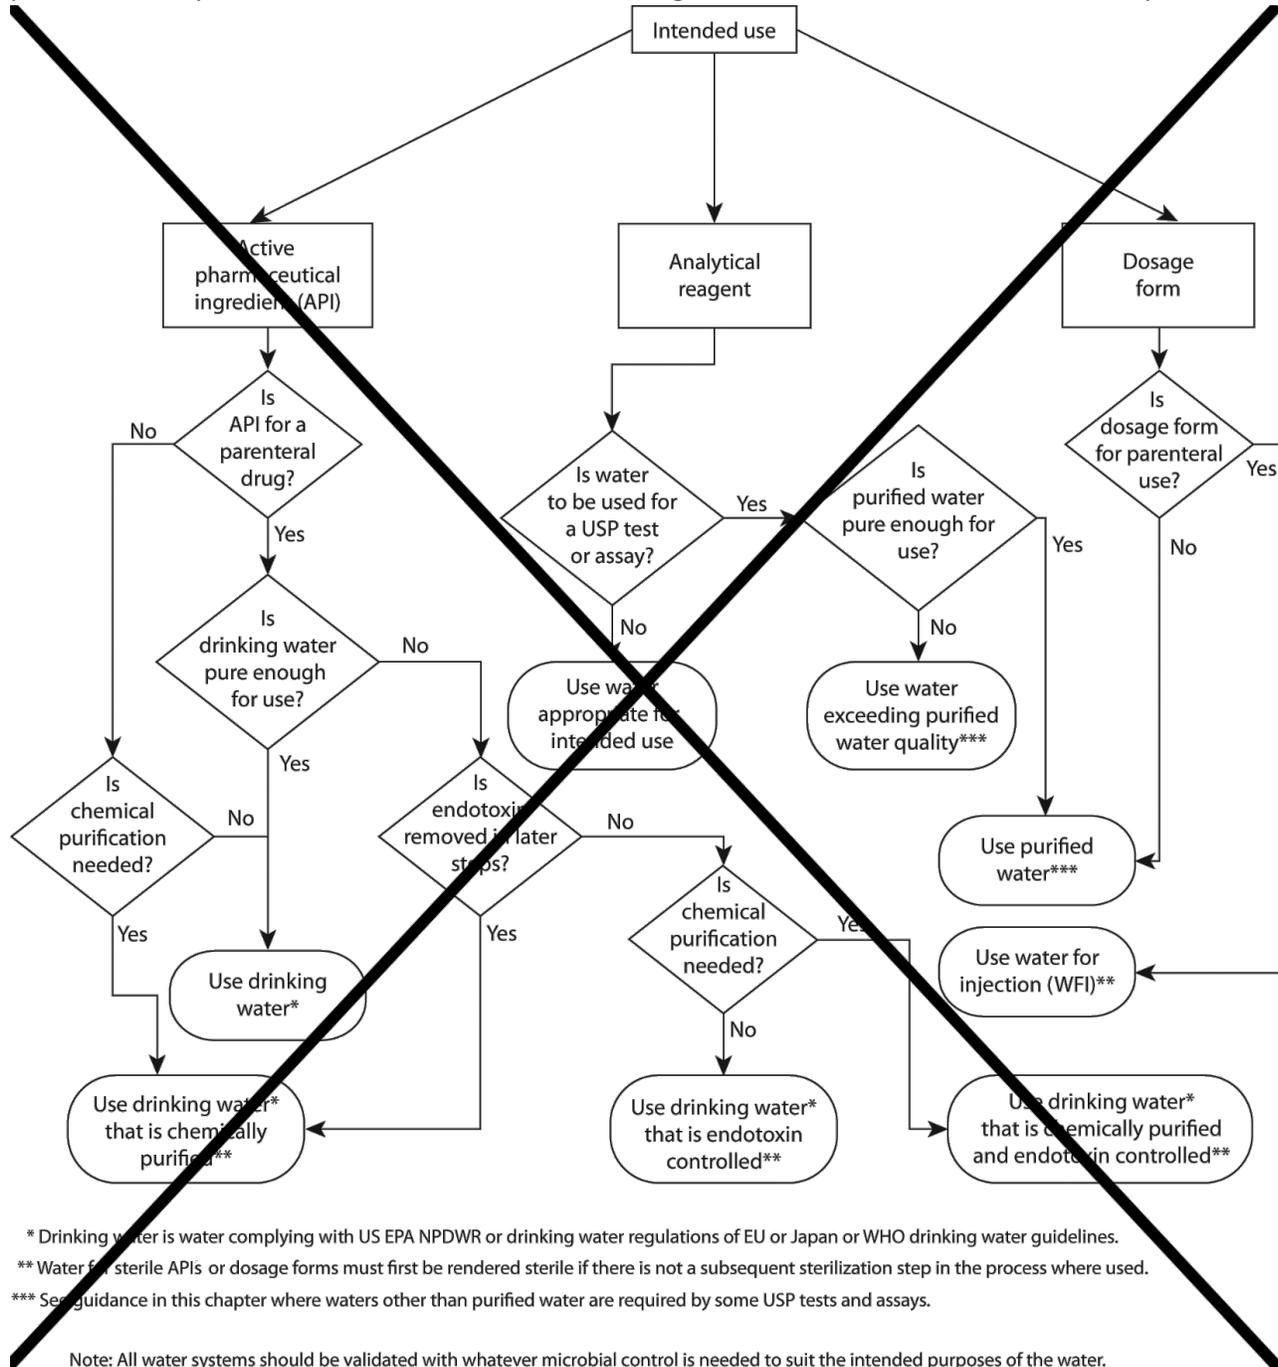

Sterile Water for Inhalation—~~*Sterile Water for Inhalation* (see the USP monograph) is *Water for Injection* that is packaged and rendered sterile and is intended for use in inhalators and in the preparation of inhalation solutions. It carries a less stringent specification for bacterial endotoxins than *Sterile Water for Injection* and therefore is not suitable for parenteral applications.~~

Nonmonographed Manufacturing Waters

In addition to the bulk monographed waters described above, nonmonographed waters can also be used in pharmaceutical processing steps such as cleaning, synthetic steps, or a starting material for further purification. The following is a description of several of these nonmonographed waters as cited in various locations within these compendia:

Drinking Water—This type of water can be referred to as Potable Water (meaning drinkable or fit to drink), National Primary Drinking Water, Primary Drinking Water, or National Drinking Water. Except where a singular drinking water specification is stated (such as the NPDWR [U.S. Environmental Protection Agency's National Primary Drinking Water Regulations as cited in 40 CFR Part 141]), this water must comply with the quality attributes of either the NPDWR, or the drinking water regulations of the European Union or Japan, or the WHO Drinking Water Guidelines. It may be derived from a variety of sources including a public water utility, a private water supply (e.g., a well), or a combination of these sources. *Drinking Water* may be used in the early stages of cleaning pharmaceutical manufacturing equipment and product-contact components. *Drinking Water* is also the minimum quality of water that should be used for the preparation of official substances and other bulk pharmaceutical ingredients. Where compatible with the processes, the allowed contaminant levels in *Drinking Water* are generally considered safe for use for official substances and other drug substances. Where required by the processing of the materials to achieve their required final purity, higher qualities of water may

be needed for these manufacturing steps, perhaps even as pure as *Water for Injection* or *Purified Water*. Such higher purity waters, however, might require only selected attributes to be of higher purity than *Drinking Water* (see Figure 2). *Drinking Water* is the prescribed source or feed water for the production of bulk monographed pharmaceutical waters. The use of *Drinking Water* specifications establishes a reasonable set of maximum allowable levels of chemical and microbiological contaminants with which a water purification system will be challenged. As seasonal variations in the quality attributes of the *Drinking Water* supply can occur, due consideration to its synthetic and cleaning uses must be given. The processing steps in the production of pharmaceutical waters must be designed to accommodate this variability.

* Drinking water is water complying with US EPA NPDWR or drinking water regulations of EU or Japan or WHO drinking water guidelines.
 ** Water for sterile APIs or dosage forms must first be rendered sterile if there is not a subsequent sterilization step in the process where used.
 *** See guidance in this chapter where waters other than purified water are required by some USP tests and assays.

Note: All water systems should be validated with whatever microbial control is needed to suit the intended purposes of the water.

Figure 2. Selection of water for pharmaceutical purposes.

Hot Purified Water—This water is used in the preparation instructions for *USP-NF* articles and

is clearly intended to be *Purified Water* that has been heated to an unspecified temperature in order to enhance solubilization of other ingredients. There is no upper temperature limit for the water (other than being less than 100°), but for each monograph there is an implied lower limit below which the desired solubilization effect would not occur.

Nonmonographed Analytical Waters

Both *General Notices and Requirements* and the introductory section to *Reagents, Indicators, and Solutions* clearly state that where the term “water”, without qualification or other specification, is indicated for use in analyses, the quality of water shall be *Purified Water*. However, numerous such qualifications do exist. Some of these qualifications involve methods of preparation, ranging from specifying the primary purification step to specifying additional purification. Other qualifications call for specific attributes to be met that might otherwise interfere with analytical processes. In most of these latter cases, the required attribute is not specifically tested. Rather, a further “purification process” is specified that ostensibly allows the water to adequately meet this required attribute.

However, preparation instructions for many reagents were carried forward from the innovator’s laboratories to the originally introduced monograph for a particular *USP-NF* article or general test chapter. The quality of the reagent water described in these tests may reflect the water quality designation of the innovator’s laboratory. These specific water designations may have originated without the innovator’s awareness of the requirement for *Purified Water* in *USP-NF* tests. Regardless of the original reason for the creation of these numerous special analytical waters, it is possible that the attributes of these special waters could now be met by the basic preparation steps and current specifications of *Purified Water*. In some cases, however, some of the cited post-processing steps are still necessary to reliably achieve the required attributes.

Users are not obligated to employ specific and perhaps archaically generated forms of analytical water where alternatives with equal or better quality, availability, or analytical performance may exist. The consistency and reliability for producing these alternative analytical waters should be verified as producing the desired attributes. In addition, any alternative analytical water must be evaluated on an application-by-application basis by the user to ensure its suitability. Following is a summary of the various types of nonmonographed analytical waters that are cited in the *USP-NF*.

Distilled Water—This water is produced by vaporizing liquid water and condensing it in a purer state. It is used primarily as a solvent for reagent preparation, but it is also specified in the execution of other aspects of tests, such as for rinsing an analyte, transferring a test material as a slurry, as a calibration standard or analytical blank, and for test apparatus cleaning. It is also cited as the starting water to be used for making *High Purity Water*. Because none of the cited uses of this water imply a need for a particular purity attribute that can only be derived by distillation, water meeting the requirements for *Purified Water* derived by other means of purification could be equally suitable where *Distilled Water* is specified.

Freshly Distilled Water—Also called “recently distilled water”, it is produced in a similar fashion to *Distilled Water* and should be used shortly after its generation. This implies the need to avoid endotoxin contamination as well as any other adventitious forms of contamination from the air or containers that could arise with prolonged storage. It is used for preparing solutions for subcutaneous test animal injections as well as for a reagent solvent in tests for which there appears to be no particularly high water purity needed that could be ascribable to being

"freshly distilled". In the test animal use, the term "freshly distilled" and its testing use imply a chemical, endotoxin, and microbiological purity that could be equally satisfied by *Water for Injection* (although no reference is made to these chemical, endotoxin, or microbial attributes or specific protection from recontamination). For nonanimal uses, water meeting the requirements for *Purified Water* derived by other means of purification and/or storage periods could be equally suitable where "recently distilled water" or *Freshly Distilled Water* is specified.

Deionized Water—This water is produced by an ion-exchange process in which the contaminating ions are replaced with either H^+ or OH^- ions. Similarly to *Distilled Water*, *Deionized Water* is used primarily as a solvent for reagent preparation, but it is also specified in the execution of other aspects of tests, such as for transferring an analyte within a test procedure, as a calibration standard or analytical blank, and for test apparatus cleaning. Also, none of the cited uses of this water imply any needed purity attribute that can only be achieved by deionization. Therefore, water meeting the requirements for *Purified Water* that is derived by other means of purification could be equally suitable where *Deionized Water* is specified.

Freshly Deionized Water—This water is prepared in a similar fashion to *Deionized Water*, although as the name suggests, it is to be used shortly after its production. This implies the need to avoid any adventitious contamination that could occur upon storage. This water is indicated for use as a reagent solvent as well as for cleaning. Due to the nature of the testing, *Purified Water* could be a reasonable alternative for these applications.

Deionized Distilled Water—This water is produced by deionizing (see *Deionized Water*) *Distilled Water*. This water is used as a reagent in a liquid chromatography test that requires a high purity. Because of the importance of this high purity, water that barely meets the requirements for *Purified Water* may not be acceptable. *High Purity Water* (see below) could be a reasonable alternative for this water.

Filtered Water—This water is *Purified Water* that has been filtered to remove particles that could interfere with the analysis where this water is specified. It is sometimes used synonymously with *Particle-Free Water* and *Ultra-Filtered Water* and is cited in some monographs and general chapters as well as in *Reagents*. Depending on its location, it is variously defined as water that has been passed through filters rated as 1.2 μm , 0.22 μm , or 0.2 μm ; or unspecified pore size. Although the water names and the filter pore sizes used to produce these waters are inconsistently defined, the use of 0.2 μm pore size filtered *Purified Water* should be universally acceptable for all applications where *Particle-Free Water*, *Filtered Water*, or *Ultra-Filtered Water* are specified.

High-Purity Water—This water may be prepared by deionizing previously distilled water, and then filtering it through a 0.45 μm rated membrane. This water must have an in-line conductivity of not greater than 0.15 $\mu S/cm$ (not less than 6.67 Megohm-cm) at 25°. If the water of this purity contacts the atmosphere even briefly as it is being used or drawn from its purification system, its conductivity will immediately increase, by as much as about 1.0 $\mu S/cm$, as atmospheric carbon dioxide dissolves in the water and equilibrates to hydrogen and bicarbonate ions. Therefore, if the analytical use requires that water conductivity remains as low as possible or the bicarbonate/carbon dioxide levels be as low as possible, its use should be protected from atmospheric exposure. This water is used as a reagent, as a solvent for reagent preparation, and for test apparatus cleaning where less pure waters would not perform acceptably. However, if a user's routinely available *Purified Water* is filtered and meets or

exceeds the conductivity specifications of *High-Purity Water*, it could be used in lieu of *High-Purity Water*.

Ammonia-Free Water—Functionally, this water must have a negligible ammonia concentration to avoid interference in tests sensitive to ammonia. It has been equated with *High-Purity Water* that has a significantly tighter *Stage 1* (see *Water Conductivity* (645)) conductivity specification than *Purified Water* because of the latter's allowance for a minimal level of ammonium among other ions. However, if the user's *Purified Water* were filtered and met or exceeded the conductivity specifications of *High-Purity Water*, it would contain negligible ammonia or other ions and could be used in lieu of *High-Purity Water*.

Carbon Dioxide-Free Water—The introductory portion of the *Reagents, Indicators, and Solutions* section defines this water as *Purified Water* that has been vigorously boiled for at least 5 minutes, then cooled and protected from absorption of atmospheric carbon dioxide. Because the absorption of carbon dioxide tends to drive down the water pH, most of the uses of *Carbon Dioxide-Free Water* are either associated as a solvent in pH-related or pH-sensitive determinations or as a solvent in carbonate-sensitive reagents or determinations. Another use of this water is for certain optical rotation and color and clarity of solution tests. Although it is possible that this water is indicated for these tests simply because of its purity, it is also possible that the pH effects of carbon dioxide-containing water could interfere with the results of these tests. A third plausible reason that this water is indicated is that outgassing air bubbles might interfere with these photometric-type tests. The boiled water preparation approach will also greatly reduce the concentrations of many other dissolved gases along with carbon dioxide. Therefore, in some of the applications for *Carbon Dioxide-Free Water*, it could be the inadvertent deaeration effect that actually renders this water suitable. In addition to boiling, deionization is perhaps an even more efficient process for removing dissolved carbon dioxide (by drawing the dissolved gas equilibrium toward the ionized state with subsequent removal by the ion-exchange resins). If the starting *Purified Water* is prepared by an efficient deionization process and protected after deionization from exposure to atmospheric air, water that is carbon dioxide free can be effectively made without the application of heat. However, this deionization process does not deaerate the water, so if *Purified Water* prepared by deionization is considered as a substitute water in a test requiring *Carbon Dioxide-Free Water*, the user must verify that it is not actually water akin to *Deaerated Water* (discussed below) that is needed for the test. As indicated in *High-Purity Water*, even brief contact with the atmosphere can allow small amounts of carbon dioxide to dissolve, ionize, and significantly degrade the conductivity and lower the pH. If the analytical use requires the water to remain as pH-neutral and as carbon dioxide free as possible, even the analysis should be protected from atmospheric exposure. However, in most applications, atmospheric exposure during testing does not significantly affect its suitability in the test.

Ammonia and Carbon Dioxide-Free Water—As implied by the name, this water should be prepared by approaches compatible with those mentioned for both *Ammonia-Free Water* and *Carbon Dioxide-Free Water*. Because the carbon dioxide-free attribute requires post-production protection from the atmosphere, it is appropriate to first render the water ammonia-free using the *High-Purity Water* process followed by the boiling and carbon dioxide-protected cooling process. The *High-Purity Water* deionization process for creating *Ammonia-Free Water* will also remove the ions generated from dissolved carbon dioxide and ultimately, by forced equilibration to the ionized state, all the dissolved carbon dioxide. Therefore, depending on its use, an acceptable procedure for making *Ammonia and Carbon Dioxide-Free Water* could be to transfer

and collect *High-Purity Water* in a carbon dioxide intrusion-protected container.

Deaerated Water—This water is *Purified Water* that has been treated to reduce the content of dissolved air by “suitable means”. In the *Reagents* section, approaches for boiling, cooling (similar to *Carbon Dioxide-Free Water* but without the atmospheric carbon dioxide protection), and sonication are given as applicable for test uses other than dissolution and drug release testing. Although *Deaerated Water* is not mentioned by name in *Dissolution* (711), suggested methods for deaerating dissolution media (which may be water) include warming to 41°, vacuum filtering through a 0.45- μm rated membrane, and vigorously stirring the filtrate while maintaining the vacuum. This chapter specifically indicates that other validated approaches may be used. In other monographs that also do not mention *Deaerated Water* by name, degassing of water and other reagents is accomplished by sparging with helium. *Deaerated Water* is used in both dissolution testing as well as liquid chromatography applications where outgassing could either interfere with the analysis itself or cause erroneous results due to inaccurate volumetric withdrawals. Applications where ambient temperature water is used for reagent preparation, but the tests are performed at elevated temperatures, are candidates for outgassing effects. If outgassing could interfere with test performance, including chromatographic flow, colorimetric or photometric measurements, or volumetric accuracy, then *Deaerated Water* should probably be used, whether called for in the analysis or not. The above deaeration approaches might not render the water “gas-free”. At best, they reduce the dissolved gas concentrations so that outgassing caused by temperature changes is not likely.

Recently Boiled Water—This water may include recently or freshly boiled water (with or without mention of cooling in the title), but cooling prior to use is clearly intended. Occasionally it is necessary to use when hot. *Recently Boiled Water* is specified because it is used in a pH-related test or carbonate-sensitive reagent, in an oxygen-sensitive test or reagent, or in a test where outgassing could interfere with the analysis, such as specific gravity or an appearance test.

Oxygen-Free Water—The preparation of this water is not specifically described in the compendia. Neither is there an oxygen specification or analysis mentioned. However, all uses involve analyses of materials that could be sensitive to oxidation by atmospheric oxygen. Procedures for the removal of dissolved oxygen from solvents, although not necessarily water, are mentioned in *Polarography* (801) and *Spectrophotometry and Light Scattering* (851). These procedures involve simple sparging of the liquid with an inert gas such as nitrogen or helium, followed by inert gas blanketing to prevent oxygen reabsorption. The sparging times cited range from 5 to 15 minutes to an unspecified period. Some *Purified Water* and *Water for Injection* systems produce water that is maintained in a hot state and that is inert gas blanketed during its preparation and storage and distribution. Although oxygen is poorly soluble in hot water, such water may not be oxygen-free. Whatever procedure is used for removing oxygen should be verified as reliably producing water that is fit for use.

Water for BET—This water is also referred to as LAL reagent water. This is often *Water for Injection*, which may have been sterilized. It is free from a level of endotoxin that would yield any detectable reaction or interference with the *Limulus Amoebocyte Lysate* reagent used in the *Bacterial Endotoxins Test* (85).

Organic-Free Water—This water is defined by *Residual Solvents* (467) as producing no significantly interfering gas chromatography peaks. Referenced monographs specify using this water as the solvent for the preparation of standard and test solutions for the *Residual*

solvents test.

Lead-Free Water—This water is used as a transferring diluent for an analyte in a *Lead* (251) test. Although no specific instructions are given for its preparation, it must not contain any detectable lead. *Purified Water* should be a suitable substitute for this water.

Chloride-Free Water—This water is specified as the solvent for use in an assay that contains a reactant that precipitates in the presence of chloride. Although no specific preparation instructions are given for this water, its rather obvious attribute is having a very low chloride level in order to be unreactive with this chloride sensitive reactant. *Purified Water* could be used for this water but should be tested to ensure that it is unreactive.

Hot Water—The uses of this water include solvents for achieving or enhancing reagent solubilization, restoring the original volume of boiled or hot solutions, rinsing insoluble analytes free of hot water soluble impurities, solvents for reagent recrystallization, apparatus cleaning, and as a solubility attribute for various *USP-NF* articles. In only one monograph is the temperature of "hot" water specified; so in all the other cases, the water temperature is less important, but should be high enough to achieve the desirable effect. In all cases, the chemical quality of the water is implied to be that of *Purified Water*.

VALIDATION AND QUALIFICATION OF WATER PURIFICATION, STORAGE, AND DISTRIBUTION SYSTEMS

Establishing the dependability of pharmaceutical water purification, storage, and distribution systems requires an appropriate period of monitoring and observation. Ordinarily, few problems are encountered in maintaining the chemical purity of *Purified Water* and *Water for Injection*. Nevertheless, the advent of using conductivity and TOC to define chemical purity has allowed the user to more quantitatively assess the water's chemical purity and its variability as a function of routine pretreatment system maintenance and regeneration. Even the presence of such unit operations as heat exchangers and use point hoses can compromise the chemical quality of water within and delivered from an otherwise well-controlled water system. Therefore, an assessment of the consistency of the water's chemical purity over time must be part of the validation program. However, even with the most well controlled chemical quality, it is often more difficult to consistently meet established microbiological quality criteria owing to phenomena occurring during and after chemical purification. A typical program involves intensive daily sampling and testing of major process points for at least one month after operational criteria have been established for each unit operation, point of use, and sampling point.

An overlooked aspect of water system validation is the delivery of the water to its actual location of use. If this transfer process from the distribution system outlets to the water use locations (usually with hoses) is defined as outside the water system, then this transfer process still needs to be validated to not adversely affect the quality of the water to the extent it becomes unfit for use. Because routine microbial monitoring is performed for the same transfer process and components (e.g., hoses and heat exchangers) as that of routine water use (see *Sampling Considerations*), there is some logic to including this water transfer process within the distribution system validation.

Validation is the process whereby substantiation to a high level of assurance that a specific process will consistently produce a product conforming to an established set of quality

attributes is acquired and documented. Prior to and during the very early stages of validation, the critical process parameters and their operating ranges are established. A validation program qualifies and documents the design, installation, operation, and performance of equipment. It begins when the system is defined and moves through several stages: installation qualification (IQ), operational qualification (OQ), and performance qualification (PQ). A graphical representation of a typical water system validation life cycle is shown in *Figure 3*.

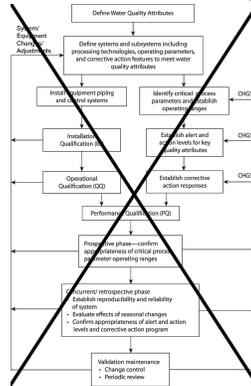

Figure 3. Water system validation life cycle.

A validation plan for a water system typically includes the following steps: (1) establishing standards for quality attributes of the finished water and the source water; (2) defining suitable unit operations and their operating parameters for achieving the desired finished water quality attributes from the available source water; (3) selecting piping, equipment, controls, and monitoring technologies; (4) developing an IQ stage consisting of instrument calibrations, inspections to verify that the drawings accurately depict the final configuration of the water system and, where necessary, special tests to verify that the installation meets the design requirements; (5) developing an OQ stage consisting of tests and inspections to verify that the equipment, system alerts, and controls are operating reliably and that appropriate alert and action levels are established (this phase of qualification may overlap with aspects of the next step); and (6) developing a prospective PQ stage to confirm the appropriateness of critical process parameter operating ranges (during this phase of validation, alert and action levels for key quality attributes and operating parameters are verified); (7) assuring the adequacy of ongoing control procedures, e.g., sanitization frequency; (8) supplementing a validation maintenance program (also called continuous validation life cycle) that includes a mechanism to control changes to the water system and establishes and carries out scheduled preventive maintenance including recalibration of instruments (in addition, validation maintenance includes a monitoring program for critical process parameters and a corrective action program); (9) instituting a schedule for periodic review of the system performance and requalification; and (10) completing protocols and documenting Steps 1 through 9.

PURIFIED WATER AND WATER FOR INJECTION SYSTEMS

The design, installation, and operation of systems to produce *Purified Water* and *Water for Injection* include similar components, control techniques, and procedures. The quality attributes of both waters differ only in the presence of a bacterial endotoxin requirement for *Water for Injection* and in their methods of preparation, at least at the last stage of preparation. The similarities in the quality attributes provide considerable common ground in the design of water systems to meet either requirement. The critical difference is the degree of control of the system and the final purification steps needed to ensure bacterial and bacterial endotoxin

removal.

Production of pharmaceutical water employs sequential unit operations (processing steps) that address specific water quality attributes and protect the operation of subsequent treatment steps. A typical evaluation process to select an appropriate water quality for a particular pharmaceutical purpose is shown in the decision tree in *Figure 2*. This diagram may be used to assist in defining requirements for specific water uses and in the selection of unit operations. The final unit operation used to produce *Water for Injection* is limited to distillation or other processes equivalent or superior to distillation in the removal of chemical impurities as well as microorganisms and their components. Distillation has a long history of reliable performance and can be validated as a unit operation for the production of *Water for Injection*, but other technologies or combinations of technologies can be validated as being equivalently effective. Other technologies, such as ultrafiltration following another chemical purification process, may be suitable in the production of *Water for Injection* if they can be shown through validation to be as effective and reliable as distillation. The advent of new materials for older technologies, such as reverse osmosis and ultrafiltration, that allow intermittent or continuous operation at elevated, microbial temperatures, show promise for a valid use in producing *Water for Injection*.

The validation plan should be designed to establish the suitability of the system and to provide a thorough understanding of the purification mechanism, range of operating conditions, required pretreatment, and the most likely modes of failure. It is also necessary to demonstrate the effectiveness of the monitoring scheme and to establish the documentation and qualification requirements for the system's validation maintenance. Trials conducted in a pilot installation can be valuable in defining the operating parameters and the expected water quality and in identifying failure modes. However, qualification of the specific unit operation can only be performed as part of the validation of the installed operational system. The selection of specific unit operations and design characteristics for a water system should take into account the quality of the feed water, the technology chosen for subsequent processing steps, the extent and complexity of the water distribution system, and the appropriate compendial requirements. For example, in the design of a system for *Water for Injection*, the final process (distillation or whatever other validated process is used according to the monograph) must have effective bacterial endotoxin reduction capability and must be validated.

UNIT OPERATIONS CONCERNS

The following is a brief description of selected unit operations and the operation and validation concerns associated with them. Not all unit operations are discussed, nor are all potential problems addressed. The purpose is to highlight issues that focus on the design, installation, operation, maintenance, and monitoring parameters that facilitate water system validation:

Prefiltration

The purpose of prefiltration—also referred to as initial, coarse, or depth filtration—is to remove solid contaminants down to a size of 7–10 μm from the incoming source water supply and protect downstream system components from particulates that can inhibit equipment performance and shorten its effective life. This coarse filtration technology utilizes primarily sieving effects for particle capture and a depth of filtration medium that has a high “dirt load” capacity. Such filtration units are available in a wide range of designs and for various applications. Removal efficiencies and capacities differ significantly, from granular bed filters such as multimedia or sand for larger water systems, to depth cartridges for smaller water

systems. Unit and system configurations vary widely in type of filtering media and location in the process. Granular or cartridge prefilters are often situated at or near the head of the water pretreatment system prior to unit operations designed to remove the source water disinfectants. This location, however, does not preclude the need for periodic microbial control because biofilm can still proliferate, although at a slower rate in the presence of source water disinfectants. Design and operational issues that may impact performance of depth filters include channeling of the filtering media, blockage from silt, microbial growth, and filtering-media loss during improper backwashing. Control measures involve pressure and flow monitoring during use and backwashing, sanitizing, and replacing filtering media. An important design concern is sizing of the filter to prevent channeling or media loss resulting from inappropriate water flow rates as well as proper sizing to minimize excessively frequent or infrequent backwashing or cartridge filter replacement.

Activated Carbon

Granular activated carbon beds adsorb low molecular weight organic material and oxidizing additives, such as chlorine and chloramine compounds, removing them from the water. They are used to achieve certain quality attributes and to protect against reaction with downstream stainless steel surfaces, resins, and membranes. The chief operating concerns regarding activated carbon beds include the propensity to support bacteria growth, the potential for hydraulic channeling, the organic adsorption capacity, appropriate water flow rates and contact time, the inability to be regenerated in situ, and the shedding of bacteria, endotoxins, organic chemicals, and fine carbon particles. Control measures may involve monitoring water flow rates and differential pressures, sanitizing with hot water or steam, backwashing, testing for adsorption capacity, and frequent replacement of the carbon bed. If the activated carbon bed is intended for organic reduction, it may also be appropriate to monitor influent and effluent TOC. It is important to note that the use of steam for carbon bed sanitization is often incompletely effective due to steam channeling rather than even permeation through the bed. This phenomenon can usually be avoided by using hot water sanitization. It is also important to note that microbial biofilm development on the surface of the granular carbon particles (as well as on other particles such as found in deionizer beds and even multimedia beds) can cause adjacent bed granules to "stick" together. When large masses of granules are agglomerated in this fashion, normal backwashing and bed fluidization flow parameters may not be sufficient to disperse them, leading to ineffective removal of trapped debris, loose biofilm, and penetration of microbial controlling conditions (as well as regenerant chemicals as in the case of agglomerated deionizer resins). Alternative technologies to activated carbon beds can be used in order to avoid their microbial problems, such as disinfectant neutralizing chemical additives and regenerable organic scavenging devices. However, these alternatives do not function by the same mechanisms as activated carbon, may not be as effective at removing disinfectants and some organics, and have a different set of operating concerns and control measures that may be nearly as troublesome as activated carbon beds.

Additives

Chemical additives are used in water systems (a) to control microorganisms by use of sanitants such as chlorine compounds and ozone, (b) to enhance the removal of suspended solids by use of flocculating agents, (c) to remove chlorine compounds, (d) to avoid scaling on reverse osmosis membranes, and (e) to adjust pH for more effective removal of carbonate and ammonia compounds by reverse osmosis. These additives do not constitute "added substances" as long as they are either removed by subsequent processing steps or are otherwise absent from the

finished water. Control of additives to ensure a continuously effective concentration and subsequent monitoring to ensure their removal should be designed into the system and included in the monitoring program.

Organic Scavengers

Organic scavenging devices use macroreticular weakly basic anion exchange resins capable of removing organic material and endotoxins from the water. They can be regenerated with appropriate biocidal caustic brine solutions. Operating concerns are associated with organic scavenging capacity; particulate, chemical and microbiological fouling of the reactive resin surface; flow rate; regeneration frequency; and shedding of resin fragments. Control measures include TOC testing of influent and effluent, backwashing, monitoring hydraulic performance, and using downstream filters to remove resin fines.

Softeners

Water softeners may be located either upstream or downstream of disinfectant removal units. They utilize sodium-based cation exchange resins to remove water hardness ions, such as calcium and magnesium, that could foul or interfere with the performance of downstream processing equipment such as reverse osmosis membranes, deionization devices, and distillation units. Water softeners can also be used to remove other lower affinity cations, such as the ammonium ion, that may be released from chloramine disinfectants commonly used in drinking water and which might otherwise carryover through other downstream unit operations. If ammonium removal is one of its purposes, the softener must be located downstream of the disinfectant removal operation, which itself may liberate ammonium from neutralized chloramine disinfectants. Water softener resin beds are regenerated with concentrated sodium chloride solution (brine). Concerns include microorganism proliferation, channeling caused by biofilm agglomeration of resin particles, appropriate water flow rates and contact time, ion exchange capacity, organic and particulate resin fouling, organic leaching from new resins, fracture of the resin beads, resin degradation by excessively chlorinated water, and contamination from the brine solution used for regeneration. Control measures involve recirculation of water during periods of low water use, periodic sanitization of the resin and brine system, use of microbial control devices (e.g., UV light and chlorine), locating the unit upstream of the disinfectant removal step (if used only for softening), appropriate regeneration frequency, effluent chemical monitoring (e.g., hardness ions and possibly ammonium), and downstream filtration to remove resin fines. If a softener is used for ammonium removal from chloramine-containing source water, then capacity, contact time, resin surface fouling, pH, and regeneration frequency are very important.

Deionization

Deionization (DI), and continuous electrodeionization (CEDI) are effective methods of improving the chemical quality attributes of water by removing cations and anions. DI systems have charged resins that require periodic regeneration with an acid and base. Typically, cationic resins are regenerated with either hydrochloric or sulfuric acid, which replace the captured positive ions with hydrogen ions. Anionic resins are regenerated with sodium or potassium hydroxide, which replace captured negative ions with hydroxide ions. Because free endotoxin is negatively charged, there is some removal of endotoxin achieved by the anionic resin. Both regenerant chemicals are biocidal and offer a measure of microbial control. The system can be designed so that the cation and anion resins are in separate or "twin" beds or they can be

mixed together to form a mixed bed. Twin beds are easily regenerated but deionize water less efficiently than mixed beds, which have a considerably more complex regeneration process. Rechargeable resin canisters can also be used for this purpose.

The CEDI system uses a combination of mixed resin, selectively permeable membranes, and an electric charge, providing continuous flow (product and waste concentrate) and continuous regeneration. Water enters both the resin section and the waste (concentrate) section. As it passes through the resin, it is deionized to become product water. The resin acts as a conductor enabling the electrical potential to drive the captured cations and anions through the resin and appropriate membranes for concentration and removal in the waste water stream. The electrical potential also separates the water in the resin (product) section into hydrogen and hydroxide ions. This permits continuous regeneration of the resin without the need for regenerant additives. However, unlike conventional deionization, CEDI units must start with water that is already partially purified because they generally cannot produce *Purified Water* quality when starting with the heavier ion load of unpurified source water.

Concerns for all forms of deionization units include microbial and endotoxin control, chemical additive impact on resins and membranes, and loss, degradation, and fouling of resin. Issues of concern specific to DI units include regeneration frequency and completeness, channeling caused by biofilm agglomeration of resin particles, organic leaching from new resins, complete resin separation for mixed bed regeneration, and mixing air contamination (mixed beds). Control measures vary but typically include recirculation loops, effluent microbial control by UV light, conductivity monitoring, resin testing, microporous filtration of mixing air, microbial monitoring, frequent regeneration to minimize and control microorganism growth, sizing the equipment for suitable water flow and contact time, and use of elevated temperatures. Internal distributor and regeneration piping for mixed bed units should be configured to ensure that regeneration chemicals contact all internal bed and piping surfaces and resins. Rechargeable canisters can be the source of contamination and should be carefully monitored. Full knowledge of previous resin use, minimum storage time between regeneration and use, and appropriate sanitizing procedures are critical factors ensuring proper performance.

Reverse Osmosis

Reverse osmosis (RO) units employ semipermeable membranes. The "pores" of RO membranes are actually intersegmental spaces among the polymer molecules. They are big enough for permeation of water molecules, but too small to permit passage of hydrated chemical ions. However, many factors including pH, temperature, and differential pressure across the membrane affect the selectivity of this permeation. With the proper controls, RO membranes can achieve chemical, microbial, and endotoxin quality improvement. The process streams consist of supply water, product water (permeate), and wastewater (reject). Depending on source water, pretreatment and system configuration variations and chemical additives may be necessary to achieve desired performance and reliability.

A major factor affecting RO performance is the permeate recovery rate, that is, the amount of the water passing through the membrane compared to the amount rejected. This is influenced by the several factors, but most significantly by the pump pressure. Recoveries of 75% are typical, and can accomplish a 1–2 log purification of most impurities. For most feed waters, this is usually not enough to meet *Purified Water* conductivity specifications. A second pass of this permeate water through another RO stage usually achieves the necessary permeate purity if other factors such as pH and temperature have been appropriately adjusted and the ammonia

from chloraminated source water has been previously removed. Increasing recoveries with higher pressures in order to reduce the volume of reject water will lead to reduced permeate purity. If increased pressures are needed over time to achieve the same permeate flow, this is an indication of partial membrane blockage that needs to be corrected before it becomes irreversibly fouled, and expensive membrane replacement is the only option.

Other concerns associated with the design and operation of RO units include membrane materials that are extremely sensitive to sanitizing agents and to particulate, chemical, and microbial membrane fouling; membrane and seal integrity; the passage of dissolved gases, such as carbon dioxide and ammonia; and the volume of wastewater, particularly where water discharge is tightly regulated by local authorities. Failure of membrane or seal integrity will result in product water contamination. Methods of control involve suitable pretreatment of the influent water stream, appropriate membrane material selection, integrity challenges, membrane design and heat tolerance, periodic sanitization, and monitoring of differential pressures, conductivity, microbial levels, and TOC.

The development of RO units that can tolerate sanitizing water temperatures as well as operate efficiently and continuously at elevated temperatures has added greatly to their microbial control and to the avoidance of biofouling. RO units can be used alone or in combination with DI and CEDI units as well as ultrafiltration for operational and quality enhancements.

Ultrafiltration

Ultrafiltration is a technology most often employed in pharmaceutical water systems for removing endotoxins from a water stream. It can also use semipermeable membranes, but unlike RO, these typically use polysulfone membranes whose intersegmental "pores" have been purposefully exaggerated during their manufacture by preventing the polymer molecules from reaching their smaller equilibrium proximities to each other. Depending on the level of equilibrium control during their fabrication, membranes with differing molecular weight "cutoffs" can be created such that molecules with molecular weights above these cutoff ratings are rejected and cannot penetrate the filtration matrix.

Ceramic ultrafilters are another molecular sieving technology. Ceramic ultrafilters are self supporting and extremely durable, backwashable, chemically cleanable, and steam sterilizable. However, they may require higher operating pressures than membrane type ultrafilters.

All ultrafiltration devices work primarily by a molecular sieving principle. Ultrafilters with molecular weight cutoff ratings in the range of 10,000–20,000 Da are typically used in water systems for removing endotoxins. This technology may be appropriate as an intermediate or final purification step. Similar to RO, successful performance is dependent upon pretreatment of the water by upstream unit operations.

Issues of concern for ultrafilters include compatibility of membrane material with heat and sanitizing agents, membrane integrity, fouling by particles and microorganisms, and seal integrity. Control measures involve filtration medium selection, sanitization, flow design (dead end vs. tangential), integrity challenges, regular cartridge changes, elevated feed water temperature, and monitoring TOC and differential pressure. Additional flexibility in operation is possible based on the way ultrafiltration units are arranged such as in a parallel or series configurations. Care should be taken to avoid stagnant water conditions that could promote microorganism growth in back-up or standby units.

Charge-Modified Filtration

Charge-modified filters are usually microbially retentive filters that are treated during their manufacture to have a positive charge on their surfaces. Microbial retentive filtration will be described in a subsequent section, but the significant feature of these membranes is their electrostatic surface charge. Such charged filters can reduce endotoxin levels in the fluids passing through them by their adsorption (owing to the endotoxin's negative charge) onto the membrane surfaces. Although ultrafilters are more often employed as a unit operation for endotoxin removal in water systems, charge-modified filters may also have a place in endotoxin removal particularly where available upstream pressures are not sufficient for ultrafiltration and for a single, relatively short-term use. Charge-modified filters may be difficult to validate for long-term or large-volume endotoxin retention. Even though their purified standard endotoxin retention can be well characterized, their retention capacity for "natural" endotoxins is difficult to gauge. Nevertheless, utility could be demonstrated and validated as short-term, single-use filters at points of use in water systems that are not designed for endotoxin control or where only an endotoxin "polishing" (removal of only slight or occasional endotoxin levels) is needed. Control and validation concerns include volume and duration of use, flow rate, water conductivity and purity, and constancy and concentration of endotoxin levels being removed. All of these factors may have to be evaluated and challenged prior to using this approach, making this a difficult-to-validate application. Even so, there may still be a possible need for additional backup endotoxin testing both upstream and downstream of the filter.

Microbial-Retentive Filtration

Microbial-retentive membrane filters have experienced an evolution of understanding in the past decade that has caused previously held theoretical retention mechanisms to be reconsidered. These filters have a larger effective "pore size" than ultrafilters and are intended to prevent the passage of microorganisms and similarly sized particles without unduly restricting flow. This type of filtration is widely employed within water systems for filtering the bacteria out of both water and compressed gases as well as for vent filters on tanks and stills and other unit operations. However, the properties of the water system microorganisms seem to challenge a filter's microbial retention from water with phenomena absent from other aseptic filtration applications, such as filter sterilizing of pharmaceutical formulations prior to packaging. In the latter application, sterilizing grade filters are generally considered to have an assigned rating of 0.2 or 0.22 μm . This rather arbitrary rating is associated with filters that have the ability to retain a high level challenge of a specially prepared inoculum of *Brevundimonas* (formerly *Pseudomonas*) *diminuta*. This is a small microorganism originally isolated decades ago from a product that had been "filter sterilized" using a 0.45 μm rated filter. Further study revealed that a percentage of cells of this microorganism could reproducibly penetrate the 0.45 μm sterilizing filters. Through historic correlation of *B. diminuta* retaining tighter filters, thought to be twice as good as a 0.45 μm filter, assigned ratings of 0.2 or 0.22 μm with their successful use in product solution filter sterilization, both this filter rating and the associated high level *B. diminuta* challenge have become the current benchmarks for sterilizing filtration. New evidence now suggests that for microbial-retentive filters used for pharmaceutical water, *B. diminuta* may not be the best model microorganism.

An archaic understanding of microbial-retentive filtration would lead one to equate a filter's rating with the false impression of a simple sieve or screen that absolutely retains particles sized at or above the filter's rating. A current understanding of the mechanisms involved in microbial retention and the variables that can affect those mechanisms has yielded a far more

complex interaction of phenomena than previously understood. A combination of simple sieve retention and surface adsorption are now known to contribute to microbial retention.

The following all interact to create some unusual and surprising retention phenomena for water system microorganisms: the variability in the range and average pore sizes created by the various membrane fabrication processes, the variability of the surface chemistry and three-dimensional structures related to the different polymers used in these filter matrices, and the size and surface properties of the microorganism intended to be retained by the filters. *B. diminuta* may not be the best challenge microorganisms for demonstrating bacterial retention for 0.2- to 0.22- μm rated filters for use in water systems because it appears to be more easily retained by these filters than some water system flora. The well-documented appearance of water system microorganisms on the downstream sides of some 0.2- to 0.22- μm rated filters after a relatively short period of use seems to support that some penetration phenomena are at work. Unknown for certain is if this downstream appearance is caused by a "blow-through" or some other pass-through phenomenon as a result of tiny cells or less cell "stickiness", or by a "growth through" phenomenon as a result of cells hypothetically replicating their way through the pores to the downstream side. Whatever is the penetration mechanism, 0.2- to 0.22- μm rated membranes may not be the best choice for some water system uses.

Microbial retention success in water systems has been reported with the use of some manufacturers' filters arbitrarily rated as 0.1 μm . There is general agreement that for a given manufacturer, their 0.1- μm rated filters are tighter than their 0.2- to 0.22- μm rated filters. However, comparably rated filters from different manufacturers in water filtration applications may not perform equivalently owing to the different filter fabrication processes and the nonstandardized microbial retention challenge processes currently used for defining the 0.1- μm filter rating. It should be noted that use of 0.1- μm rated membranes generally results in a sacrifice in flow rate compared to 0.2- to 0.22- μm membranes, so whatever membranes are chosen for a water system application, the user must verify that the membranes are suitable for their intended application, use period, and use process, including flow rate.

For microbial retentive gas filtrations, the same sieving and adsorptive retention phenomena are at work as in liquid filtration, but the adsorptive phenomenon is enhanced by additional electrostatic interactions between particles and filter matrix. These electrostatic interactions are so strong that particle retention for a given filter rating is significantly more efficient in gas filtration than in water or product solution filtrations. These additional adsorptive interactions render filters rated at 0.2-0.22- μm unquestionably suitable for microbial retentive gas filtrations. When microbially retentive filters are used in these applications, the membrane surface is typically hydrophobic (non-wettable by water). A significant area of concern for gas filtration is blockage of tank vents by condensed water vapor, which can cause mechanical damage to the tank. Control measures include electrical or steam tracing and a self-draining orientation of vent filter housings to prevent accumulation of vapor condensate. However, a continuously high filter temperature will take an oxidative toll on polypropylene components of the filter, so sterilization of the unit prior to initial use, and periodically thereafter, as well as regular visual inspections, integrity tests, and changes are recommended control methods.

In water applications, microbial retentive filters may be used downstream of unit operations that tend to release microorganisms or upstream of unit operations that are sensitive to microorganisms. Microbial retentive filters may also be used to filter water feeding the distribution system. It should be noted that regulatory authorities allow the use of microbial-

retentive filters within distribution systems or even at use points if they have been properly validated and are appropriately maintained. A point-of-use filter should only be intended to "polish" the microbial quality of an otherwise well-maintained system and not to serve as the primary microbial control device. The efficacy of system microbial control measures can only be assessed by sampling the water upstream of the filters. As an added measure of protection, in-line UV lamps, appropriately sized for the flow rate (see *Sanitization*), may be used just upstream of microbial retentive filters to inactivate microorganisms prior to their capture by the filter. This tandem approach tends to greatly delay potential microbial penetration phenomena and can substantially extend filter service life.

Ultraviolet Light

The use of low-pressure UV lights that emit a 254-nm wavelength for microbial control is discussed under *Sanitization*, but the application of UV light in chemical purification is also emerging. This 254-nm wavelength is also useful in the destruction of ozone. With intense emissions at wavelengths around 185 nm (as well as at 254 nm), medium-pressure UV lights have demonstrated utility in the destruction of the chlorine-containing disinfectants used in source water as well as for interim stages of water pretreatment. High intensities of this wavelength alone or in combination with other oxidizing sanitants, such as hydrogen peroxide, have been used to lower TOC levels in recirculating distribution systems. The organics are typically converted to carbon dioxide, which equilibrates to bicarbonate, and incompletely oxidized carboxylic acids, both of which can easily be removed by polishing ion-exchange resins. Areas of concern include adequate UV intensity and residence time, gradual loss of UV emissivity with bulb age, gradual formation of UV-absorbing film at the water contact surface, incomplete photodegradation during unforeseen source water hyperchlorination, release of ammonia from chloramine photodegradation, unapparent UV bulb failure, and conductivity degradation in distribution systems using 185-nm UV lights. Control measures include regular inspection or emissivity alarms to detect bulb failures or film occlusions, regular UV bulb sleeve cleaning and wiping, downstream chlorine detectors, downstream polishing deionizers, and regular (approximately yearly) bulb replacement.

Distillation

Distillation units provide chemical and microbial purification via thermal vaporization, mist elimination, and water vapor condensation. A variety of designs is available including single effect, multiple effect, and vapor compression. The latter two configurations are normally used in larger systems because of their generating capacity and efficiency. Distilled water systems require different feed water controls than required by membrane systems. For distillation, due consideration must be given to prior removal of hardness and silica impurities that may foul or corrode the heat transfer surfaces as well as prior removal of those impurities that could volatilize and condense along with the water vapor. In spite of general perceptions, even the best distillation process cannot afford absolute removal of contaminating ions and endotoxin. Most stills are recognized as being able to accomplish at least a 3-4 log reduction in these impurity concentrations. Areas of concern include carry-over of volatile organic impurities such as trihalomethanes (see *Source or Feed Water Considerations*) and gaseous impurities such as ammonia and carbon dioxide, faulty mist elimination, evaporator flooding, inadequate blowdown, stagnant water in condensers and evaporators, pump and compressor seal design, pinhole evaporator and condenser leaks, and conductivity (quality) variations during start-up and operation.

Methods of control may involve preliminary decarbonation steps to remove both dissolved carbon dioxide and other volatile or noncondensable impurities; reliable mist elimination to minimize feedwater droplet entrainment; visual or automated high water level indication to detect boiler flooding and boil over; use of sanitary pumps and compressors to minimize microbial and lubricant contamination of feedwater and condensate; proper drainage during inactive periods to minimize microbial growth and accumulation of associated endotoxin in boiler water; blowdown control to limit the impurity concentration effect in the boiler to manageable levels; on-line conductivity sensing with automated diversion to waste to prevent unacceptable water upon still startup or still malfunction from getting into the finished water distribute system; and periodic integrity testing for pinhole leaks to routinely assure condensate is not compromised by nonvolatized source water contaminants.

Storage Tanks

Storage tanks are included in water distribution systems to optimize processing equipment capacity. Storage also allows for routine maintenance within the pretreatment train while maintaining continuous supply to meet manufacturing needs. Design and operation considerations are needed to prevent or minimize the development of biofilm, to minimize corrosion, to aid in the use of chemical sanitization of the tanks, and to safeguard mechanical integrity. These considerations may include using closed tanks with smooth interiors, the ability to spray the tank headspace using sprayballs on recirculating loop returns, and the use of heated, jacketed/insulated tanks. This minimizes corrosion and biofilm development and aids in thermal and chemical sanitization. Storage tanks require venting to compensate for the dynamics of changing water levels. This can be accomplished with a properly oriented and heat-traced filter housing fitted with a hydrophobic microbial retentive membrane filter affixed to an atmospheric vent. Alternatively, an automatic membrane-filtered compressed gas blanketing system may be used. In both cases, rupture disks equipped with a rupture alarm device should be used as a further safeguard for the mechanical integrity of the tank. Areas of concern include microbial growth or corrosion due to irregular or incomplete sanitization and microbial contamination from unalarmed rupture disk failures caused by condensate-occluded vent filters.

Distribution Systems

Distribution system configuration should allow for the continuous flow of water in the piping by means of recirculation. Use of nonrecirculating, dead-end, or one-way systems or system segments should be avoided whenever possible. If not possible, these systems should be periodically flushed and more closely monitored. Experience has shown that continuously recirculated systems are easier to maintain. Pumps should be designed to deliver fully turbulent flow conditions to facilitate thorough heat distribution (for hot water sanitized systems) as well as thorough chemical sanitant distribution. Turbulent flow also appear to either retard the development of biofilms or reduce the tendency of those biofilms to shed bacteria into the water. If redundant pumps are used, they should be configured and used to avoid microbial contamination of the system.

Components and distribution lines should be sloped and fitted with drain points so that the system can be completely drained. In stainless steel distribution systems where the water is circulated at a high temperature, dead legs and low flow conditions should be avoided, and valved tie-in points should have length-to-diameter ratios of six or less. If constructed of heat-tolerant plastic, this ratio should be even less to avoid cool points where biofilm development

could occur. In ambient temperature distribution systems, particular care should be exercised to avoid or minimize dead leg ratios of any size and provide for complete drainage. If the system is intended to be steam sanitized, careful sloping and low point drainage is crucial to condensate removal and sanitization success. If drainage of components or distribution lines is intended as a microbial control strategy, they should also be configured to be completely dried using dry compressed air (or nitrogen if appropriate employee safety measures are used). Drained but still moist surfaces will still support microbial proliferation. Water exiting from the distribution system should not be returned to the system without first passing through all or a portion of the purification train.

The distribution design should include the placement of sampling valves in the storage tank and at other locations, such as in the return line of the recirculating water system. Where feasible, the primary sampling sites for water should be the valves that deliver water to the points of use. Direct connections to processes or auxiliary equipment should be designed to prevent reverse flow into the controlled water system. Hoses and heat exchangers that are attached to points of use in order to deliver water for a particular use must not chemically or microbiologically degrade the water quality. The distribution system should permit sanitization for microorganism control. The system may be continuously operated at sanitizing conditions or sanitized periodically.

INSTALLATION, MATERIALS OF CONSTRUCTION, AND COMPONENT SELECTION

Installation techniques are important because they can affect the mechanical, corrosive, and sanitary integrity of the system. Valve installation attitude should promote gravity drainage. Pipe supports should provide appropriate slopes for drainage and should be designed to support the piping adequately under worst case thermal and flow conditions. The methods of connecting system components including units of operation, tanks, and distribution piping require careful attention to preclude potential problems. Stainless steel welds should provide reliable joints that are internally smooth and corrosion free. Low carbon stainless steel, compatible wire filler, where necessary, inert gas, automatic welding machines, and regular inspection and documentation help to ensure acceptable weld quality. Follow up cleaning and passivation are important for removing contamination and corrosion products and to re-establish the passive corrosion resistant surface. Plastic materials can be fused (welded) in some cases and also require smooth, uniform internal surfaces. Adhesive glues and solvents should be avoided due to the potential for voids and extractables. Mechanical methods of joining, such as flange fittings, require care to avoid the creation of offsets, gaps, penetrations, and voids. Control measures include good alignment, properly sized gaskets, appropriate spacing, uniform sealing force, and the avoidance of threaded fittings.

Materials of construction should be selected to be compatible with control measures such as sanitizing, cleaning, and passivating. Temperature rating is a critical factor in choosing appropriate materials because surfaces may be required to handle elevated operating and sanitization temperatures. Should chemicals or additives be used to clean, control, or sanitize the system, materials resistant to these chemicals or additives must be utilized. Materials should be capable of handling turbulent flow and elevated velocities without wear of the corrosion resistant film such as the passive chromium oxide surface of stainless steel. The finish on metallic materials such as stainless steel, whether it is a refined mill finish, polished to a specific grit, or an electropolished treatment, should complement system design and provide satisfactory corrosion and microbial activity resistance as well as chemical sanitizability.

Auxiliary equipment and fittings that require seals, gaskets, diaphragms, filter media, and membranes should exclude materials that permit the possibility of extractables, shedding, and microbial activity. Insulating materials exposed to stainless steel surfaces should be free of chlorides to avoid the phenomenon of stress corrosion cracking that can lead to system contamination and the destruction of tanks and critical system components.

Specifications are important to ensure proper selection of materials and to serve as a reference for system qualification and maintenance. Information such as mill reports for stainless steel and reports of composition, ratings, and material handling capabilities for nonmetallic substances should be reviewed for suitability and retained for reference. Component (auxiliary equipment) selection should be made with assurance that it does not create a source of contamination intrusion. Heat exchangers should be constructed to prevent leakage of heat transfer medium to the pharmaceutical water and, for heat exchanger designs where prevention may fail, there should be a means to detect leakage. Pumps should be of sanitary design with seals that prevent contamination of the water. Valves should have smooth internal surfaces with the seat and closing device exposed to the flushing action of water, such as occurs in diaphragm valves. Valves with pocket areas or closing devices (e.g., ball, plug, gate, globe) that move into and out of the flow area should be avoided.

SANITIZATION

Microbial control in water systems is achieved primarily through sanitization practices. Systems can be sanitized using either thermal or chemical means. Thermal approaches to system sanitization include periodic or continuously circulating hot water and the use of steam. Temperatures of at least 80° are most commonly used for this purpose, but continuously recirculating water of at least 65° has also been used effectively in insulated stainless steel distribution systems when attention is paid to uniformity and distribution of such self-sanitizing temperatures. These techniques are limited to systems that are compatible with the higher temperatures needed to achieve sanitization. Although thermal methods control biofilm development by either continuously inhibiting their growth or, in intermittent applications, by killing the microorganisms within biofilms, they are not effective in removing established biofilms. Killed but intact biofilms can become a nutrient source for rapid biofilm regrowth after the sanitizing conditions are removed or halted. In such cases, a combination of routine thermal and periodic supplementation with chemical sanitization might be more effective. The more frequent the thermal sanitization, the more likely biofilm development and regrowth can be eliminated. Chemical methods, where compatible, can be used on a wider variety of construction materials. These methods typically employ oxidizing agents such as halogenated compounds, hydrogen peroxide, ozone, peracetic acid, or combinations thereof. Halogenated compounds are effective sanitizers but are difficult to flush from the system and may leave biofilms intact. Compounds such as hydrogen peroxide, ozone, and peracetic acid oxidize bacteria and biofilms by forming reactive peroxides and free radicals (notably hydroxyl radicals). The short half-life of ozone in particular, and its limitation on achievable concentrations require that it be added continuously during the sanitization process. Hydrogen peroxide and ozone rapidly degrade to water and oxygen; peracetic acid degrades to acetic acid in the presence of UV light. In fact, ozone's ease of degradation to oxygen using 254 nm UV light at use points allow it to be most effectively used on a continuous basis to provide continuously sanitizing conditions.

In-line UV light at a wavelength of 254 nm can also be used to continuously "sanitize" water

circulating in the system, but these devices must be properly sized for the water flow. Such devices inactivate a high percentage (but not 100%) of microorganisms that flow through the device but cannot be used to directly control existing biofilm upstream or downstream of the device. However, when coupled with conventional thermal or chemical sanitization technologies or located immediately upstream of a microbially retentive filter, it is most effective and can prolong the interval between system sanitizations.

It is important to note that microorganisms in a well-developed biofilm can be extremely difficult to kill, even by aggressive oxidizing biocides. The less developed and therefore thinner the biofilm, the more effective the biocidal action. Therefore, optimal biocide control is achieved by frequent biocide use that does not allow significant biofilm development between treatments.

Sanitization steps require validation to demonstrate the capability of reducing and holding microbial contamination at acceptable levels. Validation of thermal methods should include a heat distribution study to demonstrate that sanitization temperatures are achieved throughout the system, including the body of use point valves. Validation of chemical methods requires demonstrating adequate chemical concentrations throughout the system, exposure to all wetted surfaces, including the body of use point valves, and complete removal of the sanitant from the system at the completion of treatment. Methods validation for the detection and quantification of residues of the sanitant or its objectionable degradants is an essential part of the validation program. The frequency of sanitization should be supported by, if not triggered by, the results of system microbial monitoring. Conclusions derived from trend analysis of the microbiological data should be used as the alert mechanism for maintenance. The frequency of sanitization should be established in such a way that the system operates in a state of microbiological control and does not routinely exceed alert levels (see *Alert and Action Levels and Specifications*).

OPERATION, MAINTENANCE, AND CONTROL

A preventive maintenance program should be established to ensure that the water system remains in a state of control. The program should include (1) procedures for operating the system, (2) monitoring programs for critical quality attributes and operating conditions including calibration of critical instruments, (3) schedule for periodic sanitization, (4) preventive maintenance of components, and (5) control of changes to the mechanical system and to operating conditions.

Operating Procedures—Procedures for operating the water system and performing routine maintenance and corrective action should be written, and they should also define the point when action is required. The procedures should be well documented, detail the function of each job, assign who is responsible for performing the work, and describe how the job is to be conducted. The effectiveness of these procedures should be assessed during water system validation.

Monitoring Program—Critical quality attributes and operating parameters should be documented and monitored. The program may include a combination of in-line sensors or automated instruments (e.g., for TOC, conductivity, hardness, and chlorine), automated or manual documentation of operational parameters (such as flow rates or pressure drop across a carbon bed, filter, or RO unit), and laboratory tests (e.g., total microbial counts). The frequency of sampling, the requirement for evaluating test results, and the necessity for initiating corrective action should be included.

Sanitization—Depending on system design and the selected units of operation, routine periodic sanitization may be necessary to maintain the system in a state of microbial control. Technologies for sanitization are described above.

Preventive Maintenance—A preventive maintenance program should be in effect. The program should establish what preventive maintenance is to be performed, the frequency of maintenance work, and how the work should be documented.

Change Control—The mechanical configuration and operating conditions must be controlled. Proposed changes should be evaluated for their impact on the whole system. The need to requalify the system after changes are made should be determined. Following a decision to modify a water system, the affected drawings, manuals, and procedures should be revised.

SAMPLING CONSIDERATIONS

Water systems should be monitored at a frequency that is sufficient to ensure that the system is in control and continues to produce water of acceptable quality. Samples should be taken from representative locations within the processing and distribution system. Established sampling frequencies should be based on system validation data and should cover critical areas including unit operation sites. The sampling plan should take into consideration the desired attributes of the water being sampled. For example, systems for *Water for Injection*, because of their more critical microbiological requirements, may require a more rigorous sampling frequency.

Analyses of water samples often serve two purposes: in-process control assessments and final quality control assessments. In-process control analyses are usually focused on the attributes of the water within the system. Quality control is primarily concerned with the attributes of the water delivered by the system to its various uses. The latter usually employs some sort of transfer device, often a flexible hose, to bridge the gap between the distribution system use-point valve and the actual location of water use. The issue of sample collection location and sampling procedure is often hotly debated because of the typically mixed use of the data generated from the samples, for both in-process control and quality control. In these single-sample and mixed-data use situations, the worst-case scenario should be utilized. In other words, samples should be collected from use points using the same delivery devices, such as hoses, and procedures, such as preliminary hose or outlet flushing, as are employed by production from those use points. Where use points per se cannot be sampled, such as hard-piped connections to equipment, special sampling ports may be used. In all cases, the sample must represent as closely as possible the quality of the water used in production. If a point-of-use filter is employed, sampling of the water prior to and after the filter is needed, because the filter will mask the microbial control achieved by the normal operating procedures of the system.

Samples containing chemical sanitizing agents require neutralization prior to microbiological analysis. Samples for microbiological analysis should be tested immediately, or suitably refrigerated to preserve the original microbial attributes until analysis can begin. Samples of flowing water are only indicative of the concentration of planktonic (free floating) microorganisms present in the system. Biofilm microorganisms (those attached to water system surfaces) are usually present in greater numbers and are the source of the planktonic population recovered from grab samples. Microorganisms in biofilms represent a continuous

source of contamination and are difficult to directly sample and quantify. Consequently, the planktonic population is usually used as an indicator of system contamination levels and is the basis for system *Alert and Action Levels and Specifications*. The consistent appearance of elevated planktonic levels is usually an indication of advanced biofilm development in need of remedial control. System control and sanitization are key in controlling biofilm formation and the consequent planktonic population.

Sampling for chemical analyses is also done for in-process control and for quality control purposes. However, unlike microbial analyses, chemical analyses can be and often are performed using on-line instrumentation. Such on-line testing has unequivocal in-process control purposes because it is not performed on the water delivered from the system. However, unlike microbial attributes, chemical attributes are usually not significantly degraded by hoses. Therefore, through verification testing, it may be possible to show that the chemical attributes detected by the on-line instrumentation (in-process testing) are equivalent to those detected at the ends of the use-point hoses (quality control testing). This again creates a single-sample and mixed-data use scenario. It is far better to operate the instrumentation in a continuous mode, generating large volumes of in-process data, but only using a defined small sampling of that data for QC purposes. Examples of acceptable approaches include using highest values for a given period, highest time-weighted average for a given period (from fixed or rolling sub-periods), or values at a fixed daily time. Each approach has advantages and disadvantages relative to calculation complexity and reflection of continuous quality, so the user must decide which approach is most suitable or justifiable.

CHEMICAL CONSIDERATIONS

The chemical attributes of *Purified Water* and *Water for Injection* in effect prior to *USP 23* were specified by a series of chemistry tests for various specific and nonspecific attributes with the intent of detecting chemical species indicative of incomplete or inadequate purification. While these methods could have been considered barely adequate to control the quality of these waters, they nevertheless stood the test of time. This was partly because the operation of water systems was, and still is, based on on-line conductivity measurements and specifications generally thought to preclude the failure of these archaic chemistry attribute tests.

USP moved away from these chemical attribute tests to contemporary analytical technologies for the bulk waters *Purified Water* and *Water for Injection*. The intent was to upgrade the analytical technologies without tightening the quality requirements. The two contemporary analytical technologies employed were TOC and conductivity. The TOC test replaced the test for *Oxidizable Substances* that primarily targeted organic contaminants. A multistaged *Conductivity* test which detects ionic (mostly inorganic) contaminants replaced, with the exception of the test for *Heavy metals*, all of the inorganic chemical tests (i.e., *Ammonia*, *Calcium*, *Carbon dioxide*, *Chloride*, *Sulfate*).

Replacing the heavy metals attribute was considered unnecessary because (a) the source water specifications (found in the NPDWR) for individual *Heavy metals* were tighter than the approximate limit of detection of the *Heavy metals* test for *USP XXII Water for Injection* and *Purified Water* (approximately 0.1 ppm), (b) contemporary water system construction materials do not leach heavy metal contaminants, and (c) test results for this attribute have uniformly been negative—there has not been a confirmed occurrence of a singular test failure (failure of only the *Heavy metals* test with all other attributes passing) since the current heavy metal

drinking water standards have been in place. Nevertheless, because the presence of heavy metals in *Purified Water* or *Water for Injection* could have dire consequences, its absence should at least be documented during new water system commissioning and validation or through prior test results records.

Total solids and *pH* were the only tests not covered by conductivity testing. The test for *Total solids* was considered redundant because the nonselective tests of conductivity and TOC could detect most chemical species other than silica, which could remain undetected in its colloidal form. Colloidal silica in *Purified Water* and *Water for Injection* is easily removed by most water pretreatment steps and even if present in the water, constitutes no medical or functional hazard except under extreme and rare situations. In such extreme situations, other attribute extremes are also likely to be detected. It is, however, the user's responsibility to ensure fitness for use. If silica is a significant component in the source water, and the purification unit operations could be operated or fail and selectively allow silica to be released into the finished water (in the absence of co-contaminants detectable by conductivity), then either silica-specific or a total solids type testing should be utilized to monitor and control this rare problem.

The *pH* attribute was eventually recognized to be redundant to the conductivity test (which included *pH* as an aspect of the test and specification); therefore, *pH* was dropped as a separate attribute test.

The rationale used by USP to establish its *Purified Water* and *Water for Injection* conductivity specifications took into consideration the conductivity contributed by the two least conductive former attributes of *Chloride* and *Ammonia*, thereby precluding their failure had those wet chemistry tests been performed. In essence, the *Stage 3* conductivity specifications (see *Water Conductivity* (645), *Bulk Water*) were established from the sum of the conductivities of the limit concentrations of chloride ions (from pH 5.0–6.2) and ammonia ions (from pH 6.3–7.0), plus the unavoidable contribution of other conductivity-contributing ions from water (H^+ and OH^-), dissolved atmospheric CO_2 (as HCO_3^-), and an electro-balancing quantity of either Na^+ or Cl^- , depending on the pH-induced ionic imbalance (see *Table 1*). The *Stage 2* conductivity specification is the lowest value on this table, 2.1 $\mu S/cm$. The *Stage 1* specifications, designed primarily for on-line measurements, were derived essentially by summing the lowest values in the contributing ion columns for each of a series of tables similar to *Table 1*, created for each 5° increment between 0° and 100°. For example purposes, the italicized values in *Table 1*, the conductivity data table for 25°, were summed to yield a conservative value of 1.3 $\mu S/cm$, the *Stage 1* specification for a nontemperature compensated, nonatmosphere-equilibrated water sample that actually had a measured temperature of 25°–29°. Each 5° increment in the table was similarly treated to yield the individual values listed in the table of *Stage 1* specifications (see *Water Conductivity* (645), *Bulk Water*).

Table 1. Contributing Ion Conductivities of the Chloride–Ammonia Model as a Function of pH

(in atmosphere-equilibrated water at 25°)

pH	H ⁺	OH ⁻	HCO ₃ ⁻	Conductivity (μ S/cm)		NH ₄ ⁺	Combined Conductivities	Stage 3 Limit
				Cl ⁻	Na ⁺

7.0	0.03	0.02	1.97	0	1.39	1.22	4.63	4.6

As stated above, this rather radical change to utilizing a conductivity attribute as well as the inclusion of a TOC attribute allowed for on-line measurements. This was a major philosophical change and allowed major savings to be realized by industry. The TOC and conductivity tests can also be performed "off-line" in the laboratories using collected samples, although sample collection tends to introduce opportunities for adventitious contamination that can cause false high readings. The collection of on-line data is not, however, without challenges. The continuous readings tend to create voluminous amounts of data where before only a single data point was available. As stated under *Sampling Considerations*, continuous in-process data sampling is excellent for understanding how a water system performs during all of its various usage and maintenance events in real time, but is too much data for QC purposes. Therefore, a justifiable fraction or averaging of the data can be used that is still representative of the overall water quality being used.

Packaged/sterile waters present a particular dilemma relative to the attributes of conductivity and TOC. The package itself is the source of chemicals (inorganics and organics) that leach over time into the packaged water and can easily be detected by the conductivity and TOC tests. The irony of organic leaching from plastic packaging is that before the advent of bulk water TOC testing when the *Oxidizable Substances* test was the only "organic purity" test for both bulk and packaged/sterile water monographs in *USP*, that test's insensitivity to many of the organic leachables from plastic and elastomeric packaging materials was largely unrealized, allowing organic levels in packaged/sterile water to be quite high (possibly many times the TOC specification for bulk water). Similarly, glass containers can also leach inorganics, such as sodium, which are easily detected by conductivity, but poorly detected by the former wet chemistry attribute tests. Most of these leachables are considered harmless by current

perceptions and standards at the rather significant concentrations present. Nevertheless, they effectively degrade the quality of the high-purity waters placed into these packaging systems. Some packaging materials contain more leachables than others and may not be as suitable for holding water and maintaining its purity.

The attributes of conductivity and TOC tend to reveal more about the packaging leachables than they do about the water's original purity. These currently "allowed" leachables could render the sterile packaged versions of originally equivalent bulk water essentially unsuitable for many uses where the bulk waters are perfectly adequate.

Therefore, to better control the ionic packaging leachables, *Water Conductivity* (645) is divided into two sections. The first is titled *Bulk Water*, which applies to *Purified Water*, *Water for Injection*, *Water for Hemodialysis*, and *Pure Steam*, and includes the three-stage conductivity testing instructions and specifications. The second is titled *Sterile Water*, which applies to *Sterile Purified Water*, *Sterile Water for Injection*, *Sterile Water for Inhalation*, and *Sterile Water for Irrigation*. The *Sterile Water* section includes conductivity specifications similar to the *Stage 2* testing approach because it is intended as a laboratory test, and these sterile waters were made from bulk water that already complied with the three-stage conductivity test. In essence, packaging leachables are the primary target "analytes" of the conductivity specifications in the *Sterile Water* section of *Water Conductivity* (645). The effect on potential leachables from different container sizes is the rationale for having two different specifications, one for small packages containing nominal volumes of 10 mL or less and another for larger packages. These conductivity specifications are harmonized with the *European Pharmacopoeia* conductivity specifications for *Sterile Water for Injection*. All monographed waters, except *Bacteriostatic Water for Injection*, have a conductivity specification that directs the user to either the *Bulk Water* or the *Sterile Water* section of *Water Conductivity* (645). For the sterile packaged water monographs, this water conductivity specification replaces the redundant wet chemistry limit tests intended for inorganic contaminants that had previously been specified in these monographs.

Controlling the organic purity of these sterile packaged waters, particularly those in plastic packaging, is more challenging. Although the TOC test can better detect and therefore be better used to monitor and control these impurities than the current *Oxidizable Substances* test, the latter has many decades-old precedents and flexibility with the variety of packaging types and volumes applicable to these sterile packaged waters. Nevertheless, TOC testing of these currently allowed sterile, plastic-packaged waters reveals substantial levels of plastic-derived organic leachables that render the water perhaps orders of magnitude less organically pure than typically achieved with bulk waters. Therefore, usage of these packaged waters for analytical, manufacturing, and cleaning applications should only be exercised after suitability of the waters' purity for the application has been assured.

There is an analogous partitioning of *Total Organic Carbon* (643) to better control the organic packaging leachables. The first part is titled *Bulk Water*, which applies to the TOC method for *Purified Water*, *Water for Injection*, *Water for Hemodialysis*, and *Pure Steam*. The second part is titled *Sterile Water*, which applies to the TOC method for *Sterile Purified Water*, *Sterile Water for Injection*, *Sterile Water for Inhalation*, and *Sterile Water for Irrigation*. For these sterile waters, the TOC method is provided as an alternative test to the *Oxidizable Substances* test. The TOC limits for the sterile waters are set to higher values than the TOC limits for bulk waters.

MICROBIAL CONSIDERATIONS

The major exogenous source of microbial contamination of bulk pharmaceutical water is source or feed water. Feed water quality must, at a minimum, meet the quality attributes of Drinking Water for which the level of coliforms is regulated. A wide variety of other microorganisms, chiefly Gram-negative bacteria, may be present in the incoming water. These microorganisms may compromise subsequent purification steps. Examples of other potential exogenous sources of microbial contamination include unprotected vents, faulty air filters, ruptured rupture disks, backflow from contaminated outlets, unsanitized distribution system "openings" including routine component replacements, inspections, repairs, and expansions, inadequate drain and air breaks, and replacement activated carbon, deionizer resins, and regenerant chemicals. In these situations, the exogenous contaminants may not be normal aquatic bacteria but rather microorganisms of soil or even of human origin. The detection of nonaquatic microorganisms may be an indication of a system component failure, which should trigger investigations that will remediate their source. Sufficient care should be given to system design and maintenance in order to minimize microbial contamination from these exogenous sources.

Unit operations can be a major source of endogenous microbial contamination. Microorganisms present in feed water may adsorb to carbon bed, deionizer resins, filter membranes, and other unit operation surfaces and initiate the formation of a biofilm. In a high-purity water system, biofilm is an adaptive response by certain microorganisms to survive in this low-nutrient environment. Downstream colonization can occur when microorganisms are shed from existing biofilm colonized surfaces and carried to other areas of the water system. Microorganisms may also attach to suspended particles such as carbon bed fines or fractured resin particles. When the microorganisms become planktonic, they serve as a source of contamination to subsequent purification equipment (compromising its functionality) and to distribution systems.

Another source of endogenous microbial contamination is the distribution system itself. Microorganisms can colonize pipe surfaces, rough welds, badly aligned flanges, valves, and unidentified dead legs, where they proliferate, forming a biofilm. The smoothness and composition of the surface may affect the rate of initial microbial adsorption, but once adsorbed, biofilm development, unless otherwise inhibited by sanitizing conditions, will occur regardless of the surface. Once formed, the biofilm becomes a continuous source of microbial contamination.

ENDOTOXIN CONSIDERATIONS

Endotoxins are lipopolysaccharides found in and shed from the cell envelope that is external to the cell wall of Gram-negative bacteria. Gram-negative bacteria that form biofilms can become a source of endotoxins in pharmaceutical waters. Endotoxins may occur as clusters of lipopolysaccharide molecules associated with living microorganisms, fragments of dead microorganisms or the polysaccharide slime surrounding biofilm bacteria, or as free molecules. The free form of endotoxins may be released from cell surfaces of the bacteria that colonize the water system, or from the feed water that may enter the water system. Because of the multiplicity of endotoxin sources in a water system, endotoxin quantitation in a water system is not a good indicator of the level of biofilm abundance within a water system.

Endotoxin levels may be minimized by controlling the introduction of free endotoxins and microorganisms in the feed water and minimizing microbial proliferation in the system. This may

be accomplished through the normal exclusion or removal action afforded by various unit operations within the treatment system as well as through system sanitization. Other control methods include the use of ultrafilters or charge modified filters, either in-line or at the point of use. The presence of endotoxins may be monitored as described in the chapter *Bacterial Endotoxins Test* (85).

MICROBIAL ENUMERATION CONSIDERATIONS

The objective of a water system microbiological monitoring program is to provide sufficient information to control and assess the microbiological quality of the water produced. Product quality requirements should dictate water quality specifications. An appropriate level of control may be maintained by using data trending techniques and, if necessary, limiting specific contraindicated microorganisms. Consequently, it may not be necessary to detect all of the microorganisms species present in a given sample. The monitoring program and methodology should indicate adverse trends and detect microorganisms that are potentially harmful to the finished product, process, or consumer. Final selection of method variables should be based on the individual requirements of the system being monitored.

It should be recognized that there is no single method that is capable of detecting all of the potential microbial contaminants of a water system. The methods used for microbial monitoring should be capable of isolating the numbers and types of organisms that have been deemed significant relative to in-process system control and product impact for each individual system. Several criteria should be considered when selecting a method to monitor the microbial content of a pharmaceutical water system. These include method sensitivity, range of organisms types or species recovered, sample processing throughput, incubation period, cost, and methodological complexity. An alternative consideration to the use of the classical "culture" approaches is a sophisticated instrumental or rapid test method that may yield more timely results. However, care must be exercised in selecting such an alternative approach to ensure that it has both sensitivity and correlation to classical culture approaches, which are generally considered the accepted standards for microbial enumeration.

Consideration should also be given to the timeliness of microbial enumeration testing after sample collection. The number of detectable planktonic bacteria in a sample collected in a scrupulously clean sample container will usually drop as time passes. The planktonic bacteria within the sample will tend to either die or to irretrievably adsorb to the container walls, reducing the number of viable planktonic bacteria that can be withdrawn from the sample for testing. The opposite effect can also occur if the sample container is not scrupulously clean and contains a low concentration of some microbial nutrient that could promote microbial growth within the sample container. Because the number of recoverable bacteria in a sample can change positively or negatively over time after sample collection, it is best to test the samples as soon as possible after being collected. If it is not possible to test the sample within about 2 h of collection, the sample should be held at refrigerated temperatures (2°–8°) for a maximum of about 12 h to maintain the microbial attributes until analysis. In situations where even this is not possible (such as when using off-site contract laboratories), testing of these refrigerated samples should be performed within 48 h after sample collection. In the delayed testing scenario, the recovered microbial levels may not be the same as would have been recovered had the testing been performed shortly after sample collection. Therefore, studies should be performed to determine the existence and acceptability of potential microbial enumeration aberrations caused by protracted testing delays.

The Classical Culture Approach

Classical culture approaches for microbial testing of water include but are not limited to pour plates, spread plates, membrane filtration, and most probable number (MPN) tests. These methods are generally easy to perform, are less expensive, and provide excellent sample processing throughput. Method sensitivity can be increased via the use of larger sample sizes. This strategy is used in the membrane filtration method. Culture approaches are further defined by the type of medium used in combination with the incubation temperature and duration. This combination should be selected according to the monitoring needs presented by a specific water system as well as its ability to recover the microorganisms of interest: those that could have a detrimental effect on the product or process uses as well as those that reflect the microbial control status of the system.

There are two basic forms of media available for traditional microbiological analysis: "high nutrient" and "low nutrient". High nutrient media, such as plate count agar (TGYA) and m-HPG agar (formerly m-SPC agar), are intended as general media for the isolation and enumeration of heterotrophic or "copiotrophic" bacteria. Low nutrient media, such as R2A agar and NWRI agar (HPCA), may be beneficial for isolating slow growing "oligotrophic" bacteria and bacteria that require lower levels of nutrients to grow optimally. Often some facultative oligotrophic bacteria are able to grow on high nutrient media and some facultative copiotrophic bacteria are able to grow on low nutrient media, but this overlap is not complete. Low nutrient and high nutrient cultural approaches may be concurrently used, especially during the validation of a water system, as well as periodically thereafter. This concurrent testing could determine if any additional numbers or types of bacteria can be preferentially recovered by one of the approaches. If so, the impact of these additional isolates on system control and the end uses of the water could be assessed. Also, the efficacy of system controls and sanitization on these additional isolates could be assessed.

Duration and temperature of incubation are also critical aspects of a microbiological test method. Classical methodologies using high nutrient media are typically incubated at 30°–35° for 48–72 h. Because of the flora in certain water systems, incubation at lower temperatures (e.g., 20°–25°) for longer periods (e.g., 5–7 days) can recover higher microbial counts when compared to classical methods. Low nutrient media are designed for these lower temperature and longer incubation conditions (sometimes as long as 14 days to maximize recovery of very slow growing oligotrophs or sanitant-injured microorganisms), but even high nutrient media can sometimes increase their recovery with these longer and cooler incubation conditions. Whether or not a particular system needs to be monitored using high or low nutrient media with higher or lower incubation temperatures or shorter or longer incubation times should be determined during or prior to system validation and periodically reassessed as the microbial flora of a new water system gradually establish a steady state relative to its routine maintenance and sanitization procedures. The establishment of a "steady state" can take months or even years and can be perturbed by a change in use patterns, a change in routine and preventative maintenance or sanitization procedures, and frequencies, or any type of system intrusion, such as for component replacement, removal, or addition. The decision to use longer incubation periods should be made after balancing the need for timely information and the type of corrective actions required when an alert or action level is exceeded with the ability to recover the microorganisms of interest.

The advantages gained by incubating for longer times, namely recovery of injured microorganisms, slow growers, or more fastidious microorganisms, should be balanced against

the need to have a timely investigation and to take corrective action, as well as the ability of these microorganisms to detrimentally affect products or processes. In no case, however, should incubation at 30°–35° be less than 48 h or less than 96 h at 20°–25°.

Normally, the microorganisms that can thrive in extreme environments are best cultivated in the laboratory using conditions simulating the extreme environments from which they were taken. Therefore, thermophilic bacteria might be able to exist in the extreme environment of hot pharmaceutical water systems, and if so, could only be recovered and cultivated in the laboratory if similar thermal conditions were provided. Thermophilic aquatic microorganisms do exist in nature, but they typically derive their energy for growth from harnessing the energy from sunlight, from oxidation/reduction reactions of elements such as sulfur or iron, or indirectly from other microorganisms that do derive their energy from these processes. Such chemical/nutritional conditions do not exist in high-purity water systems, whether ambient or hot. Therefore, it is generally considered pointless to search for thermophiles from hot pharmaceutical water systems owing to their inability to grow there.

The microorganisms that inhabit hot systems tend to be found in much cooler locations within these systems, for example, within use-point heat exchangers or transfer hoses. If this occurs, the kinds of microorganisms recovered are usually of the same types that might be expected from ambient water systems. Therefore, the mesophilic microbial cultivation conditions described later in this chapter are usually adequate for their recovery.

“Instrumental” Approaches

Examples of instrumental approaches include microscopic visual counting techniques (e.g., epifluorescence and immunofluorescence) and similar automated laser scanning approaches and radiometric, impedometric, and biochemically based methodologies. These methods all possess a variety of advantages and disadvantages. Advantages could be their precision and accuracy or their speed of test result availability as compared to the classical cultural approach. In general, instrument approaches often have a shorter lead time for obtaining results, which could facilitate timely system control. This advantage, however, is often counterbalanced by limited sample processing throughput due to extended sample collection time, costly and/or labor-intensive sample processing, or other instrument and sensitivity limitations.

Furthermore, instrumental approaches are typically destructive, precluding subsequent isolate manipulation for characterization purposes. Generally, some form of microbial isolate characterization, if not full identification, may be a required element of water system monitoring. Consequently, culturing approaches have traditionally been preferred over instrumental approaches because they offer a balance of desirable test attributes and post-test capabilities.

Suggested Methodologies

The following general methods were originally derived from *Standard Methods for the Examination of Water and Wastewater*, 17th Edition, American Public Health Association, Washington, DC 20005. Although this publication has undergone several revisions since its first citation in this chapter, the methods are still considered appropriate for establishing trends in the number of colony-forming units observed in the routine microbiological monitoring of pharmaceutical waters. It is recognized, however, that other combinations of media and incubation time and temperature may occasionally or even consistently result in higher numbers of colony-forming units being observed and/or different species being recovered.

The extended incubation periods that are usually required by some of the alternative methods available offer disadvantages that may outweigh the advantages of the higher counts that may be obtained. The somewhat higher baseline counts that might be observed using alternate cultural conditions would not necessarily have greater utility in detecting an excursion or a trend. In addition, some alternate cultural conditions using low nutrient media tend to lead to the development of microbial colonies that are much less differentiated in colonial appearance, an attribute that microbiologists rely on when selecting representative microbial types for further characterization. It is also ironic that the nature of some of the slow growers and the extended incubation times needed for their development into visible colonies may also lead to those colonies being largely nonviable, which limits their further characterization and precludes their subculture and identification.

Methodologies that can be suggested as generally satisfactory for monitoring pharmaceutical water systems are as follows. However, it must be noted that these are not referee methods nor are they necessarily optimal for recovering microorganisms from all water systems. The users should determine through experimentation with various approaches which methodologies are best for monitoring their water systems for in-process control and quality control purposes as well as for recovering any contraindicated species they may have specified.

<i>Drinking Water</i>	Pour Plate Method or Membrane Filtration Method ^a
-	Sample volume—1.0 mL minimum ^b Growth medium—Plate Count Agar ^c Incubation time—48–72 h minimum Incubation temperature—30°–35°
<i>Purified Water</i>	Pour Plate Method or Membrane Filtration Method ^a
-	Sample volume—1.0 mL minimum ^b Growth medium—Plate Count Agar ^c Incubation time—48–72 h minimum Incubation temperature—30°–35°
<i>Water for Injection</i>	Membrane Filtration Method ^a
-	Sample volume—100 mL minimum ^b Growth medium—Plate Count Agar ^c Incubation time—48–72 h minimum Incubation temperature—30°–35°
<p>^a A membrane filter with a rating of 0.45 µm is generally considered preferable, although the cellular width of some of the bacteria in the sample may be narrower than this. The efficiency of the filtration process still allows the retention of a very high percentage of these smaller cells and is adequate for this application. Filters with smaller ratings may be used if desired, but for a variety of reasons the ability of the retained cells to develop into visible colonies may be compromised, so count accuracy must be verified by a reference approach.</p> <p>^b When colony counts are low to undetectable using the indicated minimum sample volume, it is generally recognized that a larger sample volume should be tested in order to gain better assurance that the resulting colony count is more statistically representative. The sample volume to consider testing is dependent on the user's need to know (which is related to the established alert and action levels and the water system's microbial control capabilities) and the statistical reliability of the resulting colony count. In order to test a larger sample volume, it may be necessary to change testing techniques, e.g., changing from a pour plate to a membrane filtration approach. Nevertheless, in a very low to nil count scenario, a maximum sample volume of around 250–300 mL is usually considered a reasonable balance of sample collecting and processing ease and increased statistical reliability. However, when sample volumes larger than about 2 mL are needed, they can only be processed using the membrane filtration method.</p> <p>^c Also known as Standard Methods Agar, Standard Methods Plate Count Agar, or TGYA, this medium contains tryptone (pancreatic digest of casein), glucose, and yeast extract.</p>	

IDENTIFICATION OF MICROORGANISMS

Identifying the isolates recovered from water monitoring methods may be important in instances where specific waterborne microorganisms may be detrimental to the products or processes in which the water is used. Microorganism information such as this may also be useful when identifying the source of microbial contamination in a product or process. Often a limited group of microorganisms is routinely recovered from a water system. After repeated recovery and

characterization, an experienced microbiologist may become proficient at their identification based on only a few recognizable traits such as colonial morphology and staining characteristics. This may allow for a reduction in the number of identifications to representative colony types, or, with proper analyst qualification, may even allow testing shortcuts to be taken for these microbial identifications.

ALERT AND ACTION LEVELS AND SPECIFICATIONS

Although the use of alert and action levels is most often associated with microbial data, they can be associated with any attribute. In pharmaceutical water systems, almost every quality attribute, other than microbial quality, can be very rapidly determined with near real time results. These short delay data can give immediate system performance feedback, serving as ongoing process control indicators. However, because some attributes may not continuously be monitored or have a long delay in data availability (like microbial monitoring data), properly established *Alert and Action Levels and Specifications* can serve as an early warning or indication of a potentially approaching quality shift occurring between or at the next periodic monitoring. In a validated water system, process controls should yield relatively constant and more than adequate values for these monitored attributes such that their *Alert and Action Levels and Specifications* are infrequently breached.

As process control indicators, alert and action levels are designed to allow remedial action to occur that will prevent a system from deviating completely out of control and producing water unfit for its intended use. This "intended use" minimum quality is sometimes referred to as a "specification" or "limit". In the opening paragraphs of this chapter, rationale was presented for no microbial specifications being included within the body of the bulk water (*Purified Water* and *Water for Injection*) monographs. This does not mean that the user should not have microbial specifications for these waters. To the contrary, in most situations such specifications should be established by the user. The microbial specification should reflect the maximum microbial level at which the water is still fit for use without compromising the quality needs of the process or product where the water is used. Because water from a given system may have many uses, the most stringent of these uses should be used to establish this specification.

Where appropriate, a microbial specification could be qualitative as well as quantitative. In other words, the number of total microorganisms may be as important as the number of a specific microorganism or even the absence of a specific microorganism. Microorganisms that are known to be problematic could include opportunistic or overt pathogens, nonpathogenic indicators of potentially undetected pathogens, or microorganisms known to compromise a process or product, such as by being resistant to a preservative or able to proliferate in or degrade a product. These microorganisms comprise an often ill defined group referred to as "objectionable microorganisms". Because objectionable is a term relative to the water's use, the list of microorganisms in such a group should be tailored to those species with the potential to be present and problematic. Their negative impact is most often demonstrated when they are present in high numbers, but depending on the species, an allowable level may exist, below which they may not be considered objectionable.

As stated above, alert and action levels for a given process control attribute are used to help maintain system control and avoid exceeding the pass/fail specification for that attribute. Alert and action levels may be both quantitative and qualitative. They may involve levels of total microbial counts or recoveries of specific microorganisms. Alert levels are events or levels that,

when they occur or are exceeded, indicate that a process may have drifted from its normal operating condition. Alert level excursions constitute a warning and do not necessarily require a corrective action. However, alert level excursions usually lead to the alerting of personnel involved in water system operation as well as QA. Alert level excursions may also lead to additional monitoring with more intense scrutiny of resulting and neighboring data as well as other process indicators. Action levels are events or higher levels that, when they occur or are exceeded, indicate that a process is probably drifting from its normal operating range. Examples of kinds of action level "events" include exceeding alert levels repeatedly; or in multiple simultaneous locations, a single occurrence of exceeding a higher microbial level; or the individual or repeated recovery of specific objectionable microorganisms. Exceeding an action level should lead to immediate notification of both QA and personnel involved in water system operations so that corrective actions can immediately be taken to bring the process back into its normal operating range. Such remedial actions should also include efforts to understand and eliminate or at least reduce the incidence of a future occurrence. A root cause investigation may be necessary to devise an effective preventative action strategy. Depending on the nature of the action level excursion, it may also be necessary to evaluate its impact on the water uses during that time. Impact evaluations may include delineation of affected batches and additional or more extensive product testing. It may also involve experimental product challenges.

Alert and action levels should be derived from an evaluation of historic monitoring data called a trend analysis. Other guidelines on approaches that may be used, ranging from "inspectional" to statistical evaluation of the historical data have been published. The ultimate goal is to understand the normal variability of the data during what is considered a typical operational period. Then, trigger points or levels can be established that will signal when future data may be approaching (alert level) or exceeding (action level) the boundaries of that "normal variability". Such alert and action levels are based on the control capability of the system as it was being maintained and controlled during that historic period of typical control.

In new water systems where there is very limited or no historic data from which to derive data trends, it is common to simply establish initial alert and action levels based on a combination of equipment design capabilities but below the process and product specifications where water is used. It is also common, especially for ambient water systems, to microbiologically "mature" over the first year of use. By the end of this period, a relatively steady state microbial population (microorganism types and levels) will have been allowed or promoted to develop as a result of the collective effects of routine system maintenance and operation, including the frequency of unit operation rebeddings, backwashings, regenerations, and sanitizations. This microbial population will typically be higher than was seen when the water system was new, so it should be expected that the data trends (and the resulting alert and action levels) will increase over this "maturation" period and eventually level off.

A water system should be designed so that performance based alert and action levels are well below water specifications. With poorly designed or maintained water systems, the system owner may find that initial new system microbial levels were acceptable for the water uses and specifications, but the mature levels are not. This is a serious situation, which if not correctable with more frequent system maintenance and sanitization, may require expensive water system renovation or even replacement. Therefore, it cannot be overemphasized that water systems should be designed for ease of microbial control, so that when monitored against alert and action levels, and maintained accordingly, the water continuously meets all applicable

specifications.

An action level should not be established at a level equivalent to the specification. This leaves no room for remedial system maintenance that could avoid a specification excursion. Exceeding a specification is a far more serious event than an action level excursion. A specification excursion may trigger an extensive finished product impact investigation, substantial remedial actions within the water system that may include a complete shutdown, and possibly even product rejection.

Another scenario to be avoided is the establishment of an arbitrarily high and usually nonperformance-based action level. Such unrealistic action levels deprive users of meaningful indicator values that could trigger remedial system maintenance. Unrealistically high action levels allow systems to grow well out of control before action is taken, when their intent should be to catch a system imbalance before it goes wildly out of control.

Because alert and action levels should be based on actual system performance, and the system performance data are generated by a given test method, it follows that those alert and action levels should be valid only for test results generated by the same test method. It is invalid to apply alert and action level criteria to test results generated by a different test method. The two test methods may not equivalently recover microorganisms from the same water samples. Similarly invalid is the use of trend data to derive alert and action levels for one water system, but applying those alert and action levels to a different water system. Alert and action levels are water system and test method specific.

Nevertheless, there are certain maximum microbial levels above which action levels should never be established. Water systems with these levels should unarguably be considered out of control. Using the microbial enumeration methodologies suggested above, generally considered maximum action levels are 100 cfu/mL for *Purified Water* and 10 cfu/100 mL for *Water for Injection*. However, if a given water system controls microorganisms much more tightly than these levels, appropriate alert and action levels should be established from these tighter control levels so that they can truly indicate when water systems may be starting to trend out of control. These in-process microbial control parameters should be established well below the user-defined microbial specifications that delineate the water's fitness for use.

Special consideration is needed for establishing maximum microbial action levels for *Drinking Water* because the water is often delivered to the facility in a condition over which the user has little control. High microbial levels in *Drinking Water* may be indicative of a municipal water system upset, broken water main, or inadequate disinfection, and therefore, potential contamination with objectionable microorganisms. Using the suggested microbial enumeration methodology, a reasonable maximum action level for *Drinking Water* is 500 cfu/mL. Considering the potential concern for objectionable microorganisms raised by such high microbial levels in the feed water, informing the municipality of the problem so they may begin corrective actions should be an immediate first step. In-house remedial actions may or may not also be needed, but could include performing additional coliform testing on the incoming water and pretreating the water with either additional chlorination or UV light irradiation or filtration, or a combination of approaches.

Table of Contents

1. INTRODUCTION

2. SOURCE WATER CONSIDERATIONS

3. WATERS USED FOR PHARMACEUTICAL MANUFACTURING AND TESTING PURPOSES

3.1 Bulk Monographed Waters and Steam

3.2 Sterile Monographed Waters

3.3 Nonmonographed Waters

4. VALIDATION AND QUALIFICATION OF WATER PURIFICATION, STORAGE, AND DISTRIBUTION SYSTEMS

4.1 Validation Requirement

4.2 Validation Approach

4.3 Operational Use

5. DESIGN AND OPERATION OF PURIFIED WATER AND WATER FOR INJECTION SYSTEMS

9. ALERT AND ACTION LEVELS AND SPECIFICATIONS

9.1 Introduction

9.2 Examples of Critical Parameter Measurements

9.3 Purpose of the Measurements

9.4 Defining Alert and Action Levels and Specifications

1. INTRODUCTION

Water is widely used as a raw material, inactive ingredient, medicinal vehicle, and solvent in the processing, formulation, and manufacture of pharmaceutical products (dosage forms), active pharmaceutical ingredients (APIs), API intermediates, compendial articles, and analytical reagents as well as in cleaning applications.

This is an informational chapter on pharmaceutical water topics and includes some of the chemical and microbiological concerns unique to water and its preparation and uses. The chapter provides information about water quality attributes (that may or may not be included within a water monograph) and processing techniques that can be used to improve water quality. It also discusses water system validation and gives a description of minimum water quality standards that should be considered when selecting a water source including sampling and system controls. It is equally important for water systems to be operated and maintained in a state of control to provide assurance of operational stability and therefore the capability to provide water that meets established water quality standards.

This informational chapter is intended to be educational, and the user should also refer to existing regulations or guidelines that cover U.S. and international [International Conference on Harmonisation (ICH) or World Health Organization (WHO)] good manufacturing practice (GMP) issues, as well as operational and engineering guides and/or other regulatory guidance for water [e.g., from the Food and Drug Administration (FDA), Environmental Protection Agency (EPA), or WHO]. This chapter is not, and should not be considered, an all-inclusive document on pharmaceutical waters. It contains basic information and points to be considered for the processing, holding, monitoring, and use of water. It is the user's responsibility to ensure that:

1. The selection of the type and specifications of water is appropriate for its intended use.
2. Water production and quality meet applicable governmental regulations and guidance.
3. The pharmacopeial specifications for the types of water used in monographed articles are met.
4. Water used in the preparation of reagents for analysis or the performance of required tests meets USP requirements.

Control and monitoring of the chemical and endotoxin purity of waters are important for complying with the requirements of the monographs in this compendium. Attributes listed in *USP* monographs should be considered the *minimum* requirements. More stringent requirements may be needed for some applications to ensure suitability for particular uses. Basic guidance on the appropriate applications of waters can be found in the monographs and is also discussed further in this chapter.

Control of the microbiological quality of water is also important for many of its uses. This attribute is intentionally not specified in most water monographs. Microbiological control is discussed throughout this chapter, but especially in sections 4, 5, 6, 8, and 9.

This chapter contains various chemical, microbiological, processing, and engineering concepts of importance to users of water. Water system validation, process control levels, and specifications are also presented later in this chapter.

2. SOURCE WATER CONSIDERATIONS

Source water is the water that enters the facility. The origin of this source water can be from natural surface waters like rivers and reservoirs, deep-bed well waters, sea waters, or some combination of these, potentially including multiple locations of each type of source water. Thus, source water can be supplied from these various origins (public or private), from municipalities' on-site water sourcing, or by external delivery such as a truck. It is possible that source water may not be potable and safe to drink. Such water may require pretreatment to ensure that it meets drinking water standards. It is the responsibility of the users of any source water to ensure that the water used in the production of drug substances (API), as well as water for indirect drug product contact or for purification system feed water purposes meets, at a minimum, drinking (potable) water standards as defined by the requirements of the National Primary Drinking Water Regulations (NPDWR) (40 CFR 141) issued by the U.S. EPA or the drinking water regulations of the European Union (EU) or Japan, or the WHO drinking water guidelines (see 3.3.1 *Drinking Water*). These regulations establish limits on the types and quantities of certain chemical and microbiological contaminants and ensure that the water will contain safe quantities of chemical and microbial species.

Where water supplies are from regulated water utility companies, less stringent monitoring may be possible because the attributes may be tested regularly and ensured by the supplier (see 9.4.5 *Source Water Control*). Water being withdrawn from a nonregulated supply should be sampled and tested appropriately at a suitable frequency that takes into account local environmental and seasonal changes and other quality fluctuations. Testing should ensure conformance with one of the drinking water standards discussed above.

The use of water complying with one of these designated drinking waters as a source water allows water pretreatment systems to only be challenged to remove small quantities of potentially difficult-to-remove chemicals. Control of objectionable chemical contaminants at the source water stage eliminates the need to specifically test for some of them [e.g., trihalomethanes and elemental impurities (see *Elemental Impurities—Limits* (232))] after the water has been further purified, assuming there is no opportunity for recontamination.

Source waters can be used for nonproduct contact purposes such as for non-contact cooling systems. Such water may not normally be required to meet drinking water standards. Under such circumstances, the quality standards for this water when used in a pharmaceutical facility should be subject to quality standards established by the user and defensible to regulatory agencies.

3. WATERS USED FOR PHARMACEUTICAL MANUFACTURING AND TESTING PURPOSES

There are many different grades of water used for pharmaceutical purposes. Several are described in *USP* monographs that specify uses, acceptable methods of preparation, and quality attributes. These waters can be divided into two general types: bulk waters, which are typically produced on site where they are used; and sterile waters, which are produced, packaged, and sterilized to preserve microbial quality throughout their packaged shelf life. There are several specialized types of sterile waters that differ in their designated applications, packaging limitations, and other quality attributes. Monographed waters must meet the quality attributes as specified in the related monographs, and any *Notes* appearing in those monographs should be considered and addressed.

With the exception of *Bacteriostatic Water for Injection*, the monographed bulk and sterile waters have a statement indicating that there are no added substances, or no added

antimicrobial agents. In the case of antimicrobial agents, the purpose is to ensure that the sterile water product is rendered sterile based solely on its preparation, packaging, and storage. In the case of the more general statement, "no added substances", this requirement is intended to mean "no added substances that aren't sufficiently removed". Two specific examples support this intention, but there are many examples. First, the use of softeners is commonplace. A softener replaces calcium and magnesium ions with sodium, so technically you are adding two sodium ions for each hard ion. The purpose of sodium displacement is to protect downstream equipment from the hard water. The sodium ions are eventually removed sufficiently, and this is proven when the water sample passes the test for *Water Conductivity* (645). Another specific example is the use of ozone as a sanitant that is added to the storage tank for microbial control. This could be considered an added substance, unless the ozone is destroyed before use, as is normally the case. Other notable examples include the addition of chlorine to kill bacteria in the pretreatment system, use of bisulfite to chemically reduce chlorine to chloride and protect downstream equipment, and use of a nitrogen blanket for protection from atmospheric contamination.

There are also other types of water for which there are no monographs. These are waters with names given for descriptive purposes only. Many of these waters are used in specific analytical methods. The descriptive titles may imply certain quality attributes or modes of preparation, but these nonmonographed waters may not necessarily adhere strictly to the stated or implied modes of preparation or specified attributes. Waters produced by other means or controlled by other test attributes, or even a monographed water, may equally satisfy the intended uses for these waters. It is the user's responsibility to ensure that such waters, even if produced and controlled exactly as stated, are suitable for their intended use. Wherever the term "water" is used within this compendium without other descriptive adjectives or clauses, the intent is that water of no less purity than USP Purified Water be used (see 3.1.1 *Purified Water*). A brief description of the various types of waters commonly associated with pharmaceutical applications and their significant uses or attributes follows.

Figure 1 may be helpful in understanding some of the various types of waters, their preparation, and uses.

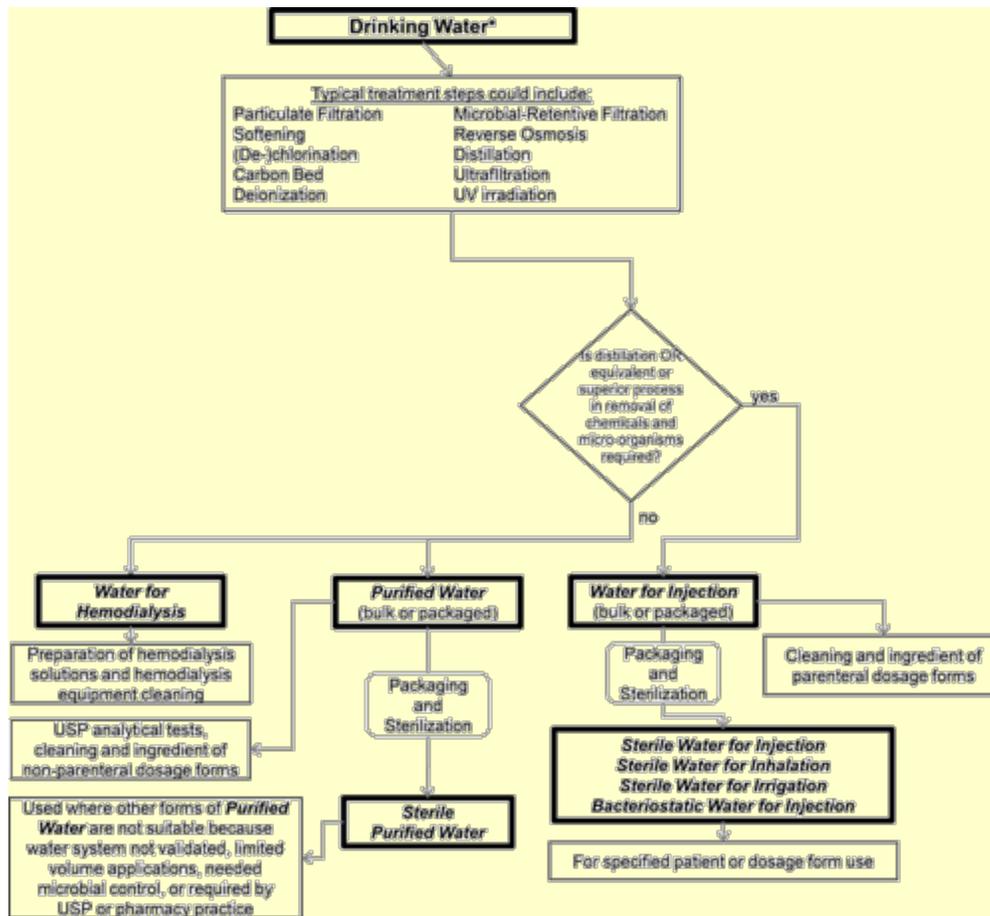

Figure 1. Water for pharmaceutical purposes. *Complying with U.S. EPA NPDWR or the drinking water regulations of EU or Japan or WHO.

3.1 Bulk Monographed Waters and Steam

The following waters are generally produced in large volumes using a multiple-unit operation water system. These waters are typically distributed in a piping system for use at the same site.

PURIFIED WATER

Purified Water (see the *USP* monograph) is used as an excipient in the production of nonparenteral preparations and in other pharmaceutical applications, such as the cleaning of nonparenteral product-contact components and equipment. Unless otherwise specified, Purified Water is also to be used as the minimum water quality for all tests and assays in which “water” is indicated (see *General Notices and Requirements 8.230.30*). This applies regardless of the font and letter case used in its spelling.

The minimal quality of source water for the production of *Purified Water* is Drinking Water whose attributes are prescribed by the U.S. EPA, EU, Japan, or WHO. This source water may be purified using unit operations that include deionization, distillation, ion exchange, reverse osmosis, filtration, or other suitable purification procedures. Purified Water must meet the requirements for ionic and organic chemical purity and must be protected from microbial contamination. Purified Water systems must be validated to reliably and consistently produce and distribute water of acceptable chemical and microbiological quality. Purified Water systems that function under ambient conditions are particularly susceptible to the establishment of

biofilms of microorganisms, which can be the source of undesirable levels of viable microorganisms or endotoxins in the water. These ambient Purified Water systems require frequent sanitization and microbiological monitoring to ensure that the water reaching the points of use has appropriate microbiological quality.

The *Purified Water* monograph also allows bulk packaging for commercial use elsewhere. In contrast to *Sterile Purified Water*, packaged *Purified Water* is not required to be sterile. Because there is potential for microbial contamination and other quality changes in this packaged nonsterile water, this form of Purified Water should be prepared and stored in a manner that limits microbial growth, and/or should be used in a timely fashion before microbial proliferation renders it unsuitable for its intended use. Also, depending on the material used for packaging, extractable compounds could be leaching into the water from the packaging. Although this article is required to meet the same chemical purity standards as the bulk water, extractables from the packaging will likely render the packaged water less chemically pure than the bulk water. The nature of these impurities may even render the water an inappropriate choice for some applications. It is the user's responsibility to ensure fitness for use of this packaged article when it is used in manufacturing, clinical, or analytical applications where the purer bulk form of the water is indicated.

WATER FOR INJECTION

Water for Injection (see the *USP* monograph) is used as an excipient in the production of parenteral and other preparations where product endotoxin content must be controlled, and in other pharmaceutical applications, such as the cleaning of certain equipment and parenteral product-contact components.

The minimal quality of source water for the production of *Water for Injection* is Drinking Water whose attributes are prescribed by the U.S. EPA, EU, Japan, or WHO. This source water may be treated to render it suitable for subsequent final purification steps, such as distillation (or whatever other validated process is used, according to the monograph). The finished water must meet all of the chemical requirements specified in the monograph, as well as an additional bacterial endotoxin specification. Because endotoxins are produced by the kinds of microorganisms that are prone to inhabit water systems, the equipment and procedures used by the system to purify, store, and distribute *Water for Injection* should be designed to control microbial contamination and must be designed to remove incoming endotoxins from the source water. *Water for Injection* systems must be validated to reliably and consistently produce and distribute this quality of water.

The *Water for Injection* monograph also allows bulk packaging for commercial use. In contrast to *Sterile Water for Injection*, packaged *Water for Injection* is not required to be sterile. However, to preclude significant changes in its microbial and endotoxins content during storage, this form of Water for Injection should be prepared and stored in a manner that limits microbial introduction and growth and/or should be used in a timely fashion before microbial proliferation renders it unsuitable for its intended use. Also, depending on the material used for packaging, extractable compounds could be leaching into the water from the packaging. Although this article is required to meet the same chemical purity standards as the bulk water, extractables from the packaging will likely render the packaged water less chemically pure than the bulk water. The nature of these impurities may even render the water an inappropriate choice for some applications. It is the user's responsibility to ensure fitness for use of this packaged article when it is used in manufacturing, clinical, or analytical applications where the

purier bulk form of the water is indicated.

WATER FOR HEMODIALYSIS

Water for Hemodialysis (see the *USP* monograph) is used for hemodialysis applications, primarily the dilution of hemodialysis concentrate solutions. The minimal quality of source water for the production of *Water for Hemodialysis* is Drinking Water whose attributes are prescribed by the U.S. EPA, EU, Japan, or WHO. *Water for Hemodialysis* has been further purified to reduce chemical and microbiological components, and it is produced and used on site. This water contains no added antimicrobial agents, and it is not intended for injection. *Water for Hemodialysis* must meet all of the chemical requirements specified in the monograph as well as an additional bacterial endotoxin specification. The microbial limits attribute for this water is unique among the "bulk" water monographs, but is justified on the basis of this water's specific application, which has microbial content requirements related to its safe use. The bacterial endotoxins attribute is likewise established at a level related to its safe use.

PURE STEAM

Pure Steam (see the *USP* monograph) is also sometimes referred to as "clean steam". It is used where the steam or its condensate would directly contact official articles or article-contact surfaces, such as during their preparation, sterilization, or cleaning where no subsequent processing step is used to remove any impurity residues. These Pure Steam applications include, but are not limited to, porous load sterilization processes, product or cleaning solutions heated by direct steam injection, or humidification of processes where steam injection is used to control the humidity inside processing vessels where the official articles or their in-process forms are exposed. The primary intent of using this quality of steam is to ensure that official articles or article-contact surfaces exposed to it are not contaminated by residues within the steam.

The minimal quality of source water for the production of *Pure Steam* is Drinking Water whose attributes are prescribed by the U.S. EPA, EU, Japan, or WHO, and which has been suitably treated. The water is then vaporized with suitable mist elimination, and distributed under pressure. The sources of undesirable contaminants within *Pure Steam* could arise from entrained source water droplets, anticorrosion steam additives, or residues from the steam production and distribution system itself. The chemical tests in the *Pure Steam* monograph should detect most of the contaminants that could arise from these sources. If an official article is exposed to *Pure Steam* and it is intended for parenteral use or other applications where the pyrogenic content must be controlled, the *Pure Steam* must additionally meet the specification for *Bacterial Endotoxins Test* (85).

These purity attributes are measured in the condensate of the article, rather than the article itself. This, of course, imparts great importance to the cleanliness of the process for *Pure Steam* condensate generation and collection, because it must not adversely impact the quality of the resulting condensed fluid.

Other steam attributes not detailed in the monograph, particularly the presence of even small quantities of noncondensable gases or the existence of a superheated or dry state, may also be important for applications such as sterilization. The large release of energy (latent heat of condensation) as water changes from the gaseous to the liquid state is the key to steam's sterilization efficacy and its efficiency, in general, as a heat transfer agent. If this phase change (condensation) is not allowed to happen because the steam is extremely hot and is in a

persistent superheated, dry state, then its usefulness could be seriously compromised. Noncondensable gases in steam tend to stratify or collect in certain areas of a steam sterilization chamber or its load. These surfaces would thereby be at least partially insulated from the steam condensation phenomenon, preventing them from experiencing the full energy of the sterilizing conditions. Therefore, control of these kinds of steam attributes, in addition to its chemical purity, may also be important for certain Pure Steam applications. However, because these additional attributes are use-specific, they are not mentioned in the *Pure Steam* monograph.

Note that lower-purity "plant steam" may be used in the following applications: 1) for steam sterilization of nonproduct-contact nonporous loads, 2) for general cleaning of nonproduct-contact equipment, 3) as a nonproduct-contact heat-exchange medium, and 4) in all compatible applications involved in bulk pharmaceutical chemical and API manufacture.

Finally, because *Pure Steam* is lethal to microbes, monitoring of microbial control within a steam system is unnecessary, as is microbial analysis of the steam condensate.

3.2 Sterile Monographed Waters

The following monographed waters are packaged forms of either *Purified Water* or *Water for Injection* that have been sterilized to preserve their microbiological properties. These waters may have specific intended uses as indicated by their names, and may also have restrictions on the packaging configurations related to those uses. In general, these sterile waters may be used in a variety of applications in lieu of the bulk forms of water from which they were derived. However, there is a substantial difference between the acceptance criteria for the chemical purities of these bulk waters versus sterile waters. The specifications for sterile waters differ from those of bulk waters to accommodate a wide variety of packaging types, properties, volumes, and uses. As a result, the inorganic and organic impurity specifications are not equivalent for bulk and packaged waters. The packaging materials and elastomeric closures are the primary sources of these impurities, which tend to increase over the shelf life of these packaged articles. Therefore, due consideration must be given to the chemical purity suitability at the time of use of the sterile forms of water when used in manufacturing, analytical, and cleaning applications in lieu of the bulk waters from which these waters were derived. It is the user's responsibility to ensure fitness for use of these sterile packaged waters in these applications. Nevertheless, for the applications discussed below for each sterile water, their respective purities and packaging restrictions generally render them suitable by definition.

STERILE PURIFIED WATER

Sterile Purified Water (see the *USP* monograph) is *Purified Water*, packaged and rendered sterile. It can be used in the preparation of nonparenteral compendial dosage forms or in analytical applications requiring *Purified Water* where 1) access to a validated *Purified Water* system is not practical, 2) only a relatively small quantity is needed, 3) *Sterile Purified Water* is required by specific monograph or pharmacy practice, or 4) bulk packaged *Purified Water* is not suitably controlled for the microbiological quality for its intended use.

STERILE WATER FOR INJECTION

Sterile Water for Injection (see the *USP* monograph) is *Water for Injection* packaged and rendered sterile. It is used for extemporaneous prescription compounding and as a sterile diluent for parenteral products. It may also be used for other applications where bulk *Water for*

Injection or *Purified Water* is indicated but access to a validated water system is not practical, or where only a relatively small quantity is needed. *Sterile Water for Injection* is packaged in single-dose containers not larger than 1 L.

BACTERIOSTATIC WATER FOR INJECTION

Bacteriostatic Water for Injection (see the *USP* monograph) is *Water for Injection*, packaged and rendered sterile, to which has been added one or more suitable antimicrobial preservatives. It is intended to be used as a diluent in the preparation of parenteral products, most typically for multi-dose products that require repeated content withdrawals. It may be packaged in single-dose or multiple-dose containers not larger than 30 mL.

STERILE WATER FOR IRRIGATION

Sterile Water for Irrigation (see the *USP* monograph) is *Water for Injection* packaged and sterilized in single-dose containers which may be larger than 1 L and allow rapid delivery of their contents. Due to its usage, *Sterile Water for Irrigation* is not required to meet *Particulate Matter in Injections* (788). It may also be used in other applications that do not have particulate matter specifications, where bulk *Water for Injection* or *Purified Water* is indicated but where access to a validated water system is not practical, or where somewhat larger quantities are needed than are provided as *Sterile Water for Injection*.

STERILE WATER FOR INHALATION

Sterile Water for Inhalation (see the *USP* monograph) is *Water for Injection* that is packaged and rendered sterile and is intended for use in inhalators and in the preparation of inhalation solutions. This monograph has no requirement to meet (788); it carries a less stringent specification for bacterial endotoxins than *Sterile Water for Injection*, and therefore is not suitable for parenteral applications.

3.3 Nonmonographed Waters

In addition to the bulk monographed waters described above, nonmonographed waters can also be used in pharmaceutical processing steps such as cleaning and synthetic steps, and also as a starting material for further purification or testing purposes. Unless otherwise specified in the compendium, the minimum quality of water is *Purified Water*. [Note—The information in this chapter is not an all-inclusive discussion of all nonmonographed waters identified in the *USP-NF*.]

DRINKING WATER

Drinking Water can be referred to as Potable Water (meaning drinkable or fit to drink), National Primary Drinking Water, Primary Drinking Water, or EPA Drinking Water. Except where a singular drinking water specification is stated (such as the U.S. EPA's NPDWR, as cited in 40 CFR Part 141), this water must comply with the quality attributes of either the NPDWR or the drinking water regulations of the EU or Japan, or the *WHO Guidelines for Drinking-Water Quality*. Drinking Water may originate from a variety of sources including a public water supply, a private water supply (e.g., a well), or a combination of these sources (see 2. *Source Water Considerations*).

Drinking Water may be used in the early stages of cleaning pharmaceutical manufacturing equipment and product-contact components. Drinking Water is also the minimum quality of water that should be used for the preparation of official substances and other bulk pharmaceutical ingredients. Where compatible with the processes, the contaminant levels

allowed in Drinking Water are generally considered safe for use in preparing official substances and other drug substances. However, where required by the processing of the materials to achieve their required final purity, higher qualities of water may be needed for these manufacturing steps, perhaps even water as pure as *Water for Injection* or *Purified Water*. Such higher-purity waters, however, might require only selected attributes to be of higher purity than Drinking Water (see *Figure 2a* and *Figure 2b*). Drinking Water is the prescribed source or feed water for the production of bulk monographed pharmaceutical waters. The use of Drinking Water specifications establishes a reasonable set of maximum allowable levels of chemical and microbiological contaminants with which a water purification system will be challenged. Because seasonal variations in the quality attributes of the Drinking Water supply can occur, it is important to give due consideration to its uses. The processing steps in the production of pharmaceutical waters must be designed to accommodate this variability.

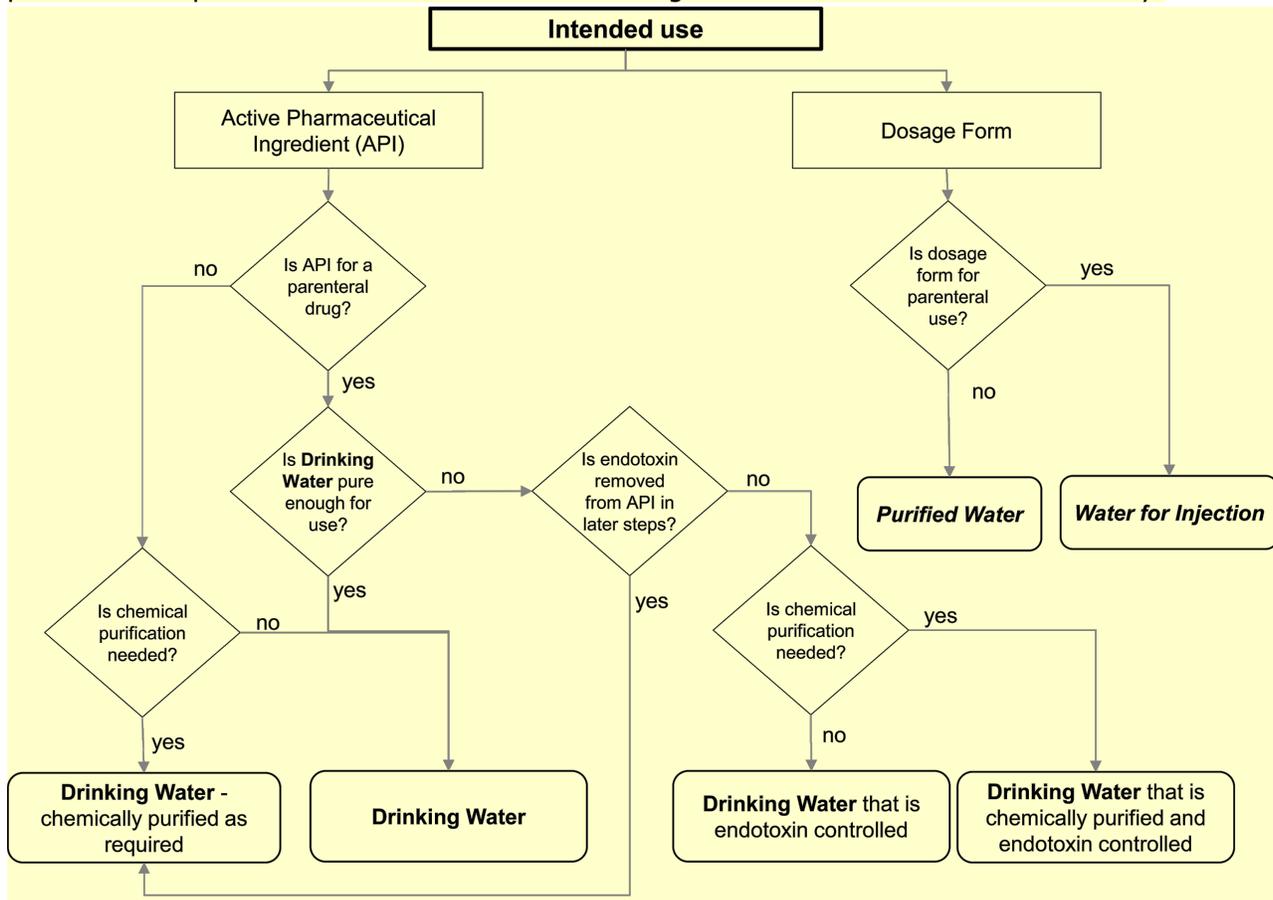

Figure 2a. Selection of water for pharmaceutical purposes: APIs and dosage forms.

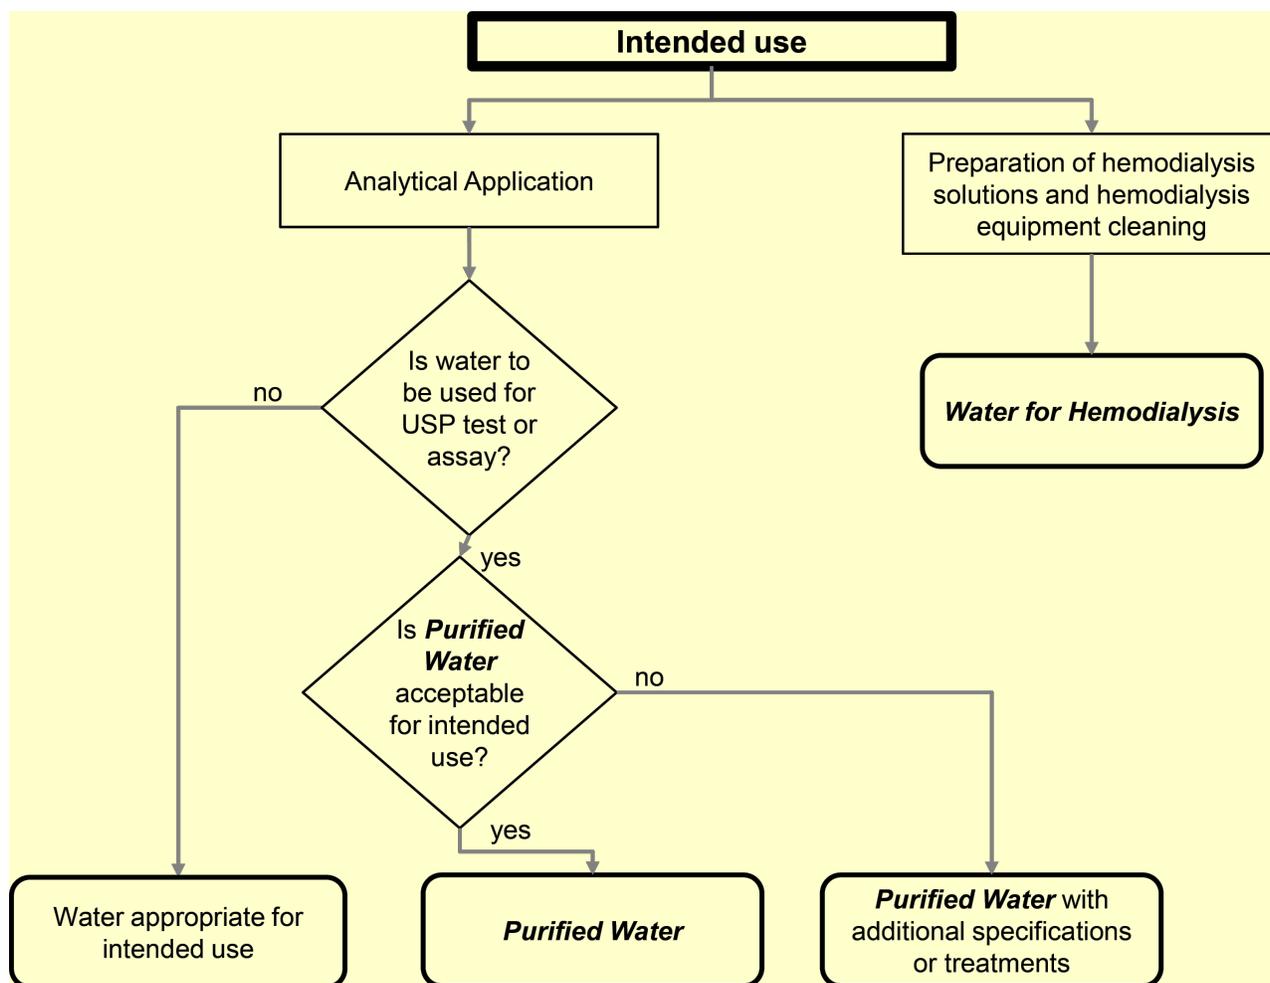

Figure 2b. Selection of water for pharmaceutical purposes: Analytical reagents.

OTHER NONMONOGRAPHED WATERS

In addition to Drinking Water, this compendium discusses waters with various other designations. These include waters of various quality levels for special uses such as, but not limited to, cleaning and testing purposes.

Both *General Notices and Requirements* (see *General Notices and Requirements 8.230.30*) and *Reagents, Indicators, and Solutions* (see introductory *RIS* section 4.7) clearly state that where the term “water” is indicated for use in analyses without grammatical qualification or other specification, the quality of the water must be *Purified Water*. However, numerous such qualifications do exist. Some of these qualifications involve adjectives describing methods of preparation, ranging from specifying the primary purification step to specifying additional purification. Other qualifications call for specific attribute “absences” to be met that might otherwise interfere with analytical processes. In most of these cases, the required attribute absences are not specifically tested. Sometimes, a further “purification process” is specified that ostensibly allows the water to adequately meet this required “absence attribute”.

However, preparation instructions for many reagents were carried forward from the innovator's laboratories to the originally introduced monograph for a particular *USP–NF* article or general test chapter. The quality of the reagent water described in these tests may reflect the water quality designation of the innovator's laboratory. These specific water designations may have originated without the innovator's awareness of the requirement for *Purified Water* in *USP–NF*

tests. Regardless of the original reason for the creation of these numerous special analytical waters, it is possible that the attributes of these special waters could now be met by the basic preparation steps and current specifications of *Purified Water*. In some cases, however, some of the cited post-processing steps are still necessary to reliably achieve the required attributes.

Users are not obligated to utilize specific and perhaps archaically generated forms of analytical water where alternatives with equal or better quality, availability, or analytical performance may exist. The consistency and reliability of operations for producing these alternative analytical waters should be verified so that the desired attributes are produced. In addition, any alternative analytical water must be evaluated on an application-by-application basis by the user to ensure its suitability. The following is a summary of the various types of nonmonographed analytical waters that are cited in the *USP-NF*. This is not an exhaustive listing. Those listed below are used in multiple locations. Several nonmonographed analytical waters and not included below because they are only found in one or perhaps two locations within this compendium.

Note that the names of many of the waters below imply a very low chemical impurity level. For example, "deionized water" implies that all the ions have been removed. However, in most cases discussed below, exposure of the water to air will result in the ingress of carbon dioxide (CO_2), leading to the formation of bicarbonate and hydrogen ions. Therefore, the removal of ions cannot be completely maintained for most analytical applications.

AMMONIA-FREE WATER

From a functional standpoint, *Ammonia-Free Water* must have a negligible ammonia concentration to avoid interference in tests sensitive for or to ammonia. Due to the nature of the uses of this water, *Purified Water* could be a reasonable alternative for these applications.

CARBON DIOXIDE-FREE WATER

Carbon Dioxide-Free Water is defined in the introductory portion of the *Reagents, Indicators, and Solutions* section of *USP-NF* as *Purified Water* that has been vigorously boiled for NLT 5 min, then cooled and protected from absorption of atmospheric carbon dioxide. Alternatively, this could be *Purified Water* that has a resistivity of NLT 18 Mohm-cm at 25°.

Because the absorption of atmospheric carbon dioxide lowers the pH of high-purity waters, most of the uses of Carbon Dioxide-Free Water are either associated as a solvent in pH-related or pH-sensitive determinations or as a solvent in bicarbonate-sensitive reagents or determinations.

The term *Carbon Dioxide-Free Water* is sometimes used improperly. Besides its use for pH or acidity/alkalinity tests, the purpose for using this water is not always clear. The intention could be to use water that was deaerated (free of dissolved air) or deionized (free of extraneous ions), or even *Purified Water* with an additional boiling step. Although boiling is highly effective for removing carbon dioxide (CO_2) as well as all other dissolved gasses, these gases are readily re-absorbed unless the water is protected. Even with protection, such as use of a stoppered container, re-absorption will occur over time as air will readily transmit through seals and diffuse through most materials. Deionization is also an efficient process for removing dissolved carbon dioxide. Carbon dioxide forms ionic bicarbonate in water, and will be subsequently removed by ion-exchange resins. However, the same problem of carbon dioxide re-absorption

will occur after the deionized water is exposed to air. Also, the deionization approach for creating Carbon Dioxide-Free Water does not deaerate the water or remove other dissolved gases such as oxygen (O₂); it only removes carbon dioxide and other ions.

Depending on the application, *Purified Water* may meet the requirements where Carbon Dioxide-Free Water is called for. This could also include pH or acidity or alkalinity tests. The pH of a sample of pure Deionized Water is, by definition, 7.0. When that same sample is exposed to typical environmental atmospheric conditions, the water sample will absorb carbon dioxide and result in a pH range of approximately 5.4–6.2 ([H⁺] is in the range of 4.0 × 10⁻⁶ M to 6.3 × 10⁻⁷ M). The added acidity caused by carbon dioxide absorption may be insignificant compared to the material being analyzed.

DISTILLED WATER

Distilled Water is produced by vaporizing Drinking Water or a higher quality of water and condensing it into a purer state. It is used primarily as a solvent for reagent preparation, and it is also specified in the execution of other aspects of tests, such as for rinsing an analyte, transferring a test material as a slurry, as a calibration standard or analytical blank, and for test apparatus cleaning. Distilled Water is also cited as the starting water to be used for making *High-Purity Water*. Because none of the cited uses of this water imply a need for a particular purity attribute that can only be derived by distillation, water meeting the requirements for *Purified Water* derived by other means of purification or *Water for Injection* could be equally suitable where Distilled Water is specified. It is the user's responsibility to verify the suitability of *Purified Water* or *Water for Injection*.

FRESHLY DISTILLED WATER

Freshly Distilled Water or "recently distilled water" is produced in the same manner as Distilled Water and should be used soon after its generation. This implies the need to avoid endotoxin contamination, as well as any other forms of contamination from the air or containers, that could arise with prolonged storage. Freshly Distilled Water is used for preparing solutions for subcutaneous test-animal injections and for a reagent solvent in tests for which there appears to be no particularly high water purity needed that could be ascribable to being "freshly distilled". In the test-animal application, the term "freshly distilled" and its testing use imply a chemical, endotoxin, and microbiological purity that could be equally satisfied by Water for Injection (although no reference is made to these chemical, endotoxin, or microbial attributes or specific protection from recontamination). For non-animal uses, water meeting the requirements for *Purified Water* derived by other means of purification and/or storage periods could be equally suitable where "recently distilled water" or Freshly Distilled Water is specified. It is the user's responsibility to verify the suitability of *Purified Water* or *Water for Injection*.

DEIONIZED WATER

Deionized Water can be produced by starting with either Drinking Water or Purified Water, depending upon monograph or testing procedures defined in the compendia. Deionized Water is produced by an ion-exchange process in which the cations and anions are replaced with H⁺ and OH⁻ ions by use of ion-exchange resins. Similar to *Distilled Water*, Deionized Water is used primarily as a solvent for reagent preparation, but it is also specified in the execution of other aspects of tests, such as for transferring an analyte within a test procedure, as a calibration standard or analytical blank, and for test apparatus cleaning. Also, none of the cited uses of this water imply any needed purity attribute that can only be achieved by deionization.

Therefore, water meeting the requirements for *Purified Water* that is derived by other means of purification could be equally suitable where Deionized Water is specified. It is the user's responsibility to verify the suitability of *Purified Water*.

DEIONIZED DISTILLED WATER

Deionized Distilled Water is produced by deionizing (see *Deionized Water*) Distilled Water. This water is used as a reagent in a liquid chromatography test that requires a low ionic or organic impurity level. Because of the importance of this high purity, water that meets the requirements for *Purified Water* may not be acceptable. High-Purity Water (see 3.3.10 *High-Purity Water*) could be a reasonable alternative to this water. It is the user's responsibility to verify the suitability of the alternative water used.

FILTERED WATER

Filtered Water is *Purified Water* that has been filtered to remove particles that could interfere with the analysis where this water is specified. It is sometimes used synonymously with Particle-Free Water and Ultra-Filtered Water and is cited in some monographs and general chapters as well as in *Reagents, Indicators, and Solutions*. Depending on its referenced location in *USP-NF*, it is variously defined as water that has been passed through filters rated as 1.2, 0.22, or 0.2 μm , or unspecified porosity rating. Even though the water names and the filter ratings used to produce these waters are defined inconsistently, the use of 0.2- μm filtered *Purified Water* should be universally acceptable for all applications where Particle-Free Water, Filtered Water, or Ultra-Filtered Water are specified.

HIGH-PURITY WATER

High-Purity Water may be prepared by deionizing previously distilled water and then filtering it through a 0.45- μm rated membrane. This water must have an in-line conductivity of NMT 0.15 $\mu\text{S}/\text{cm}$ (NLT 6.67 Megohm-cm) at 25°. If the water of this purity contacts the atmosphere even briefly as it is being used or drawn from its purification system, its conductivity will immediately increase by as much as about 1.0 $\mu\text{S}/\text{cm}$ as atmospheric carbon dioxide dissolves in the water and equilibrates to hydrogen and bicarbonate ions. Therefore, if the analytical use requires that water conductivity remains as high as possible or the bicarbonate/carbon dioxide levels be as low as possible, the water should be protected from atmospheric exposure. High-Purity Water is used as a reagent, as a solvent for reagent preparation, and for test apparatus cleaning where less stringent water specifications would not be considered acceptable. However, if a user's routinely available *Purified Water* is filtered and meets or exceeds the conductivity specifications of High-Purity Water, it could be used in lieu of High-Purity Water.

DEAERATED WATER

Deaerated Water or "degassed water" is *Purified Water* that has been treated to reduce the content of dissolved air by "suitable means" such as boiling, sonication, and/or stirring during the application of a partial vacuum, followed by immediate use or protection from air reabsorption.

OXYGEN-FREE WATER

Oxygen-Free Water is *Purified Water* that has been treated to remove or reduce dissolved oxygen. Such treatment could involve deaerating by boiling or sparging with an inert gas such as nitrogen or helium, followed by inert gas blanketing to prevent oxygen reabsorption. Any

procedure used for removing oxygen should be verified as reliably producing water that is fit for use.

WATER FOR BACTERIAL ENDOTOXINS TEST

Water for BET is also referred to as Limulus Amebocyte Lysate (LAL) Reagent Water. This type of water is often *Water for Injection*, which may have been sterilized. It is free from a level of endotoxin that would yield any detectable reaction or interference with the LAL reagent used in the BET (see (85)).

4. VALIDATION AND QUALIFICATION OF WATER PURIFICATION, STORAGE, AND DISTRIBUTION SYSTEMS

4.1 Validation Requirement

Establishing the reliability of pharmaceutical water purification, storage, and distribution systems requires demonstrating control of the process through an appropriate period of monitoring and observation. Finished water is typically continuously produced and used, while product and process attributes may only be periodically assessed. The quality of bulk finished water cannot be established by only testing monograph attributes. The unit operations in the pharmaceutical water system need to demonstrate that they are in control through monitoring of the process parameters and water quality. The advent of using conductivity and total organic carbon (TOC) to define chemical purity allows the user to more quantitatively assess the water's chemical purity and its variability as a function of routine treatment system maintenance and regeneration. Treatment processes must also demonstrate control of microbial attributes within the overall system. Some unit operations that are needed for chemical treatment may significantly increase microbial and bacterial endotoxin levels. These are later controlled by downstream unit operations. Knowledge of the treatment system processes and the effectiveness of control measures is needed to ensure that the pharmaceutical waters are acceptable for use.

Efficacy of the design, operation, sanitization, and control of the pharmaceutical water system is demonstrated through the monitoring of chemical and microbial attributes. A typical water system validation program involves an initial increased frequency of monitoring of the treatment system process parameters and sampling and testing of major process points to demonstrate the ability to produce the acceptable water and to characterize the operation of the system. This is followed by a life cycle approach of validation maintenance and monitoring.

4.2 Validation Approach

Validation is the program of documenting, to a high level of assurance, that a specific process is capable of consistently delivering product conforming to an established set of quality attributes. A validation program qualifies and documents the design, installation, operation, and performance of the system. A graphical representation of a typical water system validation life cycle is shown in *Figure 3*.

The validation protocol should be based on the boundaries of the water system and the critical water quality and process attributes needed to maintain consistent performance. The system boundary may stop at the point of use or may include the water transfer process. If the transfer process from the distribution system outlets to the water use locations (typically either with hoses or hard-piped equipment connections) is defined as outside the water system

boundary, then this transfer process still needs to be validated to not adversely affect the quality of the water as it is delivered for use. Because routine quality control (QC) microbial monitoring is performed for the same transfer process and components (e.g., hoses and heat exchangers) as that of routine water use [see 6.1.2 *Quality Control (QC) Sampling*], there is some logic to include this water transfer process within the distribution system validation.

VALIDATION ELEMENTS

Validation is accomplished through the use of a structured, documented process. The phases of this process include Design Qualification (DQ), Installation Qualification (IQ), Operational Qualification (OQ), Performance Qualification (PQ), and Validation Maintenance. The process is documented in a validation protocol. The elements may be in individual protocols for each phase, or integrated into variations of a DQ/IQ/OQ/PQ combined document format. The protocols are formally approved quality documents. Factory Acceptance Testing (FAT), Site Acceptance Testing (SAT), and commissioning testing of the system may supplement qualification tests for IQ or OQ provided that they are properly documented and reviewed; and if it can be shown that the system functionality is not affected by the transport and installation.

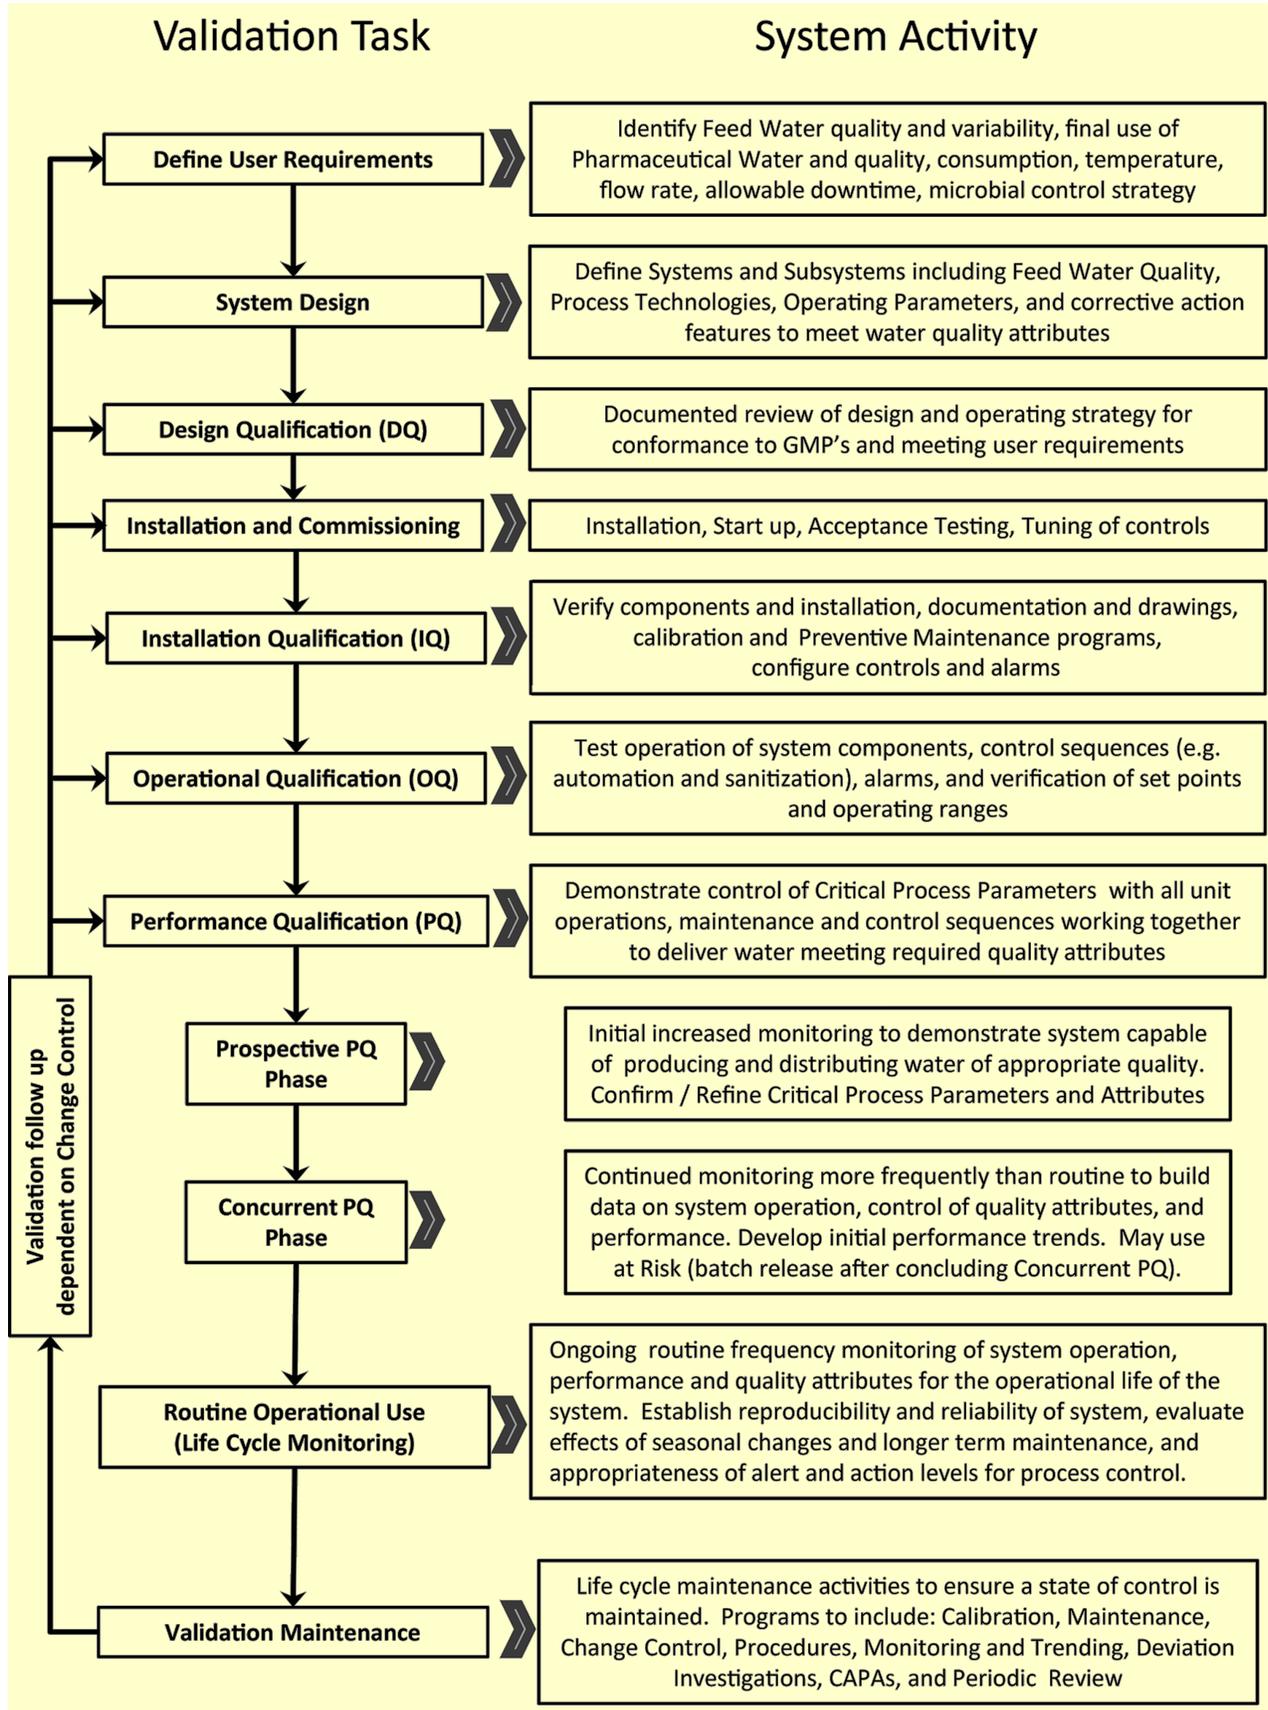

Figure 3. Water system validation life cycle.

USER REQUIREMENTS AND DESIGN QUALIFICATION, URS, FAT, SAT

The user requirements for the water system should identify the design, operation, maintenance, and quality elements needed to produce the desired water type from the available source water, including its anticipated attribute variability. The essential elements of quality need to be built in at this stage and any GMP risks mitigated to an acceptable level.

The review of the specifications, system design, components, functions, and operation should be performed to demonstrate that the system complies with GMPs and verify that the design meets the user requirements. This documented review may be performed as part of the overall design process or as a separate DQ.

INSTALLATION QUALIFICATION

An IQ protocol for a water system confirms that the system has been properly installed and documented. This may include verification of components, piping, installation, and weld quality; documentation of the specifications for all system components present; inspections to verify that the drawings accurately depict the final configuration of the water system and, where necessary, special tests to verify that the installation meets the design requirements. Additionally, the water system is readied for operational testing, including calibration of instruments, configuration of alarm levels and adjustment of operating parameters (e.g., flow rate, pressure).

OPERATIONAL QUALIFICATION

The OQ phase consisting of tests and inspections to verify that the equipment, system alerts, and controls are operating reliably and that appropriate Alert and Action Levels are established (this phase of qualification may overlap with aspects of IQ and PQ). During this phase of validation specific testing is performed for alarms, verifying control sequences, equipment functional checks, and verification of operating ranges. SOPs for all aspects of water system operation, maintenance, water use, water sampling, and testing, etc. should be in place and operator training completed. At the completion of the OQ, the water system has demonstrated that the components are operational and the system is producing suitable water.

PERFORMANCE QUALIFICATION

The prospective PQ stage considers two aspects of the water system: critical process parameters and critical water attribute parameters. These are evaluated in parallel by monitoring the water quality and demonstrating acceptable quality attributes while demonstrating control of the process parameters (see 6.3 *Validation Sampling Plans*). The initial PQ stage may result in refinement of process parameters to yield appropriate water quality. This PQ stage includes an increased frequency of monitoring for approximately 2–4 weeks, or sufficient time to generate adequate data to demonstrate that water meeting the appropriate quality attributes is produced and distributed. One of the reasons for this duration is that biofilm, the source of planktonic organisms in water samples, takes time to develop and to determine if the sanitization unit operations and processes are adequate to control microbial proliferation. The chemical control program adequacy is typically apparent in less time than it takes to see microbial control adequacy. However, chemical purification can be compromised by poor microbial control and, to a lesser degree, vice versa.

Once a level of control of microbial and chemical attributes has been demonstrated, the next phase of PQ is to continue the frequency of monitoring for approximately 2–4 weeks at a somewhat reduced level that will still give adequate data on system performance while using

the pharmaceutical water. The water may be used for manufacturing at risk, and the associated products may be released only after water quality attributes have been determined to be acceptable and this validation phase has been completed. At the completion of the second phase, the data should be formally reviewed and the system approved for operational use.

4.3 Operational Use

When the water system has been placed into operational use, monitoring of the water quality attributes and the system process parameters is performed at a routine frequency (see 6.4 *Routine Sampling Plans*) to ensure that they remain with a state of control during long-term variability from seasonal variations in source water quality, unit operation maintenance, system sanitization processes, and earlier-established Alert and Action Levels.

The water system should continue to be monitored and evaluated on an on-going basis following a life cycle approach using online instruments or samples for laboratory-based testing. The use of online instruments and process automation technology, such as conductivity, TOC, temperature, flow rate, and pressure can facilitate improved operational control of the attributes and parameters and for process release. Manual observation of operating parameters and laboratory-based testing is also appropriate and acceptable for monitoring and trend evaluation.

MONITORING

The frequency of routine monitoring should be based on the criticality of the finished water, capabilities of the process, and ability to maintain product water quality trends. Monitoring may be adjusted from the initial validation monitoring program when there is sufficient data to support a change (see 6.4 *Routine Sampling Plans*).

VALIDATION MAINTENANCE

Maintaining the validated state of control requires a life cycle approach. After the completion of the PQ and release of the water system for use, ongoing activities and programs have to be in place to maintain the validated state of control after the system has been validated and placed into service (see 5.4 *Operation, Maintenance, and Control*). This included unit operation, calibration, corrective maintenance, preventive maintenance, procedures, manuals and drawings, standardization of instruments, process parameter and quality attribute trending, change control, deviations, corrective and preventive actions (CAPA), training, records retention, logbooks, etc.

CHANGE CONTROL

Identification and control of changes made to unit operations and other system components, operation parameters, system sanitization, and laboratory processes or procedures need to be established. Not all changes will require validation follow up, but even minor ones, such as gasket elastomer changes could have an impact on quality attributes. The impact of the change on process parameters and quality attributes must be identified, evaluated and remediated. This may result in a selective validation activity to demonstrate the ongoing state of control for the system and ability to maintain water quality attributes.

Certain calibration and preventive maintenance activities may be considered routine tasks if they do not impact on system operation or water quality. Replacement of components needs to

be carefully evaluated. Replacement of components using exact parts generally does not affect system operation or control. Replacement of components with ones that have the similar functional specifications can be performed at risk with the critical specifications (e.g., material of construction, dimensions, flow rate, response factors) having been evaluated and the differences determined to be acceptable and documented within the change control system.

PERIODIC REVIEW

The water system qualification, maintenance history, calibration records, quality and process data, issues with the unit operations and any process variability, change control, and other validation maintenance data should be assessed periodically to determine impact on the state of control.

The review may result in adjustments to operating or sanitization processes, calibration or maintenance plans, or monitoring plans. This may also result in additional testing or repeating certain qualification tasks (re-qualification).

5. DESIGN AND OPERATION OF PURIFIED WATER AND WATER FOR INJECTION SYSTEMS

The design, installation, and operation of systems to produce *Purified Water* and *Water for Injection* include similar components, control techniques, and procedures. The quality attributes of the two waters differ only in the presence of a bacterial endotoxin requirement for *Water for Injection* and in their methods of preparation. The similarities in the quality attributes provide considerable common ground in the design of water systems to meet either requirement. The critical difference is the degree of control of the system and the final purification steps needed to ensure removal of bacteria and bacterial endotoxins and reductions in opportunities for biofilm re-development within those purification steps which could become *in situ* sources of bacteria and endotoxin in the finished water.

Many aspects of system design and operation relate to control and elimination of biofilm. Unit operations can cause the deterioration of water microbial attributes and the formation of biofilm on unit operation surfaces, even when properly maintained (see 8.2. *Biofilm Formation in Water Systems*).

Production of pharmaceutical water involves sequential unit operations (processing steps) that address specific water quality attributes and protect the operation of subsequent treatment steps. A typical evaluation process for selecting an appropriate water quality for a particular pharmaceutical purpose is shown in the decision trees in *Figure 2a* and *Figure 2b*. This diagram may be used to assist in defining requirements for specific water uses and in the selection of unit operations. The final unit operation used to produce *Water for Injection* is limited to distillation or other processes equivalent or superior to distillation in the removal of chemical impurities as well as microorganisms and their components, such as bacterial endotoxins. Distillation coupled with suitable pretreatment technologies has a long history of generally reliable performance (though not completely infallible) and can be validated as a unit operation for the production of *Water for Injection*. Other combinations of purification technologies may also be suitable in the production of *Water for Injection* if they can be shown through validation to be as effective and reliable as distillation in the removal of chemicals and microorganisms. The development of new designs and materials of construction for other technologies (such as reverse osmosis, electrodeionization, and ultrafiltration) that allow intermittent or continuous operation at hot bactericidal conditions show promise for a valid use

in producing *Water for Injection*.

5.1 Unit Operations Considerations

To achieve the quality attributes for pharmaceutical waters, multiple-unit operations are required. The design of the water purification system needs to take into consideration different aspects, including the source water quality, sanitization, pharmaceutical water quality attributes, uses of the water, and maintenance programs. Each unit operation contributes specific purification attributes associated with chemical and microbiological parameters.

The following is a brief description of selected unit operations and the design, installation, operation, maintenance, and monitoring parameter considerations associated with them. Not all unit operations are discussed, nor are all potential shortcomings addressed.

PREFILTRATION

The purpose of prefiltration—also referred to as initial, coarse, particulate, or depth filtration—is to remove solid contaminants from the incoming source water supply and protect downstream system components from particulates that can inhibit equipment performance and shorten their effective life. This coarse filtration technology primarily uses sieving effects for particle capture and a depth of filtration medium that has a high “dirt load” capacity. Such filtration units are available in a wide range of designs and for various applications. Removal efficiencies and capacities differ significantly, from granular bed filters such as multimedia or sand for larger water systems, to depth cartridges for smaller water systems. Unit and system configurations vary widely in the type of filtering media and the location in the process. Granular or cartridge prefilters are often situated at the beginning of the water purification system prior to unit operations designed to remove the source water disinfectants. Cartridge-type coarse filters may also be used to capture fines released from granular beds such as activated carbon and deionization beds. These locations, however, do not preclude the need for periodic microbial evaluation.

Design and operational issues that may impact the performance of depth filters include channeling of the filtering media, blockage from silt, microbial growth, and filtering-media loss during improper backwashing. Control methods involve pressure and flow monitoring during use and backwashing, sanitizing, and replacing filtering media. An important design concern is sizing of the filter to prevent channeling or media loss resulting from inappropriate water flow rates as well as proper sizing to minimize excessively frequent or infrequent backwashing or cartridge filter replacement.

ACTIVATED CARBON

Activated carbon beds, depending on the type and placement, are used to adsorb low-molecular-weight organic material, bacterial endotoxins, and oxidizing additives such as chlorine and chloramine compounds, removing them from the water. They are used to achieve certain quality attributes and to protect against reactions with downstream unit operations, stainless steel surfaces, resins, and membranes.

The chief operating concerns regarding activated carbon beds include the propensity to support bacterial growth, the potential for hydraulic channeling, the organic adsorption capacity, and insufficient contact time. Operation deficiencies may result in the release of bacteria, endotoxins, organic chemicals, and fine carbon particles.

Control measures may involve monitoring water flow rates and differential pressures, sanitizing with hot water or steam, backwashing, testing for adsorption capacity, and frequent replacement of the carbon bed. Monitoring of carbon bed unit operation may also include microbial loading, disinfectant chemical reduction, and TOC if used for TOC reduction. The use of hot water or steam for carbon bed sanitization is ineffective if there is channeling rather than even permeation through the bed. Channeling can be mitigated through design and proper flow rates during sanitization.

Microbial biofilm development on the surface of the granular carbon particles can cause adjacent bed granules to agglomerate. This may result in ineffective removal of trapped debris and fragile biofilm during backwashing, and ineffective sanitization.

Alternative technologies to activated carbon beds can be used to avoid their microbial challenges. These include disinfectant-neutralizing chemical additives and intense ultraviolet (UV) light for removal of chlorine, and regenerable organic scavenging deionizing resins for removal of organics.

ADDITIVES

Chemical additives are used in water systems 1) to control microorganisms by use of sanitizing agents, such as chlorine compounds and ozone; 2) to enhance the removal of suspended solids by use of flocculating agents; 3) to remove chlorine compounds; 4) to avoid scaling on reverse osmosis membranes; and 5) to adjust pH for more effective removal of carbonate and ammonia compounds by reverse osmosis. These additives do not constitute "added substances" as long as they are either removed by subsequent processing steps or are otherwise absent from the finished water. Control of additives to ensure a continuously effective concentration and subsequent monitoring to ensure their removal should be designed into the system and included in the monitoring program.

ORGANIC SCAVENGERS

Organic scavenging devices use macroreticular, weakly basic anion-exchange resins capable of removing negatively charged organic material and endotoxins from the water. Organic scavenger resins can be regenerated with appropriate biocidal caustic brine solutions. Operating concerns are associated with organic scavenging capacity; particulate, chemical, and microbiological fouling of the reactive resin surface; flow rate; regeneration frequency; and shedding of fines from the fragile resins. Control measures include TOC testing of influent and effluent, backwashing, monitoring hydraulic performance, and using downstream filters to remove resin fines.

SOFTENERS

Water softeners may be located either upstream or downstream of disinfectant removal units. They utilize sodium-based cation-exchange resins to remove water-hardness ions, such as calcium and magnesium, that could foul or interfere with the performance of downstream processing equipment such as reverse osmosis membranes, deionization devices, and distillation units. Water softeners can also be used to remove other lower affinity cations, such as the ammonium ion, that may be released from chloramine disinfectants commonly used in drinking water. If ammonium removal is one of its purposes, the softener must be located downstream of the disinfectant removal operation. Water softener resin beds are regenerated with concentrated sodium chloride solution (brine).

Concerns include microorganism proliferation, channeling, appropriate water flow rates and contact time, ion-exchange capacity, organic and particulate resin fouling, organic leaching from new resins, fracture of the resin beads, resin degradation by excessively chlorinated water, and contamination from the brine solution used for regeneration.

Control measures involve recirculation of water during periods of low water use; periodic sanitization of the resin and brine system; use of microbial control devices (e.g., UV light and chlorine); locating the unit upstream of the disinfectant removal step (if used only for softening); appropriate regeneration frequency; effluent chemical monitoring (e.g., hardness ions and possibly ammonium); and downstream filtration to remove resin fines. If a softener is used for ammonium removal from chloramine-containing source water, then the capacity, contact time, resin surface fouling, pH, and regeneration frequency are very important.

DEIONIZATION

Deionization (DI) and continuous electrodeionization (CEDI) are effective methods of improving the chemical quality attributes of water by removing cations and anions. DI systems have charged resins that require periodic regeneration with an acid and base. Typically, cation resins are regenerated with either hydrochloric or sulfuric acid, which replace the captured positive ions with hydrogen ions. Anion resins are regenerated with sodium hydroxide or potassium hydroxide, which replace captured negative ions with hydroxide ions. Because free endotoxin is negatively charged, some removal of endotoxin is achieved by the anion resin. The system can be designed so that the cation and anion resins are in separate or "twin" beds, or they can be blended together to form a "mixed" bed.

The CEDI system uses a combination of ion-exchange resin, selectively permeable membranes, and an electric charge, providing continuous flow (of product and waste concentrate) and continuous regeneration. Water enters both the resin section and the waste (concentrate) section. The resin acts as a conductor, enabling the electrical potential to drive the captured cations and anions through the resin and appropriate membranes for concentration and removal in the waste water stream. As the water passes through the resin, it is deionized to become product water. The electrical potential also separates the water in the resin (product) section into hydrogen and hydroxide ions. This permits continuous regeneration of the resin without the need for regenerant additives. However, unlike conventional deionization, CEDI units must start with water that is already partially purified because they generally cannot achieve the conductivity attribute of Purified Water when starting with the heavier ion load of source water.

Concerns for all forms of DI units include microbial and endotoxin control; chemical additive impact on resins and membranes; and loss, degradation, and fouling of resin. Issues of concern specific to DI units include regeneration frequency and completeness; channeling caused by biofilm agglomeration of resin particles; organic leaching from new resins; complete resin separation for mixed bed regeneration; and bed fluidization air contamination (mixed beds).

Control measures may include continuous recirculation loops, effluent microbial control by UV light, conductivity monitoring, resin testing, microporous filtration of bed fluidization air, microbial monitoring, frequent regeneration to minimize and control microorganism growth, sizing the equipment for suitable water flow and contact time, and use of elevated temperatures. Internal distributor and regeneration piping for DI bed units should be configured to ensure that regeneration chemicals contact all internal bed and piping surfaces and resins.

Rechargeable canisters can be the source of contamination and should be carefully monitored. Full knowledge of previous resin use, minimum storage time between regeneration and use, and appropriate sanitizing procedures are critical factors for ensuring proper performance.

REVERSE OSMOSIS

Reverse osmosis (RO) units use semipermeable membranes. The "pores" of RO membranes are intersegmental spaces among the polymer molecules. They are big enough for permeation of water molecules, but they limit the passage of hydrated chemical ions, organic compounds, and microorganisms. RO membranes can achieve chemical, microbial, and endotoxin quality improvement. Many factors, including pH, temperature, source water hardness, permeate and reject flow rate, and differential pressure across the membrane, affect the selectivity and effectiveness of this permeation. The process streams consist of supply water, product water (permeate), and waste water (reject). Depending on the source water, pretreatment and system configuration variations and chemical additives may be necessary to achieve the desired performance and reliability. For most source waters, a single stage of RO filtration is usually not enough to meet *Purified Water* conductivity specifications. A second pass of this permeate water through another RO stage usually achieves the necessary permeate purity if other factors such as pH and temperature have been appropriately adjusted and the ammonia from chloraminated source water has been previously removed.

Concerns associated with the design and operation of RO units include membrane materials that are sensitive to sanitizing agents and to particulate, chemical, and microbial membrane fouling; membrane and seal integrity; and the passage of dissolved gases, such as carbon dioxide and ammonia. Failure of membrane or seal integrity will result in product water contamination. Methods of control involve suitable pretreatment of the influent water stream; appropriate membrane material selection; membrane design and heat tolerance; periodic sanitization; and monitoring of differential pressures, conductivity, microbial levels, and TOC.

The development of RO units that can tolerate sanitizing water temperatures and also operate efficiently and continuously at elevated temperatures has added greatly to their microbial control ability and to the avoidance of biofouling. RO units can be used alone or in combination with DI and CEDI units, as well as ultrafiltration, for operational and quality enhancements.

ULTRAFILTRATION

Ultrafiltration is a technology that is often used near the end of a pharmaceutical water purification system for removing endotoxins from a water stream. Ultrafiltration can use semipermeable membranes, but unlike RO, these typically use polysulfone membranes with intersegmental "pores" that have been purposefully enlarged. Membranes with differing molecular weight "cutoffs" can be created to preferentially reject molecules with molecular weights above these ratings.

Ceramic ultrafilters are another molecular sieving technology. Ceramic ultrafilters are self-supporting and extremely durable; they can be backwashed, chemically cleaned, and steam sterilized. However, they may require higher operating pressures than do membrane-type ultrafilters.

All ultrafiltration devices work primarily by a molecular sieving principle. Ultrafilters with molecular weight cutoff ratings in the range of 10,000–20,000 Da are typically used in water systems for removing endotoxins. This technology may be appropriate as an intermediate or

final purification step. As with RO, successful performance is dependent upon pretreatment of the water by upstream unit operations.

Issues of concern for ultrafilters include compatibility of membrane material with heat and sanitizing agents, membrane integrity, fouling by particles and microorganisms, and seal integrity. Control measures involve filter membrane composition, sanitization, flow design (dead end vs. tangential), cartridge replacement, elevated feed water temperature, and monitoring TOC and differential pressure.

MICROBIAL-RETENTIVE FILTRATION

Microbial-retentive membrane filters have a larger effective "pore size" than ultrafilters and are intended to prevent the passage of microorganisms and similarly sized particles without unduly restricting flow. This type of filtration is widely employed within water systems for filtering the bacteria out of both water and compressed gases as well as for vent filters on tanks and stills and other unit operations.

In water systems, a filter's microbial retention characteristics exhibit different phenomena than in other aseptic filtration applications.

The following factors interact to create the retention phenomena for water system microorganisms: the variability in the range and average pore sizes created by the various membrane fabrication processes; the variability of the surface chemistry and three-dimensional structure related to the different polymers used in these filter matrices; and the size and surface properties of the microorganism intended to be retained by the filters. The typical challenge organism for these filters, *Brevundimonas diminuta*, may not be the best challenge microorganism for demonstrating bacterial retention by 0.2- to 0.22- μm rated filters for use in water systems because this challenge microorganism appears to be more easily retained by these filters than some other water system bacteria. In some situations, the appearance of water system microorganisms on the downstream sides of some 0.2- to 0.22- μm rated filters after a relatively short period of use (days to weeks) seems to support the idea that some penetration phenomenon is at work. It is not known whether this downstream appearance is caused by a "pass-through" phenomenon resulting from tiny cells or less cell "stickiness," or perhaps by a "grow through" phenomenon where cells hypothetically replicate their way through the pores to the downstream side. Whatever the penetration mechanism, 0.2- to 0.22- μm rated membranes may not be the best choice for some water system uses (see *Sterilization and Sterility Assurance of Compendial Articles* (1211)).

Nevertheless, microbial retention success in water systems has been reported with the use of filters rated as 0.2 or 0.1 μm . There is general agreement that, for a given manufacturer, their 0.1- μm rated filters are tighter than their 0.2- to 0.22- μm rated filters. However, comparably rated filters from different manufacturers may not have equivalent performance in water filtration applications because of the different filter materials, different fabrication processes, and nonstandardized microbial retention challenge processes currently used for defining the 0.1- μm filter rating. It should be noted that filters with a 0.1- μm rating may result in a lower flow rate compared to 0.2- to 0.22- μm filters, so whatever filters are chosen for a water system application, the user must verify that they are suitable for their intended application, use period, and use process, including flow rate.

For microbial retentive gas filtrations, the same sieving and adsorptive retention phenomena are at work as in liquid filtration, but the adsorptive phenomenon is enhanced by additional

electrostatic interactions between the particles and filter matrix. These electrostatic interactions are so strong, particle retention for a given filter rating is significantly more efficient in gas filtration than in water or product-solution filtrations. These additional adsorptive interactions render filters rated at 0.2–0.22 μm unquestionably suitable for microbial retentive gas filtrations. When microbial retentive filters are used in these applications, the membrane surface is typically hydrophobic (non-wettable by water). A significant area of concern for gas filtration is blockage of tank vents by condensed water vapor, which can cause mechanical damage to the tank. Control measures include electrical or steam tracing and a self-draining orientation of vent filter housings to prevent accumulation of vapor condensate. However, a continuously high filter temperature will take an oxidative toll on polypropylene components of the filter, so sterilization of the unit prior to initial use, and periodically thereafter, as well as regular visual inspections, integrity tests, and filter cartridge changes are recommended control methods.

In water applications, microbial retentive filters may be used downstream of unit operations that tend to release microorganisms or upstream of unit operations that are sensitive to microorganisms. Microbial retentive filters may also be used to filter water feeding the distribution system. It should be noted that regulatory authorities allow the use of microbial retentive filters within distribution systems or even at use points if they have been properly validated and are appropriately maintained. A point-of-use filter should only be intended to “polish” the microbial quality of an otherwise well-maintained system and not to serve as the primary microbial control device. The efficacy of system microbial control measures can only be assessed by sampling the water upstream of the filters. As an added measure of protection, in-line UV lamps, appropriately sized for the flow rate (see 5.3 *Sanitization*), may be used just upstream of microbial retentive filters to inactivate microorganisms prior to their capture by the filter. This tandem approach tends to greatly delay potential microbial penetration phenomena and can substantially extend filter service life.

ULTRAVIOLET LIGHT

The use of low-pressure UV lights that emit a 254-nm wavelength for microbial control is discussed under 5.3 *Sanitization*, but the application of UV light in chemical purification is also emerging. This 254-nm wavelength is also useful in the destruction of ozone. At wavelengths around 185 nm (as well as at 254 nm), medium-pressure UV lights have demonstrated utility in the destruction of the chlorine-containing disinfectants used in source water as well as for interim stages of water pretreatment. High intensities of 254 nm or in combination with other oxidizing sanitants, such as hydrogen peroxide, have been used to lower TOC levels in recirculating distribution systems. The organics are typically converted to carbon dioxide, which equilibrates to bicarbonate, and incompletely oxidized carboxylic acids, both of which can easily be removed by polishing ion-exchange resins.

Areas of concern include inadequate UV intensity and residence time, gradual loss of UV emissivity with bulb age, gradual formation of a UV-absorbing film at the water contact surface, incomplete photodegradation during unforeseen source water hyperchlorination, release of ammonia from chloramine photodegradation, unapparent UV bulb failure, and conductivity degradation in distribution systems using 185-nm UV lights.

Control measures include regular inspection or emissivity alarms to detect bulb failures or film occlusions, regular UV bulb sleeve cleaning and wiping, downstream chlorine detectors (when used for dechlorination), downstream polishing deionizers (when used for TOC reduction), and

regular (approximately yearly) bulb replacement. UV lamps generate heat during operation, which can cause failure of the lamps or increase the temperature of the water. Precautions should be in place to ensure that water flow is present to control excessive temperature increase.

DISTILLATION

Distillation units provide chemical and microbial purification via thermal vaporization, mist elimination, and water vapor condensation. A variety of designs is available, including single effect, multiple effect, and vapor compression. The latter two configurations are normally used in larger systems because of their generating capacity and efficiency. Source water controls must provide for the removal of hardness and silica impurities that may foul or corrode the heat transfer surfaces, as well as the removal of those impurities that could volatilize and condense along with the water vapor. In spite of general perceptions, even the best distillation process does not ensure absolute removal of contaminating ions, organics, and endotoxins. Most stills are recognized as being able to accomplish at least a 3–4 log reduction in these impurity concentrations. They are highly effective in sterilizing the feed water.

Areas of concern include carry-over of volatile organic impurities such as trihalomethanes (see 2. *Source Water Considerations*) and gaseous impurities such as ammonia and carbon dioxide, faulty mist elimination, evaporator flooding, inadequate blow down, stagnant water in condensers and evaporators, pump and compressor seal design, pinhole evaporator and condenser leaks, and conductivity (quality) variations during start-up and operation.

Methods of control may involve the following: preliminary steps to remove both dissolved carbon dioxide and other volatile or noncondensable impurities; reliable mist elimination to minimize feed water droplet entrainment; visual or automated high-water-level indication to detect boiler flooding and boil over; use of sanitary pumps and compressors to minimize microbial and lubricant contamination of feed water and condensate; proper drainage during inactive periods to minimize microbial growth and accumulation of associated endotoxin in boiler water; blow down control to limit the impurity concentration effect in the boiler to manageable levels; on-line conductivity sensing with automated diversion to waste to prevent unacceptable water upon still startup or still malfunction from getting into the finished water distribution system; and periodic testing for pinhole leaks to routinely ensure that condensate is not compromised by nonvolatilized source water contaminants.

STORAGE TANKS

Storage tanks are included in water distribution systems to optimize processing equipment capacity. Storage also allows for routine maintenance within the purification system while maintaining continuous supply to meet manufacturing needs. Design and operation considerations are needed to prevent or minimize the development of biofilm, to minimize corrosion, to aid in the use of chemical sanitization of the tanks, and to safeguard mechanical integrity.

Areas of concern include microbial growth or corrosion due to irregular or incomplete sanitization and microbial contamination from unalarmed rupture disk failures caused by condensate-occluded vent filters.

Control considerations may include using closed tanks with smooth interiors, the ability to spray the tank headspace using sprayballs on recirculating loop returns, and the use of heated,

jacketed/insulated tanks. This minimizes corrosion and biofilm development and aids in thermal or chemical sanitization. Storage tanks require venting to compensate for the dynamics of changing water levels. This can be accomplished with a properly oriented and heat-traced filter housing fitted with a hydrophobic microbial retentive membrane filter affixed to an atmospheric vent. Alternatively, an automatic membrane-filtered compressed gas blanketing system may be used. In both cases, rupture disks equipped with a rupture alarm device should be used as a further safeguard for the mechanical integrity of the tank.

DISTRIBUTION SYSTEMS

Distribution system configuration should allow for the continuous flow of water in the piping by means of recirculation. Use of no recirculating, dead-end, or one-way systems or system segments should be avoided whenever possible. If not possible, these systems should be flushed periodically and monitored more closely. Experience has shown that continuously recirculated systems are easier to maintain. Pumps should be designed to deliver fully turbulent flow conditions to facilitate thorough heat distribution (for hot-water sanitized systems) as well as thorough chemical sanitant distribution. Turbulent flow also appears to either retard the development of biofilms or reduce the tendency of those biofilms to shed bacteria into the water. If redundant components, such as pumps or filters, are used, they should be configured and used to avoid microbial contamination of the system.

Components and distribution lines should be sloped and fitted with drain points so that the system can be completely drained. In distribution systems, dead legs and low-flow conditions should be avoided, and valved tie-in points should have length-to-diameter ratios of six or less. In systems that operate at self-sanitizing temperatures, precautions should be taken to avoid cool points where biofilm development could occur. If drainage of components or distribution lines is intended as a microbial control strategy, they should also be configured to be dried completely using dry compressed gas because drained but still moist surfaces will still support microbial proliferation. Water exiting from the distribution system should not be returned to the system without first passing through all or a portion of the purification system.

The distribution design should include the placement of sampling valves in the storage tank and at other locations, such as in the return line of the recirculating water system. Direct connections to processes or auxiliary equipment should be designed to prevent reverse flow into the controlled water system. Hoses and heat exchangers that are attached to points of use to deliver water must not chemically or microbiologically degrade the water quality. The distribution system should permit sanitization for microorganism control. The system may be continuously operated at sanitizing conditions or sanitized periodically.

NOVEL/EMERGING TECHNOLOGIES

New water treatment technologies are being developed continuously. Before these technologies are utilized in pharmaceutical water systems, they should be evaluated for acceptable use in a GMP environment. Other considerations should include the treatment process, reliability and robustness, use of added substances, materials of construction, and ability to validate. Consideration should be given to recognize the areas of concern during the evaluation and to identify control measures for the technology. This should include impact on chemical and microbial attributes.

5.2 Installation, Materials of Construction, and Component Selection

Installation techniques are important because they can affect the mechanical, corrosive, and sanitary integrity of the system. Valve installation should promote gravity drainage. Pipe supports should provide appropriate slopes for drainage and should be designed to support the piping adequately under worst-case thermal and flow conditions. The methods of connecting system components—including units of operation, tanks, and distribution piping—require careful attention to preclude potential operational and microbial problems.

Stainless steel welds should provide reliable joints that are internally smooth and corrosion-free. Low-carbon stainless steel, compatible wire filler where necessary, inert gas, automatic welding machines, and regular inspection and documentation help to ensure acceptable weld quality. Follow-up cleaning and passivation of metal surfaces after installation are important for removing contamination and corrosion products and to re-establish the passive corrosion-resistant surface.

Plastic materials can be fused (welded) in some cases, and also require smooth, uniform internal surfaces. Adhesive glues and solvents should be avoided due to the potential for voids and organic extractables. Mechanical methods of joining, such as flange fittings, require care to avoid the creation of offsets, gaps, penetrations, and voids. Use of plastic materials may contribute to TOC levels.

Control measures include good alignment, properly sized gaskets, appropriate spacing, uniform sealing force, and the avoidance of threaded fittings.

Materials of construction should be selected to be compatible with control measures such as sanitizing, cleaning, or passivation. Temperature rating is a critical factor in choosing appropriate materials because surfaces may be required to handle elevated operating and sanitization temperatures. If chemicals or additives will be used to clean, passivate, or sanitize the system, materials resistant to these chemicals or additives must be utilized. Materials should be capable of handling turbulent flow and elevated velocities without erosion of the corrosion-resistant film (such as the passive chromium oxide surface of stainless steel) or reduction in wall thickness for plastics. The finish on metallic materials such as stainless steel, whether it is a refined mill finish, polished to a specific grit, or an electropolished treatment, should complement the system design and provide satisfactory corrosion and microbial activity resistance. The finish should also be a material that can be chemically sanitized. Auxiliary equipment and fittings that require seals, gaskets, diaphragms, filter media, and membranes should exclude materials that permit the possibility of extractables, shedding, and microbial activity. Insulating materials exposed to stainless steel surfaces should be free of chlorides to avoid the phenomenon of stress corrosion cracking that can lead to system contamination and the destruction of tanks and critical system components.

Specifications are important to ensure proper selection of materials and to serve as a reference for system qualification and maintenance. Information such as the manufacturer's metallurgical reports for stainless steel and reports of composition, ratings, and material-handling capabilities for nonmetallic substances should be reviewed for suitability and retained for reference. Component (auxiliary equipment) selection should be made with assurance that it does not create a source of contamination intrusion. Heat exchangers should be constructed to prevent leakage of heat transfer medium into the pharmaceutical water and, for heat exchanger designs where prevention may fail, there should be a means to detect leakage. Pumps should be of sanitary design with seals that prevent contamination of the water. Valves should have smooth internal surfaces with the seat and closing device exposed to the flushing action of water, such

as occurs in diaphragm valves. Valves with pocket areas or closing devices (e.g., ball, plug, gate, globe) that move into and out of the flow area should be avoided.

5.3 Sanitization

Microbial control in water systems is achieved primarily through sanitization practices. Systems can be sanitized using either thermal or chemical means.

THERMAL SANITIZATION

Thermal approaches to system sanitization include periodic or continuously circulating hot water and the use of steam. Temperatures of 65°–80° are most commonly used for thermal sanitization. Continuously recirculating water of at least 65° at the coldest location in the distribution system has also been used effectively in stainless steel distribution systems when attention is paid to uniformity and distribution of such self-sanitizing temperatures. These techniques are limited to systems that are compatible with the higher temperatures needed to achieve sanitization. Frequent use of thermal sanitization at appropriate temperatures should eliminate the need for other sanitization methods.

The use of thermal methods at temperatures significantly above 80° is contraindicated because it does not add to microbial control of the system or reduction of biofilm. Some methods (e.g., steam sanitizing, hot water circulation at temperatures $\geq 100^\circ$) can be less effective or even destructive because of the need to eliminate condensate or manipulate system components, stress materials of construction, deform filters, and its adverse impact on instrumentation.

Although thermal methods control biofilm development by either continuously inhibiting its growth or, in intermittent applications, by killing the microorganisms within developing biofilms, they are not effective in removing established biofilms. Killed but intact biofilms can become a nutrient source for rapid biofilm regrowth after the sanitizing conditions are removed or halted. In cases of infrequent thermal sanitizations that allow biofilm development between treatments, a combination of routine thermal treatment and periodic supplementation with chemical sanitization may be more effective. The more frequent the thermal sanitization, the more likely it is that biofilm re-development can be eliminated.

CHEMICAL SANITIZATION

Chemical methods, where compatible, can be used on a wider variety of construction materials. These methods typically use oxidizing agents such as ozone, hydrogen peroxide, peracetic acid, or combinations thereof. Halogenated compounds can be effective sanitizers but are less aggressive oxidizing agents and may be difficult to flush from the system. Chemical agents may not penetrate the full biofilm matrix or extend into all biofilm locations (such as crevices at gasketed fittings) and may leave biofilms incompletely inactivated. Compounds such as ozone, hydrogen peroxide, and peracetic acid oxidize bacteria and biofilms with reactive peroxides and by forming very reactive free radicals (notably hydroxyl radicals). The short half-life of ozone in particular, and its limitation on achievable concentrations, require that it be added continuously during the sanitization process. Hydrogen peroxide and ozone rapidly degrade to water and/or oxygen, and peracetic acid degrades to oxygen and acetic acid. The ease of degradation of ozone to oxygen using 254-nm UV lights in circulating loops allow it to be used effectively on a continuously sanitizing basis in holding tanks and on an intermittent basis (e.g., daily or weekly) in the distribution loops. The highly reactive nature of ozone requires the use of system materials and components that are even more oxidation resistant than those typically used with

the other oxidizing agents.

It is important to note that microorganisms in a well-developed biofilm can be extremely difficult to kill, even by using aggressive oxidizing chemicals. The less developed and therefore thinner the biofilm, the more effective the biofilm inactivation. Therefore, optimal microbial control is achieved by using oxidizing chemicals at a frequency that does not permit significant biofilm development between treatments.

Validation of chemical sanitization requires demonstration of adequate chemical concentrations throughout the system, exposure to all wetted surfaces including the body of use point valves, and complete removal of the sanitant from the system at the completion of treatment. Methods validation for the detection and quantification of residues of the sanitant or its objectionable degradants is an essential part of the validation program.

UV SANITIZATION

In-line UV light at a wavelength of 254 nm can also be used to continuously "sanitize" only the water circulating in the system, but these devices must be properly sized for the water flow. Such devices inactivate a high percentage (but not 100%) of microorganisms that flow through the device but cannot be used to directly control existing biofilm upstream or downstream of the device. However, when coupled with conventional thermal or chemical sanitization technologies or located immediately upstream of a microbially retentive filter, UV light is most effective and can prolong the interval between needed system re-sanitizations.

SANITIZATION PROCEDURES

Sanitization steps require validation to demonstrate the ability to reduce and hold microbial contamination at acceptable levels. Validation of thermal methods should include a heat distribution study to demonstrate that sanitization temperatures are achieved throughout the system, including the body of use point valves; sampling ports; instrument side branches; and fittings, couplings, and adapters, relying on water convection and thermal conduction through system materials for heat transfer to wetted surfaces.

The routine frequency of sanitization should be supported by the results of system microbial monitoring. Conclusions derived from trend analysis of the microbiological data should be used as the alert mechanism for the need for extraordinary maintenance. The routine frequency of sanitization should be established in such a way that the system operates in a state of microbiological control and does not regularly exceed Alert and Action Levels (see 9.4. *Defining Alert and Action Levels and Specifications*).

5.4 Operation, Maintenance, and Control

A preventive maintenance program should be established to ensure that the water system remains in a state of control. The program should include 1) procedures for operating the system, 2) monitoring programs for critical quality attributes and operating conditions including calibration of critical instruments, 3) schedule for periodic sanitization, 4) preventive maintenance of components, and 5) control of changes to the mechanical system and to operating conditions.

OPERATING PROCEDURES

Operating procedures for the water system and for performing routine maintenance and corrective action should be written, and they should also define the point when action is

required. The procedures should be well documented, and should detail the function of each job, assign who is responsible for performing the work, describe how the job is to be done, and identify acceptable operating parameters. The effectiveness of these procedures should be assessed during water system validation.

PROCESS MONITORING PROGRAM

A process-monitoring program should establish the critical quality attributes and operating parameters that are documented and monitored. The program may include a combination of in-line sensors and/or automated instruments (e.g., for temperature, TOC conductivity, hardness, and chlorine), automated or manual documentation of operational parameters (such as flow rates or pressure drop across a carbon bed, filter, or RO unit), and laboratory tests (e.g., total microbial counts). The frequency of sampling, the requirement for evaluating test results, and the necessity of initiating corrective action should be included.

ROUTINE MICROBIAL CONTROL

Sanitization may be integral to operation and maintenance, and necessary on a routine basis, depending on system design and the selected units of operation, to maintain the system in a state of microbial control. Technologies for sanitization are described above in more detail in 5.3 *Sanitization*.

PREVENTIVE MAINTENANCE

A preventive maintenance program should be in effect. The program should establish what preventive maintenance is to be performed, the frequency of maintenance work, and how the work should be documented.

CHANGE CONTROL

The mechanical configuration, operating conditions, and maintenance activities of the water system must be controlled. Proposed changes should be evaluated for their impact on the whole system. The need to requalify the system after changes are made should be determined. After a decision is made to modify a water system, the affected drawings, manuals, and procedures should be revised. Portions or operations of the water system that are affected by the modification should be tested to demonstrate a continued state of control. The extent and duration of testing should be related to the risk impact of the change to the system.

6. SAMPLING

The testing of water samples from a water system is critical to the ongoing control of the system and assessment of the quality of the water being used. If improperly collected, a sample could yield a test result that is unrepresentative of the sample's purpose. This could lead to inaction when remediation is needed or to unnecessary remediation when none is necessary. It could also lead to misinterpretations of product impact. Therefore, properly collecting water samples, understanding their purpose, and establishing appropriate water system sampling plans are essential to water quality control and system control.

6.1 Purposes and Procedures

To assess a particular water quality attribute, a sample of the water usually must be removed from a water system for specific quality attribute testing. This sample may be analyzed by in-

line/on-line instruments or it may be completely removed from the system as a "grab sample" in a container for off-line testing. In-line/on-line testing avoids the exogenous contamination potential of grab samples that could lead to artifactually variable data trends and incorrect decisions on system performance, maintenance, and utilized water quality, as well as initiating fruitless causative investigations. However, in-line/on-line testing may not be suitable for the purpose of the resulting data, making the off-line testing of grab samples the only suitable approach.

The data from water testing are generally used for one of two purposes: for process control (PC) of the water purification and distribution system or for quality control (QC) of the water being drawn from the system for some application or use. In many cases, depending on the sampling location and sampling process, the resulting data can be used for both PC and QC purposes.

PROCESS CONTROL (PC) SAMPLING

Because PC sampling is intended to reflect the quality of the water behind the valve and within the distribution system, coming from the purification system, or between its purification steps, efforts should be made to avoid contaminating the water as it drawn from the system so that its test results accurately reflect the water quality within the system at that location. This may require the use of strategically located sampling ports, in addition to points of use.

If microbial testing is needed for PC purposes, the sampling valve should have a properly installed, sanitary design that uses vigorous pre-sampling flushing. This flushing shears off fragile biofilm structures growing on surfaces within the valve and water path before the sample is collected. This avoids biasing the microbial count of perhaps pristine water in the system behind that valve. A fully open valve flush (at >8 ft/s velocity within the valve and connector) for at least 30 s typically provides sufficient shear forces to adequately remove any fragile biofilm structures. Additional control measures for preventing sample contamination could also include stringent pre- and post-sampling outlet sanitation, the use of sterile hoses and gaskets or other connectors to direct the water flow, and other measures.

The data from PC sampling indicate how well the system is maintaining the water quality at that sampling location. These data are subsequently used to signal when some extraordinary intervention might be needed, in addition to normal maintenance and system sanitization operations, to restore the system to the expected level of purity.

PC sampling can only be used to indicate the quality of the water being delivered to the points of use (for QC purposes) if it has been shown to be representative of that point-of-use quality. This may be possible with chemical attributes which are typically not affected by the fluid path of the water delivery process, but is generally not possible with microbial attributes, which can be greatly affected by localized biofilms along that fluid path. If this fluid path is not utilized for PC sampling, then the resulting data typically cannot be used for QC purposes.

QUALITY CONTROL (QC) SAMPLING

QC sampling is intended to reflect the quality of water that is being used. These samples should be collected at the true point of use, that is, where the water is delivered for use, not where it leaves the water system. QC sampling must utilize that same delivery path and components utilized for a water transfer during actual water use. This includes the same valves, hoses, heat exchangers, flow totalizers, hard-piped connections, and other components utilized during

water use.

In addition to the water transfer components, QC sampling must also use the same water transfer process employed during water use, including the same pre-use outlet and delivery path flushing procedure and the same outlet, fitting, and hose sanitization practices employed during actual water use. The water delivery process and components used for QC sampling must be identical to manufacturing practices at every system outlet for the QC sample to mimic the quality of water being used by accumulating the same chemical and microbial contaminant levels it would during actual use from that outlet location.

Where permanent connections from the water system to equipment are present, accommodation should be made in the design to collect samples from locations as close to the equipment as possible. For example, samples can be collected from special sample ports or other valves near the equipment connection that allow the collected water sample to accurately reflect the water quality that is used. Where the water transfer conduit is designed and/or definitively treated to eliminate all contaminating influences prior to water transfer through that conduit, QC sampling locations within the distribution system can reflect the quality of the water that is actually used for QC purposes at those permanent connections. However, the success of the design and treatments intended to eliminate these contaminating influences must be verified. This is typically done during water system validation.

Where routine water use practices involve contamination-prone activities, such as no pre-use flushing or poor hose storage/sanitization/replacement practices, these water use practices should be improved to reduce the potential for delivering contaminated water from the water system and for unacceptable QC sample testing results that reflect that same contamination.

6.2 Attributes and Sampling Locations

The tests being performed on the samples are relevant to the sampling location and purpose of the sample. In-process monitoring of nonmonograph attributes may be indicated for specific unit operations. For instance, before and after a softener, it may be important to determine water hardness to verify softener efficacy. Before and after an activated carbon bed/filter, it may be important to verify chlorine or TOC removal and/or reduction or test for an increase in microbial count. Before a distillation unit, it may be important to quantitate the incoming bacterial endotoxin level to ensure that the still is not being over-challenged beyond its typical 3–4 log purification capability. However, once the water is in the distribution system, the compendial attributes of importance typically include at least conductivity, TOC, and microbial count. In Water for Injection systems and other systems or system locations where bacterial endotoxin control is important, endotoxin is also assayed. Other tests may be necessary depending on the intended uses of the water.

CHEMICAL ATTRIBUTES

Dissolved chemical contaminants detected by conductivity or TOC testing tend to be uniformly distributed in the water throughout the water system. However, there are exceptions where localized chemical contamination sources can occur, such as from a coolant-leaking heat exchanger in a sub-loop, or at a point of use, or within a dead leg. These chemical contaminants may only be seen at the associated outlets and not systemically. However, in the absence of localized contamination influences, chemical attributes are candidates for on-line testing at fixed strategic locations within the distribution system, such as near a circulating loop return, and are generally reflective of the same chemical quality at all locations and points

of use within the distribution system. Nevertheless, the suitability of the on-line locations of these instruments for QC release purposes must be verified as being representative of the use-point water quality. This is usually done during water system validation.

MICROBIAL ATTRIBUTES

The same uniformity scenario cannot be assumed for microbial attributes. Planktonic organisms in a water sample could have originated from biofilms in the purification or distribution systems releasing more or less uniform levels of planktonic organisms into the circulating water, as detectable in samples from all outlets. However, a local biofilm developing within a water delivery conduit (such as a use-point outlet valve and transfer hose) in an otherwise pristine biofilm-free water system could release planktonic organisms detectable only in water delivered through that conduit. Therefore, QC release samples for assessing the quality of water that is delivered by the system during water use must be collected after the water has traversed the same fluid conduit (including the same preparatory activities such as outlet sanitization and pre-flushing) from the water distribution system to the specific locations where the water is used.

On-line microbial water sampling/testing has value in pharmaceutical water systems only for PC purposes unless the water is taken from the point of use in the same manner as routine water usage, in which case the data can also have a QC release purpose. Microbial counts detected from strategic sampling ports continue to have PC and investigational value, but generally cannot be substituted for QC release testing except in certain scenarios, as described in 6.1.2 *Quality Control (QC) Sampling*.

6.3 Validation Sampling Plans

The initial sampling plan for a pharmaceutical water system is usually developed for a validation program (see 4. *Validation and Qualification of Water Purification, Storage, and Distribution Systems*). This strategy is for characterization of the system's ability to purify, distribute, and deliver pharmaceutical water. Typically, the initial validation sampling is for a short duration (e.g., at least 2–4 weeks) at a high sampling frequency to generate a significant body of data that will allow detection of short-term or localized chemical or microbial quality deviations from all outlets. These data provide an initial assessment of system performance to guide decisions about using the water for operational purposes.

The initial validation sampling plan is re-evaluated when the pharmaceutical water is placed into operation, typically to reduce the amount of data being generated while not compromising the ability to identify anomalous operations/events, especially during the early life cycle of the water system. In the absence of such quality deviations during the initial sampling period, the sampling frequency can be lessened for a period of time (e.g., at least 2–4 additional weeks) to ensure that somewhat longer-term adverse quality trends are not apparent. During this second period of time, the water may be considered for at-risk routine use, pending the acceptable completion of the second validation sampling period. After successful completion, monitoring can eventually be lessened again to what will become the routine sampling plan.

Periodic review of the water system operation and monitoring needs to be performed to assess seasonal source water variability, effectiveness of sanitization, and routine maintenance events. Periodic review should be performed during the complete life cycle of the water system, typically annually, for evidence of longer-term data trends and quality deviations.

The routine sampling plan should be re-evaluated periodically based on the available data to determine the appropriate frequency and sample locations. This review offers an opportunity to improve data evaluation and reduce workloads based on what that data indicate relative to process and quality control. The routine sampling plan should have a rationale for the frequency and locations that are selected to justify how the resulting data will be used to characterize the overall operation of the system and the release of the water for use.

6.4 Routine Sampling Plans

SOURCE WATER SAMPLING

As mentioned in earlier sections, the source water for pharmaceutical water systems must comply with the standards for one of the Drinking Waters listed in the associated compendial water monograph or in *General Notices and Requirements*. When a municipality or other water authority is providing this Drinking Water, they are required to comply with the local Drinking Water Regulations for the water supplied to a drinking or potable water distribution piping grid for that region. The quality of that water by the time it reaches the pharmaceutical user is dependent on a number of factors including distance from the input source, duration of travel within the piping, and condition of the piping in that potable water distribution grid, any of which could have adversely affected some of its initial chemical and/or microbial attributes. Based on a risk assessment, it may be prudent to verify full compliance with regulations using water collected from sample ports prior to the pretreatment system, or other equivalent Drinking Water outlets within the facility. If the water complies, then continued assurance of compliance could be verified using Drinking Water Regulation test results provided by the water authority or by periodic retesting of selected or all the Drinking Water attributes by the user or by both the user and the water authority. If private sourced water is utilized, it is the user's responsibility to demonstrate full Drinking Water regulation compliance, using water samples from such sampling ports on a periodic basis as determined by a risk analysis.

These pre-pretreatment sampling ports could, at the user's discretion, be used to periodically monitor other source water attributes that could affect specific pretreatment or purification unit operations. Depending on the user's source water quality consistency and a risk assessment of its potential impact on the purification process, the periodically monitored attributes could include microbial count, absence of coliforms, bacterial endotoxin levels, conductivity, TOC, pH, hardness, chlorine, silica, turbidity or silt density index, and others. These data could be useful in investigations and for operational adjustments to critical unit operation parameters and maintenance procedures, or for feedback to the potable water provider if unusual trends are observed.

PRETREATMENT AND PURIFICATION SYSTEM SAMPLING

The location and frequency of sampling from ports within the pretreatment and purification systems may be selected based on a risk analysis of unit operation purpose. The purpose of this sampling is primarily for PC, for example, to ensure maintenance of acceptable unit operation performance, to assess maintenance procedure efficacy, and to investigate the need for remedial action. Quality deviations in the early portions of the purification process can affect unit operation efficiency but usually do not impact the finished water quality or acceptable use.

PURIFIED WATER DISTRIBUTION SYSTEM SAMPLING

Purified Water distribution system sampling is intended to provide continuing assurance of ongoing PC and compliance with the user's finished water chemical and microbiological requirements. Generally, the locations for that sampling and the frequency of testing the specific attributes are a matter of process and quality control consistency, as well as risk tolerance in the event of a deviation.

Depending on the water system design, the chemical attributes of a water system tend to be relatively constant and more uniformly distributed than the microbiological attributes. Therefore, less frequent sampling at only selected locations could be justified for chemical testing based on familiarity with system design and the existence of historically consistent operational data. However, with some purification system designs, the chemical quality could change dramatically in a short period of time (such as from the exhaustion of deionization beds), so frequent or even continuous in-line/on-line monitoring of the chemical attributes would be advisable to be able to recognize and correct the cause of the problem before non-compliant water is produced and used.

For microbial testing, all use points and critical sample ports in a distribution system are typically sampled routinely, including those that are infrequently used by manufacturing. There is no prescribed sampling frequency for Purified Water system outlets, so typical outlet sampling frequencies vary from daily to monthly, with sampling occurring somewhere in the system at least at weekly intervals.

A risk analysis is suggested for determining the sampling plan for a Purified Water system. Factors in this analysis could include (but are not limited to) the test result history for the entire water system as well as specific outlets, the criticality of specific outlets to manufacturing, the usefulness of selected sample ports as indicators of ongoing system control, and the scope of impact on products and activities should an unfavorable test result occur. For the scope of impact, the less frequent the sampling, the more products and processes will be impacted by an unfavorable test result.

WATER FOR INJECTION DISTRIBUTION SYSTEM SAMPLING

The sampling plans for Water for Injection distribution systems (as well as any water system where some level of bacterial endotoxin control is needed) utilize the same general sampling approaches as do Purified Water systems. However, the regulatory expectations for Water for Injection distribution system sampling plans are more prescriptive because microbial control must be much more stringent as it is related to the bacterial endotoxin attribute. In general, water sampling for microbial and bacterial endotoxin testing is expected to occur daily somewhere in the system, with each outlet being sampled NLT weekly.

6.5 Non-Routine Sampling

Non-routine sampling can also be performed on the water system for episodic events or reasons for which the routine sampling plans are insufficient to capture the needed information. Examples include change control purposes such as evaluating potential changes to sampling, testing, maintenance procedures, or system design; data or event excursion investigation purposes; or simply for long-term informational purposes and establishing baselines for future investigational value. The purpose of the non-routine sampling dictates the sampling procedures to be used, the attributes to be tested, and the location and repeating occurrence (if any) of that testing. It should also be noted that such non-routine sampling may be done from sampling ports that may or may not be routinely tested. Sampling ports can be positioned

in a water system purely for investigational, non-routine sampling, and as such, they do not need to be part of a routine sampling plan.

7. CHEMICAL EVALUATIONS

7.1 Chemical Tests for Bulk Waters

The chemical attributes of Purified Water and Water for Injection that were in effect prior to *USP 23* were specified by a series of chemistry tests for various specific and nonspecific attributes with the intent of detecting chemical species indicative of incomplete or inadequate purification. Although these methods could have been considered barely adequate to control the quality of these waters, they nevertheless stood the test of time. This was partly because the operation of water systems was, and still is, based on on-line conductivity measurements and specifications generally thought to preclude the failure of these archaic chemistry attribute tests.

In 1996, USP moved away from these chemical attribute tests, switching to contemporary analytical technologies for the bulk waters *Purified Water* and *Water for Injection*. The intent was to upgrade the analytical technologies without tightening the quality requirements. The two contemporary analytical technologies employed were TOC and conductivity. The TOC test replaced the test for *Oxidizable Substances* that primarily targeted organic contaminants. A multi-staged *Conductivity* test that detects ionic (mostly inorganic) contaminants replaced, with the exception of the test for *Heavy Metals*, all of the inorganic chemical tests (i.e., *Ammonia*, *Calcium*, *Carbon Dioxide*, *Chloride*, *Sulfate*).

Replacing the heavy metals attribute was considered unnecessary because 1) the source water specifications (found in the U.S. EPA's NPDWR) for individual heavy metals were tighter than the approximate limit of detection of the *Heavy Metals* test for *USP XXII Water for Injection* and *Purified Water* (approximately 0.1 ppm), 2) contemporary water system construction materials do not leach heavy metal contaminants, and 3) test results for this attribute have uniformly been negative; there has not been a confirmed occurrence of a singular test failure (failure of only the *Heavy Metals* test with all other attributes passing) since the current heavy metal drinking water standards have been in place.

Total Solids and *pH* were the only tests not covered by conductivity testing. The test for *Total Solids* was considered redundant because the nonselective tests of conductivity and TOC could detect most chemical species other than silica, which could remain undetected in its colloidal form. Colloidal silica in *Purified Water* and *Water for Injection* is easily removed by most water pretreatment steps, and even if present in the water, it constitutes no medical or functional hazard except in extreme and rare situations. In such extreme situations, other attribute extremes are also likely to be detected. It is, however, the user's responsibility to ensure fitness for use. If silica is a significant component in the source water, and the purification unit operations could fail and selectively allow silica to be released into the finished water (in the absence of co-contaminants detectable by conductivity), then either silica-specific testing or a total-solids type testing should be utilized to monitor for and control this rare problem.

The *pH* attribute was eventually recognized to be redundant to the conductivity test (which included *pH* as an aspect of the test and specification); therefore, *pH* was discontinued as a separate attribute test.

The rationale used by USP to establish its *Purified Water* and *Water for Injection* conductivity specifications took into consideration the conductivity contributed by the two least-conductive former attributes of *Chloride* and *Ammonia*, thereby precluding their failure had those wet chemistry tests been performed. In essence, the *Stage 3* conductivity specifications (see *Water Conductivity* (645), *Bulk Water*) were established from the sum of the conductivities of the limit concentrations of chloride ions (from pH 5.0 to 6.2) and ammonia ions (from pH 6.3 to 7.0), plus the unavoidable contribution of other conductivity-contributing ions from water (H^+ and OH^-), dissolved atmospheric carbon dioxide (as HCO_3^-), and an electro-balancing quantity of either sodium (Na^+) or chlorine (Cl^-), depending on the pH-induced ionic imbalance (see *Table 1*). The *Stage 2* conductivity specification is the lowest value in this table, 2.1 $\mu S/cm$. The *Stage 1* specifications, designed primarily for on-line measurements, were derived by essentially summing the lowest values in the contributing ion columns for each of a series of tables similar to *Table 1*, created for each 5° increment between 0° and 100°. For example purposes, the italicized values in *Table 1*, the conductivity data table for 25°, were summed to yield a conservative value of 1.3 $\mu S/cm$, the *Stage 1* specification for a nontemperature-compensated, nonatmosphere-equilibrated water sample that actually had a measured temperature of 25°–29°. Each 5° increment in the table was similarly treated to yield the individual values listed in the table of *Stage 1* specifications (see *Water Conductivity* (645), *Bulk Water*).

Table 1. Contributing Ion Conductivities of the Chloride-Ammonia Model as a Function of pH
(in atmosphere-equilibrated water at 25°)

pH	Conductivity ($\mu S/cm$)						Combined Conductivities	Stage 3 Limit
	H^+	OH^-	HCO_3^-	Cl^-	Na^+	NH_4^+

6.1	0.28	0	0.25	1.01	0.90	0	2.44	2.4
6.2	0.22	0	0.31	1.01	0.99	0	2.53	2.5
6.3	0.18	0	0.39	0.63	0	1.22	2.42	2.4
6.4	0.14	0.01	0.49	0.45	0	1.22	2.31	2.3
6.5	0.11	0.01	0.62	0.22	0	1.22	2.18	2.2
6.6	0.09	0.01	0.78	0	0.04	1.22	2.14	2.1
6.7	0.07	0.01	0.99	0	0.27	1.22	2.56	2.6
6.8	0.06	0.01	1.24	0	0.56	1.22	3.09	3.1
6.9	0.04	0.02	1.56	0	0.93	1.22	3.77	3.8
7.0	0.03	0.02	1.97	0	1.39	1.22	4.63	4.6

As stated above, this rather radical change to utilizing a conductivity attribute as well as the

inclusion of a TOC attribute allowed for on-line measurements. This was a major philosophical change and allowed industry to realize substantial savings. The TOC and conductivity tests can also be performed off-line in the laboratories using collected samples, although sample collection tends to introduce opportunities for adventitious contamination that can cause false high readings. The collection of on-line data is not, however, without challenges. The continuous readings tend to create voluminous amounts of data, where previously only a single data point was available. As stated under 6. *Sampling Considerations*, continuous in-process data are excellent for understanding how a water system performs during all of its various usage and maintenance events in real time, but this is too much data for QC purposes. Therefore, for example, one can use a justifiable portion of the data (at a designated daily time or at the time of batch manufacturing) or the highest value in a given period as a worst case representation of the overall water quality for that period. Data averaging is generally discouraged because of its ability to obscure short-lived extreme quality events.

7.2 Chemical Tests for Sterile Waters

Packaged/sterile waters present a particular dilemma relative to the attributes of conductivity and TOC. The package itself is the major source of chemicals (inorganics and organics) that leach over time into the packaged water and can easily be detected by the conductivity and TOC tests. The irony of organic leaching from plastic packaging is that before the advent of bulk water TOC testing, when the *Oxidizable Substances* test was the only "organic purity" test for both bulk and packaged/sterile water monographs in *USP*, the insensitivity of that test to many of the organic leachables from plastic and elastomeric packaging materials was largely unrecognized, allowing organic levels in packaged/sterile water to be quite high (possibly many times the TOC specification for bulk water).

Similarly, glass containers can also leach inorganics, such as sodium, which are easily detected by conductivity but poorly detected by the former wet chemistry attribute tests. Most of these leachables are considered harmless based on current perceptions and standards at the rather significant concentrations present. Nevertheless, they effectively degrade the quality of the high-purity waters placed into these packaging systems. Some packaging materials contain more leachables than others and may not be as suitable for holding water and maintaining its purity.

The attributes of conductivity and TOC tend to reveal more about the packaging leachables than they do about the water's original purity. These currently "allowed" leachables could render the sterile packaged versions of originally equivalent bulk water essentially unsuitable for many uses where the bulk waters are perfectly adequate.

Therefore, to better control the ionic packaging leachables, (645) is divided into two sections. The first is titled *Bulk Water*, which applies to *Purified Water*, *Water for Injection*, *Water for Hemodialysis*, and *Pure Steam*, and includes the three-stage conductivity testing instructions and specifications. The second section is titled *Sterile Water*, which applies to *Sterile Purified Water*, *Sterile Water for Injection*, *Sterile Water for Inhalation*, and *Sterile Water for Irrigation*. The *Sterile Water* section includes conductivity specifications similar to the *Stage 2* testing approach because it is intended as a laboratory test, and these sterile waters were made from bulk water that already complied with the three-stage conductivity test. In essence, packaging leachables are the primary target analytes of the conductivity specifications in the *Sterile Water* section of (645). The effect on potential leachables from different container sizes is the rationale for having two different specifications, one for small packages containing nominal

volumes of 10 mL or less and another for larger packages. These conductivity specifications are harmonized with the *European Pharmacopoeia* conductivity specifications for Sterile Water for Injection. All monographed waters, except *Bacteriostatic Water for Injection*, have a conductivity specification that directs the user to either the *Bulk Water* or the *Sterile Water* section of (645). For the sterile packaged water monographs, this water conductivity specification replaces the redundant wet chemistry limit tests intended for inorganic contaminants that had previously been specified in these monographs.

Controlling the organic purity of these sterile packaged waters, particularly those in plastic packaging, is more challenging. Although the TOC test can better detect these impurities and therefore can be better used to monitor and control these impurities than the current *Oxidizable Substances* test, the latter has a history of use for many decades and has the flexibility to test a variety of packaging types and volumes that are applicable to these sterile packaged waters. Nevertheless, TOC testing of these currently allowed sterile, plastic-packaged waters reveals substantial levels of plastic-derived organic leachables that render the water perhaps orders of magnitude less organically pure than is typically achieved with bulk waters. Therefore, usage of these packaged waters for analytical, manufacturing, and cleaning applications should only be exercised after the purity of the water for the application has been confirmed as suitable.

8. MICROBIAL EVALUATIONS

This section of the chapter presents a discussion about the types and sources of microorganisms and whether certain microbes are prone to colonize pharmaceutical water systems. This section also addresses microbiological examination of water samples, including a discussion on recovery methods.

8.1 Microorganism Types

Microorganisms are ubiquitous and their natural habitats are extremely diverse. Based on comparative ribosomal RNA sequencing, the phylogenetic tree of life consists of three domains: Bacteria and Archaea (both prokaryotes), and Eukarya (eukaryotes). Most microorganisms that contaminate pharmaceutical products are prokaryotic bacteria and eukaryotic fungi (yeasts and molds). These microbes are typical isolates from pharmaceutical environments, including the associated personnel, and a few are frank or opportunistic pathogens. Contamination with viruses is a concern in bioprocessing that uses animal cells.

ARCHAEANS

Microbes from the domain Archaea are phylogenetically related to prokaryotes but are distinct from bacteria. Many are extremophiles, with some species capable of growing at very high temperatures (hyperthermophiles) or in other extreme environments beyond the tolerance of any other life form. In general, most extremophiles are anaerobic or microaerophilic chemolithoautotrophs. Because of their unique habitats, metabolism, and nutritional requirements, Archaeans are not known to be frank or opportunistic pathogens, and they are not capable of colonizing a pharmaceutical water system.

BACTERIA

Bacteria are of immense importance because of their rapid growth, mutation rates, and ability to exist under diverse and adverse conditions. Some are very small and can pass through

0.2- μm rated filters. Others form spores, which are not part of their reproductive cycle. Bacterial spore formation is a complex developmental process that allows the organisms to produce a dormant and highly resistant cell in times of extreme stress. Bacterial endospores can survive high temperatures, strong UV irradiation, desiccation, chemical damage, and enzymatic destruction, which would normally kill vegetative bacteria.

Using a traditional cellular staining technique based on cell wall compositional differences, bacteria are categorized into Gram positive and Gram negative, although many sub-groups exist within each category based on genomic similarities and differences.

8.1.2.1 Gram positives: Gram-positive microbes are common in a pharmaceutical manufacturing environment but not in water systems. This is because Gram positives are generally not suited to surviving in a liquid environment that has the chemical purity of a pharmaceutical-grade water system. Gram positives include the spore-forming bacteria from the genus *Bacillus*, which are common soil and dust contaminants, and the non-sporulating bacteria from the genera *Staphylococcus*, *Streptococcus*, and *Micrococcus*, which normally colonize human skin and mucous membranes. Other types of Gram-positive bacterial contaminants include organisms from the genera *Corynebacterium*, *Mycobacterium*, *Arthrobacter*, *Propionibacterium*, *Streptomyces*, and *Actinomyces*. This latter group of microbes can be found in various natural habitats including the human skin and soil.

Although Gram-positive bacteria can be detected in pharmaceutical water samples, their recovery is often associated with faulty aseptic technique during sampling or testing, or associated with exogenous contamination sources. Although these non-aquatic microorganisms could be present in source water and could, in rare circumstances, make their way into the early stages of a water purification unit operation, Gram-positive bacteria are not known to colonize water systems. In addition, these microbes will likely be removed by one or more of the purification unit operations prior to the ultimate creation of the pharmaceutical-grade water.

8.1.2.2 Gram negatives: These types of bacteria are found in soil, water, plants, and animals. Gram-negative bacteria are of keen interest to pharmaceutical manufacturers, primarily due to their production of endotoxins, a topic discussed in 8.4 *Endotoxin*. Some Gram-negative bacteria prefer aquatic habitats and tend to colonize water systems and other wet environments as biofilms, a topic discussed in 8.2 *Biofilm Formation in Water Systems*.

8.1.2.3 Mycoplasma: Organisms from the genus *Mycoplasma* are the smallest of the bacteria. Unlike other bacteria, these organisms do not have a cell wall and many exist as intracellular or animal parasites. Mycoplasmas also require specific nutrients for survival, including cholesterol, and they cannot survive in a hypotonic environment such as pure water. Based on these facts, this type of bacteria is not a concern for pharmaceutical-grade water systems.

FUNGI

Fungi are mainly aerobic mesophilic microbes. They exist as unicellular (yeast) and multicellular filamentous (mold) organisms. Molds are often found in wet/moist but usually non-aquatic environments, such as soil and decaying vegetation. Examples of common environmental molds include those from the genera *Aspergillus*, *Penicillium*, *Fusarium*, *Cladosporium*, and *Alternaria*. As mold matures it develops spores, which, unlike bacterial spores, are part of their reproductive cycle and are less resistant to adverse conditions. Mold spores are easily spread through air and materials, and could contaminate grab water samples.

Yeasts are often associated with humans and vegetation. Examples of yeasts commonly found in pharmaceutical environments include the genera *Candida*, *Saccharomyces*, and *Rhodotorula*.

Some molds and yeasts are considered human pathogens and a few mold species produce mycotoxins. Neither yeasts nor molds are suited for colonization or survival in pharmaceutical water systems. Their recovery is often associated with faulty aseptic technique during sampling or testing, or associated with exogenous contamination sources. These non-aquatic microorganisms, if present in source water, could make their way into the early stages of a water purification system; however, they will likely be removed by one or more of the purification unit operations.

VIRUSES

A virus is a small infectious agent unlike eukaryotes and prokaryotes. This is because viruses have no metabolic abilities of their own. Viruses are genetic elements containing either DNA or RNA that replicate within host cells. Human pathogenic viruses, especially those of fecal origin, could be present in source water. However, they are easily neutralized by typical water purification treatments, such as chlorination. Therefore, it is unlikely that viruses will be present or will proliferate (due to the absence of host cells) in pharmaceutical-grade waters.

THERMOPHILES

Thermophiles are heat-loving organisms and can be either bacteria or molds. Thermophilic and hyperthermophilic aquatic microorganisms (see 8.1.1 *Archaeans*) require unique environmental and nutritional conditions to survive. These conditions do not exist in the high-purity water of pharmaceutical water systems, whether ambient or hot, to support their growth. Bacteria that are able to inhabit hot pharmaceutical water systems are invariably found in much cooler locations within these hot systems; for example, within infrequently used outlets, ambient subloops off of hot loops, use-point and sub-loop cooling heat exchangers, transfer hoses and connecting pipes, or dead legs. These bacterial contaminants are the same mesophilic (moderate temperature-loving) types found in ambient water systems and are not thermophiles. Based on these facts, thermophilic bacteria are not a concern for hot pharmaceutical-grade water systems.

8.2 Biofilm Formation in Water Systems

A biofilm is a three-dimensional structured community of sessile microbial cells embedded in a matrix of extracellular polymeric substances (EPS). Biofilms form when bacteria attach to surfaces in moist environments and produce a slimy, glue-like substance, the EPS matrix, while proliferating at that location. This slimy matrix facilitates biofilm adhesion to surfaces as well as the attachment of additional planktonic cells to form a microbial community.

The EPS matrix of biofilms that colonize water systems also facilitates adsorption and concentration of nutrients from the water and retains the metabolites and waste products produced by the embedded biofilm cells, which can serve as nutrients for other biofilm community members.

This EPS matrix is also largely responsible for biofilm's resistance to chemical sanitizers, which must penetrate completely through the matrix to contact and kill the biofilm cells within the matrix. Heat sanitization approaches do not generally have these EPS matrix penetration difficulties, so they are usually considered superior to chemicals in killing biofilms where materials of construction allow.

The three-dimensional structure of a well-developed biofilm, as well as the biofilm's creation and release of small, motile "pioneer cells" for further colonization, are facilitated through gene expression modulating "quorum sensing" chemicals released in tiny amounts by individual biofilm cells and concentrated to a functional level within this same EPS matrix. So, the EPS matrix of biofilms is primarily responsible for the biofilm's success in colonizing and proliferating in very low nutrient-containing high-purity water systems. The EPS matrix also explains the difficulty in killing and/or removing biofilms from water purification and distribution system surfaces.

BIOFILM-FORMING BACTERIA IN WATER SYSTEMS

Common microorganisms recovered from water system samples include Gram-negative bacteria from the genera *Pseudomonas*, *Ralstonia*, *Burkholderia*, *Stenotrophomonas*, *Comamonas*, *Methylobacterium*, and many other types of *Pseudomonas*-like organisms known collectively as pseudomonads. These types of microbes, found in soil and source water, tend to colonize all water system distribution and purification system surfaces including activated carbon beds, deionizing resin beds, RO systems, membrane filtration modules, connecting piping, hoses, and valves. If not controlled, they can compromise the functionality of purification steps in the system and spread downstream, possibly forming biofilms on the distribution system surfaces such as tanks, piping, valves, hoses, and other surfaces, from where they can be sheared or otherwise released into the finished water used in processes and products.

Some of the biofilm pseudomonads are opportunistic human pathogens and may possess resistance to commonly used pharmaceutical product preservatives, particularly when imbedded in EPS matrix flocs sheared from water system biofilms. Several pseudomonads are also capable of utilizing a wide variety of carbon sources as nutrients, allowing them to colonize austere, adventitious nutrient environments such as water systems. This nutritional diversity also makes them capable of growing to very high numbers in some pharmaceutical products and raw materials, thus leading to product adulteration and potential risk to patient health. Given that these bacteria are commonly found in aqueous environments, endotoxin control for Water for Injection systems (and some Purified Water systems) through biofilm control becomes critical.

NON-BIOFILM-FORMING BACTERIA IN WATER SYSTEMS

Other types of non-pseudomonad Gram-negative bacteria are generally non-aquatic by nature. They include coliforms from the genera *Escherichia*, *Salmonella*, *Shigella*, *Serratia*, *Proteus*, *Enterobacter*, and *Klebsiella*, which are used as indicators of fecal contamination. Although some of these bacteria can be human enteric pathogens, these non-pseudomonads are not suited to colonizing or surviving in pharmaceutical water systems owing to the water's chemical purity. In fact, non-pseudomonad enteric bacteria are extremely unlikely contaminants of pharmaceutical water systems unless local sewage and source water controls are not in place. Such controls are required in order to comply with the source water requirements for making USP-grade waters as described in their respective monographs.

8.3 Microorganism Sources

EXOGENOUS CONTAMINATION

Exogenous microbial contamination of bulk pharmaceutical water comes from numerous possible sources, including source water. At a minimum, source water should meet the microbial quality attributes of Drinking Water, which is the absence of fecal coliforms (*E. coli*). A wide variety of other types of microorganisms, chiefly Gram-negative bacteria, may be present in the incoming

water. If appropriate steps are not taken to reduce their numbers or eliminate them, these microorganisms may compromise subsequent water purification steps.

Exogenous microbial contamination can also arise from maintenance operations, equipment design, and the process of monitoring, including:

- Unprotected, faulty, or absent vent filters or rupture disks
- Backflow from interconnected equipment
- Non-sanitized distribution system openings for component replacements, inspections, repairs, and expansions
- Inadequate drain air-breaks
- Innate bioburden of activated carbon, ion-exchange resins, regenerant chemicals, and chlorine-neutralizing chemicals
- Inappropriate rinsing water quality after regeneration or sanitization
- Poor sanitization of use points, hard-piped equipment connectors, and other water transfer devices such as hoses
- Deficient techniques for use, sampling, and operation

The exogenous contaminants may not be normal aquatic bacteria but rather microorganisms of soil, air, or even human origin. The detection of non-aquatic microorganisms may be an indication of sampling or testing contamination or a system component failure, which should trigger investigation and remediation. Sufficient care should be given to sampling, testing, system design, and maintenance to minimize microbial contamination from exogenous sources.

ENDOGENOUS CONTAMINATION

Endogenous sources of microbial contamination can arise from unit operations in a water purification system that is not properly maintained and operated. Microorganisms present in source water may adsorb to carbon bed media, ion-exchange resins, filter membranes, and other equipment surfaces, and initiate the formation of biofilms.

Downstream colonization can occur when microorganisms are shed from existing biofilm-colonized surfaces and carried to other areas of the water system. Microorganisms may also attach to suspended particles such as carbon bed fines or fractured resin particles. When the microorganisms become planktonic, they serve as a source of contamination to subsequent purification equipment and to distribution systems.

Another source of endogenous microbial contamination is the distribution system itself. Microorganisms can colonize pipe surfaces, rough welds, misaligned flanges, valves, and dead legs, where they proliferate and form biofilms. Once formed, biofilms can become a continuous source of microbial contamination, which is very difficult to eradicate. Therefore, biofilm development must be managed by methods such as frequent cleaning and sanitization, as well as process and equipment design.

8.4 Endotoxin

Endotoxins are lipopolysaccharides found in and shed from the cell envelope that is external to the cell wall of Gram-negative bacteria. Some grades of pharmaceutical waters, such as those used in parenteral applications (e.g., *Water for Injection*, *Water for Hemodialysis*, and the sterilized packaged waters made from *Water for Injection*) strictly limit the amount of endotoxins that may be present because these compounds are pyrogenic.

SOURCES

Endotoxins may occur as collections of lipopolysaccharide molecules associated with living microorganisms, fragments of dead microorganisms, the EPS matrix surrounding biofilm bacteria, or free molecular clusters or micelles containing many lipopolysaccharide molecules. The monomeric form of the endotoxin molecule does not exist in high-purity water because of its amphiphilic nature. Endotoxins may be introduced into the system from the source water or may be released from cell surfaces of bacteria that colonize the water system. For example, a spike in endotoxin may occur following sanitization as a result of endotoxin release from killed cells. Endotoxin quantitation in water samples is not a good indicator of the level of biofilm development in a water system because of the multiplicity of endotoxin sources.

REMOVAL AND CONTROL

To control endotoxin levels in water systems, it is important to control all potential sources of contamination with Gram-negative bacteria as well as free endotoxin in the water. Contamination control includes the use of upstream unit operations to reduce bioburden from incoming water, as well as engineering controls (e.g., heat sanitization, equipment design, UV sanitizers, filters, material surface, and flow velocity) to minimize biofilm development on piping surfaces and to reduce re-inoculation of the system with free-floating bacteria.

Endotoxin remediation may be accomplished through the normal exclusion or removal action afforded by various unit operations within the treatment system. Examples of endotoxin removal steps in a water purification train include RO, deionization, ultrafilters, and endotoxin-adsorptive filters.

8.5 Test Methods

Microbes in water systems can be detected as exemplified in this section or by methods adapted from *Microbial Enumeration Tests* (61), *Tests for Specified Microorganisms* (62), or the current edition of *Standard Methods for the Examination of Water and Wastewater* by the American Public Health Association. This section describes classical culture approaches to bioburden testing, with a brief discussion on rapid microbiological methods.

Every water system has a unique microbiome. It is the user's responsibility to perform method validation studies to demonstrate the suitability of the chosen test media and incubation conditions for bioburden recovery. In general, users should select the method that recovers the highest planktonic microbial counts in the shortest time, thus allowing for timely investigations and remediation. Such studies are usually performed before or during system validation. In addition, the chosen method should be reassessed periodically, as the microbiome of a new water system gradually establishes a steady state relative to the system's routine maintenance, use, and sanitization procedures.

The steady state condition can take months or even years to be achieved, and can be affected by a change in source water quality, changes in finished water purity by using modified or increasingly inefficient purification processes, changes in finished water use patterns and volumes, changes in routine and preventative maintenance or sanitization procedures and frequencies, or any type of system intrusion (e.g., component replacement, removal, or addition).

MICROBIAL ENUMERATION CONSIDERATIONS

Most microbial contaminants in water systems are found primarily as biofilms on surfaces, with only a very small percentage of the microbiome suspended in the water, or planktonic, at any

given time. Although it would seem logical to directly monitor biofilm development on surfaces, current technology for surface evaluations in an operating water system makes this impractical in a GMP environment. Therefore, an indirect approach must be used: the detection and enumeration of planktonic microorganisms that have been released from biofilms. This planktonic microbiome will impact the processes or products where the water is used.

The detection and enumeration of the planktonic microbiome can be accomplished by collecting samples from water system outlets. Planktonic organisms are associated with the presence of biofilms as well as free-floating bacteria introduced into the system (pioneer cells), which may eventually form new biofilms. Therefore, by enumerating the microorganisms in water grab samples, the overall state of control over biofilm development can be assessed. This assessment has historically been accomplished with classical cultural techniques, which are viewed as the traditional method. However, nutritional limitations of the growth media may not satisfy growth requirements of organisms present in the water system that originated from a biofilm. As a result, traditional cultural methods may only detect a fraction of the biofilm bacteria present in the water sample. Other options are available, such as rapid microbiological methods.

There is no ideal cultural enumeration method that will detect all microorganisms in a water sample, although some media or incubation temperatures may be better than others. However, from a PC perspective, this limitation is acceptable because it is the relative changes in the trends for water sample microbial counts that indicate the state of PC.

THE CLASSICAL CULTURAL APPROACH

Classical cultural approaches for microbial testing of water include but are not limited to pour plates, spread plates, membrane filtration, and most probable number (MPN) tests. These methods are generally easy to perform, and provide excellent sample processing throughput. Method sensitivity can be increased via the use of larger sample sizes. This strategy is used in the membrane filtration method. Cultural approaches are further defined by the type of medium used in combination with the incubation temperature and duration. This combination should be selected according to the monitoring needs of a specific water system and its ability to recover the microorganisms of interest, i.e., those that could have a detrimental effect on the products manufactured or process uses, as well as those that reflect the microbial control status of the system.

8.5.2.1 Growth media: The traditional categorization is that there are two basic forms of media available: "high nutrient" and "low nutrient". Those media traditionally categorized as high-nutrient include Plate Count Agar (TGYA), Soybean Casein Digest Agar (SCDA or TSA), and m-HPC Agar (formerly m-SPC Agar). These media are intended for the general isolation and enumeration of heterotrophic or copiotrophic bacteria. Low-nutrient media, such as R2A Agar and NWRI Agar (HPCA), have a larger variety of nutrients than the high-nutrient media. These low-nutrient media were developed for use with potable water due their ability to recover a more nutritionally diverse population of microorganisms found in these environments. The use of R2A may not be the best choice for high-purity water systems. Even though high-purity water creates an oligotrophic environment, it has been shown empirically that in many high-purity compendial waters, the microbial count disparity between low- and high-nutrient media is dramatically less to nil, compared to potable water. Nevertheless, using the medium that has been demonstrated, through validation studies, to be the most optimal for the microbiome in a particular water system is essential.

8.5.2.2 Incubation conditions: Duration and temperature of incubation are also critical aspects of microbiological testing. Classical compendial methods (e.g., (61)) specify the use of high-nutrient media, typically incubated at 30°–35° for NLT 48 h. Given the types of microbes found in many water systems, incubation at lower temperatures (e.g., ranges of 20°–25° or 25°–30°) for longer periods (at least 4 days) could recover higher microbial counts than classical compendial methods. Low-nutrient media typically require longer incubation conditions (at least 5 days) because the lower nutrient concentrations promote slower growth. Even high-nutrient media can sometimes yield higher microbial recovery with longer and cooler incubation conditions. The decision to test a particular system using high- or low-nutrient media, higher or lower incubation temperatures, and shorter or longer incubation times should be based on comparative cultivation studies using the native microbiome of the water system. The decision to use media requiring longer incubation periods to recover higher counts should be also be balanced with the timeliness of results. Detection of marginally higher counts at the expense of a significantly longer incubation period may not be the best approach for monitoring water systems. Some cultural conditions using low-nutrient media lead to the development of microbial colonies that are much less differentiated in colonial appearance, an attribute that microbiologists rely on when selecting representative microbial types for further characterization. The nature of some of the slow growers and the extended incubation times needed for their development into visible colonies may also lead to those colonies becoming dysgonic and difficult to subculture. This could limit their further characterization, depending on the microbial identification technology used.

SUGGESTED CLASSICAL CULTURAL METHODS

The example methods presented in *Table 2* are optional and may or may not be optimal for recovering microorganisms, including those considered objectionable, or biofilms. Users should determine through experimentation which methods are best for in-process and QC monitoring, as well as for recovering specific microorganisms that could be found in the water system and might be objectionable for the intended water use.

Table 2. Example Culture Methods

<i>Drinking Water:</i>	Pour Plate Method or Membrane Filtration Method ^a
	Suggested Sample Volume—1.0 mL ^b
	Growth Medium—Plate Count Agar ^c
	Incubation Time—48-72 h ^d
	Incubation Temperature—30°-35° ^e
<i>Purified Water:</i>	Pour Plate Method or Membrane Filtration Method ^b
	Suggested Sample Volume—1.0 mL for pour plate or 100 mL for membrane filtration ^b
	Growth Medium—Plate Count Agar ^c
	Incubation Time—48-72 h ^d
	Incubation Temperature—30°-35° ^e
<i>Water for Injection:</i>	Membrane Filtration Method ^a
	Suggested Sample Volume—200 mL ^b
	Growth Medium—Plate Count Agar ^c
	Incubation Time—48-72 h ^d
	Incubation Temperature—30°-35° ^e
<p>^a A membrane filter with a rating of 0.45 µm is generally considered preferable to smaller porosity membranes.</p> <p>^b Sample size must be appropriate for the expected microbial count of the water in order to derive statistically valid colony counts.</p> <p>^c For optimum recovery, an alternative medium may be more appropriate (e.g., m-HPC, TSA/SCDA, R2A).</p> <p>^d For optimum recovery, alternative incubation times may be needed.</p> <p>^e For optimum recovery, alternative incubation temperatures may be needed.</p>	

For media growth promotion, use at a minimum *Pseudomonas aeruginosa* ATCC 9027 and *Bacillus subtilis* ATCC 6633. Additional organisms should be used to represent those that are considered objectionable and/or typically isolated from the water system (house isolates).

MICROBIAL IDENTIFICATION

In addition to the enumeration of the bioburden in the water, there is a need to identify and/or select for certain microbial species that could be detrimental to products or processes. Some bacteria may also be resistant to preservatives and other antimicrobial chemicals used in liquid and semi-solid products, thus leading to potential product spoilage. For example, *Pseudomonas aeruginosa* and *Burkholderia cepacia*, as well as some other pseudomonads, are known opportunistic pathogens. As such, it may be appropriate to consider these species as objectionable microorganisms for the type of water used to manufacture liquid and semi-solid products. There is a higher risk of infection if these organisms are found in products targeted for susceptible patient populations (e.g., the very young, the very old, and the immunocompromised) or products contacting highly susceptible tissues (e.g., inhaled products or some topical products). However, if the product where the water is used carries an absence

specification for a particular pathogenic species that is not capable of living in a high-purity water system, then these non-aquatic species should not be candidates for routine water testing.

For PC, it is valuable to know the microbial species present in the normal microbiome of a water system, even if they are not specifically objectionable. If a new species is detected, it may be an indication of a subtle process change or an exogenous intrusion. The identity of the microorganism may be a clue as to its origin and can help with implementation of corrective or preventive action. Therefore, it is industry practice to identify the microorganisms in samples that yield results exceeding established Alert and Action Levels. It may also be of value to periodically identify the normal microbiome in a water system, even if counts are below established Alert Levels. This information can provide perspective on the species recoveries from Alert and Action Level excursion samples, indicating whether they are new species or just higher levels of the normal microbiome. Water system isolates are often incorporated into a company culture collection for use in tests such as preservative challenge tests, microbial method validation/suitability testing, and media growth promotion.

RAPID MICROBIOLOGICAL METHODS

In recent years, new technologies that enhance microbial detection and the timeliness of test results have been adopted by pharmaceutical QC testing labs. Rapid Microbiological Methods (RMM) are divided into four categories: Growth-Based, Viability-Based, Artifact-Based, and Nucleic Acid-Based. Examples of RMM used for the evaluation of microbial quality of water systems include:

- Microscopic visual epifluorescence membrane counting techniques
- Automated laser scanning membrane counting approaches
- Early colony detection methods based on autofluorescence, ATP, bioluminescence, or vital staining
- Genetic-based detection/quantitation

Some of these methods provide greater precision, accuracy, and speed of microbial detection, compared to classical cultural approaches. These advantages are counterbalanced by limited sample processing throughput due to larger sample requirements and/or labor-intensive sample processing, or other instrument and sensitivity limitations.

In addition, some of these RMM kill the microbial cells to detect their presence. This precludes subsequent characterization, or identification, which are often necessary for system control and QC testing. Consequently, culturing approaches have traditionally been preferred over some of the rapid microbiological technologies because cultures offer a balance of desirable test attributes and post-test capabilities.

9. ALERT AND ACTION LEVELS AND SPECIFICATIONS

9.1 Introduction

Establishment of Alert and Action Levels for any manufacturing process facilitates appropriate and timely control. In the case of a pharmaceutical water system, the key PC parameters can be specific chemical, physical, and microbiological attributes of the water produced. Typically, most chemical attributes can be determined in real time or in the lab within a few min after sample collection. Physical attributes such as the pressure drop across a filter, temperature,

and flow rate—which are sometimes considered critical for operation or sanitization of the water system—must be measured *in situ* during operation. Obtaining timely microbial data is more challenging compared to chemical and physical attributes, often taking several days. This limits the ability to control microbial attributes in a timely manner, and therefore requires a more challenging evaluation of the test results and conservative implementation of PC levels. This section provides guidance on the establishment and use of Alert and Action Levels, as well as Specifications to assess the suitability of the water and the water system for use in production.

9.2 Examples of Critical Parameter Measurements

Examples of measurements and parameters that are important to water system processes and products are described below. The list, which is not intended to be exhaustive or required, contains some examples of parameters that could be measured to demonstrate that the system is in a state of control.

Examples of measurements that could be critical to the purification or sanitization process include:

- Temperature, for thermally sanitized systems
- % Rejection of an RO system
- Endotoxin levels of feed water to a distillation system
- Chlorine presence immediately prior to an RO system

Examples of measurements that could be critical to the water distribution process include:

- Return/end-of-loop line pressure, to forewarn of a negative pressure from simultaneous use of too many outlets
- Beginning and end-of-loop flow rate, to forewarn of an excessively high flow rate at the UV lamps if too many outlets are open
- Flow rate, to ensure that sufficient water is available for operations

Examples of measurements that could be critical to final water quality include:

- Conductivity
- TOC
- Endotoxin—for Water for Injection systems
- Particulate matter
- Bioburden
- Ozone or other chemicals—for chemically sanitized systems

9.3 Purpose of the Measurements

Although the purpose of each measurement varies, the results can be used to provide system performance feedback, often immediately, serving as ongoing PC and product quality indicators. At the same time, the results provide information necessary for making decisions regarding the immediate processing and usability of the water (see 6.1 *Purposes and Procedures*). However, some attributes may not be monitored continuously or may have a long delay in data availability (e.g., microbial data). Regardless, both real-time data and data with longer cycle times can be used to properly establish Alert and Action Levels, which can serve as an early warning or indication of a potentially approaching quality shift.

As PC indicators, Alert and Action Levels are trigger points for the potential need for investigation and/or remedial action, to prevent a system from deviating from normal conditions

and producing water unsuitable for its intended use. This "intended use" minimum quality is sometimes referred to as a "Specification" or "Limit", and may include limits for conductivity and TOC listed in water monographs, or other specifications required for these waters that have been defined by the user internally.

In all cases, the validity of the data should be verified to ensure that the data are accurate and consistently representative of the water quality in the system, regardless of whether the sample was collected from a sampling port or use point. The resulting data must not be unduly biased, positively or negatively, due to the sampling method, the environment in the vicinity of the sampling location, the test procedure, instrumentation, or other artifacts that could obscure or misrepresent the true quality of the water intended by the purpose of the sampling, i.e., for PC or for QC.

9.4 Defining Alert and Action Levels and Specifications

Data generated from routine water system monitoring should be trended to ensure that the system operates in a state of chemical and microbiological control. To assist with the evaluation of system performance, companies should establish in-process control levels based on historical data or a fraction of the water Specifications (as long as this latter approach yields values with relevance to process performance).

When establishing Alert and Action Levels and Specifications, a two- or three-tier approach is typically used. In a three-tier approach, the typical structure is to establish in-process controls using *Alert Level*, *Action Level*, and *Specification*. Alert and Action Levels are used as proactive approaches to system management prior to exceeding Specifications. The criteria for defining and reacting to adverse trends should be set by the user. These levels should be set at values that allow companies to take action to prevent the system from producing water that is unfit for use. Water Specifications or Limits represent the suitability for use of the water.

In a two-tier approach, a combination of the above terminology is used, depending on the parameter to be monitored. For example, if the attribute does have a monograph specification, the two tiers are Alert Level (or Action Level) and Specification. If the attribute does not have a limit/specification, the two tiers are usually Alert Level and Action Level.

A single-tier approach is possible, but this is risky and difficult to manage. With this approach, where the water/system is either acceptable or not acceptable, the single-tier method does not allow for any adjustment, correction, or investigation prior to stopping production.

However, certain sampling locations, such as sampling ports that are not used for manufacturing products or processes, do not represent the finished water quality where a Specification could be applied. In these locations, a two-tier approach (Alert and Action Levels only) could be applied. In some sampling locations, a single PC level might possibly be appropriate, depending on the attribute.

ALERT LEVEL

An Alert Level for a measurement or parameter should be derived from the normal operating range of the water system. Specifically, Alert Levels are based on the historical operating performance under production conditions, and then are established at levels that are just beyond the majority of the normal historical data. The Alert Level for a parameter is often a single value or a range of values, such as:

- Higher than typical conductivity or TOC

- Higher than typical microbial count
- Higher than typical endotoxin level
- Low temperature during thermal sanitization
- pH range control prior to an RO
- Ozone concentration in a storage tank

Various methods, tools, and statistical approaches are available for establishing Alert Levels, and the user needs to determine the approaches that work for their application. Some numerical examples are two or three standard deviations Ω (or more) in excess of the mean value, or some percentage above the mean value but below a Specification. An event-based example could be the appearance of a new microorganism or a non-zero microbial count where zero is the norm.

When an Alert Level is exceeded, this indicates that a process or product may have drifted from its normal operating condition or range. Alert Level excursions represent a warning and do not necessarily require a corrective action. However, Alert Level excursions may warrant notification of personnel involved in water system operation, as well as the QA personnel. Alert Level excursions may also lead to additional monitoring, with more intense scrutiny of the resulting and neighboring data as well as other process indicators.

ACTION LEVEL

An Action Level is also based on the same historical data, but the levels are established at values (or ranges) that exceed the Alert Levels. The values/ranges are determined using the same types of numerical or event-based tools as the Alert Levels, but at different values.

In a three-tier approach, it is good practice to select an Action Level that is more than the Alert Level, but less than the Specification to allow the user to make corrective actions before the water would go out of compliance.

Exceeding a quantitative Action Level indicates that the process has allowed the product quality or other critical parameter to drift outside of its normal operating range. An Action Level can also be event-based. In addition to exceeding quantitative Action Levels, some examples of event-based Action Level excursions include, but are not limited to:

- Exceeding an Alert Level repeatedly
- Exceeding an Alert Level in multiple locations simultaneously
- The recovery of specific objectionable microorganisms
- A repeating non-zero microbial count where zero is the norm

If an Action Level is exceeded, this should prompt immediate notification of both QA staff and the personnel involved in water system operations and use, so that corrective actions can be taken to restore the system back to its normal operating range. Such remedial actions should also include investigative efforts to understand what happened and eliminate or reduce the probability of recurrence. Depending on the nature of the Action Level excursion, it may be necessary to evaluate its impact on the water uses during the period between the previous acceptable test result and the next acceptable test result.

SPECIAL ALERT AND ACTION LEVEL SITUATIONS

In new or significantly altered water systems, where there is limited or no historical data from which to derive trends, it is common to establish initial Alert and Action Levels based on equipment design capabilities. These initial levels should be within the process and product

Specifications where water is used. It is also common for new water systems, especially ambient water systems, to undergo changes, both chemically and microbiologically, over time as various unit operations (such as RO membranes) exhibit the effects of aging. This type of system aging effect is most common during the first year of use. As the system ages, a steady state microbial population (microorganism types and levels) may develop due to the collective effects of system design, source water, maintenance, and operation, including the frequency of re-bedding, backwashing, regeneration, and sanitization. This established or mature microbial population may be higher than the one detected when the water system was new. Therefore, there is cause for the impurity levels to increase over this maturation period and eventually stabilize.

Some water systems are so well controlled microbially—such as continuously or intermittently hot Water for Injection distribution systems—that microbial counts and endotoxin levels are essentially nil or below the limit of reasonable detectability. This common scenario often coincides with a very low Specification that is poorly quantifiable due to imprecision (as much as two-fold variability) of the test methods that may be near their limits of detection. In such systems, quantitative data trending has little value, and therefore, quantitative PC levels also have little value. The non-zero values in such systems could be due to sporadic sampling issues and not indicative of a water system PC deviation; however, if these non-zero values occur repeatedly, they could be indicative of process problems. So, an alternative approach for establishing Alert and Action Levels with these data could be the use of the incident rate of non-zero values, with the occasional single non-zero “hit” perhaps being an Alert Level (regardless of its quantitative value), and multiple or sequential “hits” being an Action Level. Depending on the attribute, perhaps single hits may not even warrant being considered an Alert Level, so only a multiple-hit situation would be considered actionable. It is up to the user to decide on their approach for system control, i.e., whether to use one, two, or three levels of controls for a given water system and sampling location, and whether to establish Alert and Action Levels as quantitative or qualitative hit-frequency values.

SPECIFICATIONS

Water Specifications or Limits are set based on direct potential product and/or process impact and they represent the suitability for use of the water. The various bulk water monographs contain tests for *Conductivity*, *TOC*, and *Bacterial Endotoxins* (for Water for Injection). Aside from the monographs for *Water for Hemodialysis* and multiple sterile waters, microbial specifications for the bulk waters are intentionally not included in their monograph tests. The need for microbial specifications for bulk waters (*Purified Water* and Water for Injection) depends on the water use(s), some of which may require strict control (e.g., very low bioburden, absence of objectionable organisms, or low ionic strength) while others may require no specification due to the lack of impact. For example, microbial specifications are appropriate and typically expected for water that is used in product formulations and final equipment rinses. However, where the water is used for analytical reagent preparation or for cleaning processes that conclude with a final antimicrobial heat drying or solvent rinsing step, the microbial quality of the water is likely less of a concern. The decision to establish microbial Specifications for bulk pharmaceutical waters should be based on a formal risk assessment of its uses and justified by scientific rationale.

It is very important to understand the chemical and microbial quality of the water in its final form as it is delivered from a water system to the locations where it is used in manufacturing activities and other points of use. The quality of the water within the water system could be

compromised if it picks up chemical or microbial contaminants during its delivery from the system to the points of use. These points of use, where cumulative contamination could be present, are the locations where compliance with all the water Specifications is mandated.

As discussed above, compliance with chemical Specifications can be confirmed periodically between uses, immediately prior to use, or even while the water is being utilized in product manufacturing. While the use of RMM may provide for timely microbial data, the use of conventional cultivative microbiological testing usually delays confirmation of microbial compliance until after the water has been used. However, for some applications, this logistical limitation should not eliminate the need for establishing microbial Specifications for this very important raw material.

The manufacturing risk imposed by these logistics accentuates the value of validated microbial control for a water system. It also emphasizes the value of unbiased microbial monitoring of samples collected from pertinent locations, with evaluation of the resulting data against well-chosen, preferably trend-derived Alert and Action Levels, which can facilitate remedial PC to preclude Specification excursions.

Users should establish their own quantitative microbial Specifications suited to their water uses. But these values should not be greater than 100 cfu/mL for *Purified Water* or 10 cfu/100 mL for *Water for Injection* unless specifically justified, because these values generally represent the highest microbial levels for pharmaceutical water that are still suitable for manufacturing use.

A Specification excursion should prompt an out-of-specification (OOS) investigation. The investigation is performed to determine 1) the root cause of the excursion so that CAPA may be taken for remediation purposes, and 2) assess the impact on affected processes and finished products where the water was used. Product disposition decisions must be made and are dependent on factors which could include:

- Role of water in the product or in-process material
- Chemical or microbial nature of the attribute whose Specification value was exceeded
- Level of product contamination by the water
- Presence of objectionable microorganisms
- Any downstream processing of affected in-process materials that could mitigate the OOS attribute
- Physical and chemical properties of the finished product where the water was used that could mitigate the OOS attribute
- Product administration routes and potentially sensitive/susceptible users

SOURCE WATER CONTROL

The chemical and microbial attributes of the starting source water are important to the ability of the water system to remove or reduce these impurities to meet the finished water Specifications (see 2. *Source Water Considerations*). Using the example microbial enumeration methods in *Table 2*, a reasonable maximum bacterial Action Level for source water is 500 cfu/mL. This number is derived from U.S. EPA NPDWR where it is used as an Action Level for the water authority indicating the need for improving disinfection and water filtration to avoid the penetration of viral, bacterial, and protozoal pathogens into the finished Drinking Water. It is not, however, a U.S. EPA heterotrophic plate count Specification or Maximum Contaminant Level (MCL) for Drinking Water.

Nevertheless, of particular importance could be the microbial and chemical quality of this

starting water because the water is often delivered to the facility at a great distance from its source and in a condition over which the user has little or no control. High microbial and chemical levels in source water may indicate a municipal potable water system upset, a change in the supply or original water source, a broken water main, or inadequate disinfection, and therefore, potentially contaminated water with objectionable or new microorganisms or coincidental chemical contaminants.

Considering the potential concern about objectionable microorganisms and chemical contaminants in the source water, contacting the water provider about the problem should be an immediate first step. In-house remedial actions could also be needed, including performance of additional testing on the incoming water (as well as the finished water in some cases) or pretreating the water with additional microbial and chemical purification operations (see 5.1 *Unit Operations Considerations*).

■ 2S (USP39)

BRIEFING

⟨1239⟩ **Vaccines for Human Use—Viral Vaccines.** This new general information chapter addresses a need for the description of best practices in the development, production, and testing of viral vaccines for human use. This chapter will serve as a useful addition to an existing family of vaccine-related chapters, which includes *Vaccines for Human Use—Polysaccharide and Glycoconjugate Vaccines* ⟨1234⟩, *Vaccines for Human Use—General Considerations* ⟨1235⟩, and *Vaccines for Human Use—Bacterial Vaccines* ⟨1238⟩ thus far. The General Chapters—Biological Analysis Expert Committee presents ⟨1239⟩, which describes the different types of viral vaccines with their advantages and challenges. Sections of ⟨1239⟩ also address the raw materials, primary cell lines, seed lot systems and cell banks, culture and harvest, purification, intermediates, drug substance, drug product, and lot release tests for viral vaccines.

1. INTRODUCTION

Vaccines for the prevention of at least 15 human viral diseases have been commercialized in the United States (*Table 1*); others have been licensed outside the U.S. Together, these vaccines have formed a primary public health measure for the prevention of these viral diseases worldwide. Other viral vaccines are in development and in clinical trials. For the purposes of this chapter, a viral vaccine is a vaccine that prevents a viral disease; this includes products derived from cultured viruses and those derived from recombinant expression of viral antigens. General considerations for both viral and bacterial vaccines are provided in *Vaccines for Human Use—General Considerations* (1235).

Table 1. Examples of Human Diseases Preventable with Viral Vaccines

Live Attenuated Virus Vaccines	Inactivated Virus Vaccines
<ul style="list-style-type: none"> • Adenovirus types 4 and 7 • Influenza A and B • Japanese encephalitis • Measles • Mumps • Poliomyelitis types 1, 2, and 3 • Rotavirus • Rubella • Smallpox • Yellow fever • Varicella-zoster (separately, chickenpox, and shingles) 	<ul style="list-style-type: none"> • Hepatitis A • Poliomyelitis types 1, 2, and 3 • Rabies
	Subunit Virus Vaccines
	<ul style="list-style-type: none"> • Influenza A and B
	Recombinant Virus-Like Particle Vaccines
	<ul style="list-style-type: none"> • Hepatitis B • Human papillomavirus types 6, 11, 16, and 18

1.1 General Categories of Viral Vaccines

There are currently four general categories of viral vaccines that have received regulatory approval: live attenuated, inactivated, virus-derived subunit vaccines, and virus-like particle (VLP) vaccines using recombinant proteins. Other strategies, including DNA-based vaccines, are in development. The characteristics, advantages, and challenges of commercially available viral vaccines are listed in *Table 2*.

Table 2. Characteristics, Advantages, and Challenges of Different Types of Viral Vaccines

Live Attenuated Viral Vaccines		
Characteristics	Advantages	Challenges
<ul style="list-style-type: none"> • Able to replicate in the host • Attenuated in pathogenicity • Elicit both antibodies and cell-mediated immunity 	<ul style="list-style-type: none"> • May elicit broader immune responses than other vaccine types (i.e., both humoral and cellular) • May require fewer doses • Highly effective • Protection is generally longer lasting 	<ul style="list-style-type: none"> • Limited understanding of mechanism and stability of attenuation • Ensuring stability • Analysis • Manufacture • Possible pathogenic reversion • Possible transmission to another person via "shedding" • Controlling reactogenicity
Inactivated, Subunit, and Recombinant VLP Viral Vaccines		
Characteristics	Advantages	Challenges
<ul style="list-style-type: none"> • Unable to replicate in the host • Not pathogenic • Elicit mostly humoral immune responses 	<ul style="list-style-type: none"> • Cannot multiply or revert to pathogenicity • Generally less reactogenic • Not transmissible to another person • More stable than live viral vaccines 	<ul style="list-style-type: none"> • Ensuring sufficient immunogenic potency • May require adjuvant to enhance immune responses • Stimulating cell-mediated immune responses • May require multiple doses • Variable efficacy

Viral vaccines may be based on live viruses that have been attenuated to reduce or eliminate their ability to cause disease. Attenuation, the loss of virulence, results from reassortment or from mutations induced by passage of the virus in semi-permissive or atypical animal cells (or animals), or under altered growth conditions (e.g., at temperatures lower than the host's body temperature), or both. Variants (mutants) of the virus exist that induce reduced disease pathology in their original host and are selected. Such variants, nevertheless, are still able to replicate and are still fully immunogenic. The development of these vaccines is not

standardized, and the passage and propagation is varied dependent on each virus. The virus is often passaged in alternate hosts for varying periods and then tested in the desired host after several passages to determine whether the vaccine is sufficiently attenuated pathogenically but still immunogenic enough to elicit protective responses (i.e., to avoid over-attenuation leading to loss of immunogenicity).

Because live vaccines are grown in animal cells (e.g., primary chick embryo cells) or human cells (e.g., MRC-5, WI-38), contamination by extraneous viruses and other adventitious agents already present in these substrates or introduced during manufacturing (e.g., raw material contamination) is a potential risk. This risk of contamination requires a control strategy for manufacturing and testing that will ensure vaccine purity and safety.

1.2 Inactivated Viral Vaccines

Inactivated viral vaccines are produced by culturing and isolating a virus and then inactivating it. Inactivated viral vaccines may or may not be purified after harvest and before inactivation. Although many such vaccines have been successful in controlling viral diseases, not all viral proteins are equally immunogenic, and an unbalanced presentation (greater number of less immunogenic proteins) can dampen the immune response to protective antigens. Modification of the primary protective antigens can induce atypical immune responses that may enhance disease upon natural infection. This phenomenon was observed for formalin-inactivated measles virus and respiratory syncytial virus in early vaccines developed in the 1960s. Because of this experience, the use of live attenuated measles vaccines is now recommended.

1.3 Subunit Vaccines

Subunit vaccines are composed of viral components, which may be extracted from cultured virus or produced via recombinant technology. Traditional inactivated influenza vaccine components (influenza A and B) are grown in embryonated eggs, and the hemagglutinin (HA) and neuraminidase (NA) antigens are purified following membrane solubilization (splitting).

1.4 Virus-like Particle Vaccines

VLP vaccines, in which recombinant viral antigens are assembled (or self-assembled) into particles or are incorporated into a lipid vesicle, have been developed for hepatitis B and human papillomavirus (HPV) infections. The most common recombinant platforms are yeast and insect cell lines. Although they are more immunogenic than the monomeric antigen, all currently manufactured VLP vaccines based on recombinant protein technology require the addition of adjuvants (e.g., aluminum salts, monophosphoryl lipid A) to optimize immunogenicity. These vaccines have advantages and challenges similar to those of inactivated viral vaccines.

2. RAW MATERIALS

Raw materials can directly affect the identity, strength, purity, and quality of viral vaccines. A consistent manufacturing process is critically dependent on the use of consistent raw materials. This applies during seed banking, fermentation, harvest, purification, and formulation

(see <1235>). Unlike bacterial cultures, which can often be maintained productively with relatively few and simple culture medium components, cultures of eukaryotic animal and insect cells require a large number of components to sustain cell growth and viral replication; basal media often contain over 60 ingredients. Culture ingredients must be selected carefully, especially for enveloped viruses, as many of these can only be partially purified without sustaining loss of infectivity or antigenicity. In such cases, the suitability of raw material for human administration can be a key criterion. A formal risk analysis of all raw materials should be performed to assess any risk of low-level contamination by unwanted entities.

Expectations for the types and composition of media to be used for cell culture in preparing viral vaccines are discussed in <1235>. Low molecular weight components (approximately 1000 Da or less) are usually synthesized chemically, although some can be derived from animal- or plant-sourced raw materials. These small molecule components should conform to applicable compendial requirements where they exist, although some may require further qualification via specific tests (e.g., *Bacterial Endotoxins Test* <85>). Use testing often takes the form of a cell-growth promotion test. Virus-growth promotion tests are more difficult to configure, because detection of virus-neutralizing antibodies is more straightforward in a serial-dilution format against a reference serum. Eukaryotic cells in culture typically require additives, such as cytokines, growth factors, attachment factors, lipid carriers, and other beneficial components as well (see *Growth Factors and Cytokines Used in Cell Therapy Manufacturing* <92>). These can sometimes be supplied individually from recombinant sources, but other times animal blood serum (e.g., fetal bovine serum) with or without protein hydrolysates is added to the culture medium as a simple solution for these requirements.

For animal-derived raw materials in particular, it is important to guard against entry of adventitious agents into the process. Many vaccine viruses cannot be purified away from environmental contaminants, and therefore prevention of entry is required to ensure the safety of the product during the manufacturing operation. Animal raw materials are controlled in several ways. The origin of the herd(s) or flock(s) used are documented, and sometimes controlled or isolated and monitored, to ensure the absence of disease. The material is harvested from the animals under controlled conditions using standardized, documented practices. Preferably, these conditions and practices are specifically designed for pharmaceutical use to ensure that the raw material is not inadvertently contaminated with other viruses or microbes. Therefore, the material is processed and stored appropriately to avoid contamination. In addition, it is usually treated to eliminate any microbe that may have been introduced from the source or during processing. These treatments may include terminal sterile filtration, UV or gamma irradiation, detergents, heat, or a combination thereof.

Quantitative risk analysis with careful documentation should be performed on all of these factors that impact viral safety to ensure an appropriate level of product safety. For specific guidance on bovine serum quality attributes, sourcing, and testing, see *Bovine Serum* <1024> and *Fetal Bovine Serum—Quality Attributes and Functionality Tests* <90>.

3. EGGS AND PRIMARY CELL LINES USED IN VIRAL VACCINE PRODUCTION

3.1 Maintenance of Flocks

For *in ovo* cultured vaccines, the eggs are derived from isolated flocks of birds that are established for several generations and tested to ensure absence of common transmissible

pathogens before, during, and after use for specific-pathogen-free (SPF) egg laying. Potential contaminants of the avian flocks (including those that infect nonhuman species) are routinely tested for and monitored. Flock origin and husbandry, isolation and management practices, health history, and testing should be clearly documented.

3.2 Handling of Eggs

The number of eggs used for vaccine production is variable, depending on the validated process in the manufacturers' license. Upon arrival at the facility, the eggs are first candled, i.e., held up to light to view the embryo to determine embryo viability and lack of contamination for egg selection. The eggs are then sanitized and injected with virus, which is allowed to propagate until harvest. Embryo age, candling procedures, sanitization methods, and injection and incubation methods are all critical manipulations in the manufacturing process and should be clearly documented.

3.3 Primary Avian Embryo Cell Lines

For vaccines produced in primary avian embryo cells, the above practices should be followed and described to the step of sanitization. Embryo retrieval, tissue dissection, and dissociation methods before *in vitro* culture should be conducted under highly controlled environmental conditions and with reagents of appropriate quality; the methods and raw materials should be described. For these cultures, a substantial portion of cells is held aside uninfected for several weeks after the virus culture has been completed to ensure detection of any slow-growing microbes or viral agents. These uninfected control cell cultures are propagated and handled following the same process used for the virus-inoculated cells to help ensure that the cells used for vaccine production are free of adventitious agents.

If feasible, control cells should be evaluated for the presence of adventitious agents in conjunction with product testing using the same tests that are performed on the production cultures. This time period may be 14 days or more, when needed to allow for detection of potential adventitious agents that may be latent, endogenous, or poorly replicating. The susceptibility of the cell substrate to infection by adventitious agents of potential concern can influence the tests needed to confirm absence of contamination. Tests on the production control cultures must be sensitive and specific enough to detect cytopathicity, hemadsorption, and the presence of retroviruses. Retroviruses may be either endogenous (i.e., encoded within the cell substrate genome) or exogenously acquired, such as avian leucosis viruses. Testing of the cell substrate should address the potential that infectious retrovirus could contaminate the product.

3.4 Primary Cell Lines from Other Animal Sources

Primary cell cultures from tissues can be cultured *in vitro* and used for vaccine production. Animals used to generate the primary cells or cell bank must be screened for potential viruses or have their serum tested to detect specific antibodies (see *Virology Test Methods* (1237) for specific guidance). Use of controlled colonies, herds, or flocks is recommended to monitor for specific pathogens. The use of primary cells requires additional testing from each manufacturing run to ensure the absence of contamination by infectious agents. To support the reduction of animal use, diploid and continuous cell lines are recommended. Continuous cell lines can be characterized extensively, and the culture conditions can be optimized and standardized by use

of a cell banking system.

4. SEED LOT SYSTEMS AND CELL BANKS

For the production of vaccines from cultured virus, two cell banks are required: one for the cell substrates and another for the viral seed lots. General information on the development, characterization, testing, and production of cell banks and the related documentation requirements is provided in (1235). In cases where recombinant technology is used to develop the seed, the applicable guidance regarding information that should be supplied regarding the characterization and expression of such recombinant vectors can be found in *Quality of Biotechnological Products: Analysis of the Expression Construct in Cells Used for Production of r-DNA Derived Protein Products* (1048).

4.1 Cell Substrate Master Cell Bank

The prerequisite for viral vaccine manufacture is the establishment of cell cultures to be used for viral production. Many types of cell substrates are used for the production of viral vaccines, including banked cells that have been cryopreserved and characterized extensively. The latter include normal diploid cells, continuous aneuploid cells, and cells that have been genetically modified to allow virus propagation. These cells may be from mammalian, avian, or insect species. At their origin or during the course of culture for banking, they may have been exposed to raw materials and environments that create quality risk. The testing scheme takes into account all of these factors. Cell banks should be established under current Good Manufacturing Practices (cGMP). See also *Vaccines for Human Use—Bacterial Vaccines* (1238) for additional information.

The Master Cell Bank (MCB) is generally made from a cell line or primary source of cells that has been prepared for banking by expanding cultures in a progressively greater number of vessels. The propagation of cells is carried out whenever possible without the use of antimicrobials (in particular, use of penicillin and other β lactam compounds in the culture media should be avoided). The source of cells, from isolation through to development of the MCB, should be well known, and the propagation should be conducted with appropriate controls on the environment, raw materials, and methods, with thorough documentation. Donor tissue, species, and medical history should be described where relevant. All propagations of the final cell line should be documented, including, as applicable, the method of subculture, any use of animal-derived material, a record of subcultivations, and information on storage conditions. The documentation must include the constituents of the culture medium, in particular materials of human or animal origin such as serum, enzymes, protein hydrolysates, or other living cells.

Cell lines derived from human origin should include relevant information from the original donor, such as tissue or organ of origin, ethnic background, geographical origin, age, sex, and if available, health status or medical history including any exposure to pathogenic agents. If the tissue is of fetal origin, the age of the fetus and reasons for tissue harvest should be documented along with the information above, if known, for the parents. All information must be documented, because these parameters may influence in vitro lifespan and cell bank testing requirements. The same procedure should be followed for the establishment of animal cell lines. Additional procedures used to produce the cell bank (e.g., physical or chemical procedures, added nucleotide sequences, genetic manipulation, cloning, or selection) should be documented.

4.2 Characterization of the Master Cell Bank

Extensive testing is carried out on the MCB to confirm the identity, purity, and suitability of the cell substrate for vaccine production. The cell bank must be free of cells from other cell lines present in the manufacturing facility, as well as adventitious agents and endogenous viral contamination. For general considerations concerning adventitious agents testing, see *Viral Safety Evaluation of Biotechnology Products Derived from Cell Lines of Human or Animal Origin* (1050), and for vaccine specifics see (1235). The end-of-production cells are also characterized to demonstrate the stability of characteristics and confirm the absence of extraneous agents that might be present in the MCB.

The stability (including genetic stability) of master and working cell banks in real time should be demonstrated, as described in (1048). Stability of cell-line viability under the cryopreservative storage conditions must be demonstrated using real-time testing; see *Cryopreservation of Cells* (1044) for guidance on cryopreservation of cell lines. Frozen cell bank preparations should be tested for consistency of recovery by determining the viability of cells from vials representative of the beginning, middle, and end of the cryopreservation process. The location of the cells in cryovials or ampules in the vapor or liquid phase of liquid nitrogen must be documented. It is recommended to have at least two separate controlled storage areas for the vials to avoid loss due to facility/equipment failures. Use of qualified shipping containers and manipulation of all vials should be controlled and documented to ensure the consistency of cell bank inventory. A working cell bank (WCB) is generally derived from the MCB, and these two cell banks should be prepared in a similar manner if possible. However, the MCB and WCB preparations may differ from those used in the production process, or from clinical trial materials or commercial supply. The preparation procedures for all cell culture processes must be documented, along with details on process changes. Comparability of product quality must be demonstrated when changes between WCBs occur. This ensures the consistency and long-term supply for vaccine production. Identity testing of the cell substrate is required for each WCB to ensure lineage to the MCB. In cases where recombinant vectors are used, construct purity should be verified from MCB to WCB.

Manufacturers should describe their strategy for providing a continuous supply of cells. The lot size and anticipated use rate of the cell banks for production should be documented, including the details for the subculture and population-doubling level. The qualification of master and working cell banks should be established to ensure an adequate supply of equivalent cells able to support production over the lifespan of the product. A flow chart can be used to illustrate the preparation of the cell banking system.

4.3 Viral Seed Lots

A master virus seed bank preparation is established under cGMP conditions in a manner similar to the preparation of the cell banking process, as described in (1235). Details on the derivation, including the sourcing of all biological materials used—plasmids, animal raw materials (e.g., fetal bovine serum), donor isolate and strain—must be recorded carefully, and reagents must be of appropriate quality. Tests for identity, sterility, mycoplasma, and adventitious agents should be performed on the basis of established compendial and regulatory requirements. Specific tests for additional agents that could potentially be present must also be carried out on the master virus seed preparation (risk based analysis approach) depending on the historical manipulation of the virus isolate (raw materials, agents, and biological reagents that the seed was in

contact with). The master virus seed bank is used to produce a working virus seed bank. The subsequent testing of the working virus seed preparation is dependent on the extent of testing carried out on the master seed, as well as the process and raw materials used to produce the working virus seed preparation.

4.4 Storage

To ensure consistent production of the viral vaccine product, a well-defined storage system is required. Virus seed preparations are frozen and stored in at least two separate controlled areas to avoid loss due to facility/equipment failure. Manipulation of all vials must be controlled and documented to ensure the consistency of virus seed stock inventory. Virus seeds must be stored at -60° or below.

The stability of the master and working virus seed preparations under the frozen storage conditions must be demonstrated using real-time testing. Virus replication (infectivity testing) can be determined during routine production of clinical trial material. Trending the infectivity titer will alert the manufacturer to any stability issues and the need to produce a new working virus seed preparation. The master virus seed preparation should also be monitored in real time during the preparation of new working virus seed preparations. In the event that the master viral seed is not required for an extended period of time, a stability protocol with defined testing intervals should be implemented. If the infectious titers of the working virus seed are not decreasing, and it was produced in a manner similar to the master virus seed preparation, testing of the master virus seed preparation may be reduced or stopped to conserve the supply.

4.5 Recombinant Cell Lines

To date, the production of recombinant viral antigens has used yeast and insect cell lines. The requirements, as for any other recombinant expression system, are set out in (1235). For cell lines containing exogenously assembled expression constructs (recombinant cell lines), characterization of nucleotide and amino acid sequences should be performed. Extensive characterization of cell banks should use the most relevant qualified technology. The chapter (1048) provides advice on the characterization of the engineered cell line and expression construct.

5. CULTURE AND HARVEST

5.1 *In ovo* Cultivation

Culture of viruses *in ovo* is fairly straightforward. Common egg culture variables include: the amount of virus inoculated per egg, the mode of inoculation, harvest timing, and sometimes incubation conditions such as temperature, depending on the virus strain. These factors have to be optimized for each individual serotype and master/working seed (for influenza viruses in particular), and the impact of all of these factors should be investigated and documented. Flock genetics, nutrition, and age can all affect *in ovo* virus propagation, as can egg sanitization procedures that may compromise the allantoic membrane cells. These factors should also be investigated and documented; however, for influenza, these will not usually be optimized for each season's production campaign.

5.2 Establishment of Primary Cell Cultures

Procedures for recovery of primary cells should be described from organ recovery through dispersed cell suspension, with attention paid to reproducibility of the cell substrate's properties in culture. This analysis may involve subsequent growth reproducibility, or if minimal growth is involved, it should be aimed at reproducibility of metabolism and viral receptivity/productivity. In cases where whole organism harvest is involved (e.g., whole avian embryo dissociation), only a fraction of the resulting cells may be susceptible to viral infection. Other cells from the harvest provide supporting matrix and other factors and can potentially inhibit virus replication. Preferably, a modern process would be used to characterize the spectrum of cells harvested and their differentiation state under production culture conditions, thereby ensuring the reproducibility of these factors. Under conditions suitable for viral replication, little or no growth is expected of the cells.

5.3 Cell Culture

Culture for viral vaccine production generally consists of two phases: a cell growth phase and a virus production phase. These processes are often complicated due to the diversity of cell types and their general dependence on a surface for growth. Virus properties—including replication cycle speed, yield of virus from the cells, and stability of infectious virus or antigen under culture conditions—also exert major influences on process technology, configuration, and operation in the manufacturing setting. Reproducibility of the cell processing steps is critical, and therefore good documentation of each manipulation ensures consistency of a key parameter for product manufacturing.

The virus culture process begins with the establishment of a receptive cell mass of sufficient size to produce a batch, which is typically about 10^5 to 10^6 doses of vaccine. Generally, about 10^6 – 10^8 cells are cryopreserved in one or more aliquots, whereas about 10^8 – 10^{12} cells may be required for a production batch. Historically, processes have also used secondary or tertiary cultures, in which primary tissues are grown for several cell divisions to increase the biomass size and batch size, to minimize the amount of primary tissue required per batch, or both. Recovery of cells from cryopreservation involves thawing the cells and diluting out the cryoprotective (banking) medium such that maximum cell viability is preserved and reproducible cell growth is ensured. Practices should be documented and justified on the basis of development experiments; typical parameters investigated are thaw rates and temperatures, dilution rates, and dilution factors.

A protocol must be devised that results in reproducible cell numbers in a state conducive to virus production. This requires passaging the cells, and for attachment-dependent cells, providing a larger surface area for growth. Cell expansion output:input ratios for a passage are typically 2:1–20:1, depending on the cell type and growth medium. In certain contexts, cells require a minimum threshold concentration to provide each other with growth factors, and this requirement may reduce the passage ratio. Other cell types, or media that provide these growth factors, can allow much lower inocula and larger ratios.

Two typical objectives for expansion passaging reproducibility are 1) ensure that cells experience a minimal "lag phase" (sometimes caused by the need for sufficient production and accumulation of growth factors and cellular attachment factors), and 2) ensure that cells do not grow to the point of stagnation/death (often caused by nutrient exhaustion, or by crowding on the surface that causes "contact inhibition" of growth). Either of these issues can

lead to a lag phase in the next passage. Early cell expansion is usually performed in a separate production area to avoid the potential for cross-contamination. The earliest, small-volume passages are often conducted in open laboratory vessels (e.g., flasks, roller bottles); however, it is highly desirable to use closed containers to facilitate aseptic handling of containers and to minimize or eliminate operator exposure risk. Control of the environment and aseptic handling practices are written into the procedures for use during development and are maintained during manufacturing.

The final cell expansion is typically an integral part of virus production, with goals of achieving the final biomass required for production and producing cells that are highly productive for virus. In batch or fed-batch cultures, a "cell density effect" may exist, whereby growth to higher cell concentrations correlates with lower virus productivity on a per-cell basis. This can be caused by many factors and should be characterized to ensure that the process operates in a robust and predictable manner.

5.4 Virus Culture

The final cell expansion and virus culture are typically a biphasic process in which the cells are grown in the final production vessel(s) and then are inoculated with virus. The viral inoculation often coincides with medium replacement or addition, as well as alteration of other culture parameters such as temperature. If cell growth is conducted in a serum-containing medium, the medium for viral production is usually switched to a serum-free medium to minimize serum carryover into the harvest. If the virus is secreted into the medium and cannot be purified rigorously after harvest, extensive washing may be required to reduce residual serum to acceptable levels (see 21 CFR § 610.15 *Constituent materials*). Documentation of washing effectiveness should be developed. Replacement of serum may be required for maximal virus growth, and this may require the addition of other protein sources such as albumin, transferrin, or insulin.

Virus infection results are known to be sensitive to cell concentration; history; time of harvest; future cell substrate growth trajectory at the point of infection; and the "multiplicity of infection" (MOI), which is the number of infectious virus particles inoculated per cell. These factors affect the quantities of infectious virus and total virus and can govern the quality of a vaccine via the ratio of infectious to total virus, coupled with the degradation products that may have reduced immunogenicity. In addition to assessing titers over the duration of infection, it is useful to characterize virus stability under culture conditions with cell-free culture broth samples, because this can illuminate whether titer changes are due to changes in synthesis or degradation. High MOIs over repeated passages are generally undesirable, especially for RNA viruses, because of the propagation of defective genomes that are trans-complemented by co-infection of a cell by another viral genome. Genetic stability of the vaccine virus should be well characterized. During development, the infection parameters need extensive characterization against all of the key quality attributes for the vaccine to ensure a robust process; thus, these parameters should be described.

Virus disposition upon replication is a significant determinant of the infection process configuration. Enveloped viruses are typically 1) secreted into the culture medium as they acquire their lipid envelope or 2) as secretory vesicles fuse with the plasma membrane. For these viruses, multiple batch-wise harvests of the culture supernatant are common, and re-feeding the culture upon harvest can promote higher yields. Perfusion processes are not often used because of product dilution and the difficulty, as well as added expense, of downstream concentration. For lytic viruses, destruction of the cells allows only for a single harvest;

depending on the time elapsed from infection to lysis, feeding of the culture may maximize yields. Other viruses remain intracellular, and processes for these may allow for extensive feeding to accumulate virus product. If the cell integrity is not compromised, washing to remove undesirable medium constituents may be performed at the end of the culture. Many parameters of the culture environment also affect virus growth and stability, and it is expected that all relevant process parameters will be controlled to meet product quality expectations, as well as their acceptable ranges ("operating space") as defined in *Guidance for Industry: Q8(R2) Pharmaceutical Development*. It is important to note that there is biological variability in cell growth; transient viral infections occur and are inherently variable; virus-host cell interactions are ill defined; and the analytics for potency and other parameters are highly variable and should be defined. Consequently, despite efforts to characterize viral vaccines and their processes, it is not uncommon to experience root mean square (RMS) variances of 50%–100% in process output, even for a well-controlled process, unlike some other biological medicines.

Influenza vaccine produced using a baculovirus expression system, with the viruses grown in insect cell lines, is manufactured in much the same way as virus in any other cell line. Cells are grown in serum-free medium composed of chemically defined lipids, vitamins, amino acids, and mineral salts. Recombinant HAs are extracted from the cells with octylphenol ethoxylate and purified by column chromatography. Harvest time is an important parameter. All processing of the cell banks and baculovirus seed lots, as well as subsequent cell cultures, is done under aseptic conditions in an area where no other cells are being handled. Several single harvests may be pooled before testing. No antibiotics are added at the time of harvesting or at any later stage of manufacturing. Control cells are tested for absence of arboviruses in addition to other adventitious agents.

5.5 Culture Process Technologies and Facility

Because of safety concerns regarding the use of tumorigenic cell types, the cells used for viral vaccine culture are almost uniformly dependent on an attachment surface for growth. The few anchorage-independent exceptions [e.g., Madin-Darby canine kidney (MDCK) cells for influenza] will become more commonly used as regulatory paradigms for tumorigenic and designer cells are developed. The attachment requirement creates a need to supply not only soluble nutrients but also an attachment surface for the common cell types (e.g., MRC-5 and Vero). Given the large variability in virus yields and production volumes, surface area requirements can differ substantially. This has created a situation in which a variety of technologies are used for cultivation. For small-scale operations, simple adaptation of laboratory vessels may suffice, and scale-up consists of scale-out, i.e., increasing the number of vessels. Beyond a certain point, aseptic risk precludes further scale-out. Intermediate scales of culture involve the use of specialized culture vessels, along with robotics where scale-out strategies are still used. Many of these technologies use disposable vessels and reactors with a focus on 1) minimizing the risk of contamination, and 2) the compatibility of product contact surfaces with the cells and virus. An extractable/leachable assessment should be performed for each disposable system used (see *The Biocompatibility of Materials Used in Drug Containers, Medical Devices, and Implants* (1031)).

Large-scale production is performed in engineered bioreactor systems that use agitation technology similar to that for bacterial vaccines and other biologicals. In the most common reactors using agitation, attachment-dependent cells use "microcarrier" technology, which consists of small beads of about 150- μm diameter that are easily suspended by agitation and

provide a very large surface area in a given volume of culture. Other configurations with packed or static beds are also used for these systems. The vessels used can be made of either disposable plastics or stainless steel. Compatibility of the material with the medium and the cells, and the absence of leaching, should be established for either type of vessel, as well as for fittings and probes used in monitoring and controlling the cultures. For nondisposable equipment, cleaning and sterilization procedures must be established, validated, and well documented. For reactors with loose or suspended carriers, the carriers should be readily excluded from the product stream and should not shed pieces or chemicals that are not suitable for human administration.

For all systems, the environment should be designed appropriately, reflecting the need for aseptic manipulations if they are required for either culturing or bioreactor set-up. In addition, the potential for spills or breakage and the risk of operator exposure need to be taken into account, especially when culturing wild-type virus strains. In a multi-product facility, changeover procedures that minimize the potential for cross-contamination, and validation of inactivation should be established and documented. Operator training and facility management procedures must be established for handling cultures and avoiding contamination of the product, the facility, and the operators themselves.

Note that production of recombinant viral antigens in yeast or insect cell lines does not involve infection of the growing cell, and the requirements are essentially the same as those for other recombinant proteins, described in the relevant compendial guidance for recombinant protein products.

6. PURIFICATION

A general overview of purification for viral-derived vaccines is presented in (1235). For live attenuated and inactivated virus vaccines, the desired antigen is a virus entity that is amplified from a working virus seed, in a complex biological substrate, and generally with minimal downstream processing to prepare the drug substance. Although inactivated virus vaccines also require virus seed expansion, virus inactivation and purification are necessarily more complex to ensure complete removal of infectious virus, removal of inactivating agents, and maintenance of the desired antigenic properties.

Many factors should be considered in developing a downstream purification strategy, with the understanding that all processing steps will result in some loss of viable virus. Downstream processing steps are designed to: 1) remove cellular debris (host cell protein and DNA) from the vaccine harvest; 2) remove impurities or reduce their levels; 3) concentrate virus; 4) add a virus stabilizer; and 5) filter sterilize the virus preparation to meet a specified level of adventitious agent removal (limited in the case of live-virus vaccines).

6.1 Live Attenuated and Inactivated Viral Vaccines

After removal of cellular debris, further purification can be accomplished by using zonal centrifugation on a density gradient or by column chromatography. Nucleic acid in Vero cell-produced vaccines can be reduced by treatment with suitable endonucleases, and removed by ultrafiltration using a 50 kDa membrane or by ion-exchange chromatography. The resulting drug product may be stabilized (via cryoprotectant or lyophilization formulation), sterile filtered (using a 0.22- μm pore size filter), or both, and should be stored frozen at less than -60° .

7. VIRAL INACTIVATION

Because of the pathogenic nature of the viruses (e.g., hepatitis A, Japanese encephalitis, rabies, and poliomyelitis), many viral antigens must be inactivated while maintaining their antigenic properties. Inactivation may involve use of chemicals, detergents/surfactants, or irradiation, or various combinations thereof. Removal or reduction of the inactivating chemicals/detergents/surfactants from the antigen to acceptable levels may be achieved by centrifugation, chromatography, ultrafiltration, diafiltration, or combinations thereof.

7.1 Subunit Vaccines

Although the seasonal influenza vaccines (influenza A and B) are prepared either in embryonated eggs or via cell culture, the derived virus is processed using different manufacturing methods to make the drug substance. The drug substances can be a live attenuated virus, a detergent-solubilized "split vaccine", or a subunit vaccine resulting from purification of the surface glycoproteins (HA and NA) from the internal nucleocapsids. To produce the split virus and subunit vaccines, the whole virus is subjected to disruption with a surfactant, which solubilizes the viral membrane. For subunit vaccines, the internal subviral core of the virus is separated from the surface proteins on the basis of their differing sedimentation rates. With split-virus vaccines, the choice and use of surfactant ensures that the subviral core itself is disassembled. Diafiltration is normally used to remove the surfactant and other media components from the product, and then the process is terminated with a sterile filtration step to produce a monovalent bulk solution.

7.2 Recombinant VLP Vaccines

Recombinant proteins that are components of VLP vaccines, such as hepatitis B and HPV, undergo more rigorous purification processes. As with inactivated viral vaccines, the purification methods must maintain the desired antigenic properties. Overall, the purification schemes are similar to those used for other viral vaccines. After fermentation, the cells are harvested and purified by downstream processing. This may involve chromatography, precipitation, microfiltration, ultrafiltration, or other techniques that will be specific for the vaccine being produced by each manufacturer. After purification, the VLPs may be mixed or adsorbed onto an adjuvant to increase the immune response.

Characterization of the recombinant monomeric antigens follows the typical requirements for recombinant proteins and would include peptide mapping coupled to mass spectrometry to assess the integrity of the primary structure, as well as SDS-PAGE and other appropriate assays. Characterization of the intact VLPs will focus on assessing the size distribution of the particles using techniques such as transmission electron microscopy (TEM) or cryo-electron microscopy (cryoEM) and dynamic light scattering (DLS).

Testing for adsorbed VLPs (MBAP) includes differential scanning calorimetry (DSC), immunogenicity in animals, and a sandwich ELISA *in vitro* relative potency (IVRP) assay used to measure the antigenicity of the drug substance.

7.3 In-Process Controls

Manufacturers identify critical process parameters and perform appropriate tests to monitor the

purification process. Among the latter are filter integrity tests, microbial enumeration tests (see *Microbiological Examination of Non-Sterile Products: Microbial Enumeration Tests* (61)), bacterial endotoxin tests (see (85)), and other suitable tests for known process residues of concern. Process residuals include raw materials, culture medium components (e.g., serum and antibiotics), cell substrates (e.g., proteins and DNA), buffer components (EDTA), and other materials (endonucleases, protamine sulfate, detergents/surfactants) used in purification. In addition to in-process control tests, manufacturers may perform in-process monitoring tests to monitor total protein, specific antigens, or ancillary materials at various steps in the purification process of intermediates. These in-process monitoring tests are carried out to gather product and process knowledge to evaluate consistency in the manufacturing process.

To demonstrate process performance and reliability, manufacturers should characterize inherent process-related impurities (e.g., protein, DNA, and lipids). Process validation studies may be carried out to demonstrate sufficient and consistent removal of residuals to an acceptable level such that routine testing is no longer required. If material must be sterile, analysts can perform *Sterility Tests* (71).

8. INTERMEDIATES

Intermediates are defined as the unformulated active (immunogenic) drug substances that are further processed before final formulation and can be stored for long periods of time ((1235)). Examples of intermediates for U.S. licensed viral vaccines include: live attenuated (e.g., influenza, measles, mumps, rubella, and yellow fever); inactivated whole (e.g., rabies); subunit (e.g., influenza); and VLP (e.g., hepatitis B and HPV). If intermediates are to be stored, stability release tests should be performed before proceeding to the next steps. Hold times for intermediates should be validated through a formal stability study/program. Stored intermediates are often suitable for more detailed characterization studies than are harvest bulks or final products. Some release tests are routinely performed before the intermediates are converted to the final bulk; this varies depending on the individual vaccines.

8.2 Tests for Intermediates

UNPROCESSED BULK HARVEST

In general, viral safety lot release testing is done at the bulk harvest stage before any purification. This is true regardless of whether the assay detects infectious virus or viral components. The presence of host cell DNA may need to be assessed in the case of biologics manufactured in animal cells. A hold step may be introduced at this processing step, for example to combine two or more single virus harvests for further processing.

Table 3. Typical In-Process Testing of the Unprocessed Cell Harvest

Assay	Purpose	Method
Adventitious agent	Verify absence of viral contamination	Tissue culture with cytopathic effect (CPE) and hemadsorption end points
Mycoplasma	Detect mycoplasma	Cell culture, polymerase chain reaction (PCR), growth, or fluorescent staining as end points (<i>Mycoplasma Tests</i> (63))
Sterility	Find evidence of microbial or fungal contamination	(71)
Potency	Measure quantity of infectious virus	Tissue culture with plaque or Tissue Culture Infective Dose (TCID ₅₀) end points; RNA quantification

In-process adventitious agent inactivation steps are not included for live viral vaccines, because these steps could compromise the live nature of the vaccine itself. As a result, it may not be possible to validate clearance of any adventitious agents. For this reason, comprehensive testing for adventitious agents and qualification and control of the vaccine source materials are essential as part of vaccine safety control. Bioburden is monitored according to (61).

Other product-specific testing may be appropriate. For example, for live influenza vaccines, each lot of viral harvest is tested for the cold-adapted phenotype (can grow at 25°), the temperature-sensitive phenotype (restricted replication at 37°–39°), and the attenuation phenotype (restricted replication in the upper and lower respiratory tract of ferrets). Each lot of viral harvest is also tested extensively by in vitro and in vivo methods for adventitious and contaminating agents. Viral harvests from the three strains (H₁N₁, H₃N₂, and B) are subsequently blended and diluted as required to the desired potency to produce bulk vaccine.

Table 4. Tests for Inactivated Virus Bulks

Assay	Purpose	Method
Completeness of inactivation	Demonstrate inactivation of virus	Hemagglutination assay or infectivity assay
Bioburden	Find evidence of microbial or fungal contamination	(61)
Antigen content	Quantify viral dose	Single-radial-immunodiffusion assays (SRID) or other immunological method

Table 5. Typical Tests for Post-Purification Live Viral Vaccine

Assay	Purpose	Method
Adventitious agents	Detect adventitious viral contamination	Product-enhanced reverse transcriptase assay (PERT) or dual-template reverse transcriptase assay
Identity	Identify product	Electrophenotyping, plaque neutralization, RNA hybridization, PCR
Residual DNA	Measure the level of residual DNA	2-(<i>N</i> -Bis-(3-dimethylaminopropyl)-amino)-4-(2,3-dihydro-3-methyl-(benzo-1,3-thiazol-2-yl)-methylidene)-1-phenyl-quinolinium fluorescent DNA binding dye or PCR
Potency	Measure quantity of infectious virus	Tissue culture with plaque or TCID ₅₀ end points; RNA quantitation
Sterility	Ensure absence of viable microorganisms	<71>

Table 6. Tests for Recombinant Viral Antigen Intermediates

Assay	Purpose	Method
Total protein	Measure antigen content	Appropriate protein assay
Antigen content and identification	Determine content, identity, molecular weight	Radioimmunoassay (RIA), ELISA, immunoblot, SRID, and reducing SDS-PAGE
Percent intact monomer for VLPs	Characterization	Purity assay
VLP size and structure	Characterization	Dynamic light scattering (<i>Spectrophotometry and Light-Scattering</i> (851))
Aluminum content for VLP	Purity	Appropriate assay
Identity	Identity	Immunological assay or PCR
Host cell- and vector-derived DNA	Purity	PCR, fluorescent DNA-binding dyes
Residual host cell proteins	Purity	Appropriate assay
Purity	Purity	LC or SDS-PAGE
Degree of adsorption if adsorbed	Characterization	Separation, then content of adjuvant by appropriate method (e.g., GC for 3-O-desacyl-4'-monophosphoryl lipid A)
Residual cesium, if cesium used in gradient purification	Safety	Appropriate assay
pH	Characterization	<i>pH</i> (791)
Endotoxin content	Safety	(85)
Bioburden or sterility	Safety	(61) (71)

9. DRUG SUBSTANCE

The drug substance is the final bulk antigen following the manufacturing process that is ready for the addition of other ingredients, such as adjuvants, and others to produce the finished dosage formulation. The resulting material, which may be sterile filtered or aseptically processed and then tested for sterility, becomes the vaccine drug substance.

Drug substances can be stored in containers at temperatures (e.g., below -60°) that ensure their stability before further processing. Hold times for drug substances should be validated through a formal stability study/program. Testing of the drug substance must be performed to ensure its identity and purity. Product- and process-related impurities are monitored to confirm that their levels meet the requested specifications. Because viral vaccine drug substances generally have high potency, and subsequent dilution to the drug product potency may be significant, measurements of process impurities are best obtained from the drug substance rather than from the final container.

Examples of release tests for the drug substance include:

- Appearance
- Identity of antigen
- Potency/activity, or quantity of epitope or antigen
- Infectious titer (live attenuated viral vaccines)
- Protein integrity and purity (e.g., by SDS-PAGE)
- Monomer content in VLP vaccines
- Pyrogenicity or endotoxin content
- Sterility
- Mycobacteria
- Mycoplasma/spiroplasma

Table 7. Typical Release Tests for Different Types of Viral Vaccine Drug Substance

Live Attenuated Viral Vaccines	Inactivated Viral Vaccines	Subunit or Recombinant VLP Vaccines
Appearance	Appearance	Appearance
Identity	Identity	Identity of antigens
Potency	Immunogenicity	Antigen or epitope quantity
Infectious titer	Completeness of inactivation	Protein content
Adventitious agents such as mycobacteria, mycoplasma, spiroplasma, arbovirus, porcine or bovine viruses	Pyrogenicity or endotoxin content	Particle size (VLPs, virosomes) and size heterogeneity
Host cell proteins or surrogates	Host cell proteins or surrogates	Pyrogenicity or endotoxin content
Reverse Transcriptase (RT) assay	Residual inactivation reagents	Host cell proteins or surrogates
Endotoxin	Aluminum content (if adjuvanted)	Adjuvant content (if adjuvanted)
Sterility	Sterility	Sterility
Bovine serum albumin	Process residuals	Process residuals

In addition to the examples listed above, other methodologies can be applied for identity and purity evaluation. For instance, specific impurities that must be measured are agreed upon between manufacturers and the licensing authority during the licensure process.

9.1 Final Container

General requirements for vaccine products are provided in <1235>. This includes requirements for labeling and assessing the stability of vaccines.

Mechanically, the processes of formulation and filling for viral vaccines have changed little over time. Formulation is usually a simple dilution of high-potency drug substance to the appropriate strength for filling, taking into account yield losses expected through subsequent temperature exposures (including freeze-thaw cycles), and where applicable, lyophilization yield losses. Some inactivated, subunit, and recombinant VLP vaccines are produced as formulations that are adjuvanted, alum adsorbed, or both. The aluminum adsorption is commonly done as part of drug substance processing, with dilution into more aluminum to maintain constancy of adjuvant dose. It is important to note that production of drug product lots involves filling containers into the tens or hundreds of thousands, and special attention must be paid to ensuring homogeneity of product over very many vessels with volumes ranging from 0.1 to 10 mL. For live products, thermal degradation can occur over the course of the filling operation, which should be considered in process design. For products containing aluminum suspensions, homogeneity of the suspension is a significant concern. For all viral vaccines, product is "overfilled", both with respect to volume—to ensure the ability to withdraw a full dose—and with respect to potency—to ensure a statistically acceptable probability that each container receives the

declared potency at the end of expiry, given the variability of the process and assays used.

10. DRUG PRODUCT AND LOT RELEASE TESTS

Drug product is defined in 21 CFR § 210.3(b)(4) as "a finished dosage form, for example, tablet, capsule, solution, etc., that contains an active drug ingredient generally, but not necessarily, in association with inactive ingredients. The term also includes a finished dosage form that does not contain an active ingredient but is intended to be used as placebo." In compliance with 21 CFR § 600 *Biological Products: General*, and in particular, 21 CFR § 601.2, *Applications for biologics licenses; procedures for filing*, the manufacturer "shall submit data derived from nonclinical laboratory and clinical studies which demonstrate that the manufactured product meets prescribed requirements of safety, purity, and potency...". Documentation of the viral vaccine drug product includes: components used in manufacture; composition of the drug product; specification for each component; manufacturing and packaging procedure and in-process controls for the drug product; and specifications necessary to ensure identity, strength, quality, purity, and potency in accordance with 21 CFR § 211, *Current Good Manufacturing Practice for Finished Pharmaceuticals*.

Chapter (1235) summarizes the lot release procedure in accordance with 21 CFR § 610.1 and 21 CFR § 610.2. Samples and protocols for viral vaccines containing all appropriate tests are submitted to the Food and Drug Administration (FDA) for review, testing, or both. If the FDA determines that the lot meets the standards of safety, purity, and potency required for the particular vaccine as contained in its license, the lot is approved for release, distribution, and marketing. The lot release protocol for each viral vaccine includes the specific potency test, as well as common tests such as visual inspection of final vials, safety, sterility, and purity testing for each lot.

10.1 Potency Assays

General requirements for potency tests are described in (1235). Many types of potency-indicating tests exist for viral vaccines, and the selected potency test depends on the type of vaccine.

For the attenuated viral vaccines, the possible potency assays may be:

- A quantitative plaque formation assay, which assesses the ability of the virus to infect cells
- An end-point dilution assay (TCID₅₀)
- A virus neutralization assay
- A quantitative PCR assay, which specifically quantifies the amount of viral nucleic acid present in the sample

For inactivated, subunit, or recombinant VLP vaccines, the potency assay may be:

- An immunogenicity assay, which determines the ability of the vaccine to induce a specific antibody response
- A neutralization assay, which assesses the ability of the vaccine to induce a specific

antibody response which neutralizes the (infectivity/pathogenicity) of the target virus

- A mass-based assay, which quantifies the amount of antigen that is present in the vaccine
- An antigen quantification assay, typically using a monoclonal antibody to quantify the protective epitope present in the vaccine

10.2 Common Tests

Tests for general safety, sterility, purity, residual moisture, identity, and constituent materials are as described in <1235>, except as described below. Modifications to the requirements for a general safety test for inactivated influenza virus vaccine are described in 21 CFR § 610.11a and indicate a test for endotoxin. Viral and rickettsial vaccines and antigens are generally exempted from a requirement for a pyrogenicity test.

10.3 Manufacturing Residuals

Expectations for the control of manufacturing residuals, including surfactants and those chemicals used in the inactivation process(es) are described in <1235>. The chemicals are reduced to a minimum, often by dilutions included in the manufacturing process. Formaldehyde and other chemicals used to manufacture vaccines must be minimized. Limits are set on their residual content in the final vaccine, and content specifications are defined in the approved product license application.

Requirements to control residual material from cell substrates are described in <1235>, including the steps that should be taken to prevent potential complications for hyperresponsive recipients of these vaccines.

10.4 Preservatives

The chapter <1235> provides information on the acceptable use of antimicrobial preservatives, the types of preservatives used, the minimization of thimerosal content, and the production of thimerosal-free vaccines. Limits and content specifications are set for each vaccine in the product license.

10.5 Excipients

Formulation chemicals for viral vaccines are often introduced during drug substance production, during the infection phase, or at harvest to enhance process productivity, particularly for enveloped live virus vaccines. Non-enveloped viruses or vaccines with extensive purification may introduce formulation chemicals only at the end of the purification process. A notable exception is formulation for combination viral vaccines, where the individual viruses may need stabilizers that are different from the global optimum for the mixture. In these cases, the final formulation of chemicals may be introduced late in the process to preserve maximum potency. Formulation components may be included to minimize oxidation, to compete for other reactions that would damage the product, to provide pH buffering or tonicity, and in the case of lyophilized formulations, to replace water that would otherwise bind to proteins or provide other functions in the lyophilization process (e.g., cake formation/integrity). Chemically defined components are desirable, and all components should meet appropriate pharmacopeial

standards. In some instances, macromolecules such as albumin or dextran or fragments thereof (such as hydrolyzed gelatin) may be included in formulations to function as highly effective stabilizing agents. For those that originate from animal or plant sources or for new excipients, risk assessment should be conducted on the origin and processing of the materials to ensure freedom from infectious agents, and for other biological safety aspects (see *Excipient Biological Safety Evaluation Guidelines* (1074)). Where pharmacopeial monographs exist, they should conform. In addition to stabilizing agents, viral vaccines may contain preservatives, especially if the final container contains multiple doses. Preservatives should meet antimicrobial effectiveness testing requirements in the formulation (see *Antimicrobial Effectiveness Testing* (51)). It is common for preservatives to reduce the sensitivity of drug product sterility testing, and this needs to be addressed during sample qualification for release testing to ensure adequate safety (see *Validation of Microbial Recovery from Pharmacopeial Articles* (1227)). In addition, some formulations may be incompatible with other in vitro or in vivo safety testing and may require alterations of conditions or sample pretreatments to achieve valid test results.

10.6 Adjuvants

Aluminum compounds including aluminum potassium sulfate (alum), aluminum phosphate, aluminum hydroxide, and combinations of these compounds are currently approved adjuvants for vaccine use. Chapter (1235) outlines sections of the 21 CFR § 610.15 regulation governing the use of aluminum and the allowed amounts. Aluminum is quantitated using colorimetric, titrimetric, or emission or atomic absorption spectroscopic methods of analysis (see *Aluminum* (206)). The degree of adsorption of protein components to the adjuvant should be determined. The adjuvant monophosphoryl lipid A (MPL) is also licensed for vaccine use. It is quantified either through degradation to fatty acid methyl esters (FAMES) and quantification by GC, or through quantification of the glucosamine content.

10.7 Alternative Tests

See (1235).

11. OTHER REQUIREMENTS

Retention samples are held by the manufacturer for at least 6 months after the expiration date, in accordance with 21 CFR § 600.213. Enough material from each lot of each product is held for examination and testing for safety and potency.

Records are maintained concurrently with each step in the manufacture and distribution of product such that at any time, successive steps of manufacture and distribution may be traced (see 21 CFR § 600.12).

For storage conditions, shelf life, and expiry date see 21 CFR § 610.50 and 21 CFR § 610.53.

11.1 Container

The final container for the drug product is typically a vial with a rubber stopper, or a pre-filled syringe with a glass barrel and rubber plunger. Vial/syringe material is typically USP Type I borosilicate glass (*Containers—Glass* (660)), treated to prevent delamination (spalling) resulting from heat sterilization or with certain formulations, or to prevent vaccine adsorption. Adsorption

is prevented by selecting appropriate liquid formulation components, which may include proteins or mild non-ionic detergents; they also prevent virus aggregation and promote a more consistent product. Plastic containers have been introduced recently. Stopper and plunger components are typically butyl rubber compounds, which can be polytetrafluoroethylene or silicone coated to minimize vaccine adsorption, leaching of extractable components, or both. Sterilization methods should be characterized to ensure that they do not alter the container material properties with respect to vaccine interactions; for example, moisture absorbed during steam sterilization may add moisture over time to lyophilized vaccines, and ionizing radiation may alter the surface chemistry of polymer compounds. All containers and product-contact components should meet USP Class VI extractables testing (see <1031>) for the formulation chemistry and sterilization methods of interest.

11.2 Labeling

The requirements for container labeling and package labeling are described in <1235>. Regarding the information insert (label), vaccine product labeling is regulated in compliance with 21 CFR § 201 and 21 CFR § 610. Requirements have been set for both container labeling and package labeling.

11.3 Shelf Life, Expiry Dates, and Storage Conditions

The requirement to conduct a formal stability study to ensure that a product remains within specification, in line with 21 CFR § 211.166, 21 CFR § 610.50, and 21 CFR § 610.53, is described in <1235>. Additional guidance and detail on the general principles of stability testing for biologics can be found in *Quality of Biotechnological Products: Stability Testing of Biotechnological/Biological Products* <1049>. ■2S (USP39)

BRIEFING

<1602> **Spacers and Valved Holding Chambers Used with Inhalation Aerosols—Characterization Tests**, PF 40(1) [Jan.–Feb. 2014]. This proposed new USP general information chapter addresses the testing of spacers and valved holding chambers (VHCs), which are widely prescribed for use with inhalation aerosols. It is a companion chapter to *Inhalation and Nasal Drug Products: Aerosols, Sprays, and Powders—Performance Quality Tests* <601> and has been revised on the basis of comments received. Regulatory agencies worldwide have increasingly recognized that spacers and VHCs modify inhalation aerosols [commonly known as pressurized metered-dose inhalers (pMDIs)] plumes to the extent that quality data should be required to evaluate the performance of specific add-on device(s) and products from pMDI drug product users. The existing methods for evaluating inhalation aerosols rely on sampling at a constant flow rate; however, spacers and VHCs are typically prescribed for patients who delay inhalation following pMDI actuation (poor pMDI technique). This chapter addresses aspects of spacer and VHC use through development of patient-use procedures. Much of the content of this chapter is based on CAN/CSA/Z264.1-02 “Spacers and Holding Chambers for Use with Metered-Dose Inhalers” published by the Canadian Standards Association. The information given herein is not to be construed as guidance for batch release testing. Where measures of performance of a spacer/VHC are given, they are indicative in nature based on experience associated with the development of the predecessor Canadian Group standard and are therefore not intended as specifications. The rationale for development

of <1602> was published in a *Stimuli* article in *PF* 37(4) [July–Aug. 2011].

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

- 4.2 With Facemask

1. INTRODUCTION

1.1 Background

Spacers and valved holding chambers (VHCs) are widely used in conjunction with inhalation aerosols [commonly known as pressurized metered-dose inhalers (pMDIs)]. When used correctly, VHCs assist with the administration of inhalation aerosols to patients who have poor coordination of pMDI actuation and inhalation, and VHCs reduce oro-pharyngeal deposition of

the drug. Patients using these devices breathe tidally when inhaling their medication, regardless of any delay, and this is particularly true for young and elderly users. Also, spacers and VHCs often come with a facemask instead of the mouthpiece normally supplied for inhalation aerosols. These add-on devices interface with the actuator/mouthpiece of the pMDI and provide additional volume for the aerosol plume to develop. In this chapter, these aspects are addressed by providing patient-use appropriate procedures that have been evaluated extensively.

Although existing methods for evaluating inhalation aerosols rely on sampling at a constant flow rate, spacers and VHCs are typically prescribed for patients who have poor inhalation technique, i.e., they delay inhalation after actuating the pMDI. This chapter describes tests that are intended to provide information on how the spacer/VHC modifies the aerosol emitted by the pMDI.

1.2 Purpose

The purpose of *Spacers and Valved Holding Chambers Used with Inhalation Aerosols—Characterization Tests* (1602) is to define standardized methods for characterizing the in vitro performance of a given pMDI drug product with a specific spacer and VHC, and this chapter may be used to develop specifications that could be used in a product quality control environment. It is recognized that spacer/VHC configurations will modify the emitted dose delivered compared with the dose indicated on the label by the manufacturer of the pMDI product, chiefly by removing almost all of the portion of the dose contained in particles too large to penetrate to the airways of the lungs. This chapter does not advise on the outcome of such changes, rather the interpretation of data obtained using the methods described should be developed by the user after discussion with the appropriate receiving organization.

1.3 Rationale

Following the process described in the predecessor Canadian Group standard (CAN/CSA/Z 264.1-02: 2008; Canadian Standards Association, Mississauga, Ontario, Canada), (1602) includes separate testing by a multi-stage cascade impactor to determine aerosol aerodynamic particle size distribution (APSD) and tests mimicking fully coordinated and fully uncoordinated use, with tidal breathing simulated to establish emitted mass (EM) with the pMDI-spacer/VHC coupled to a breathing simulator. It is now possible to combine both APSD and EM measurements by means of a mixing induction port (Copley Scientific Ltd., Nottingham, UK, or RDD-Online, Richmond, VA, USA). However, the more conservative approach adopted herein reflects the absence of method validation data for multiple marketed drug products delivered by pMDI. Spacers and VHCs modify the APSD substantially from what is emitted by the pMDI when used alone. In particular, almost all of the mass fraction of drug associated with particles having ballistic trajectories, by virtue of propellant expansion upon actuation, are contained within the add-on device. The user should refer to the Canadian Group standard for further interpretation of changes in APSD brought about by the presence of a spacer or VHC.

1.4 Recommendations

The use of the induction port identified in *Inhalation and Nasal Drug Products: Aerosols, Sprays, and Powders—Performance Quality Tests* (601) is recommended for compliance with the pharmacopeial standard. However, it is acknowledged that alternative designs of the

induction port, as yet to be included as pharmacopeial standards, offer unique testing opportunities. These are either anatomically correct or idealized to have aerosol transport properties similar to an anatomically correct induction port. Given the widespread use of spacers/VHCs for infants and small children, it is important to note that many of these anatomically appropriate induction ports are scaled in terms of such potential users (e.g., the "Alberta" idealized induction ports, developed at the University of Edmonton, Canada, and available from Copley Scientific Ltd., Nottingham, UK). The user is free to adopt such an induction port but should specify the induction port design and age group with which the induction port will be used.

The evaluation of facemask performance requires a model face of the appropriate age range specified in the labeling for the add-on device (i.e., infant, small child, or adult). This arrangement is necessary because there is no other way to accurately simulate the magnitude of the dead space or test for the possibility of leak pathways between facemask and face, both of which are known to influence efficiency of the drug delivery. An adult face model is available from Copley Scientific Ltd, Nottingham, UK, but there are currently no commercially available infant or small-child face models. Therefore, because the use of a face model might be an appropriate way to test these add-on devices, the user will need to either acquire a model from one of the research laboratories where age-appropriate face models have been developed and validated, or develop and validate their own design. Whichever pathway is chosen, a description of the model, in particular the dimensions of the face where the facemask comes into contact, should be provided in the data report to the recipient.

1.5 Definitions of Key Terms Relating to This Chapter

Spacers: Open tubes that do not have a valve at the exit nearest the patient interface (either the mouthpiece or facemask) to retain the aerosol before the user can inhale (see *Figure 1*). Spacers simply increase the distance between the pMDI mouthpiece and the mouth of the patient. If the patient exhales instead of inhaling, the medication will be blown out of the spacer and lost to aerosol collection.

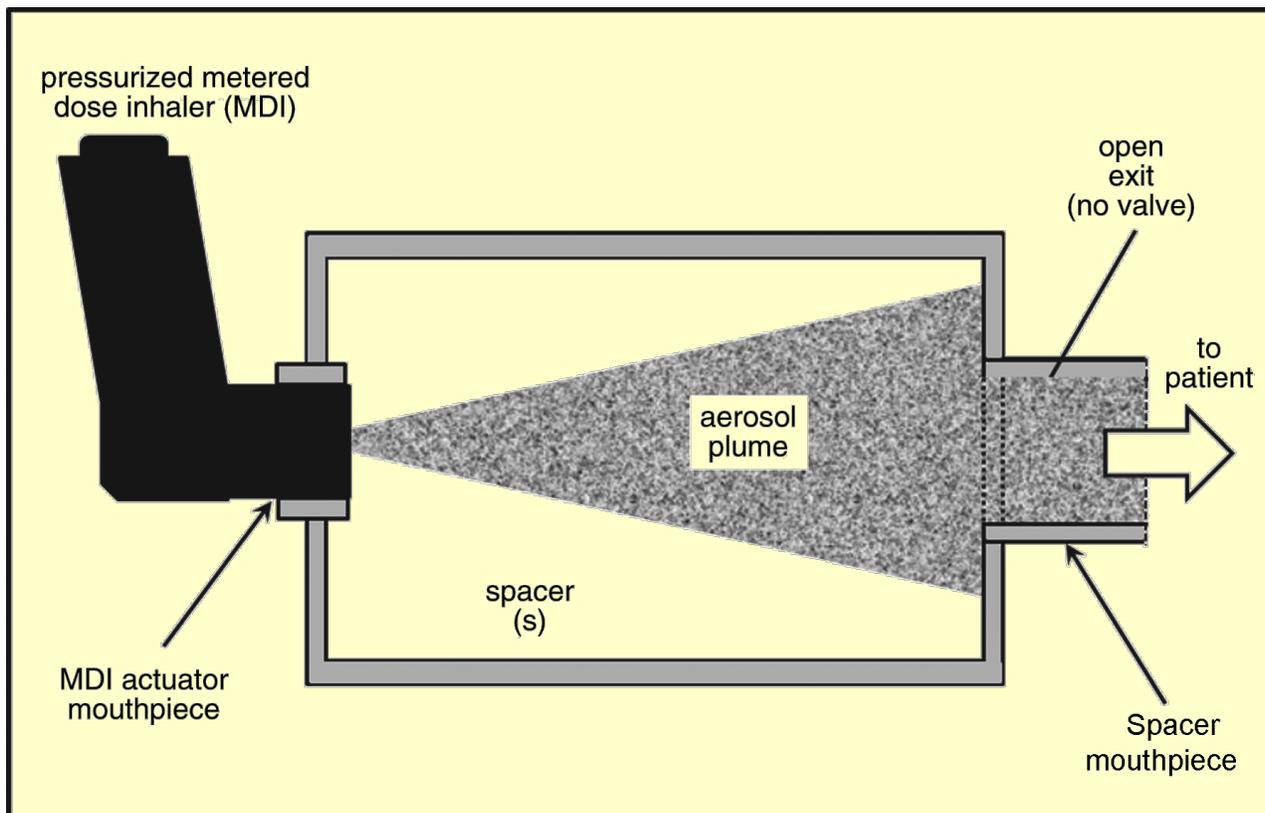

Figure 1. Open-tube spacer with no mechanism for aerosol conservation during exhalation.

VHCs: Contain at least one valve that opens to allow the patient to inhale aerosol on inspiration. This inhalation valve remains closed at other times during each breathing cycle (see *Figure 2*). Some VHCs may also contain an exhalation valve that is open only during exhalation to direct the exhaled flow away from the inhalation valve.

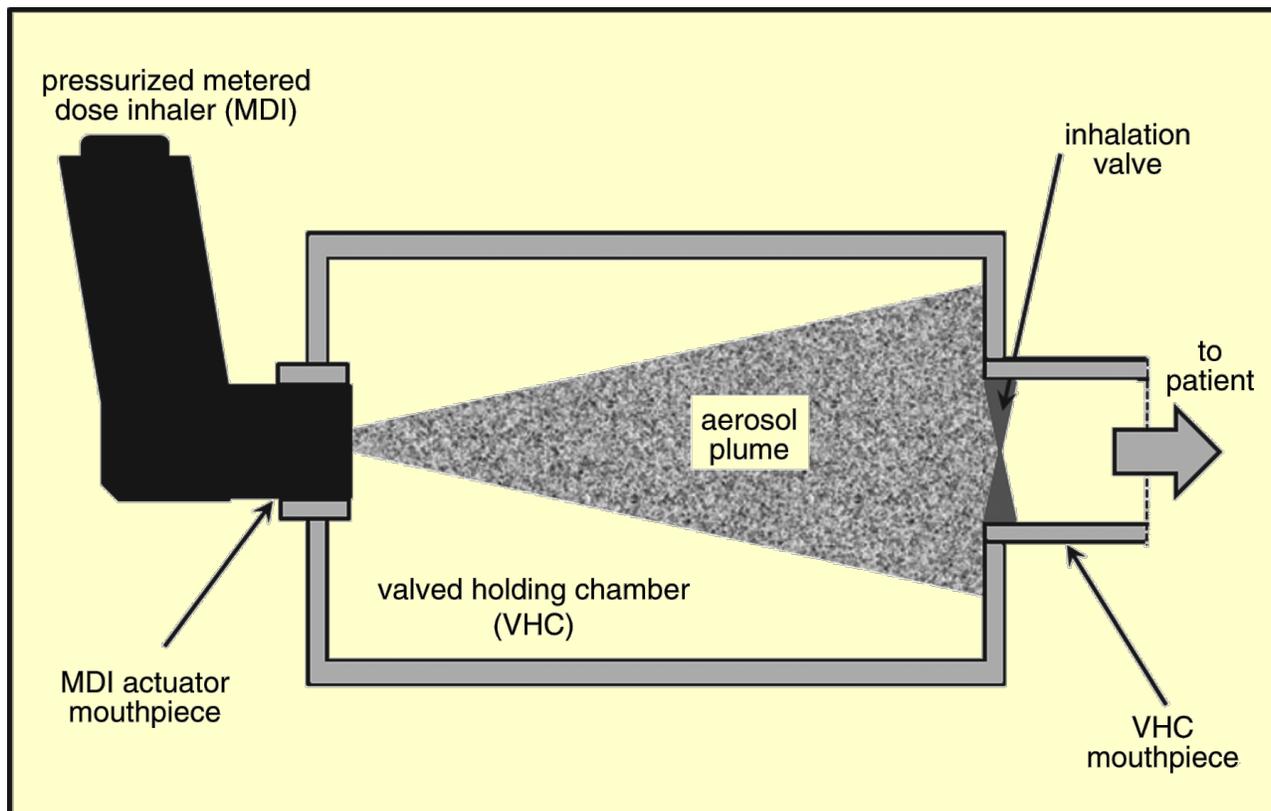

Figure 2. Conventional VHC with valve opening upon inhalation, accepting pMDI with forward-firing actuator mouthpiece.

Integral actuator: A companion piece with some spacers and VHCs that accepts a pMDI canister removed from its actuator-mouthpiece. This so-called “reverse firing” feature enables the design to be modified such that the built-in actuator faces away from rather than toward the user. In the example illustrated in *Figure 3*, the spacer operates in this way. It has some of the characteristics of a VHC, in that an air dam is created by closure of the valve located distally from the user on exhalation into the chamber. This type of spacer can therefore be evaluated as if it were a VHC, because the aerosol released on pMDI actuation is conserved during exhalation.

Note—With all types of spacers/VHCs, the aerosol characteristics in terms of the APSD may be different from those of the pMDI alone.

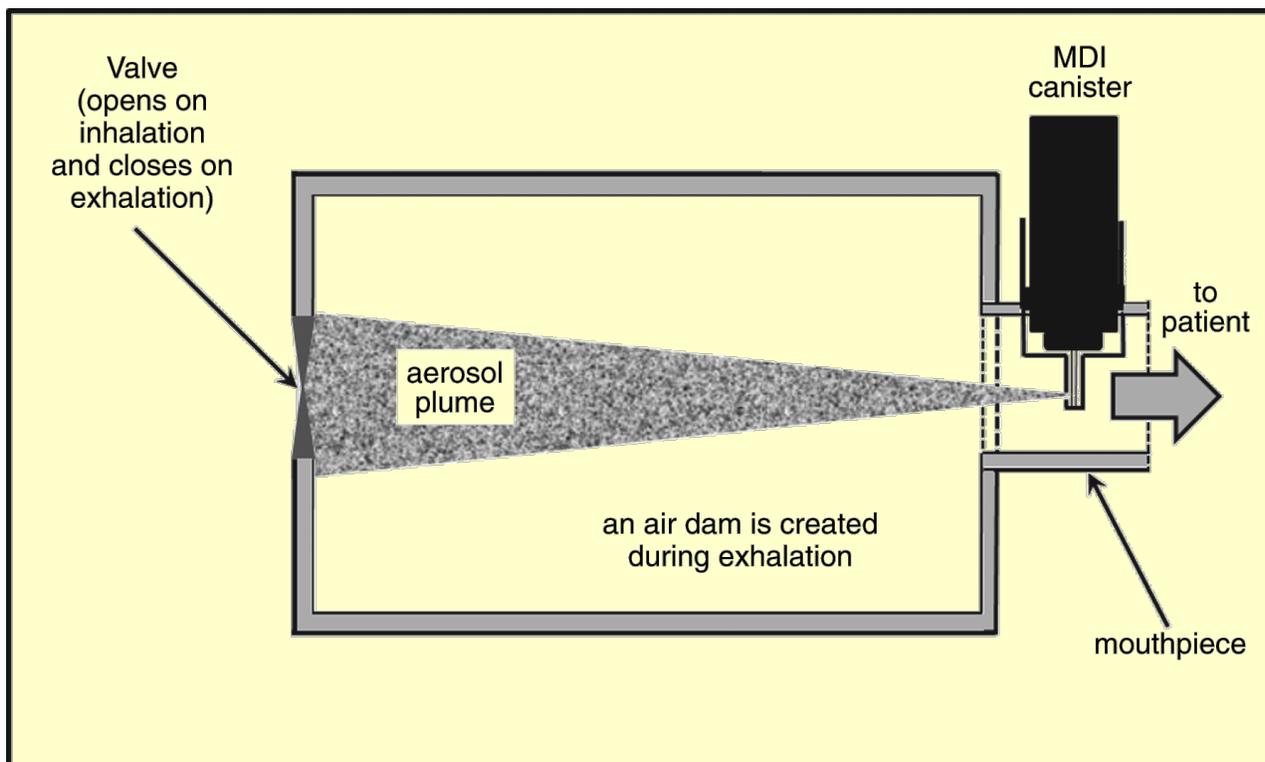

Figure 3. Holding chamber with “reverse-firing” integral actuator for pMDI canister.

1.6 Choice of Drug Product with Which to Test

It is understood that testing will take place with each single active-component drug product or with each strength of multi-strength drug products for which the spacer/VHC is indicated for use on the prescribing information for the add-on device, or as requested by the recipient of the data.

2. TEST METHOD SELECTION

2.1 Spacer/VHC Configurations

Four spacer/VHC configurations have been identified that require different test methods to complete the evaluation process (see *Table 1*).

Table 1. Identification of Test Conditions based on Configuration of the Spacer/VHC

Condition	Spacer	VHC	Facemask	Mouthpiece
A	+ ^a	- ^b	-	+
B	+	+	+	-
C	-	+	-	+
D	-	+	+	-

^a + denotes that this item was part of the condition.

^b - denotes that this item was not part of the condition.

In condition A, the device being tested is a spacer with a mouthpiece. Likewise, in condition B,

the device under test is a spacer with a facemask. In condition *C*, the device is a VHC with a mouthpiece, and in condition *D* the device is a VHC with a facemask. The evaluation of devices without patient interface (i.e., those intended for use by patients on mechanical ventilation) is outside the scope of this chapter.

PATHWAY A

Pathway A (see *Figure 4*) is selected for a spacer with a mouthpiece and comprises two tests: 1) APSD measurement with no delay (see *Part 1A* testing); and 2) EM by breathing simulation—fully coordinated (see *Part 2A* testing). Testing with a delay would be inappropriate for this configuration because the medication cannot be retained by the spacer during the delay interval.

PATHWAY B

Pathway B (see *Figure 4*) is selected for a VHC with a mouthpiece and comprises four tests: 1) APSD measurement with no delay (see *Part 1A* testing); 2) APSD measurement with delay (see *Part 1B* testing); 3) EM by breathing simulation—fully coordinated (see *Part 2A* testing); and 4) EM by breathing simulation—fully uncoordinated (see *Part 2B* testing).

PATHWAY C

Pathway C (see *Figure 4*) is selected for a spacer with a facemask and comprises one test with the facemask in place: 1) EM by breathing simulation—fully coordinated. Note that this class of device may also be evaluated for APSD measurement with no delay (see *Pathway A, Figure 4*) by removing the facemask and coupling the spacer on-axis to the induction port entry with a suitable connector. Testing with delay would be inappropriate for this configuration, because the medication cannot be retained by the spacer during the delay interval.

PATHWAY D

Pathway D (see *Figure 4*) is selected for a VHC with a facemask and comprises two tests with the facemask in place: 1) EM by breathing simulation—fully coordinated; and 2) EM by breathing simulation—fully uncoordinated. Note that this class of device may also be evaluated for APSD measurement with and without delay (see *Pathway B, Figure 4*) by removing the facemask and coupling the VHC on-axis to the induction port entry with a suitable connector.

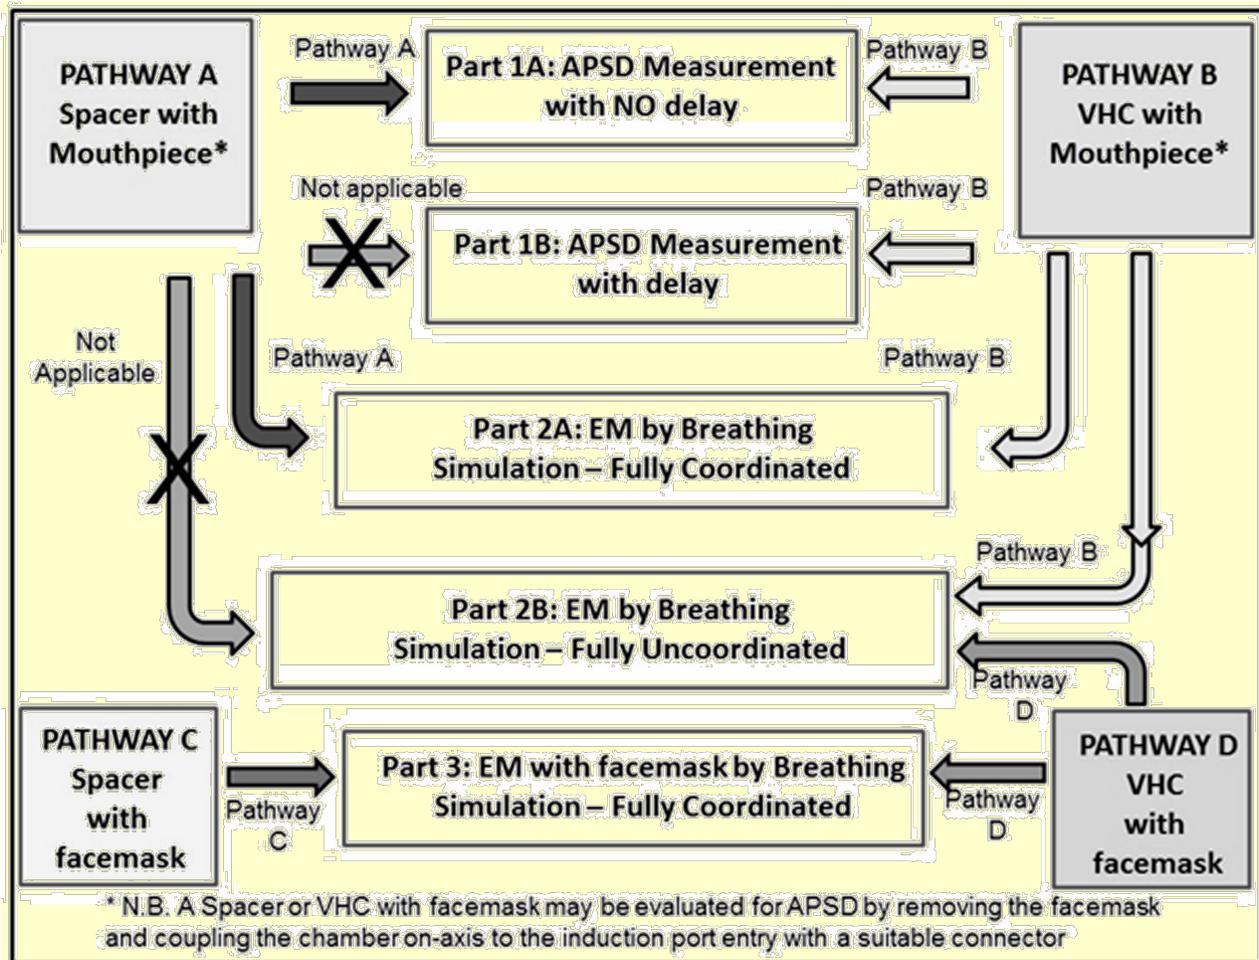

Figure 4. Decision tree for test selection by add-on device type.

2.2 Comments on Test Methods

The tests in *Parts 1A and 1B* (see *Table 2*) are an extension of the procedures described in (601). However, sampling at a constant flow rate via a cascade impactor does not do more than enable the assessment of the APSD of the emitted aerosol. In the later parts of chapter *Products for Nebulization—Characterization Tests* (1601), tests are described in which tidal breathing is simulated to assess spacer/VHC performance in terms of the delivered dose (equivalent to EM) in situations that are more representative of patient use. In *Part 1A* (see *Table 2*), the purpose is to enable the determination of metrics for which a direct comparison can be made with and without the add-on device. This methodology is the same as that described using either *Apparatus 1* or *Apparatus 6* in (601) and is therefore not repeated here. In *Part 1B* (see *Table 2*), delayed sampling is introduced because add-on devices, especially VHCs, are widely prescribed for individuals who, for whatever reason, are unable to coordinate pMDI actuation with the onset of inhalation as described for the pMDI alone in “patient information” and “instructions for use”.

Table 2. In Vitro Tests for Spacers and VHCs

Test	Delay at Constant Flow Rate	Breathing Simulation	Suitability	Clinical Relevance
Part 1A: Measurement of APSD with 4-L sample volume	None	Not applicable	Spacers and VHCs	Baseline performance compared with pMDI alone
Part 1B: Measurement of APSD with 4-L sample volume	For example 2, 5, or 10 s ^a	Not applicable	VHCs only	Simulation of a delay by a poorly coordinated user
Part 2: Measurement of EM with sufficient number of inhalations following guidance in the patient instructions to ensure that the drug is delivered from the VHC as intended ^b	Not applicable	Filter collection of aerosol simulating tidal breathing in coordinated and uncoordinated use	VHCs only	Simulation of optimum use (fully coordinated with pMDI actuation) and fully uncoordinated use
Part 3: Measurement of EM delivered by facemask with sufficient number of inhalations following guidance in the patient instructions to ensure that the drug is delivered from the VHC as intended ^b	Not applicable	Filter collection of aerosol behind lips or at nares of model, simulating tidal breathing in coordinated use	VHCs only	Simulation of use with facemask applied with a 1.6- kg force ^c
<p>^a Other delay intervals may also be used as required, if validated and justified.</p> <p>^b Representative breathing patterns for different patient ages are listed in <i>Table 2</i>; other patterns may be used as required, if validated and justified.</p> <p>^c 1.6-kg applied force has been shown to be clinically appropriate, but the force used may differ from this value if justified.</p>				

The tests in *Part 2* (see *Table 2*) evaluate the performance of the inhalation valve (and exhalation valve, if equipped) of the add-on device. This evaluation is accomplished by simulating tidal breathing, with parameters that are appropriate for the intended user group (e.g., infant, small child, or adult). This testing approach creates the continually varying flow conditions that are expected in use. Note that in the determination of EM, a sufficient number of inhalations should be taken, following the advice provided by the manufacturer of the VHC, to ensure that the intended amount of drug is delivered.

All of the above tests are undertaken with the facemask removed from the spacer/VHC equipped with this type of patient interface. This modification is allowed so that the device can be readily interfaced by fitting the facemask adapter directly to the entry of the induction port, without the complication of a direct facemask-to-induction port connection, whose internal

dead space would likely be both ill defined and unrepresentative of the “in-use” condition. Spacers/VHCs using a facemask as the patient interface should be evaluated ideally with the facemask in place (see *Rationale*). The desirable approach is such that in vitro testing makes use of a model face and is representative of the age range for which the spacer/VHC is intended. There are currently no commercially available model faces; however, the peer-reviewed literature contains several articles providing the necessary technical information to enable suitable age-appropriate model(s) to be created for the purpose of testing spacer/VHCs. It is also important that the surfaces of the face coming into contact with the facemask have mechanical characteristics (i.e., deformability) that are representative of the skin and underlying soft tissues when the facemask is applied to the face with an appropriate force. In *Part 3* (see *Table 2*), the spacer/VHC is evaluated by a breathing simulation with the facemask fitted, mimicking similar fully coordinated use as defined in *Part 2* (see *Table 2*). By comparing the EM of the drug with and without the use of a facemask, it is possible to assess the influence of the facemask.

Note—Not all of the tests described in this chapter are applicable to open-tube spacers because such devices require fully coordinated use; otherwise, drug delivery will be significantly reduced. *Figure 4* shows the decision tree to be followed so that the tests chosen are appropriate to the type of add-on device being evaluated.

Table 2 further defines the test, method, applicable device, and clinical relevance of the procedures that are described in this chapter. Example delay intervals of 2, 5, and 10 s are noted in the table, although other delay intervals may be substituted or added as required and justified. For the testing in *Part 3* (see *Figure 4*), it is recognized that currently there is no standardized and commercially available series of models representing the most widely recognized age categories for which this interface may be developed, i.e., infant, small child, and adult. However, several face models have been described in the peer-reviewed literature or are in late-stage development and validation. During the interim period, before validated commercially available models become available, the user is advised to select one of these models or develop their own, providing justification for the selection as required. Additionally, *Table 3* shows representative tidal-breathing patterns for the various patient age categories from neonate to adult.

Table 3. Representative Tidal Breathing Patterns

Parameter	Pediatric			Adult	
	Neonate	Infant	Small Child	Normal 1 ^a	Normal 2 ^a
Tidal volume (mL)	25	50	155	770	500
Frequency (min ⁻¹)	40	30	25	12	13
Duty cycle (%) ^{b,c}	25	25	33	33	33
Minute volume (mL)	1000	1500	3875	9240	6500

^a *Normal 1* represents a resting adult of average build; *Normal 2* represents an active adult of large build.

^b Duty cycle = (inspiratory time/total time for a single inspiratory/expiratory cycle) × 100 for regular tidal breathing.

^c *I/E* ratio may also be used as an alternative to duty cycle, where *I/E* = inspiratory time/expiratory time.

3. MEASUREMENT OF APSD

3.1 No Delay between the pMDI Actuation and Sampling Onset

BACKGROUND

In *Part 1A* (see *Figure 4*), the measurement of APSD from the spacer or VHC with no delay following actuation of the inhaler is defined as an important test of the optimum performance of the device in the hands of the patient. This test also provides information with which to compare the in vitro performance of the pMDI with and without the add-on device present.

TEST PROTOCOLS

If the spacer/VHC is intended for adult use, and comparison is being made with the pMDI alone, follow the procedure given for *Apparatus 1* or *Apparatus 6*, as required, in (601). *Apparatus 1* is the Andersen 8-stage "non-viable" cascade impactor without preseparator, and *Apparatus 6* is the Next Generation Impactor, also without preseparator. Alternatively, the model 150 Marple-Miller impactor (MSP Corp., St. Paul, MN), which has the same stage cut-point sizes at 30 L/min as those of *Apparatus 2*, may be used.

If the spacer/VHC is intended for neonates, infants, or small children, it may be appropriate to use an alternative apparatus that operates at the reduced flow rate(s) more appropriate for these classes of patients. Examples are *Apparatus 6* operated at 15.0 L/min or the pediatric

version of *Apparatus 2* (model 150P Marple-Miller impactor) that functions at either 4.9 or 12.0 L/min.

Conduct the evaluation with the mouthpiece of the spacer or VHC, if so equipped, connected to the test apparatus. If the spacer or VHC is equipped with a facemask, remove the facemask and perform the evaluation with the add-on device connected to the test apparatus by means of the facemask adapter.

In the group of VHCs to be tested, remove each device from its packaging (if supplied), and prepare it for the test by prewashing in accordance with the manufacturer's instructions, if so indicated. If no instructions for preparation are provided, test the device out of the package without prewashing, and note this information in the test report.

Connect the spacer or VHC via the mouthpiece or facemask adapter to the entry to the induction port described in (601). This connection can be made either with a short piece of flexible tubing or with a purpose-built coupling that ensures on-axis alignment with the entry to the induction port. If flexible tubing is used for this connection, ensure that the add-on device is supported in such a way that its long axis aligns with the axis of the induction port entry. Care should be taken to ensure that the coupling, however constructed, does not result in a significant loss of the drug and/or change in measured APSD.

Verify that the coupling is leak tight by first connecting the calibrated gas flow meter to the entry of the induction port and then verifying that the flow rate specified for the test is within $\pm 5\%$ of the desired flow rate. This is achieved by applying a vacuum to the test apparatus by means of an appropriate regulation valve located between the cascade impactor and vacuum source. Remove the flow meter from the induction port and connect the spacer/VHC as described above. Verify that the volumetric flow rate determined by attaching the same flow meter to the pMDI mouthpiece acceptance port of the spacer/VHC is NLT 95% of that obtained at the first flow rate measurement at the entry of the induction port. Turn off the source of vacuum to this apparatus after this check has been completed, and remove the flow meter, insuring the connection between the spacer/VHC and induction port is not disturbed.

The practice of actuating the pMDI with the spacer or VHC initially disconnected from the induction port and then rapidly connecting the add-on device after pMDI actuation should be discouraged, because there is always a small delay interval and medication will be lost in an uncontrolled manner from an open-tube spacer if this procedure is followed.

Follow the directions in the patient information and instructions for use for the pMDI to prime it before inserting into the pMDI adapter of the spacer/VHC. In the case of an add-on device equipped with an integral actuator, after priming the pMDI canister in its mouthpiece adapter as supplied, remove the canister from the adapter, and clean the external valve stem with a suitable wipe. Insert the canister valve stem into the receptacle following the *Instructions for Use* for the particular add-on device, taking care to avoid premature actuation.

In cases where more than one actuation of the pMDI is needed to collect sufficient mass of drug product, follow the directions in the patient information and instructions for use; if no directions are provided, allow a minimum of 30 s between actuations. Turn on the vacuum to the cascade impactor before delivering any actuations. It is important to deliver the minimum number of actuations to obtain an adequate sample of the size-fractionated drug mass for measurements to be made to the same degree of precision as would be the case if the pMDI was evaluated alone.

After the pMDI actuation and aerosol sampling are completed, recover the drug from each component of the cascade impactor, including the induction port, and also from within the spacer/VHC by using a validated method appropriate to the product being measured. Carefully remove the backup filter of the cascade impactor, whose purpose is to capture the drug mass

passing the last impaction stage, from its location, and place it in a suitable container. For each sample, add a known volume of a suitable solvent to the container, and agitate to dissolve the collected drug. Transfer a sample to a cuvette or vial for drug assay using a syringe equipped with an in-line filter to retain any suspended material. Care must be taken with the recovery of a drug retained by the add-on device, because a greater volume of solvent may be needed, compared with volumes needed for recovery from each impaction plate/cup of the impactor. Perform separate assays to measure the mass of drug recovered from each component, using a validated procedure.

Repeat the measurement with the required number of devices and replicates per device.

Typically, five separate spacers or VHCs are each tested once, but other testing protocols may be adopted as required, if validated and justified. These protocols may include replicate measurements per device to obtain information about intra- as well as inter-device performance. Calculate the mean value for each metric described below, together with its standard deviation (SD). Determine the coefficient of variation (CoV) as a percentage, based on the formula:

$$\text{CoV} = [(\text{SD}/\text{mean}) \times 100]$$

Measurements

Total mass of drug collected: This procedure is not a test of the product or add-on device but serves as a system suitability test to ensure that the results are valid. The total mass of drug collected comprises the sum of the drug mass in all of the components, including the pMDI mouthpiece and from within the spacer/VHC [material balance (MB)] divided by the number of actuations of the pMDI. Note that typically up to 5% of the target-delivered label claim may be retained by the cascade impaction apparatus as inter-stage wall losses.

The total mass of drug emitted: The total mass of drug emitted from the spacer/VHC with zero seconds delay [delivered dose, equivalent to emitted mass (EM)] is determined from the sum of the values for the mass of drug collecting in all of the components of the test apparatus divided by the number of actuations of the pMDI. Spacers and VHCs are intended to reduce the mass of coarse particles inhaled by the patient; therefore, an important part of data interpretation of the APSD should involve separate assessments of the pertinent subfractions relevant to the inhalation aerosol product. The precise size limits for these subfractions will be agreed with the recipient of the test data. However, to provide initial guidance on this matter, it is suggested that the following be considered as a minimum:

- Determination of the mass of drug retained by the spacer/VHC together with the mass recovered from the induction port
- Stage-by-stage profile of the remaining EM

Further interpretation of these data is at the discretion of the user. The performance of the spacer/VHC is compared with that of the metered-dose pMDI alone, following the procedure described in (601).

3.2 Delay between the pMDI Actuation and Sampling Onset

[Note—This test is inappropriate for spacers.]

BACKGROUND

This test requires the adaptation of USP's *Apparatus 1* and *Apparatus 6* to accept a means by

which the delay interval can be realized. The actuation of the pMDI into the VHC on test with its mouthpiece or facemask adapter disconnected from the entry to the induction port, followed by connection to the port with the vacuum applied to the apparatus immediately after the delay interval has elapsed, is difficult to perform accurately and may result in leakage or an inaccurate realization of the delay interval. For these reasons, an apparatus of the type described in *Figure 5* is recommended, because it enables the VHC mouthpiece/facemask adapter to remain in position throughout the measurement. The methodology for delay testing is based on the apparatus illustrated, but other equipment offering similar capability may be used if validated.

TEST PROTOCOLS

The vertically mounted shutter plate comprises a circular opening in its upper half and is mounted at setup such that the gap between the VHC mouthpiece/facemask adapter and induction port entry is closed, as illustrated (see *Figure 5*). The induction port and VHC adapter fit tightly into the mounting block. In this position, when vacuum is applied to the test apparatus, air is sampled by the apparatus at the desired flow rate via a bypass channel on the side of the adapter facing the induction port. This arrangement avoids the need to start the flow through the apparatus after the delay interval has elapsed, so that the cascade impactor is always operated at a constant flow rate.

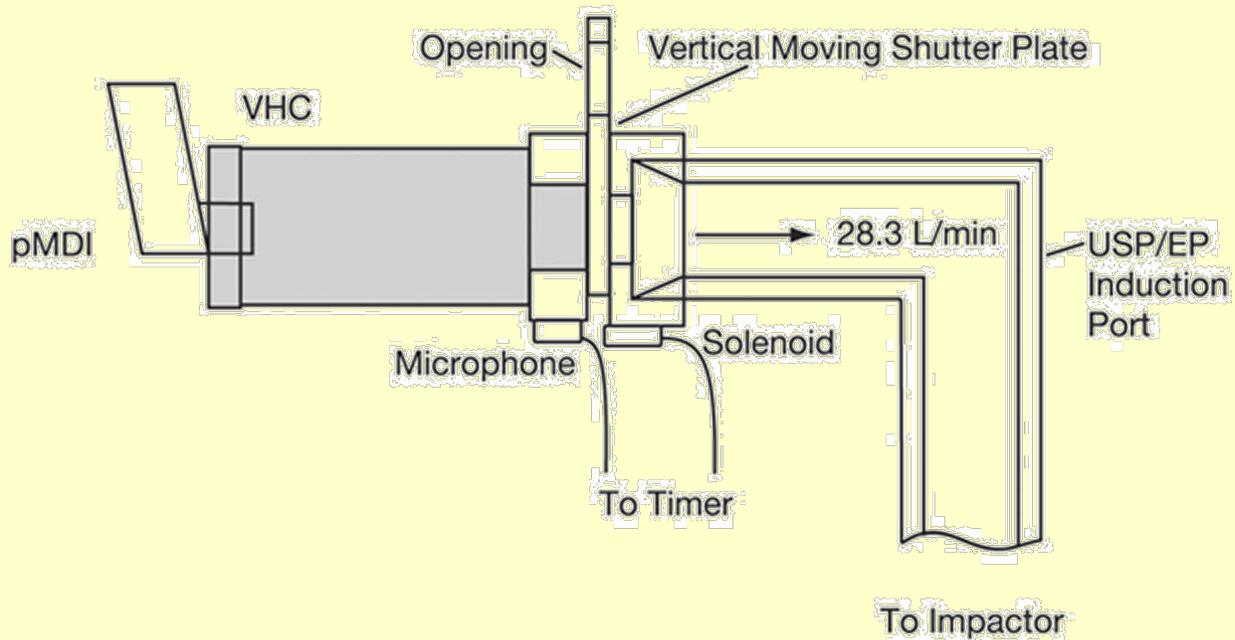

Figure 5. "Delay" apparatus shown with a USP/EP induction port and 8-stage Andersen cascade impactor.

In the configuration described in *Figure 5*, when the pMDI is actuated, a microphone located on the adapter block detects the sound emitted at actuation of the pMDI, starting a timer that operates a solenoid valve that retracts a pin immediately after the preset delay interval has expired. This process permits gravity to operate on the shutter, which drops to the lower position in which the aperture is aligned with the VHC mouthpiece/facemask adapter and induction port entrance. The aerosol retained within the VHC is sampled as soon as the shutter moves to the "open" position. This procedure avoids the risk of capturing any "blow-by" aerosol

that might escape the VHC as the propellant expands immediately following pMDI actuation but would not be inhaled by a user. If blow-by is observed, it should be noted in the test report. In the configuration shown in *Figure 5*, the adapter introduces <5 mL of additional volume to the aerosol pathway from the VHC to the filter, and the minimum delay interval achievable is 1 s. Example delay intervals of 2, 5, and 10 s have been noted earlier in this chapter, although other delay interval(s) may be substituted or added if required and justified.

Securely attach the exit port from the delay apparatus to the entry of the induction port. Connect the VHC via the patient interface (mouthpiece or facemask adapter) to the entry port of the delay apparatus and verify that the coupling is leak tight. This check is most easily done by connecting a calibrated gas flow meter to the port for the pMDI (pMDI adapter) on the VHC and verifying that the volumetric flow rate is NLT 95% of that obtained with the same flow meter connected to the entry of the induction port. This should be done before attaching the delay apparatus, with the vacuum source applied to the test apparatus to achieve the appropriate nominal flow rate. Turn off the vacuum source to this apparatus after this check has been completed, and remove the flow meter. Reconnect the VHC, and turn on the vacuum source again.

Before actuating the pMDI for the first time into the VHC being tested, ensure that the delay apparatus is set such that the shutter is in the "up" or "closed" position. Select the desired delay interval for the timer.

Follow the directions in the patient information and instructions for use before inserting the actuator/mouthpiece of the pMDI into the pMDI adapter of the VHC before the first actuation into the test apparatus. If the spacer/VHC is designed with an integral actuator, after priming the pMDI canister in its mouthpiece adapter as supplied, remove the canister from the adapter and clean the external valve stem with a suitable wipe. Insert the canister valve stem into the receptacle following the instructions for the particular add-on device, taking care to avoid premature actuation.

In cases where more than one actuation of the pMDI is needed to collect sufficient mass of drug product, follow the directions in the patient instructions, or if no direction is provided, allow a minimum of 30 s between actuations. Deliver the minimum number of actuations needed to obtain an adequate sample of the size-fractionated drug mass so that measurements can be made to the same degree of precision as if the pMDI was evaluated alone. Reposition the shutter of the delay apparatus in the up or closed position, and check that the timer is set for the desired delay after each pMDI actuation.

After the sampling part of the measurement is completed, recover the drug from each component of the cascade impactor, including the induction port, and from within the spacer/VHC by using a validated method appropriate to the specific product. In the configuration shown in *Figure 5*, the surface area of the shutter that is exposed to aerosol particles is minimal. Therefore, recovery of drug from this component needs to be done only for the most accurate work; in which case, the inner surfaces of the aperture in the shutter plate and the exit port are washed with recovery solvent. Care should be taken with the recovery of drug retained by the VHC, because a greater volume of solvent than is needed for recovery from each impaction plate/cup of the impactor may be needed to be sure that drug is quantitatively recovered. Assay for the mass of drug recovered from each component separately by using a validated procedure.

Repeat the measurement with the required number of devices and replicates per device.

Typically, five separate spacers or VHCs are each tested once, but other designs, including replicate measurements per device, may be adopted as required, if validated and justified.

Calculate the mean values for each metric described below, together with its SD. Determine the

coefficient of variation (CoV) as a percentage, based on the formula:

$$\text{CoV} = [(\text{SD}/\text{mean}) \times 100]$$

Measurements

Total mass of drug collected: The total mass of drug collected in all of the components, including the pMDI mouthpiece and from within the spacer/VHC (material balance) is divided by the number of actuations of the pMDI. The component of the dose that may escape past the inhalation valve of the VHC on pMDI actuation (due to momentary pressurization of the interior of the chamber) is termed blow-by, and it may not be captured for the assay. If this phenomenon is observed, it must be noted. [Note—Quantification of blow-by is not a practical proposition because the act of collecting the aerosol will inevitably apply back-pressure to the valve, reducing or eliminating the phenomenon altogether.]

The performance of the spacer/VHC tested with delay is compared with that of the spacer/VHC tested with no delay, following the procedure described in (601).

VHCs are intended to reduce the mass of coarse particles inhaled by the patient, so an important part of data interpretation of the APSD should involve separate assessments of the pertinent subfractions relevant to the inhalation aerosol product. The precise size limits for these subfractions will be agreed with the recipient of the test data. However, to provide initial guidance on this matter, it is suggested that the following be considered as a minimum:

- Determination of the mass of drug retained by the spacer/VHC together with the mass recovered from the induction port
- Stage-by-stage profile of the remaining EM

Further interpretation of these data is at the discretion of the user.

4. MASS OF DRUG DELIVERED FROM A SPACER/VHC WHILE SIMULATING PATIENT TIDAL BREATHING

4.1 Without Facemask

Cascade impactors used in the assessment of APSD are designed to operate at fixed flow rates. However well the add-on device may perform during an in vitro test of function using such an apparatus, the operation of critical moving components (i.e., inhalation and exhalation valves of VHCs) is not evaluated in the way that these components would perform when the VHC is used by the patient. An additional test that simulates tidal breathing is therefore included, because this type of respiratory pattern is most commonly encountered with patients using an add-on device, particularly neonates, infants, and children who are incapable of a forced inhalation maneuver. Several representative, age-related breathing patterns are listed in *Table 2*.

There is no breathing simulator recognized in (601). However, (1601) provides for the use of a commercially available breathing simulator that is able to generate the same breathing profiles as those specified in *Table 2*. The methodology provided assumes that equipment meeting this standard is available. *Figure 6* illustrates schematically a setup that has been effective for these measurements, but other configurations may be used as required, if validated and justified.

The filter system used to collect the aerosol at the mouthpiece/facemask adapter of the spacer/VHC should be a suitably validated, low-resistance filter capable of quantitatively

collecting the aerosol and enabling recovery of the drug substance with use of an appropriate solvent. If the filter is contained in its own housing, the dead volume of the filter casing shall not exceed 10% of the tidal volume used in the breath simulation. This restriction will likely make it necessary to use filters without a separate housing when performing tests that simulate neonatal or infant use.

The first part of the test is suitable for both spacers and VHCs, because it simulates the delivery of medication mimicking a fully coordinated user actuating the pMDI at the onset of inhalation. However, the second part of the test is only suitable for VHCs because the pMDI is actuated at the onset of exhalation to simulate a fully uncoordinated user.

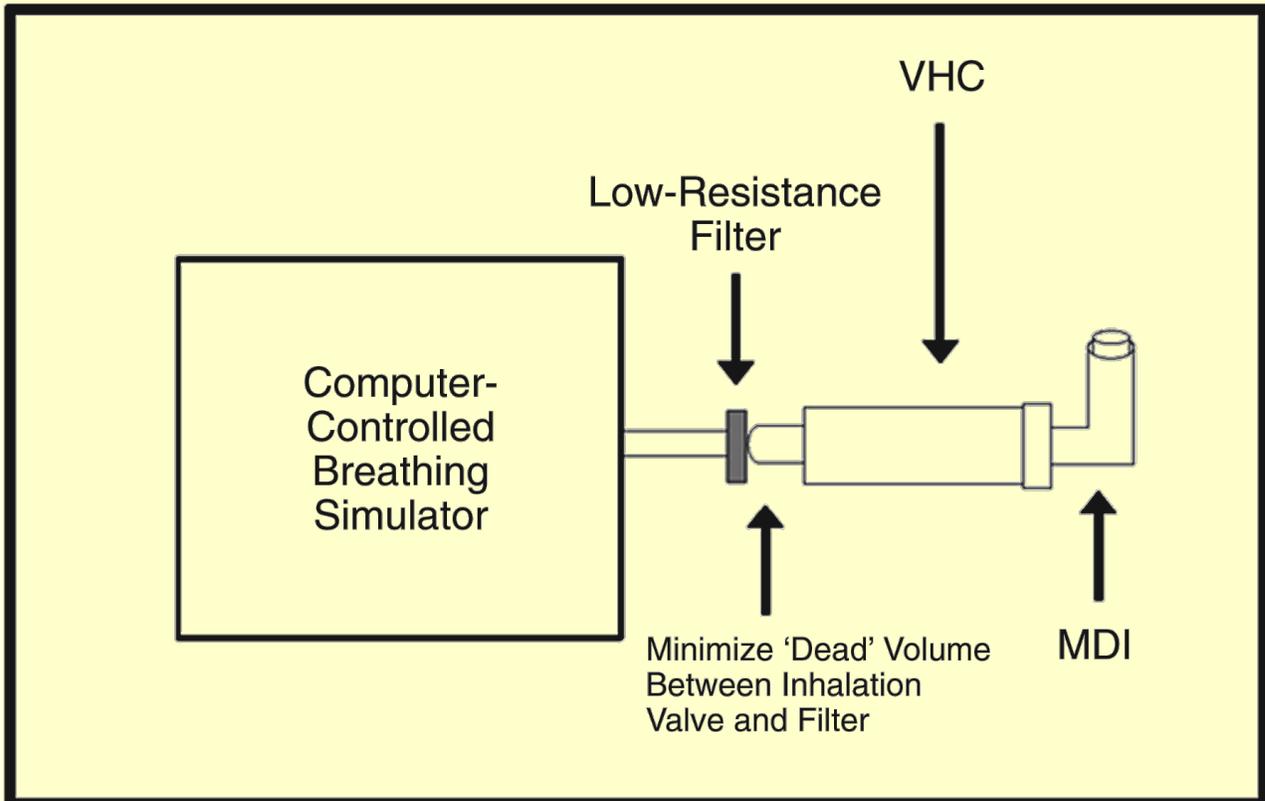

Figure 6. VHC evaluation by breathing simulator.

TEST, PART 1

Set the breathing simulator to the required breathing pattern (identified from *Table 2*) in accordance with the manufacturer's instructions. Alternative breathing patterns may be used if required. Ensure that the simulator has been calibrated before use so that the actual volumes and frequency are within $\pm 5\%$ of the indicated value during each breathing cycle. Calibration syringes are available from various suppliers of mechanical ventilation equipment to verify volumes. To verify frequency, the method varies among breathing simulator manufacturers, and therefore the advice of the particular supplier/manufacturer should be sought if the method is not explicitly stated in the operating instructions for the apparatus.

Ensure that the selected flow waveform from the *Breathing simulator* (Figure 6) is stable before proceeding. Remove each device in the group of spacers or VHCs to be tested from its packaging (if supplied), and prepare for the test by prewashing in accordance with the manufacturer's instructions, if indicated. If no instructions for preparation are provided, test the devices out of package without prewashing and note this fact in the test report.

Connect the mouthpiece or facemask adapter of the spacer/VHC to the appropriate port of the

breathing simulator by means of a short length of flexible hose. Locate the aerosol filter as close as possible to the mouthpiece of the spacer/VHC using an adapter or other means that will enable an airtight seal to be formed with the minimum amount of space (dead volume) between the device and the filter. Ensure that the adapter does not restrict the path of the aerosol.

Filtrete™ (3M Corp, St. Paul, MN) is a suitable electret filter medium that readily releases collected drug quantitatively upon addition of a suitable solvent during the assay procedure. However, other suitable filter media may be used provided that the tester is satisfied that the filter is capable of collecting the entire emitted dose and that drug recovery for assay is quantitative.

Follow the directions in the patient information and instructions for use for the pMDI to prime it before inserting into the pMDI adapter of the spacer/VHC before the first actuation into the test apparatus. In the case of an add-on device equipped with an integral actuator, after priming the pMDI canister in its mouthpiece adapter as supplied, remove the canister from the adapter, and clean the external valve stem with a suitable wipe. Insert the canister valve stem into the receptacle by following the instructions for use for the particular add-on device, taking care to avoid premature actuation. This test typically should require only one actuation of the pMDI into the spacer/VHC per determination. However, for certain highly potent products delivering low unit mass of drug per actuation, more than one actuation of the pMDI may be needed to collect a sufficient mass of drug product. Under such circumstances, follow the directions in the patient information and instructions for use for the pMDI, or allow a minimum of 30 s between actuations if no direction is provided. It is important to deliver the minimum number of actuations to obtain an adequate sample of the drug mass for measurements to be made with acceptable precision.

For the first part of the test, perform a single actuation timed to coincide with the beginning of an inhalation. Allow sampling to occur for five additional breathing cycles. If additional actuations are required to improve analytical sensitivity, ensure that the sampling time is of sufficient length for the spacer/VHC to be emptied of remaining aerosol before the next actuation is delivered, and do not disconnect the spacer/VHC from the breathing simulator between actuations.

Remove the filter carefully from its location, and place it in a suitable container. Add a known volume of a suitable solvent to the container and agitate to dissolve the collected drug. Transfer a sample to a cuvette or vial for drug assay using a syringe equipped with an in-line filter to retain any suspended material. Recover the mass of drug from the filter by using a validated procedure appropriate to the specific product, and assay for the mass of drug collected by using a validated procedure. Calculate the total mass of drug per actuation; this is the emitted mass in the "fully coordinated" condition (EM_c). Repeat the measurement with the required number of devices and replicates per device.

TEST, PART 2

[Note—This part of the test is inappropriate for spacers.] For the second part of the test, either clean the VHC between measurements, or evaluate a new VHC out of its packaging, as required and justified. Report whether cleaning or replacement of the VHC was carried out. Repeat the procedure above in *Test, Part 1* with the same VHC, this time actuating the pMDI timed to coincide with the onset of exhalation. Calculate the total mass of drug per actuation; this is the EM in the "fully uncoordinated" condition (EM_{uc}). Repeat the measurement with the required number of devices and replicates per device.

Construct a table of data showing the mass of drug collected on the filter for each individual measurement of EM_c and EM_{uc} . Calculate the mean and SD for each group of measurements. In the example shown in Table 4, there are three separate VHCs (VHC-1, VHC-2, and VHC-3), each tested three times (R1, R2, and R3) for each condition.

Table 4. Emitted Mass of Drug with VHC Evaluated by Tidal Breathing Simulator

Condition	VHC-1			VHC-2			VHC-3			Group	
	R1	R2	R3	R1	R2	R3	R1	R2	R3	Mean	SD
Coordinated	EM_{c1-1}	EM_{c1-2}	EM_{c1-3}	EM_{c2-1}	EM_{c2-2}	EM_{c2-3}	EM_{c3-1}	EM_{c3-2}	EM_{c3-3}	\overline{EM}_c	SD_c
Uncoordinated	EM_{uc1-1}	EM_{uc1-2}	EM_{uc1-3}	EM_{uc2-1}	EM_{uc2-2}	EM_{uc2-3}	EM_{uc3-1}	EM_{uc3-2}	EM_{uc3-3}	\overline{EM}_{uc}	SD_{uc}

4.2 With Facemask

The purpose of this test is to provide confirmation that the emitted mass from a spacer/VHC equipped with a facemask is comparable to that obtained in the fully coordinated simulation

with the facemask removed. Facemasks are widely prescribed for infants, small children, and adults who lack coordination to use a mouthpiece-based product. The evaluation of spacers/VHCs supplied with a facemask, rather than a mouthpiece, requires additional attention beyond the methods described previously, because the facemask itself has a major part to play in the transport of the drug-containing aerosol particles from the add-on device to the patient (*Figure 7*). It is therefore important that the facemask be tested in situ as part of the add-on device, rather than separately. A critical component of the test apparatus is the representation of a human face appropriate to the age range for which the add-on device is intended (e.g., neonate, infant, small child, or adult). This is an active topic of research and there are, as of yet, no standardized models that can be defined as apparatus in a way that is similar to what is done for cascade impactors in the aerodynamic particle size analysis of pMDI-generated aerosols, although an adult face model is available commercially (Copley Scientific Ltd., Nottingham, UK). A review of face models [see Mitchell, JP. Appropriate face models for evaluating drug delivery in infants and small children: the current situation and prospects for future advances. *J Aerosol Med.* 2008;21(1):97–111] provides a summary of the prerequisites for a model face suitable for spacer/VHC facemask testing.

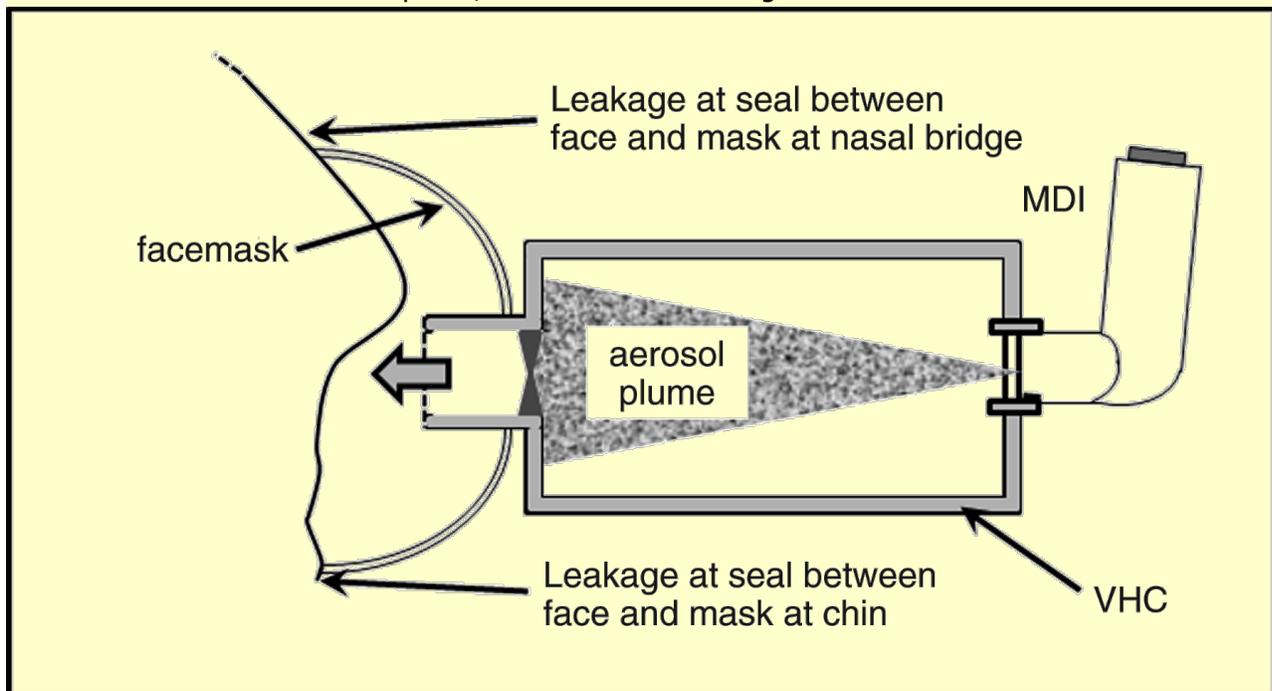

Figure 7. VHC with facemask applied to face.

Prerequisites for face models are the following:

- Appropriate facial dimensions for the intended user age range
- Ability to apply the facemask with the predicted amount of dead space when it is applied with a clinically appropriate force to the model
- Physiologically accurate soft facial tissue modeling around the chin, cheeks, and nose where the facemask makes contact
- Means of correctly mounting the spacer/VHC so that the facemask is oriented with the correct alignment to the face, as would occur when in use by a patient

[Note—Some models may include anatomically accurate realization of the upper airway (nasal or oropharynx), with the aerosol collection filter located at the distal port of the model

representing the entry to the lungs.] For the sake of simplicity and to realize a measure of spacer/VHC performance comparable to the measure obtained with facemask removed in *Part 2* (see *Figure 4*), it is assumed that the model face simulates open-mouth breathing without an anatomically accurate upper airway, and that the aerosol collection filter is located in a cavity immediately behind the lips of the model. The mass of drug is reported as the emitted mass (EM_{facemask}).

Select a face model appropriate to the intended age range for the spacer/VHC-facemask, and mount the face model in an appropriate fixture. The fixture should enable the facemask to be located at an appropriate angle to the face model, such that an effective seal between the facemask and face model is created with a clinically appropriate force. This is typically a loading force of 1.6 kg but may differ from this value if justified by the design of the facemask. The arrangement shown schematically in *Figure 8* is one way of achieving the desired result, but other approaches may be adopted as required, if validated and justified.

Locate and secure the filter media in the cavity behind the lips of the face model. Filtrete™ (3M Corp, St. Paul, MN) is a suitable Electret filter medium that readily releases collected drug quantitatively upon addition of a suitable solvent during the assay procedure. However, another suitable filter medium may be used, provided that the tester is satisfied that it is capable of collecting the entire emitted dose, and that drug recovery for the assay is quantitative.

Verify that a seal has been obtained between the facemask and face model. This is conveniently done by connecting the outlet (distal) port of the face model, using a short length of flexible hose, to an in-line calibrated gas flow meter whose distal port is in turn connected to the vacuum source via a regulating valve capable of setting the flow rate to a suitable value, typically 30 L/min. Connect a similar flow meter to the port for the pMDI (pMDI adapter) on the spacer/VHC, and verify that the volumetric flow rate is NLT 90% of that obtained with the in-line flow meter between face model and regulating valve. Turn off the vacuum source after this check has been completed, and disconnect the flexible hose from the in-line flow meter. Remove the upstream flow meter from the pMDI adapter of the spacer/VHC.

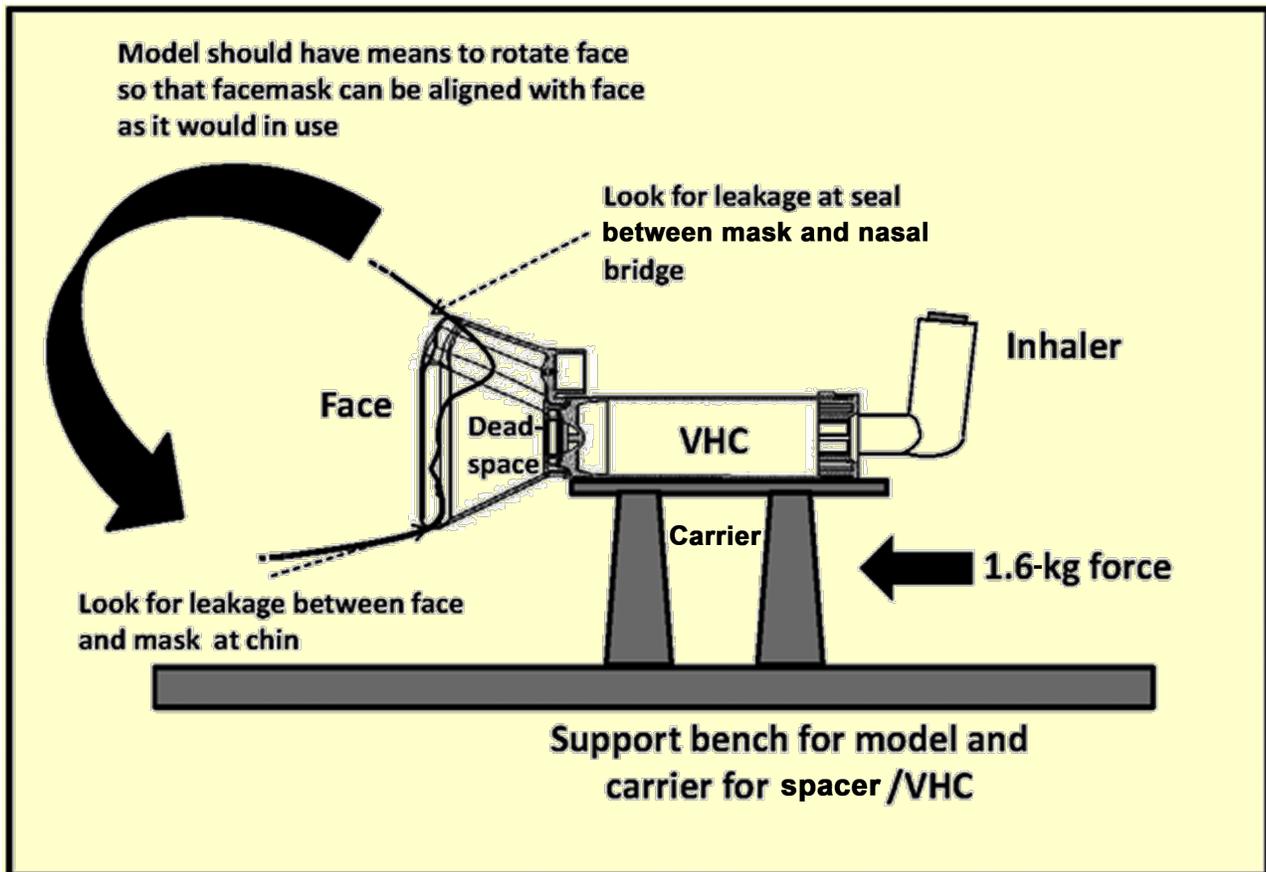

Figure 8. Mount for face model with alignment fixture including carriage for spacer/VHC; a fixed (i.e., 1.6-kg) weight acts on the pulley below the VHC and draws the carriage toward the face with the required force.

Connect the outlet (distal) port of the face model to the appropriate port of the breathing simulator using a short length of flexible hose. Set the breathing simulator to the required breathing pattern (identified from *Table 2*) in accordance with the manufacturer's instructions. Alternative breathing patterns may be used if required. Ensure that the simulator has been calibrated before use so that the actual volumes and frequency are within $\pm 5\%$ of the indicated value during each breathing cycle. Calibration syringes are available from various suppliers of mechanical ventilation equipment to verify volumes. To verify frequency, the method varies among breathing simulator manufacturers, and therefore the advice of the particular supplier/manufacturer should be sought if the method is not explicitly stated in the operating instructions for the apparatus. Ensure that the selected flow waveform from the breathing simulator is stable before proceeding.

Follow the directions in the patient information and instructions for use for the pMDI to prime it before inserting it into the pMDI adapter of the spacer/VHC before the first actuation into the test apparatus. In the case of an add-on device equipped with an integral actuator, after priming the pMDI canister in its mouthpiece adapter as supplied, remove the canister from the adapter, and clean the external valve stem with a suitable wipe. Insert the canister valve stem into the receptacle according to the instructions for use for the particular add-on device, taking care to avoid premature actuation. Typically, it should require only one actuation of the pMDI into the spacer/VHC per determination. However, for certain highly potent products delivering a low-unit mass of drug per actuation, more than one actuation of the pMDI may be

needed to collect a sufficient mass of drug product. Under such circumstances, follow the directions in the patient instructions, or allow a minimum of 30 s between actuations if no direction is provided. Deliver the minimum number of actuations needed to obtain an adequate sample of the drug so that mass measurements can be made with acceptable precision. Perform a single actuation, timed to coincide with the beginning of an inhalation. Allow sampling to occur for five additional breathing cycles. If additional actuations are required to improve analytical sensitivity, ensure that the sampling time is of sufficient duration for the spacer/VHC to be emptied of remaining aerosol before the next actuation is delivered, and do not disconnect the spacer/VHC from the breathing simulator between actuations.

Following the tests, remove the filter carefully from its location, and place it in a suitable container. Add a known volume of a suitable solvent to the container and agitate to dissolve the collected drug. Transfer a sample to a cuvette or vial for drug assay using a syringe equipped with an in-line filter to retain any suspended material. Recover the mass of drug from the filter by using a validated method appropriate to the specific product, and assay for the mass of drug collected by using a validated procedure. Calculate the total mass of drug per actuation; this is the emitted mass in the “fully coordinated” condition with facemask fitted to the add-on device (EM_{c-fm}). Repeat the measurement with the required number of devices and replicates per device.

Construct a table of data showing the mass of drug collected on the filter for each individual measurement of EM_{c-fm} . Transfer the values of EM_c from the test undertaken in *Part 2* (see *Figure 4*) in which the facemask adapter was removed for comparison of emitted mass, simulating fully coordinated use by a breathing simulator. Calculate the mean and SD for each group of measurements. In the example shown in *Table 5*, there are three separate VHCs (VHC-1, VHC-2, and VHC-3), each tested three times (R1, R2, and R3) for each condition. However, other designs may be used following discussion between the user and recipient of the data.

1. INTRODUCTION

Chirality is a ubiquitous aspect of the world of three spatial dimensions. Molecules that possess sufficient structural complexity so that their mirror-image structures are nonsuperimposable are termed chiral. For chiral pharmaceutical molecules, two important structural measures critical to their physical characterization are absolute configuration (AC) and enantiomeric excess (EE), also termed enantiomeric purity. The AC of a chiral molecule specifies its three-dimensional structure in space and distinguishes it from its mirror-image structure. Structures related by mirror symmetry are known as "enantiomers". The AC of a particular enantiomer is critical to its action as a pharmaceutical agent because mirror-image structures, i.e., enantiomers, have different therapeutic effects, both desired and undesired. The EE of a sample specifies, usually as an excess percentage, the relative amounts of enantiomers. An EE of 100% is a pure enantiomer (100% enantiomeric purity), 0% is a racemic mixture with equal amounts of enantiomers and no excess, and -100% specifies a pure sample of the opposite enantiomer with respect to the EE definition.

The principal chapter that addresses molecular chirality in the *USP* is *Optical Rotation* (781). The optical rotation (OR) of a sample is the measure of the angle of rotation of a plane of polarized light by a chiral sample at a particular wavelength, typically in the visible or near-UV region. The AC and EE of any sample are determined by a measure of its OR if the measurement has been previously calibrated using a sample of known AC and EE. The sign of the OR determines the larger enantiomer amount, and the magnitude of the OR determines the EE, where 100% EE corresponds to the maximum OR possible for the chiral molecule under consideration. Although OR is a simple, well-established method for determining AC and EE relative to their known calibrations, not all molecules have measurable OR, particularly with limited sample quantities in which the presence of chiral impurities cannot be determined by an OR measurement. The OR is simply a number with no structural information about the sample molecule.

In the past several decades, the AC of an unknown chiral molecule has been determined using

the Bijvoet method of single-crystal X-ray crystallography. The Bijvoet method requires a single high-purity crystal of the molecule with a single chiral phase. Analysis by this method is not always possible, e.g., for noncrystallizable liquids or insoluble solids, and in many cases analysis using the Bijvoet method requires lengthy efforts and time to achieve crystallization.

This general information chapter presents a technique for the determination of AC that relies on vibrational circular dichroism (VCD), a procedure that is now widely used throughout the pharmaceutical industry for chiral molecules for which the AC is unknown. The technique involves comparing the measured VCD spectrum for a chiral molecule to the quantum chemistry calculation for the same molecule. If the measured and calculated VCD spectra show agreement on the principal features and their signs, this means that the AC of the physical sample is the same as the AC of the structure used in the calculation. If the signs are opposite, the AC of the sample is the opposite of that used in the calculation.

As described below, statistical methods have been developed for assessing the degree of confidence that the AC has been correctly determined by the VCD method. Usually the AC of a chiral molecule is specified by connecting its structural chirality, labeled with *R* or *S* for chiral centers or *P* or *M* for chiral axes, to the sign of its measured OR as (+) or (-). Once the AC of a molecule has been determined by VCD, for example, (*S*)-(-)- α -pinene, its VCD spectrum can become a USP Reference Standard of the AC of this molecule, and the AC of any subsequent sample of this molecule can be determined by comparison to its VCD Reference Standard. An important advantage of determining AC by VCD is the spectral richness of a VCD spectrum that supports the simultaneous determination of the structural identity of the molecule and its absolute chirality. In contrast to OR, every chiral molecule has a VCD spectrum, because all molecules have infrared (IR) absorption bands, each one of which acts as a chromophore for a VCD spectrum. VCD also is sensitive to molecular conformations. As demonstrated below, information about the conformation of a chiral molecule is obtained as a bonus from the VCD determination of AC, but AC is the principal informational content of chiral pharmaceutical molecules. An extensive body of literature describing the AC of biological molecules has been created over the past 30 years and can be used as a basis for determining secondary and higher-order structural states of biological drug substances. Stereo-specific methods using VCD can be developed to characterize the production, formulation, and stability of biopharmaceutical products.

This chapter also presents a method for the determination of EE using VCD. EE determination with VCD takes advantage of the fact that the magnitude of a VCD spectrum, measured as the circular polarization absorbance difference for a constant parent IR absorbance spectrum, is directly proportional to EE with no offset. Thus, the maximum relative size of a VCD spectrum is obtained for an EE of 100%, is zero for an EE of 0% (racemic mixture), and is maximum with opposite signs (all positive VCD bands are negative and all negative VCD bands are positive) for an EE of -100%. The advantage of VCD EE determination is that the EE of any molecular sample can be determined by a single VCD measurement once the relative size of VCD for 100% EE (or any %EE value) is known for that molecule. Separation of enantiomers with chiral chromatography is not needed.

2. DEFINITION OF VIBRATIONAL CIRCULAR DICHROISM

VCD is defined as:

$$\Delta A = A_L - A_R$$

ΔA = the difference in the IR absorbance

A_L = sample absorbance A for left circularly polarized (LCP) radiation

A_R = sample absorbance A for right circularly polarized (RCP) radiation

Unpolarized IR absorbance intensity is defined as the average of LCP and RCP intensities:

$$A = (A_L + A_R)/2$$

The IR intensities of enantiomers are identical, whereas enantiomers have equal and opposite-signed VCD intensities.

3. VCD INSTRUMENTATION

The measurement of a VCD spectrum and its parent mid-IR spectrum is based on Fourier transform-IR (FT-IR) absorption spectroscopy. The optical-electronic layout for the measurement of VCD using an FT-VCD spectrometer is illustrated in *Figure 1*. The output beam of an FT-IR spectrometer is optically filtered and then linearly polarized before passage through a photoelastic modulator (PEM). The zinc selenide (ZnSe) PEM, typically used for VCD measurement, changes the polarization state of the beam between LCP and RCP at a frequency of 37 kilocycles/s (37 kHz). A sample solution in a standard IR cell is placed in the beam, and a liquid nitrogen-cooled detector of mercury-cadmium telluride (MCT) detects the transmitted beam. The detector produces signals in two frequency ranges: 1) I_{DC} , in the range of 1–2 kHz, represents the FT-IR interferogram; and 2) I_{AC} , centered at 37 kHz, represents the FT-VCD interferogram. The FT-IR interferogram may be directly Fourier transformed to yield the IR spectrum. After synchronous demodulation (using a lock-in amplifier or purely numerical processing) with a reference at 37 kHz, the VCD interferogram can be Fourier transformed to yield the VCD spectrum. Both the IR and VCD spectra are presented in dimensionless absorbance units, A , and hence the ratio of the VCD to the IR intensity for any band in the spectrum yields the dimensionless anisotropy ratio for that vibrational transition. *Figure 1* illustrates the minimum setup for VCD measurement, but technically advanced instruments use two PEMs to increase baseline stability and two sources to increase signal quality or reduce sample measurement time. Measurement of VCD in other spectral regions, for example, the hydrogen-stretching or near-IR, can be carried out with appropriate changes in sources, polarizers, filters, PEM, cells, and detectors.

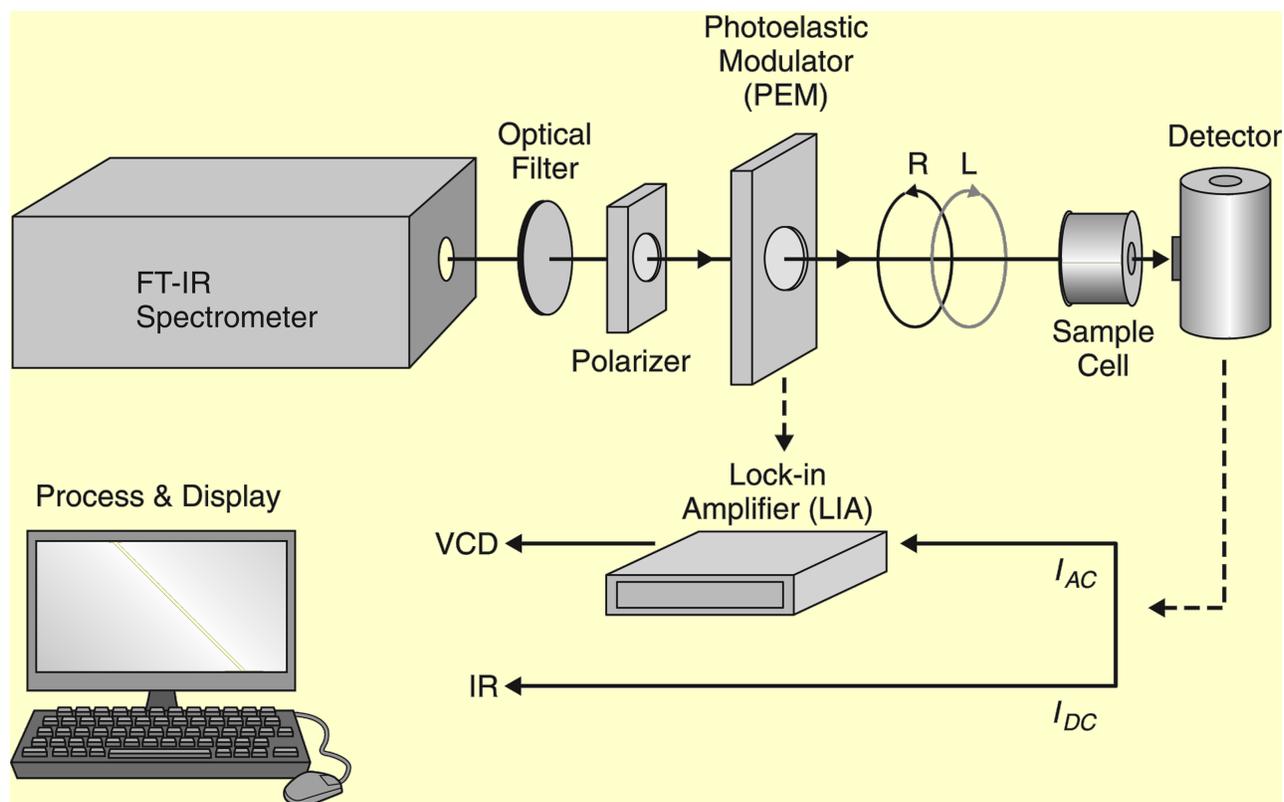

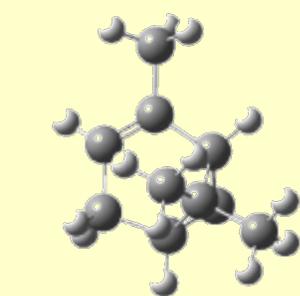

Figure 1. Diagram illustrating the typical features of an FT-VCD spectrometer for the measurement of the IR and VCD spectra of a chiral sample.

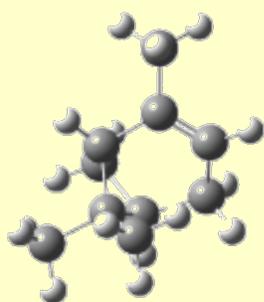

4. MEASUREMENT OF VCD SPECTRA

Figure 2 shows the IR and VCD spectra for (+)-*R*- and (–)-*S*- α -pinene as a neat liquid measured at 4 cm^{-1} spectral resolution for 1 h. Also shown are the stereo-structures of the two opposite enantiomers (+)-*R*- and (–)-*S*- α -pinene. This figure shows that the IR spectra are nearly identical (superimposed dash and solid traces) for these enantiomers and that IR is therefore blind to chirality. By contrast, the corresponding VCD spectra have intensities that are equal in magnitude with opposite signs for each band in the spectrum. The two stereo-structures for α -pinene are presented in a form that makes clear their mirror symmetry, and it follows that mirror-symmetric pairs of chiral molecules have mirror-symmetric VCD spectra about the zero baseline. The VCD baseline for these spectra is offset slightly above zero and can be baseline corrected as discussed below. Inspection of the intensity scales for the IR and VCD spectra reveals that the VCD intensities are approximately four orders of magnitude smaller than the corresponding IR intensities. Finally, each band in the IR spectrum has a corresponding VCD band. The richness of the resolved spectral bands in the VCD spectrum, each one representing what has traditionally been called a chromophore in electronic CD (ECD), gives VCD its exceptional combination of structural richness and stereochemical specificity.

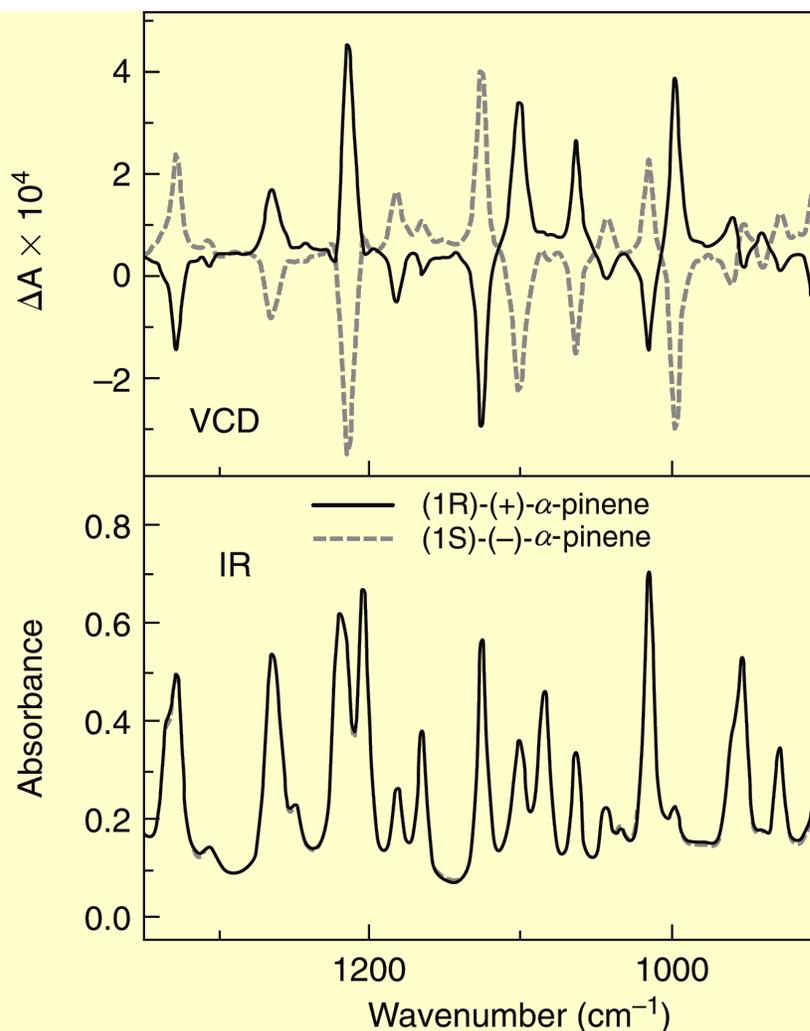

VCD and IR Spectra α -Pinene Enantiomers

(S)-(-)- α pinene

(R)-(+)- α pinene

Enantiomers: IR spectra are identical, VCD spectra are opposite in sign

Figure 2. IR (lower) and VCD (upper) of (1S)-(-)- α -pinene (dash) and (1R)-(+)- α -pinene (solid). To the left are presented the quantum chemistry-optimized stereostructures of (1S)-(-)- α -pinene (upper) and (1R)-(+)- α -pinene (lower). The IR and VCD spectra were measured at 4 cm^{-1} spectral resolution, and the VCD spectra were averaged for 1 h.

Sampling requirements for VCD are similar to those needed to obtain a good IR spectrum. Ideally, as shown in *Figure 2*, analysts choose a combination of path length and sample concentration to obtain an average IR absorbance value A in the range between 0.2 and 0.8 and concentrations between 0.1 and 1.0 M, depending on the molecular weight of the sample. Typical path lengths for organic solvents are in the range of 50–100 μm , and sample quantities needed are typically 5–10 mg, although amounts as small as 2 mg are possible. Typical solvents for VCD measurement of organic molecules are deuterated solvents that have reduced solvent absorption in the mid-IR region. Besides hydrogen-free solvents, such as carbon tetrachloride (CCl_4), other commonly used solvents for VCD are deuterated chloroform (CDCl_3) and deuterated dimethyl sulfoxide (DMSO-d_6).

IR and VCD spectra can be plotted either in absorbance units, as A and ΔA that reflect the sampling conditions, or in molar absorption coefficients ϵ and $\Delta\epsilon$ that remove the concentration and path length dependence of the intensity to give a molecular-level property

that can be compared quantitatively to calculated IR and VCD intensities. The conversion between these two sets of quantities is given by:

$$A = \epsilon C \times l$$

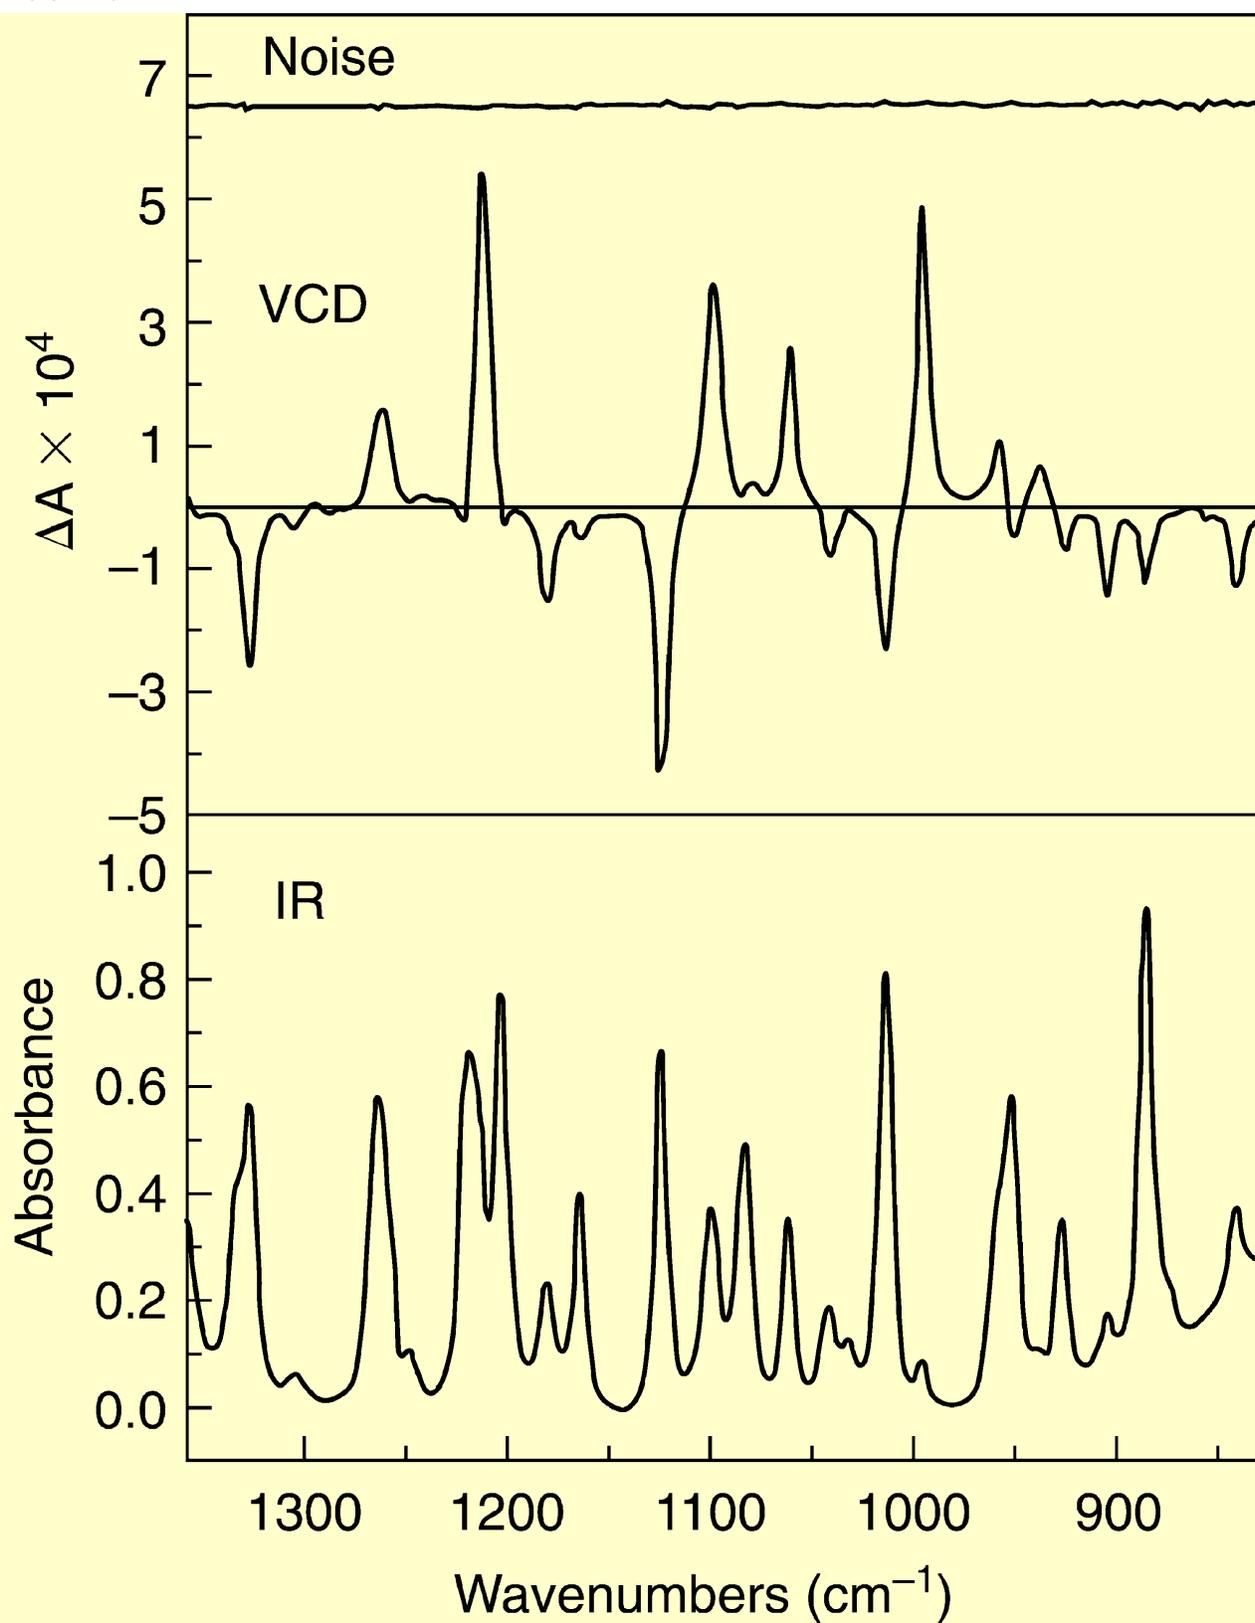

- A = IR absorbance
 ϵ = molar absorption coefficient
 C = concentration (mol/L)
 l = path length (cm)

and

$$\Delta A = \Delta \epsilon C \times l$$

- ΔA = difference in the IR absorbance
 $\Delta \epsilon$ = difference in molar absorption coefficient

A useful dimensionless measure of the intrinsic strength of a VCD band is the anisotropy ratio, defined as $g = \Delta A/A = \Delta \epsilon / \epsilon$. Including the spectral frequency dependence of IR and VCD, the measured spectra are expressed respectively either as $A(\nu)$ and $\Delta A(\nu)$ or as $\epsilon(\nu)$ and $\Delta \epsilon(\nu)$. VCD spectra require baseline corrections for instrumentation and solvent intensity. Deviations from a perfectly flat baseline with zero offset must be removed before a final calibrated VCD spectrum is complete. Solvent baseline correction can be achieved for VCD spectra by subtraction of the VCD spectrum of the solvent in the same sample cell. If the opposite enantiomer or racemic mixture of the sample is available, baseline correction can be achieved as one-half the difference between these two equal and opposite VCD spectra in the case of enantiomers or as simple subtraction in the case of the racemic mixture. Baseline deviations are caused by the unavoidable presence of linear birefringence in the optical elements of the instrument and the sample cell that can become important for all but the largest VCD intensities. An example of a baseline-corrected VCD spectrum is presented in *Figure 3*, along with the corresponding IR and VCD noise spectrum. The spectrum of this sample of neat (–)-(*S*)- α -pinene was collected for a period of 1 h at 4 cm^{-1} spectral resolution in barium fluoride (BaF_2) with a path length of $75 \text{ }\mu\text{m}$. The noise spectrum is less than 1×10^{-5} absorbance (A) units across the spectrum. The IR, VCD, and noise spectra presented in *Figure 3* may be taken as a validation standard for the performance of a mid-IR FT-VCD instrument, as described in *Vibrational Circular Dichroism Spectroscopy* (782).

Simultaneous, two enantiomers, total 3.5 hour

Figure 3. IR absorbance A (bottom), baseline-corrected VCD (middle), and VCD noise spectrum (top) for (-)-(1S)- α -pinene as a neat liquid averaged for 1 h at 4 cm^{-1} spectral resolution and

in a 75- μm path-length barium fluoride cell.

5. QUALITATIVE AND QUANTITATIVE ANALYSIS

5.1 Ensure That Signs and Intensities Are Correct

Qualitative analysis can be carried out with VCD by comparing the VCD spectrum of an unknown to a reference spectrum of that molecule to identify common features and to confirm that the VCD spectrum of the sample is a close match to the reference spectrum.

Quantitative analysis using VCD involves measuring the VCD intensity of the sample molecule and comparing it to a standard reference spectrum for that molecule. In this way, the concentration and the %EE of the sample can be determined as follows. The intensity of the IR spectrum relative to the IR standard of the sample determines the concentration for measurements with the same path length. After normalizing the IR intensity of the unknown sample to the standard, the relative intensities of the VCD determine the %EE of the sample. Such comparisons need to be carried out with all sampling conditions being the same, including the solvent and instrument spectral resolution.

To determine that the VCD intensities are correct, the uncalibrated VCD intensities must be calibrated. This is accomplished by placing a multiple-wave plate in the sample position, followed by a polarizer that is either parallel or perpendicular to the instrument polarizer in *Figure 1*. Measurement of the VCD spectrum of this multiple-wave plate set-up for two settings of the wave plate and polarizer that differ by 90° produces two sets of curves that have crossing points. The curve connecting the crossing points follows the shape of a first-order Bessel function and represents unit VCD intensity. Dividing this curve into the uncalibrated VCD spectrum produces a VCD spectrum with the correct calibrated intensities. The two calibration curves and their crossing-point curve are illustrated in *Figure 4*.

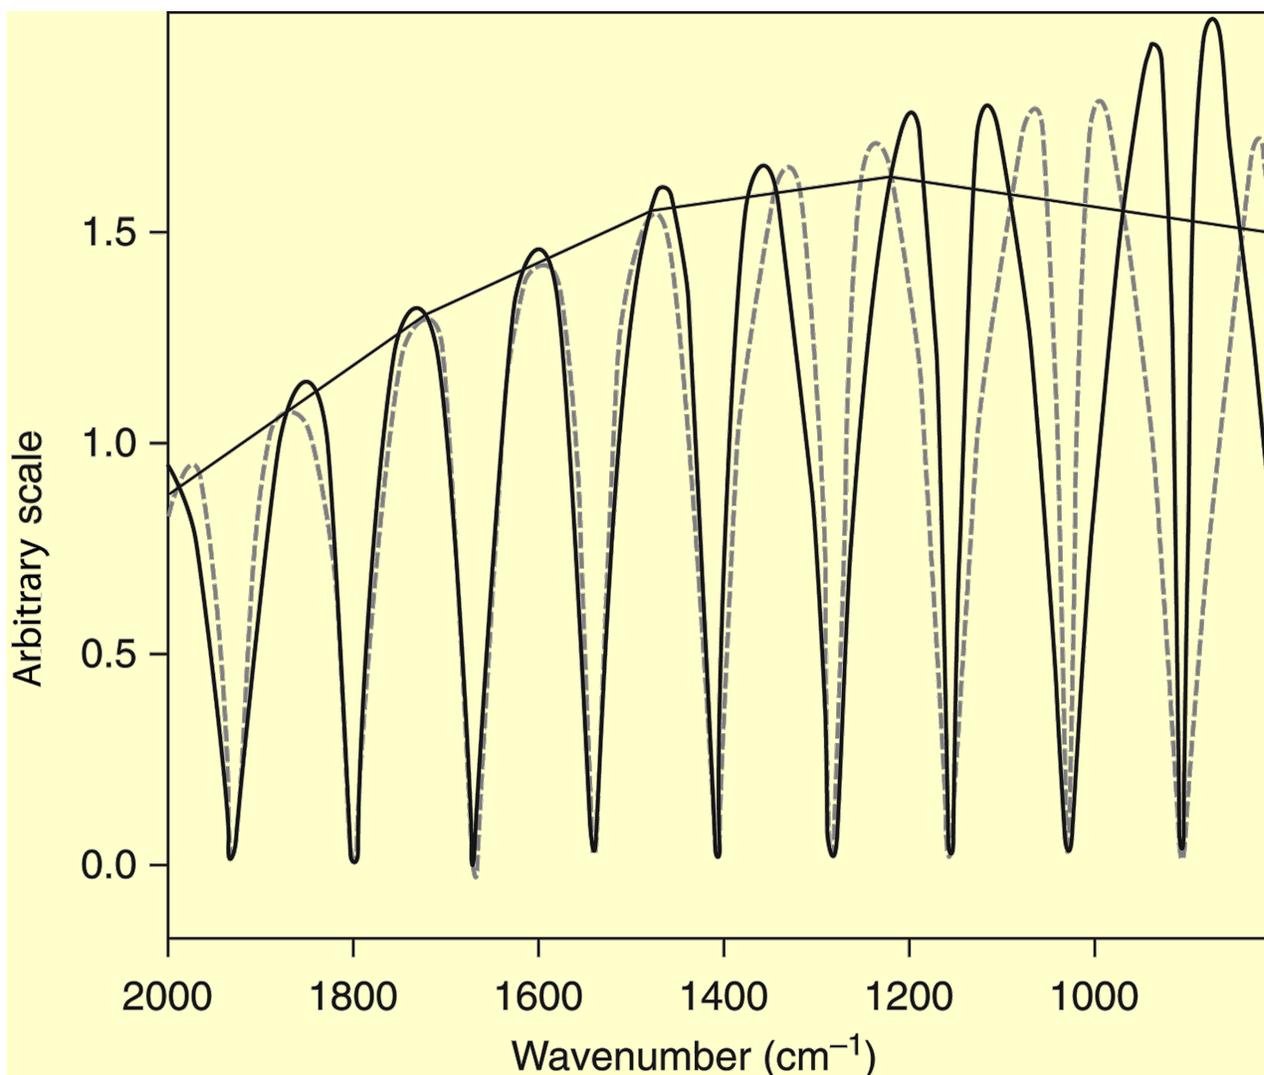

Figure 4. Calibration curves for VCD intensity generated by placing a multiple-wave plate and a polarizer in the IR beam and connecting the crossing points with a curve representing unit VCD intensity for maximum VCD intensity at 1200 cm^{-1} .

5.2 Determination of the Noise Level at Each Point in the Spectrum

A critical factor in quantitative analysis using VCD is the degree of accuracy of the spectrum as given by the VCD noise level and baseline stability of the measurement. The noise level depends on a number of factors such as the D^* value of the detector, the amount of radiation passing through the sample from the source, and the amount of absorption of the sample. The noise level is obtained by dividing the VCD measurement into two halves. Addition of these halves gives the VCD spectrum, including noise, whereas subtraction eliminates the VCD features and leaves the equivalent noise spectrum. An example of a VCD noise spectrum is given in *Figure 3*, which shows, from bottom to top, the IR, VCD, and VCD noise spectra for a measurement of $(-)$ -*S*- α -pinene. The VCD noise level can be reduced by increasing the measurement time through co-addition of the spectra, as desired.

5.3 VCD Baseline Accuracy

A second critical factor in the measurement of a VCD spectrum is the characteristics of the

VCD baseline, namely its location, straightness, and stability. The VCD zero intensity line between positive and negative VCD intensities needs to lie as close as possible to the electronic zero of the measurement (zero of spectral display). Due to the sensitivity of the VCD intensity scale, some offset of the baseline from electronic zero almost always occurs, as discussed above in reference to the need for baseline correction of the VCD spectra of α -pinene in *Figure 2* and as carried out for *Figure 3*. Use of α -pinene as a validation standard is advantageous, because α -pinene has an unusually large intensity and thus, its spectrum is relatively easy to measure on a regular basis. α -Pinene can also be used as a measure of the baseline of a VCD measurement relative to the electronic zero of the measurement. This is illustrated in *Figure 5*, where the VCD spectra of (–)- α -pinene (*dash*) and (+)- α -pinene (*black*) are presented along with the VCD spectrum of a racemic mixture [equal quantities of (–)- α -pinene and (+)- α -pinene, hence cancelling the VCD intensity] of α -pinene (*gray*). The VCD spectrum of the racemic mixture of α -pinene is the VCD baseline for this measurement. A typical standard for baseline quality is deviations from electronic zero of <10% of the maximum separation of positive and negative VCD intensity of the neat α -pinene spectrum, or approximately 1×10^{-4} . The baseline illustrated in *Figure 5* satisfies this standard to within 5%. The baseline at 1350 cm^{-1} is slightly above electronic zero and has maximum excursions away from electronic zero of <0.00005 , or 5×10^{-5} at 1170 cm^{-1} , which can be compared to the maximum positive and negative intensity values of (–)- α -pinene of $+5 \times 10^{-4}$ at 1220 cm^{-1} and a negative peak value of -4×10^{-4} at 1130 cm^{-1} .

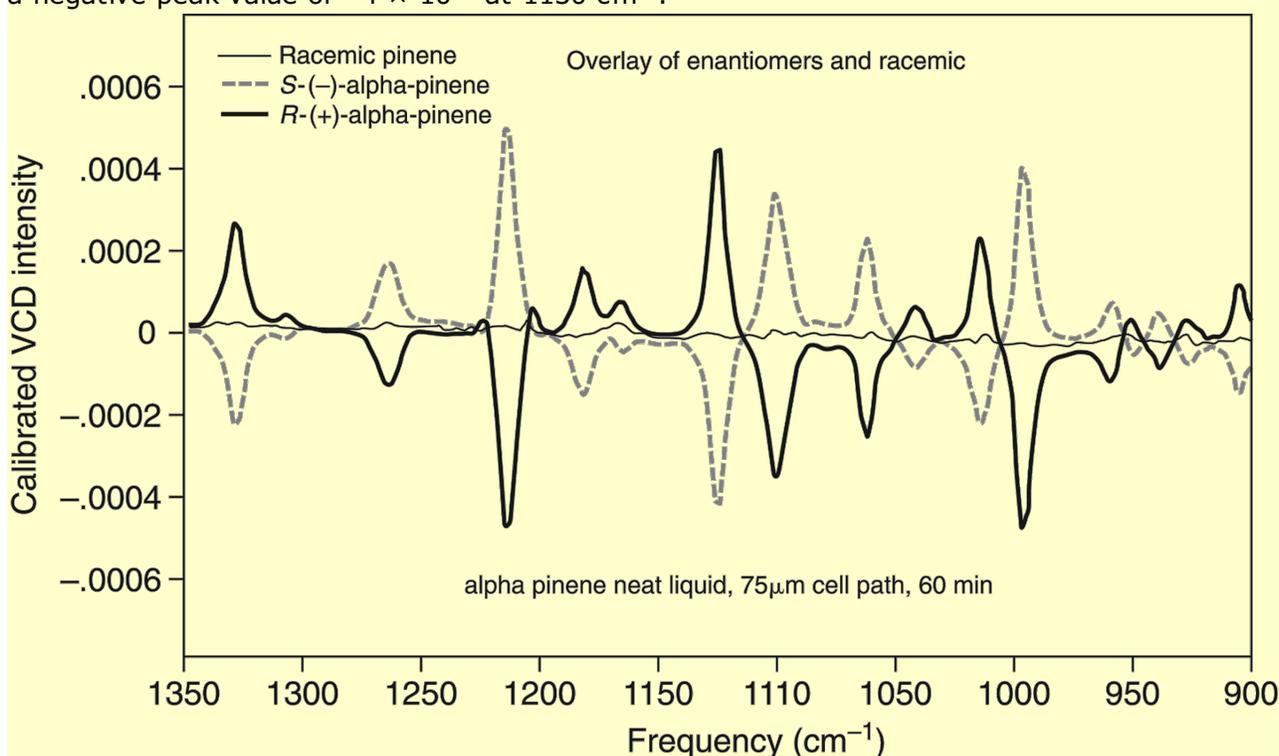

Figure 5. VCD spectrum of *R*-(+)- α -pinene (black), *S*-(-)- α -pinene (dash), and Racemic (gray) α -pinene as a neat liquid for a 60-min measurement in a 75- μm path-length barium fluoride cell.

5.4 VCD Baseline Absorption Artifacts and Single-Enantiomer Measurement Capability

For tests of baseline accuracy and stability, the sample camphor in carbon tetrachloride

solution is used as a qualification standard and provides a more stringent test than α -pinene, because the VCD spectrum of camphor is approximately one-fifth the magnitude, relative to the IR absorbance spectrum, of that of neat α -pinene. The VCD spectra of both enantiomers, as well as two measures of the VCD baseline, are provided in *Figure 6*. It is clear, as in *Figure 2* and *Figure 5*, that the VCD spectra of enantiomers, in this case (+)-camphor and (-)-camphor, are equal in intensity and opposite in sign relative to the VCD baseline to within the noise level of the measurement. The two VCD baselines provided are both zero VCD measurements. The VCD spectrum of racemic camphor [equal mixture of (+)-camphor and (-)-camphor] is the true VCD baseline for the individual (+)-camphor and (-)-camphor spectra, even if there are offsets (artifacts) due to absorption bands in the IR spectrum of camphor. The absence of such artifacts to within the noise level of the measurement is demonstrated by the congruence of the VCD spectrum of the racemic mixture and that of the solvent, carbon tetrachloride. Because carbon tetrachloride has no significant level of absorbance in the region of the spectrum displayed, the agreement of these two baselines within the noise level demonstrates the absence of baseline artifacts in the VCD spectrum of racemic camphor, and therefore, for the VCD measurement of either of the two enantiomers of camphor.

Achieving a VCD baseline that is free of absorption artifacts is usually done by optical alignment of the VCD instrument such that the baseline is as close as possible to the true electronic zero of the instrument of the measurement. In *Figure 6*, the VCD baseline can be seen to wander above and below zero across the spectrum, but in this case, the deviations from the electronic zero are small (approximately 2×10^{-5}) and $<20\%$ of the positive and negative maximum VCD intensities of the spectrum (approximately 1×10^{-4}). This value of deviation is consistent with the maximum baseline magnitudes discussed above for α -pinene and displayed in *Figure 5*, because α -pinene has a much larger (approximately $5\times$) VCD spectrum, relative to its IR spectrum, than camphor. The baselines for camphor in *Figure 6* are noisier than that of α -pinene in *Figure 5*, because the VCD spectrum scale is smaller and the measurement time is 20 min instead of 1 h. As in *Figure 3*, the VCD baseline can be corrected by subtraction of an appropriate baseline spectrum, racemic or solvent. In *Figure 7*, the baseline-corrected VCD spectra for both enantiomers and the racemic mixture have been obtained by subtraction of the VCD spectrum of the solvent carbon tetrachloride. As a result the VCD zero baseline and the instrument electronic zero are the same to within the noise level, and the mirror symmetric properties of these spectra are even more apparent. This VCD test verifies that by subtracting the VCD spectrum of the solvent, an accurate VCD spectrum of camphor can be obtained using only one enantiomer, either the (+)- or (-)-enantiomer, and hence, the instrument possesses a single-enantiomer VCD measurement capability.

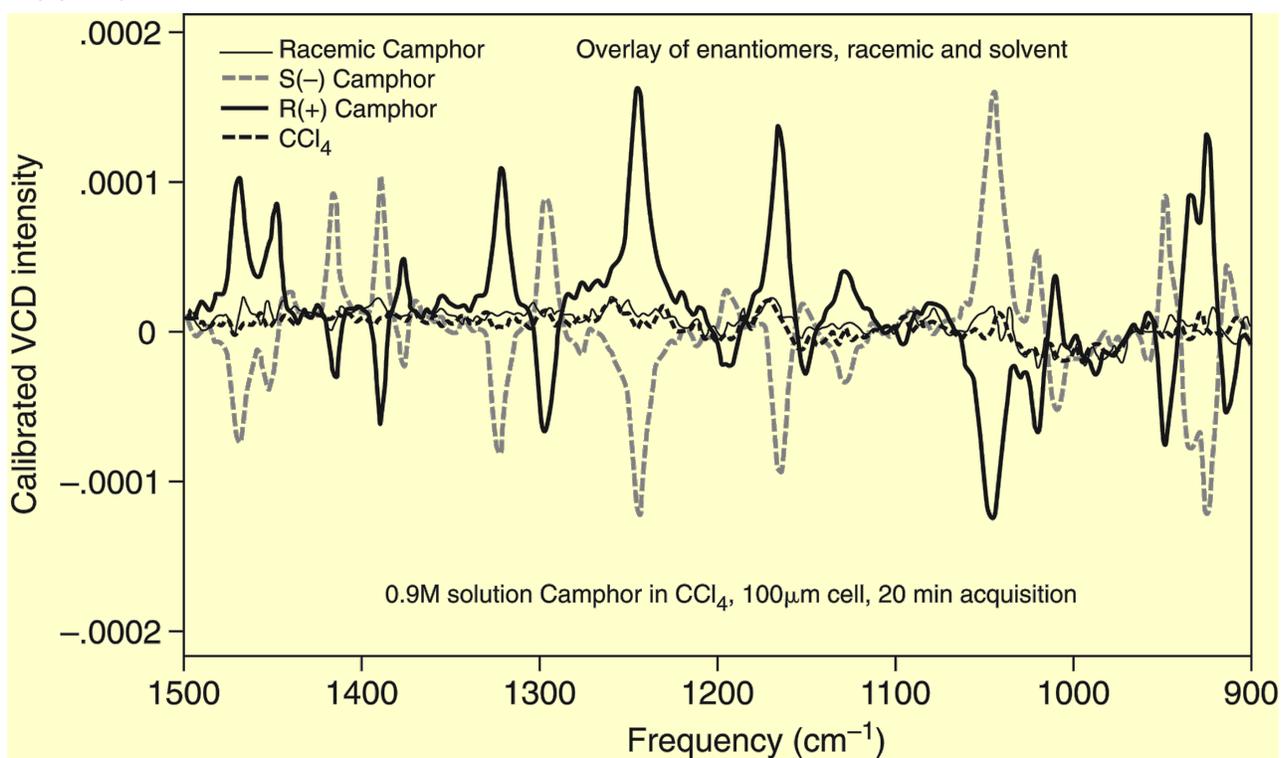

Figure 6. VCD spectrum of *R*(+)-Camphor (black), *S*(-)-Camphor (gray dash), and Racemic Camphor mixture (gray) as a 0.9 M solution in carbon tetrachloride. Also provided with the same cell and path length is the VCD spectrum of pure carbon tetrachloride (black dash). The sampling conditions were a spectral collection time of 20 min with a 100- μm path-length barium fluoride cell.

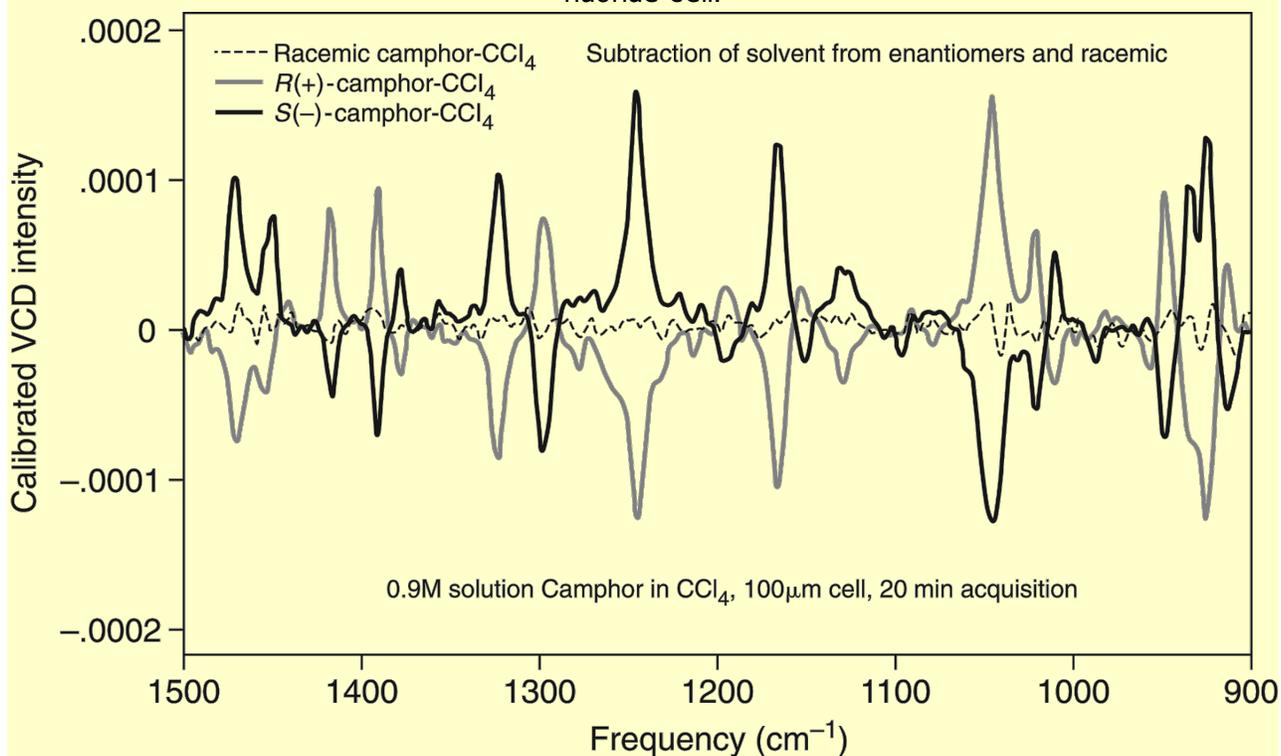

Figure 7. Solvent baseline-corrected VCD spectrum of *R*(+)-camphor- CCl_4 (gray), *S*(-)-camphor- CCl_4 (black), and Racemic camphor- CCl_4 mixture (dash) of the VCD spectra shown in Figure 6.

5.5 VCD Measurement Stability and Noise Level Reduction

Comparison of VCD measurements of camphor for 20 min to that measured over a period of 4 h in blocks of 20 min permits evaluation of instrument measurement stability as well as the reduction of noise level over time. In *Figure 8*, 12 such 20-min VCD spectra measured in 4 h are presented to show the stability of a VCD spectrum over time. It is clear that there are no deviations of VCD spectra outside the noise level of any one 20-min spectrum, and hence, there is no long-term drift in the VCD baseline over this time period.

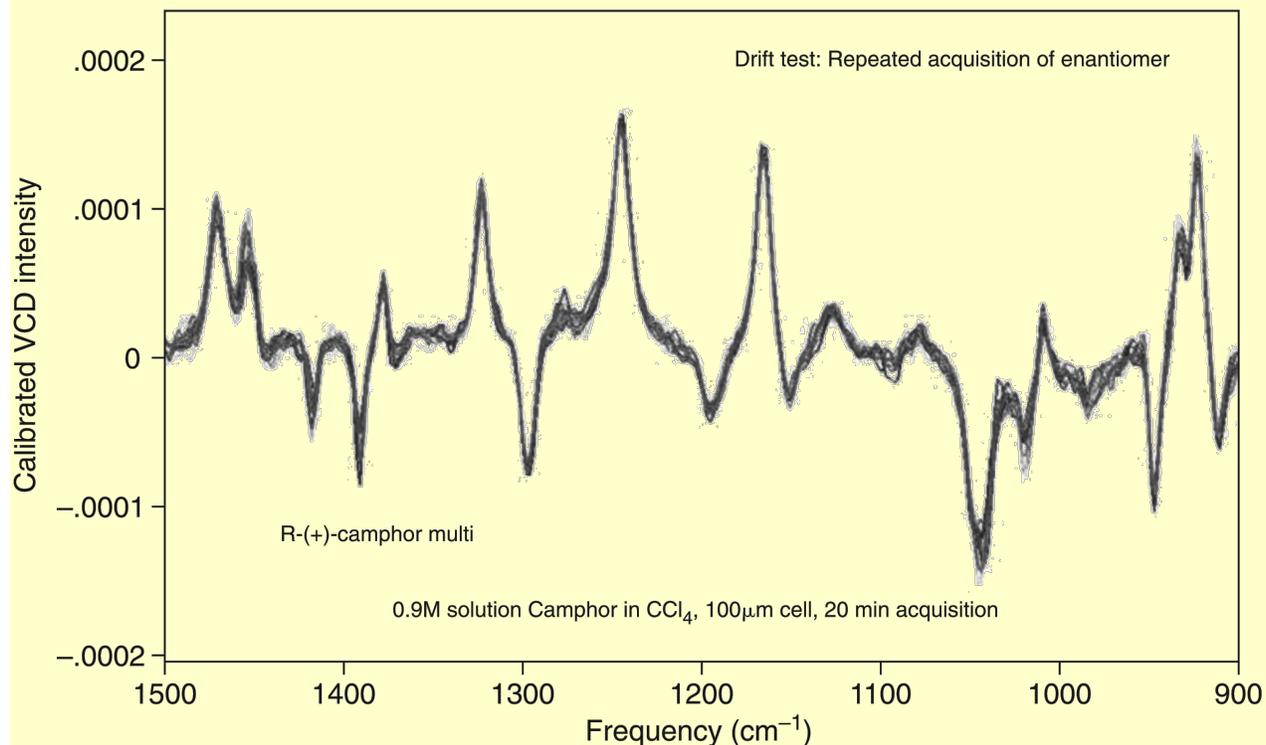

Figure 8. Superposition of twelve 20-min VCD spectra of *R*-(+)-camphor under the conditions of *Figure 6* and *Figure 7*.

If the twelve blocks of 20-min VCD spectra in *Figure 8* are averaged, the resulting 4-h VCD spectrum can be compared to a 20-min VCD spectrum of the same sample to demonstrate the noise reduction that is achieved upon signal averaging, provided there are no other systematic noise sources in the VCD spectrometer. In this case, the noise reduction should be a factor of the square root of 12, or approximately 3.5. Thus, the signal-to-noise ratio should improve by a factor of 3.5. Such a comparison is provided in *Figure 9*.

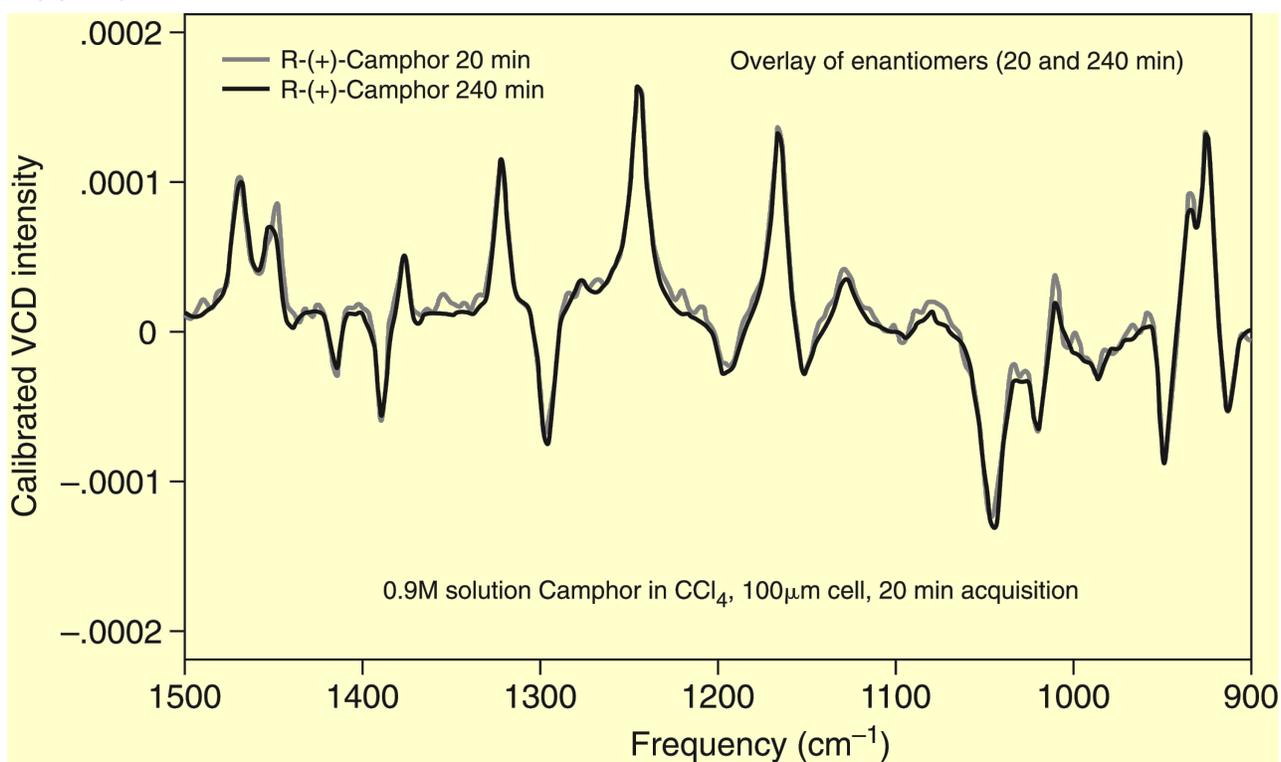

Figure 9. Comparison of the 4-h average of twelve 20-min VCD spectra [*R*-(+)-camphor 240 min; (gray)] to one 20-min measurement of camphor [*R*-(+)-camphor 20 min; black], under the conditions of *Figures 6, 7, and 8*, showing improvement in signal-to-noise ratio with increased collection time.

The noise level can be visualized directly on a 5× more sensitive scale to better evaluate the noise levels by comparing the noise spectrums, as illustrated and described for *Figure 3*, for the 4-h and 20-min VCD measurements. This is presented in *Figure 10*.

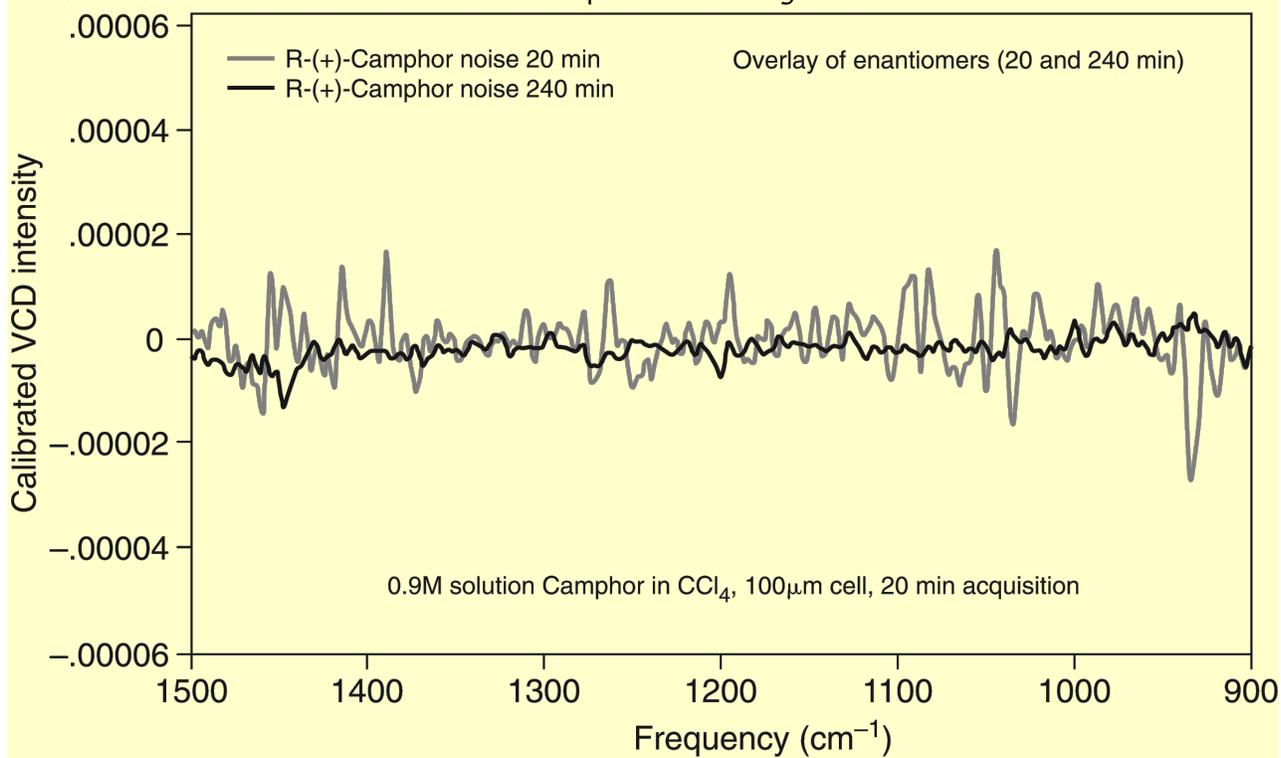

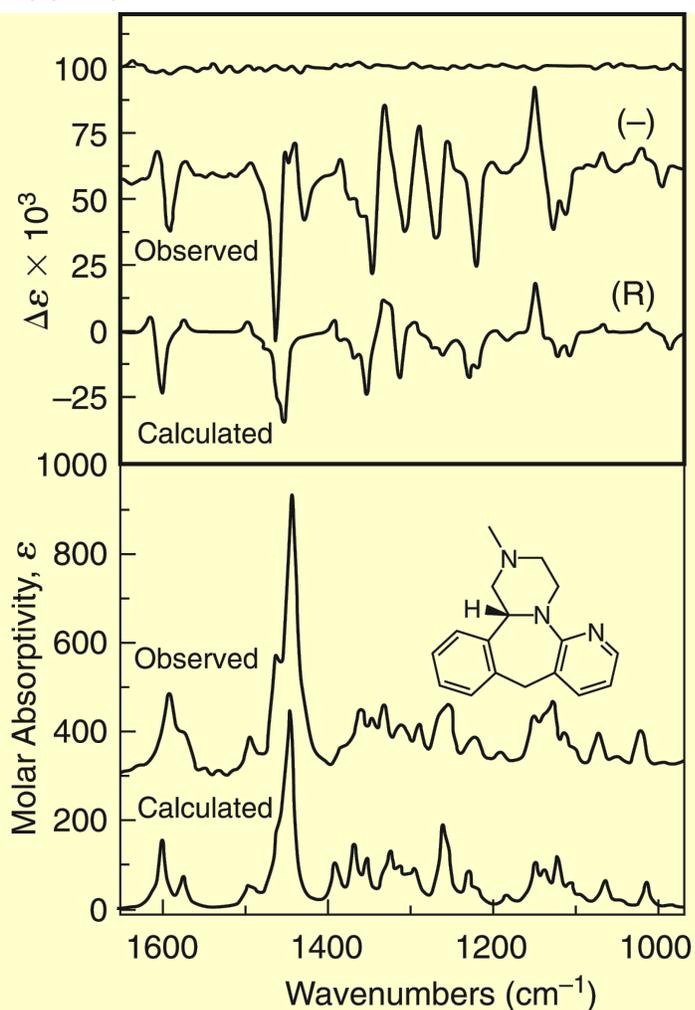

Figure 10. Comparison of the VCD noise spectra of *R*-(+)-camphor for one 20-min measurement [*R*-(+)-camphor noise; (gray)] versus a 4-h measurement [*R*-(+)-camphor noise; (black)] under the conditions of *Figure 5*, *Figure 6*, *Figure 7*, and *Figure 8*, where the intensity scale is approximately 5× more sensitive than those in *Figure 7* and *Figure 8*.

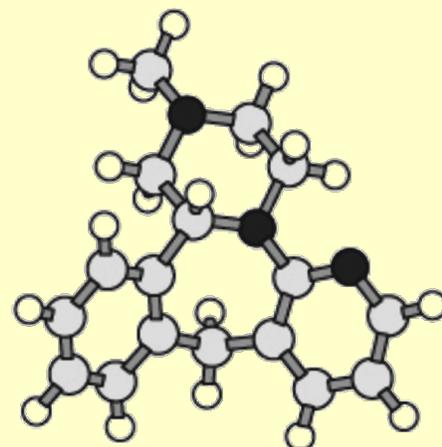

6. DETERMINATION OF ABSOLUTE CONFIGURATION

The IR and VCD spectra of a sample are measured in solution in a matter of min to h without the requirement of prior crystallization or high sample optical purity. The AC of an unknown sample is determined by comparison of its measured VCD spectrum to a VCD quantum chemistry calculation of the same molecule, where the AC used in the calculated VCD spectrum is chosen arbitrarily. If the signs of the bands in the measured VCD spectrum match those in the calculated VCD spectrum, the AC of the sample is identical to that used in the calculation. If the signs are opposite, then the sample has the opposite AC compared with that calculated. An example of the determination of the AC of a pharmaceutical molecule is shown in *Figure 11*. The AC of mirtazapine, which is sold in racemic form, is determined by comparison of the measured IR and VCD spectra of the (–)-enantiomer to the calculated IR and VCD spectra of the *R*-enantiomer. The close match in VCD signs—vibrational frequencies, intensities of the observed and calculated spectra, and IR frequencies and intensities—demonstrates clearly that the AC of mirtazapine is (–)-*R*. Also shown in *Figure 11* is the stereo-specific quantum chemistry calculated structure of *R*-mirtazapine.

Helv. Chim. Acta, 85, 1160 (2002)

Figure 11. Comparison of the measured (Observed) and calculated IR and VCD spectra of mirtazapine, allowing assignment of its AC to (-)-R. Reproduced in part with permission from John Wiley & Sons.

Vibrational circular dichroism (VCD) is used to identify **unambiguously** the absolute configuration of Mirtazapine as (-)-R and solution conformation as shown above

If the AC of a molecule has previously been established, for example, by X-ray crystallography, a VCD calculation of the molecule is not necessary (but could be performed as a check of the X-ray assignment), and the measured VCD spectrum of the molecule may be taken as a Reference Standard for the AC of the molecule, supported, for example, by USP. For a molecule with unknown structural chirality, the determination of its AC by VCD requires a comparison of the measured and calculated IR and VCD spectra, $\epsilon(\nu)$ and $\Delta\epsilon(\nu)$, as shown in *Figure 11*. The key point of the comparison is correlating the major VCD bands to determine whether they have the same or opposite signs. The IR spectrum is a guide in the process. Seeing a close correspondence between the calculated and measured IR spectra provides confidence that a good vibrational force field has been calculated and the most important vibrational bands are correlated. If a corresponding correlation of the signs of the major VCD bands can be made, as in *Figure 11*, then the AC has been determined.

When the measured and calculated VCD spectra are compared, the magnitudes of the corresponding intensities are not critical. What is important is the relative intensities of the bands in the two spectra, and in fact, the comparison of measured and calculated spectra can

be made using different sets of intensities for $\epsilon(\nu)$ and $\Delta\epsilon(\nu)$ for the calculated spectra and $A(\nu)$ and $\Delta A(\nu)$ for the measured spectra. In general, an exact match of the measured and calculated band frequencies is not expected because of several limitations of the calculations. Examples of these limitations include the assumption of the harmonic approximation when some anharmonicity is present in the measured spectra, the need to ignore the effects of solvent interactions with the chiral solute molecule, limitations in the size of the basis set used for the quantum calculation, and the choice of density functional required for the density functional theory (DFT) calculation.

7. CALCULATION OF VCD SPECTRA

To determine the AC of a molecule with unknown chirality using the VCD method as an alternative to, or supplement to, X-ray crystallography, analysts conduct a quantum chemistry calculation of the IR and VCD intensities of the molecule. Since the late 1990s, commercial DFT software has been available and can be used effectively by a trained user because it does not require special expertise or extensive experience in quantum chemistry calculations. For example, VCD calculations are now part of some undergraduate chemistry curricula. The following steps are required to perform a DFT calculation of IR and VCD:

1. The stereo-specific structure of the molecule is entered through a visual graphics interface
2. The quantum chemistry program then automatically performs the following steps:
 - a. The geometry is optimized to a minimum energy conformation.
 - b. A force field is calculated that determines the vibrational modes of the molecule, with $3N-6$ modes for a molecule with N atoms.
 - c. Atomic polar tensors that yield the IR spectrum are calculated.
 - d. Atomic axial tensors that yield the VCD spectrum are calculated.
3. The output of the calculation consists of a table where, for each mode i there is a frequency ν_i , IR intensity (dipole strength) D_i , and VCD intensity (rotational strength) R_i .
4. Commercially available programs calculate the IR and VCD spectra for the molecule using the following steps.
 - a. A lineshape $f(\nu)$ is applied to each dipole and rotational strength value, D_i and R_i , centered at each vibrational frequency ν_i .
 - b. Summation of these normal mode line-shaped intensities automatically produces the final calculated IR and VCD spectra $\epsilon(\nu)$ and $\Delta\epsilon(\nu)$ that can be compared directly to the corresponding measured IR and VCD spectra.

Another important factor that often is encountered in the assignment of the AC of pharmaceutical molecules and natural products (because of the structural complexity of these types of molecules) is the presence of more than one important conformer under the

measurement conditions. The fractional populations of different conformers can be predicted by using their relative calculated energies in the Boltzmann distribution. The lowest-energy conformer has the highest fractional population and so on, to increasingly less-populated conformers with higher relative energies. To calculate the VCD, one must calculate the IR and VCD of each important conformer and then add these spectra together, weighted by the fractional Boltzmann population. Usually, one can ignore the spectral contributions of conformers that account for less than a few percent of the total population.

Programs for calculating VCD and IR spectra to the level of accuracy sufficient for comparison to measured IR and VCD are available commercially from a variety of sources. First, one needs a program for evaluating and finding the geometry of all the lowest-energy conformations of a chiral molecule. A variety of programs using molecular mechanics are available for this purpose. Second, one needs a full quantum chemistry software program for calculating the ab initio force fields, vibrational frequencies, and VCD and IR intensities for each of the lowest-energy conformers. A common chemical model of sufficient accuracy for AC determination is DFT, using a basis set minimum of 6-31G(d), and a choice of hybrid functionals, such as B3LYP or B3PW91. Higher-level basis sets and alternative choices of hybrid functionals may be made. Finally, one needs a software method for comparing measured and calculated VCD and IR spectra to assess the degree of spectral agreement between the measured and calculated spectra, and hence the level of confidence that the correct assignment of AC has been predicted. Additional details are described below.

In *Figure 12*, the AC of the bioactive enantiomer of the analgesic (*S*)-(+)-ibuprofen is determined by comparing the measured and calculated IR and VCD spectra. The calculated IR and VCD are the sums of the IR and VCD conformer spectra, one for each conformer, weighted by the fractional populations 0.37, 0.36, 0.12, and 0.07, plus smaller contributions from another eight conformers that have a total contribution of 0.08. Clearly, there are two important conformers that are nearly equally populated, and the basic features of the final IR and VCD spectra are determined by these spectra. As a result of this analysis, not only has VCD been able to confirm the AC of (+)-ibuprofen as *S*, but two dominant solution-state conformers have been identified, along with two additional less-populated conformers.

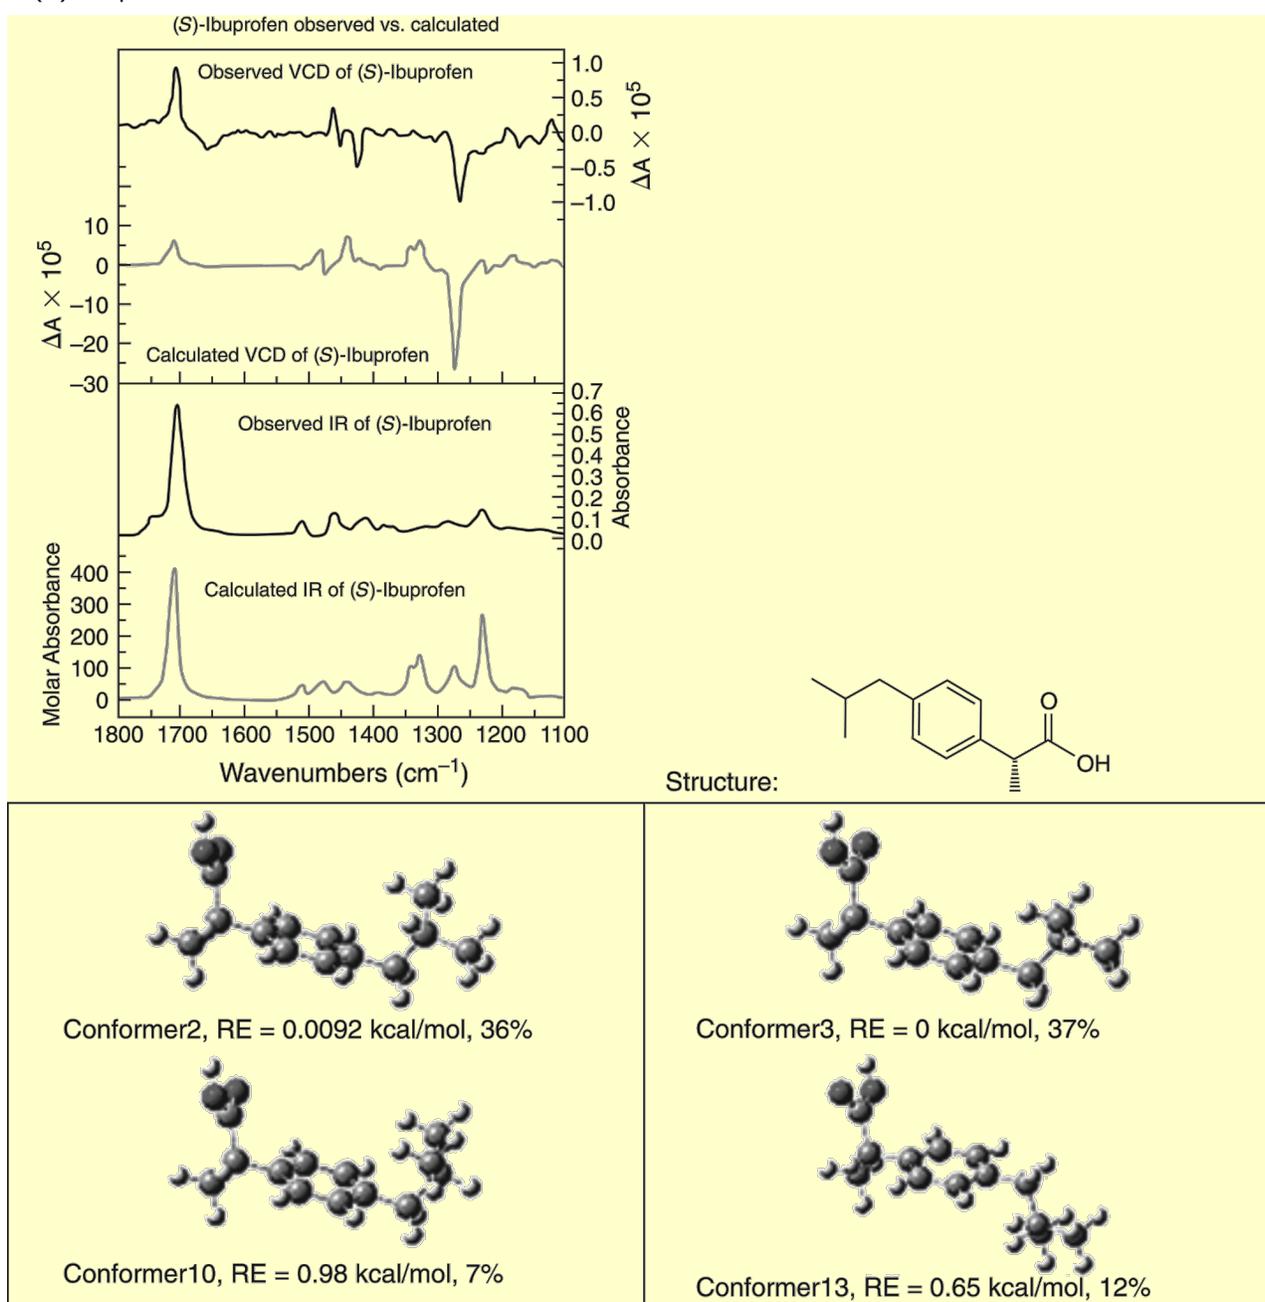

Figure 12. On the right are displayed the measured (Observed; +) and calculated (S) IR and VCD spectra of (+)-ibuprofen (above) and the stereostructure of (S)-ibuprofen (below). To the left are displayed the stereostructures, relative energy (RE), and percentage Boltzmann population (BP) for the four most important solution-state conformers.

8. COMPARISON OF MEASURED AND CALCULATED SPECTRA

To provide an unbiased statistical measure of the degree of similarity between measured and calculated IR and VCD spectra, an analytical method based on a convolution algorithm has been developed. The degree of similarity, or congruence, between a measured and a calculated spectrum can be calculated and used to determine a degree of confidence that the AC determined by visual inspection is correct.

8.1 Degree of Confidence of Correct Assignment

The results of the use of such statistical measures are shown in *Figure 13*. The degree of similarity (the total neighborhood similarity, TNS) of the measured and calculated IR is 92.5, where 100 is a perfect match. The same TNS measure for the VCD is 82.2. Because VCD bands can be either positive or negative, a more refined analysis is carried out for VCD, and only regions of sign agreement are compared for each enantiomer. In this case, the value of the signed neighborhood similarity (SNS) for the *S*-enantiomer is 92.8, and for the *R*-enantiomer it is only 12.1. Clearly, the analysis confirms the visual agreement of the measured VCD spectrum (*upper solid line*) and the calculated VCD spectra (*lower solid line*) for the *S*-enantiomer versus the *R*-enantiomer (*dashed line*). An additional numerical comparison is calculated as the enantiomeric similarity index (ESI), which equals $SNS(S) - SNS(R)$. The result (*black dot*) is then plotted against a database of 89 prior correct VCD assignments, where the axes are SNS (*vertical*) and ESI (*horizontal*). The closer a statistical point is to the *upper right-hand corner* of the plot, the higher the similarity of the comparison and the higher the degree of confidence. The upper right-hand corner of the plot is defined as 100% spectral similarity. The degree of confidence is a statistical measure that is set to be 100% confidence for points clustered in the *upper right-hand region* of the plot. Statistical measures such as these eliminate the reliance on only visual judgment for the comparison of measured and calculated VCD spectra and provide a statistical basis for assigning a degree of similarity between the measured and calculated spectra.

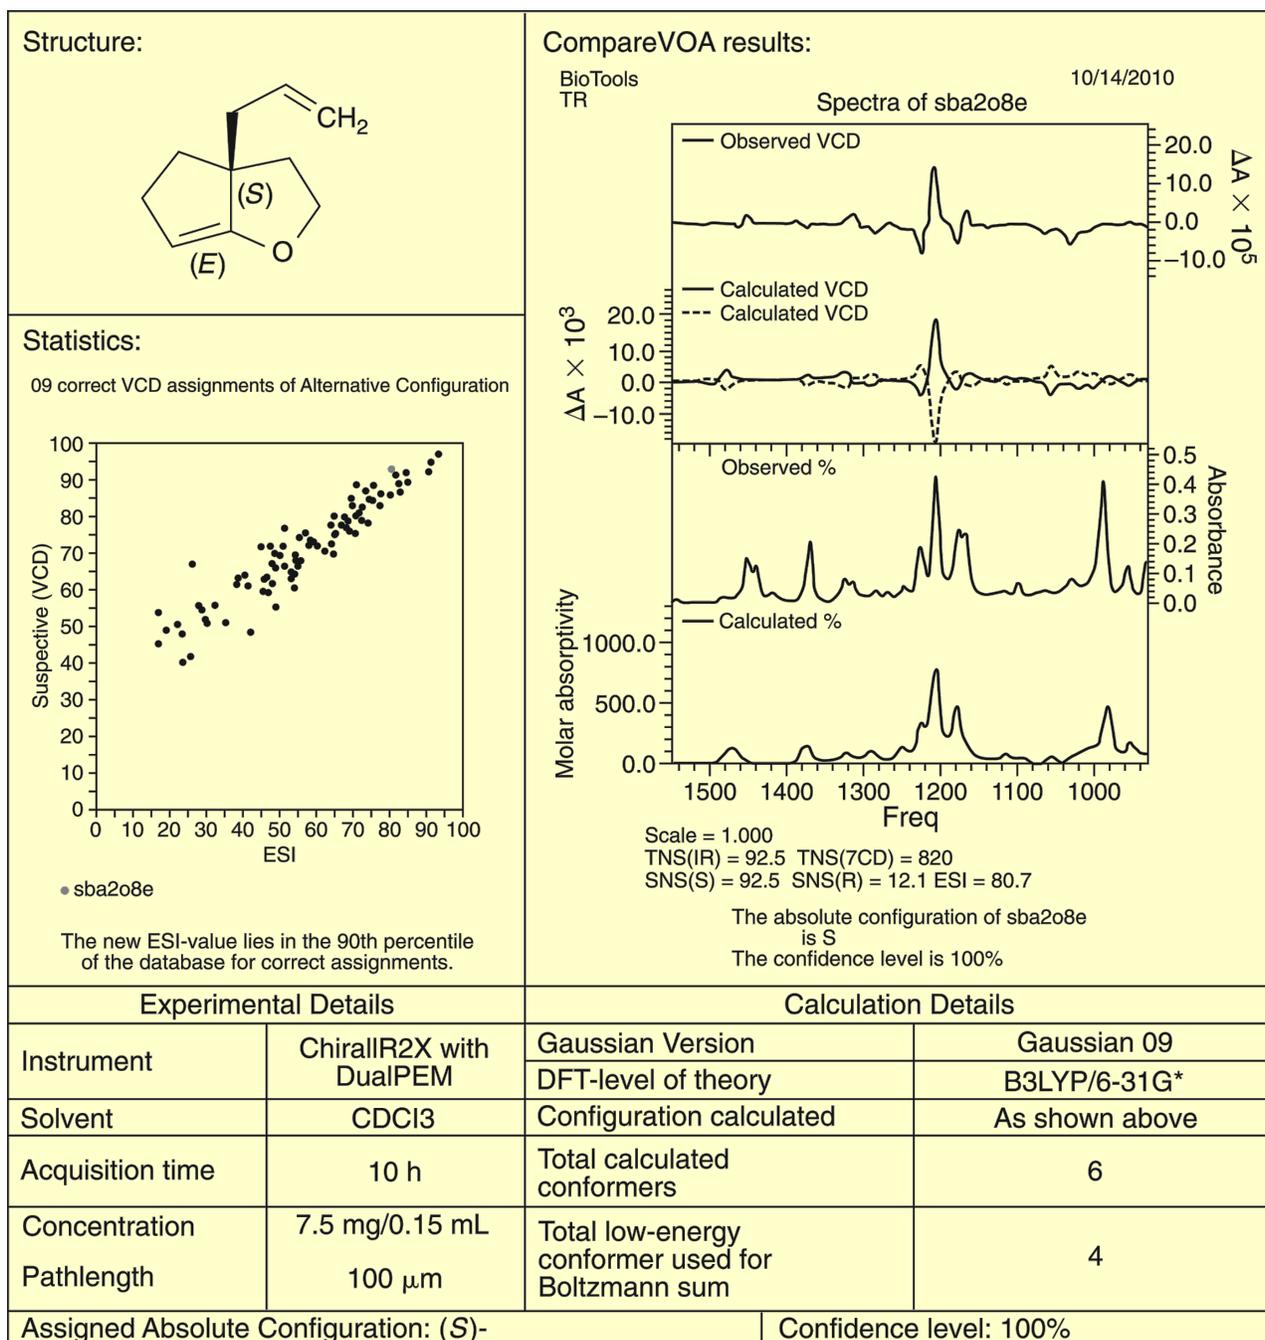

Figure 13. Output of a commercial program for comparison of measured (Observed) VCD and IR spectra with calculated VCD spectra of both enantiomers and the calculated IR spectrum. Statistical data are explained in the text.

9. DETERMINATION OF ENANTIOMERIC EXCESS

After AC, the next most important property of a chiral sample is the EE, as described in the *Introduction*. For enantiomers labeled *R* and *S*, the EE for the *R* enantiomer is defined as $EE = (N_R - N_S) / (N_R + N_S)$ and $\%EE = EE \times 100\%$. Here, N_R represents the number of moles of the *R* enantiomer present in the sample; or for a solution, N_R can represent the concentration of the *R* enantiomer. Thus, $\%EE$ for the *R* enantiomer can vary from +100% to -100%.

VCD spectra also can be used to determine the EE of a sample once the sample has been calibrated by a single IR and VCD measurement of a sample with a known EE. VCD scales linearly with EE with a maximum VCD intensity for a given IR intensity at 100% EE, one-half VCD intensity for the same IR intensity at 50% EE, and zero VCD for the racemic mixture of 0% EE. These points are illustrated in *Figure 14* for 11 measurements of *R*-(+)- α -pinene for which the %EE decreases from 100% to 6.7%. The IR spectra are identical, but the VCD spectra grow smaller linearly as EE is reduced by the addition of measured amounts of the opposite enantiomer to the sample cell. The degree of accuracy of this determination of %EE was slightly >1%, as indicated in the plot of actual prepared EE versus VCD predicted EE, using a partial least-squares chemometric analysis as presented in *Figure 15*.

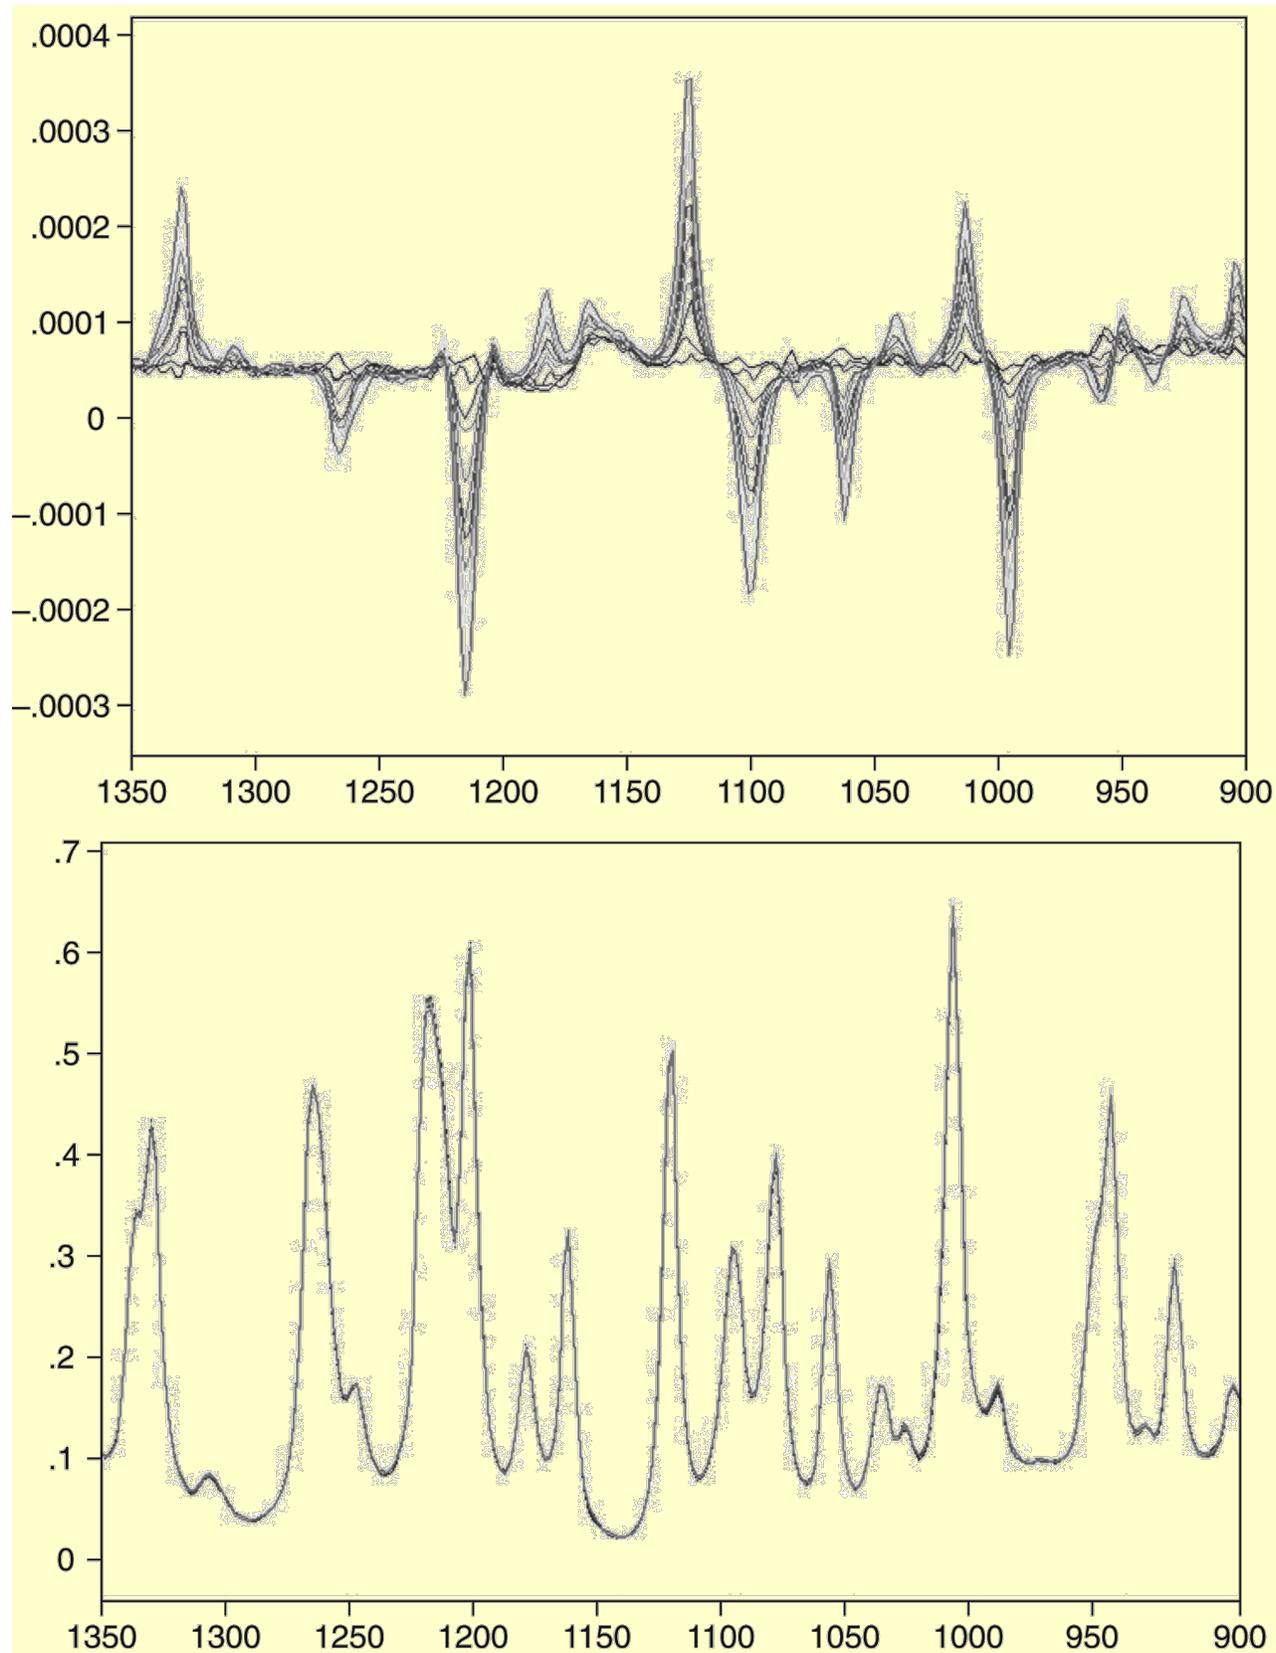

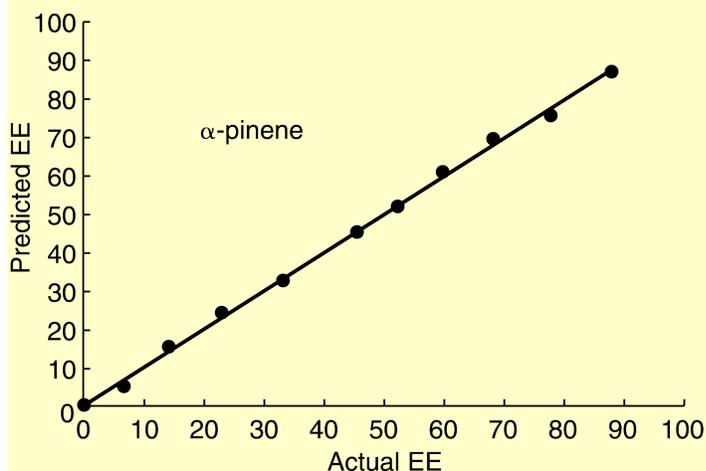

Figure 14. Superposition of 11 VCD (upper) and IR (lower) spectra of a 3.1 M solution of (+)-*(R)*- α -pinene in carbon tetrachloride for samples with %EE values of 100.0%, 88.2%, 77.8%, 68.4%, 60.2%, 52.4%, 45.5%, 33.3%, 23.1%, 14.3%, and 6.7%. Reproduced in part with

Actual EE%	Predicted EE%	Variance (EE%)
88.2	87.2	1.0
77.8	75.9	1.9
68.4	69.7	-1.3
60	61.3	-1.3
52.4	52.2	0.2
45.5	45.3	0.2
33.3	32.8	0.5
23.1	24.4	-1.3
14.3	15.4	-1.1
6.7	4.9	1.8
0	0.3	-0.3
RMSD	1.15	
STDEV	1.21	

Figure 15. Plot and corresponding table of actual versus VCD predicted values of %EE using partial least-squares (PLS) chemometric analysis that achieves a root-mean-square deviation (RMSD) of 1.15 and a standard deviation error of cross-validation (STDEV) of 1.21.

10. CONCURRENT USE OF VCD FOR ABSOLUTE CONFIGURATION AND ENANTIOMERIC EXCESS

10.1 Chiral Raw Material Identification

Currently, there is no routine, real-time chiral measurement for material identification (ID). Chiral drug substances must comply with the *USP* monograph tests that typically rely upon nonchiral test procedures such as mid-IR spectroscopy (*Mid-Infrared Spectroscopy* (854) and *Mid-Infrared Spectroscopy—Theory and Practice* (1854)). In practice, near-IR [see the proposals in *PF* 41(1) for *Near-Infrared Spectroscopy* (856) and *Near-Infrared Spectroscopy* (1119)] is used in many manufacturing facilities. For near-IR analysis of solids, analysts commonly use fiber-optic probes and then confirm the raw material by comparison of the measured spectrum against that of the *USP* Reference Standard. To determine the AC and EE of a chiral material, analysts must make a separate optical rotation measurement, which requires large amounts of sample in a 10-cm path-length cell, where uncertainty errors are possible for materials with small OR values.

A single measurement of the VCD spectrum and its associated IR spectrum in the mid-IR or near-IR region of a raw material, either as a crystalline solid or in solution, simultaneously contains information for the three critical measures: ID, AC, and EE. By comparison to a *USP* Reference Standard, the simultaneous measurement of IR and VCD spectra of a test material identifies the sample and the presence of impurities and separates impurities into achiral (IR only) or chiral (IR and VCD). The signs of the VCD identify the AC of the dominant enantiomer, and the ratio of the VCD to the IR gives the EE, as described above. Typical VCD accuracy for EE determinations is in the range of 0.1%–1%.

10.2 Chiral Quality Control

VCD can be used as a chiral measure for characterization of raw materials for process analytical technology (PAT) during development, synthesis, formulation, and final production of drug

substances and drug products. VCD also can be used to test the interaction between formulated chiral drug substances and excipients. Currently, there are no protocols for monitoring EE as a quality control measure in the pharmaceutical industry. Because of the importance of chirality as a critical measure of sample integrity, there is a need for the incorporation of a new technology, such as VCD, to ensure the desired level of chiral quality of pharmaceutical products from discovery through to final formulation.

1. INTRODUCTION

Radioactive drugs and devices require specialized techniques in their production, testing, handling, dispensing, and administration to ensure optimal effectiveness and maintain safety for workers, patients, and the public. All operations involving these articles should be carried out by or under the supervision of personnel who have been appropriately trained in the handling of radioactive materials.

The facilities for the production, storage, and use of radioactive drugs and devices are generally subject to licensing by the U.S. Nuclear Regulatory Commission, an appropriate State agency, or similar governmental agencies outside of the United States. Most radioactive drugs and devices, although not identified as hazardous drugs, are classified as hazardous materials and are therefore subject to other regulations relating to transportation, environmental release, and workplace safety.

The purpose of this chapter is to provide information regarding radioactivity—including definitions, types of decay, and general considerations relating to radioactive decay, counting, radionuclide production, purity, and labeling—as well as instrumentation for detection and measurement of radioactive emissions.

Specific information on standards for radionuclide identification and assay, including instrument qualification, performance checks, identification of radionuclides and radionuclidic impurities, and assay of radionuclides are provided in *Radioactivity* (821).

2. TYPES OF DECAY

Radioactive decay is the process by which an unstable nuclide transitions to a lower energy configuration. Depending on the particular starting radionuclide, the result of the transition may be either a stable nuclide or a different radionuclide. Typically, these transitions are accompanied by the emission of radiation from the nucleus, which is broadly classified as either particulate or nonparticulate. Some radionuclides emit multiple types of radiation in this process, whereas others emit only a single type. The main types of particulate radiation commonly seen in nuclear medicine are alpha, beta, and positron. Nonparticulate types of

radiation include gamma rays and X-rays. Strictly speaking, X-rays do not originate in the nucleus but rather in the electron orbitals; however, X-rays are the result of interactions between radiation from the nucleus and the orbital electrons. Nuclear medicine imaging is accomplished through detection and localization of nonparticulate radiation, whereas therapeutic effects arise from the energy deposited in the target organ by particulate radiation.

2.1 Alpha Decay

Alpha decay is radioactive decay with the emission of alpha particles, or helium nuclei, and is generally limited to elements with an atomic number >83 . In some cases, beta particles and gamma rays may also be emitted during alpha decay. An example of a radionuclide that decays by alpha decay is:

2.2 Beta Decay

Beta decay is radioactive decay with the emission of an electron. This type of decay typically occurs in neutron-excessive radionuclides wherein a neutron is transformed into a proton. In some cases, the emission of a positively charged electron, or positron, may occur. This type of decay typically occurs in neutron-deficient radionuclides with a lower atomic number wherein a proton is transformed into a neutron. In some cases, gamma rays may also be emitted during beta decay. An example of beta decay through emission of an electron is:

An example of beta decay through emission of a positron (β^+) is:

Because a positron is an anti-electron, when it interacts with an electron, the two particles annihilate, and their combined mass is transformed into energy in the form of two 511 kiloelectronvolt (keV) gamma rays. These gamma rays are produced simultaneously and travel away from the point of interaction in nearly opposite directions. These two characteristics form the basis for positron emission tomography (PET) imaging techniques.

2.3 Electron Capture Decay

Electron capture is radioactive decay that involves nuclear capture of an inner orbital electron, nuclear transformation of a proton into a neutron, and emission of one or more gamma rays. Electron capture generally occurs in higher atomic number radionuclides that are neutron deficient. An example of a radionuclide that decays by electron capture decay is:

2.4 Isomeric Transition

An isomeric transition is radioactive decay that involves a transition between nuclear isomers with the emission of one or more gamma rays. In contrast to other types of decay, the number of protons and neutrons remains the same in an isomeric transition. Isomeric transition generally occurs in radionuclides that are metastable. An example of a radionuclide that decays by isomeric transition is:

3. GENERAL CONSIDERATIONS

3.1 Radioactivity

Radioactive decay is a first-order process (i.e., a fraction of atoms decay per unit time). The rate of decay for each radionuclide is a unique and constant value, which gives rise to the term "decay constant".

Each radionuclide's rate of decay is a unique and constant value (its decay constant) and can be described by the following equation:

$$A = \lambda N$$

A = amount of radioactivity in a source at a given time

λ = rate of decay of the radionuclide

N = number of radioactive atoms

The traditional unit for radioactivity is the Curie (Ci), which is equal to 3.7×10^{10} atoms undergoing radioactive decay, or disintegrations per second (dps). Commonly used prefixes associated with the Ci include the millicurie (mCi) and the microcurie (μ Ci). The SI unit for radioactivity is the Becquerel (Bq), which is equal to 1 dps. Commonly, prefixes associated with the Bq include the megabecquerel (MBq) and the gigabecquerel (GBq). Hence, 1 Ci = 37 GBq.

3.2 Fundamental Decay Law

The decay of a radioactive source is described by the equation:

$$N_t = N_0 e^{-\lambda t}$$

N_t = number of radioactive atoms remaining at elapsed time t

t = time elapsed (time unit, such as s, min, or h)

N_0 = number of radioactive atoms when $t = 0$

λ = decay constant of the specific radionuclide

The above equation can be rewritten in terms of radioactivity:

$$A_t = A_0 e^{-\lambda t}$$

A_t = amount of radioactivity at elapsed time (t)

t = time elapsed (time unit, such as s, min, or h)

A_0 = amount of radioactivity when $t = 0$

λ = decay constant of the specific radionuclide

"Decay tables" that provide radionuclide-specific decay factors (i.e., fraction remaining) calculated from $A_0 e^{-\lambda t}$ at various elapsed times (t) are commonly available.

The half-life is defined as the time interval required for a quantity of radioactivity to decay to one-half of its initial value and is related to the decay constant λ by the equation:

$$T_{1/2} = 0.69315/\lambda$$

$T_{1/2}$ = half-life of the radionuclide

λ = decay constant of the specific radionuclide

The activity of a pure radioactive substance as a function of time can be obtained from the exponential equation, from decay tables, or by graphical means based on the half-life (*Figure 1*).

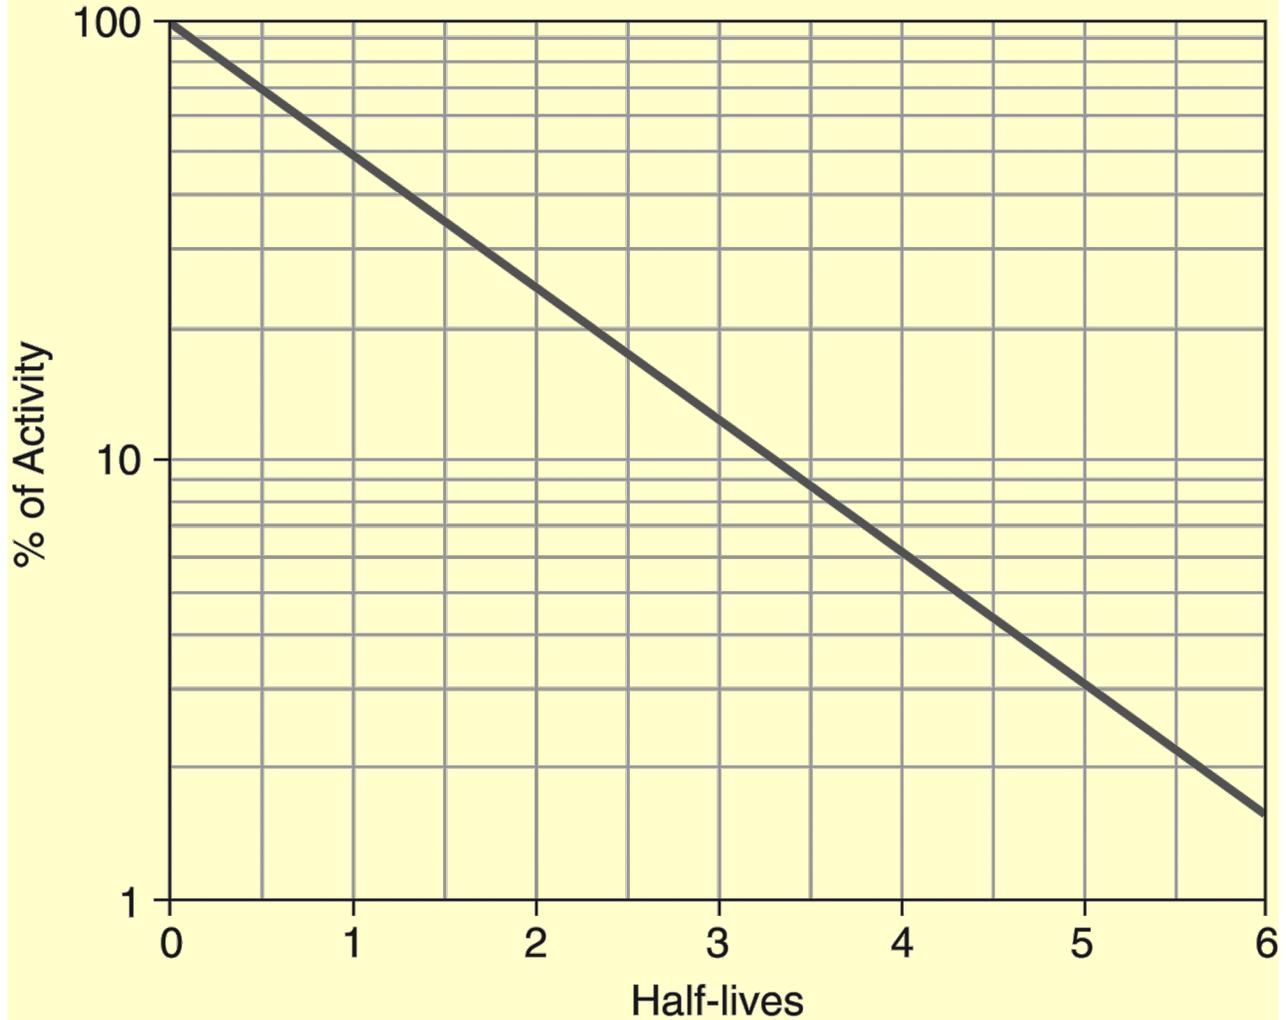

Figure 1. Normalized decay chart.

3.3 Counting Efficiency

The validity of any radionuclide measurement is dependent upon the reproducibility of the relationship between the source, the detector, and its surroundings. Appropriate allowances should be made for source configuration. Measurements of radioactivity require calculation of a calibration factor, or efficiency, and are dependent on the type of detector, the container in which the radioactivity is placed, and the source-detector geometry. The basic efficiency equation for detectors designed to count discrete decay events over a period of time is given as:

$$\text{disintegrations/s} = (\text{counts/s}) / \epsilon$$

ϵ = efficiency or calibration factor

Because 1 dps is defined as 1 Bq, the above equation gives radioactivity in units of Bq. Through the application of the appropriate unit conversion, Bq can be transformed into μCi or any other unit of radioactivity. Detectors should be calibrated with a source of known radioactivity and in a fixed geometry.

3.4 Background

Cosmic rays, radioactivity present in the detector or shielding materials, and radiation from improperly shielded sources contribute to the background radiation. All radioactivity measurements should be corrected by subtracting the background count rate from the gross count rate in the test sample.

3.5 Statistics of Counting

Modern radiation detection systems often incorporate statistical analysis into their software. The user should understand the use and limitations of these programs to ensure accurate results.

Because the process of radioactive decay is a random phenomenon, the events being counted form a random sequence in time. Therefore, counting for any finite time can yield only an estimate of the true counting rate. The precision of this estimate, being subject to statistical fluctuations, is dependent upon the number of counts accumulated in a given measurement and can be expressed as:

$$\Sigma = \sqrt{n}$$

Σ = standard deviation

n = number of counts accumulated in a given measurement

The probability of a single measurement falling within $\pm 100/\sqrt{n}\%$ of the mean of a great many measurements is 0.68, which means that if each count were to lie within $\pm 100/\sqrt{n}\%$ of the mean for approximately two-thirds of the observations, then approximately one-third of the observations would lie outside of this interval.

Because of the statistical nature of radioactive decay, repeated counting of an undisturbed source will yield count-rate values in accordance with the frequency of a normal distribution.

Any deviations in these values from the normal distribution conform to the chi-square (χ^2) statistical test. For this reason, the χ^2 test is frequently applied to determine the performance and correct operation of a counting assembly. The term "figure of merit" of a radioactive counting instrument is expressed as:

$$\text{Figure of merit} = \epsilon^2/B$$

ϵ = counter efficiency

B = background count rate (dps)

In the selection of instruments and conditions for assay of radioactive sources, the figure of merit should be maximized.

3.6 Minimum Detectable Activity

In situations where only very small quantities of radioactivity are to be measured, the lower limit of the ability of the instrument to detect that particular radionuclide should be known. The "minimum sensitivity", also referred to as "limit of detection", is defined as the net count rate above background that must be exceeded before a sample is deemed to contain detectable radioactivity with a specified level of confidence. The minimum sensitivity is generally considered to be 3 standard deviations above the mean background count rate and is calculated as:

$$\text{Minimum sensitivity} = (3 \times \sqrt{B})/t$$

B = background count rate (dps)

t = count time

The minimum detectable activity is defined as the smallest quantity of radioactivity that can be measured under the specific conditions of minimum sensitivity and counting efficiency of the instrument. It is calculated as:

$$\text{Minimum detectable activity} = (\text{Minimum sensitivity})/(\epsilon \times F)$$

ϵ = counting efficiency

F = unit conversion factor

For example, if minimum sensitivity is in units of dpm and minimum detectable activity is desired to be in units of Bq, then $F = 60 \text{ dpm/Bq}$. If minimum sensitivity is in units of cpm and minimum detectable activity is desired to be in units of μCi , then $F = 2.2 \times 10^6 \text{ dpm}/\mu\text{Ci}$.

3.7 Limit of Quantification

The limit of quantification is the smallest quantity of radioactivity that can be quantitatively determined with suitable precision and accuracy. The limit of quantification is used particularly for the determination of impurities and degradation products. In practical terms, the limit of quantification is usually considered to be 10 standard deviations above the mean background count rate.

3.8 Counting Losses

The minimum time interval that is required for the counter to resolve two consecutive signal pulses is known as the dead time. The dead time is typically on the order of microseconds for proportional and scintillation counters and to hundreds of microseconds for Geiger counters. Nuclear events occurring within the dead time of the counter will not be registered. The corrected count rate, R , can be calculated using the formula:

$$R = r/(1 - r \times \tau)$$

r = observed count rate

τ = dead time

The correction formula assumes a nonextendable dead time. The observed count rate, r , refers to the gross sample count rate and is not to be corrected for background before use in this

equation. For general validity, the value of $r \times T$ should not exceed 0.1.

3.9 Linearity and Range

When a radiation detection instrument is used in a quantitative measurement, the instrument should be suitable for the type(s) of radiation to be measured, and the instrument response should be linear over the range of measurements or a correction factor should be applied. Normally, a minimum of five different quantities of radioactivity are used to establish linearity. These quantities should bracket the range of radioactivity levels that are routinely measured in a particular application.

3.10 Calibration Standards

All radioactivity assays should be performed using measurement systems that have been calibrated with appropriately certified radioactivity standards. Such calibration standards may be purchased either directly from an appropriate National Metrology Institute (NMI) or from other sources that have established traceability to the NMI, through participation in a program of inter-comparative measurements. Where such calibration standards are unavailable, nuclear decay data required for calibration can be obtained from the Evaluated Nuclear Structure Data File maintained at the Brookhaven National Laboratory.¹

3.11 Production of Radionuclides

The various radionuclides found in nature generally have undesirable properties for nuclear medicine applications, including very long half-lives (e.g., thousands or millions of years), decay with emissions of alpha or beta particles, and low isotopic purity because of the presence of other isotopes of that element. Because of these properties, naturally occurring radionuclides are rarely used for radiopharmaceuticals, except for some alpha-emitting members of the actinide decay series, which are used for certain therapeutic radiopharmaceuticals, e.g., radium-223.

There are four common production routes for artificially produced radionuclides: fission, neutron activation, charged-particle-induced reactions (cyclotron), and radionuclide generators. Fission by-products refer to radionuclides that are obtained as by-products of the fission of uranium (uranium-235). These radionuclides, whether directly produced fission fragments or subsequent members in a decay chain originating from a fission fragment, can be chemically separated into individual forms from the mixture of fission products. Desirable properties of fission by-products include high isotopic purity and moderate cost. Undesirable properties may include beta-particle emissions, low specific activity of certain radionuclides, and the limited selection of radionuclides produced. Examples of fission by-products used in nuclear medicine applications include iodine-131 and xenon-133. Currently, the most widely used fission by-product is molybdenum-99, which is used in technetium-99m generators.

Neutron activation refers to the production of radionuclides in a nuclear reactor by bombarding target atoms with thermal neutrons. Nuclear transformations, induced by neutron capture, result in isotopes possessing one additional neutron, and thus an atomic mass increased by one. The excess energy of the newly formed isotope is emitted as a gamma ray. These reactions are often termed (n,γ) reactions. Desirable properties of neutron-activated

radionuclides include a wide variety of isotopes that can be produced and the moderate cost to produce them. Undesirable properties may include decay with beta-particle emissions and relatively low isotopic purity (i.e., unreacted stable target atoms are mixed with their radioisotope products). Because of their beta emissions, however, several of these radionuclides have been used in therapeutic radiopharmaceuticals. Examples of neutron-activated radionuclides used in therapeutic radiopharmaceuticals include strontium-89, yttrium-90, iodine-131, samarium-153, and lutetium-177.

Cyclotron production of radionuclides occurs by bombarding stable atoms with charged particles (e.g., protons or deuterons) that have been accelerated in the cyclotron's oscillating electromagnetic field. Nuclear transformations induced by particle capture usually result in a radioisotope of a different element with the emission of one or more neutrons or protons. For example, if a proton is captured and a neutron is emitted, the reaction is often termed a (p,n) reaction. Desirable properties of cyclotron-produced radionuclides include: the wide variety of isotopes that can be produced, the availability of alternate production schemes, radionuclide decay by electron capture or positron decay rather than by beta decay, and high isotopic purity. Undesirable properties may include: contaminating radioisotopes from side reactions and the relatively high cost of radionuclide product. Examples of cyclotron-produced radionuclides used in nuclear medicine applications include carbon-11, fluorine-18, gallium-67, indium-111, iodine-123, and thallium-201.

Generators refer to a special method of radionuclide production whereby a short-lived radionuclide results or is generated from the decay of a longer-lived radionuclide. The longer-lived parent radionuclide is generally bound to a column, and the short-lived radionuclide daughter product is then extracted (eluted) from the column. After elution, subsequent decay of the long-lived parent radionuclide generates more of the short-lived radionuclide daughter product, which can then be extracted. A generator provides a specific radionuclide in sequential elutions over a prolonged period of time. Desirable properties of generator-produced radionuclides include: ready availability, portability, low-to-moderate cost, variety of radionuclides and type of decay, and relatively high isotopic purity. Undesirable properties may include the limited number of parent-daughter pairs and the potential for generator breakthrough of the parent radionuclide in the eluate. Examples of generator-produced radionuclides used in nuclear medicine applications include technetium-99m (daughter of molybdenum-99), rubidium-82 (daughter of strontium-82), and gallium-68 (daughter of germanium-68). The characteristics of all four production methods are summarized in *Table 1*.

Table 1. Production Methods of Radionuclides

Production Method	Nuclear Reactor (fission by-product)	Nuclear Reactor (neutron activation)	Cyclotron	Radionuclide Generator
Bombarding particle	Neutron	Neutron	Proton, deuteron, triton, alpha	Production by decay of parent
Product	Neutron excess	Neutron excess	Neutron poor	Neutron poor or excess
Typical decay pathway	β^-	β^-	Positron emission, electron capture	Several modes
Typically carrier free	Yes	No	Yes	Yes
High specific activity	Yes	No	Yes	Yes
Relative cost	Moderate	Moderate	High	Low to moderate
Radionuclides for nuclear medicine applications	Molybdenum-99, iodine-131, xenon-133	Iodine-131, strontium-89, yttrium-90, samarium-153, lutetium-177	Thallium-201, iodine-123, gallium-67, indium-111, fluorine-18, carbon-11	Technetium-99m, krypton-81m, gallium-68, rubidium-82

Other methods of radionuclide production have been developed but currently are not used to produce radionuclides used in radiopharmaceuticals.

3.12 Carrier

The total mass of radioactive atoms or molecules in a radiopharmaceutical is directly proportional to the amount of radioactivity and is usually too small to be measured by ordinary chemical or physical methods. For example, 37 MBq (1 mCi) of iodine-131 has a mass of 8×10^{-9} g. Because such small quantities behave in an anomalous manner, such as nonspecific adsorption to container walls, a carrier may be added during processing to permit ready handling. Amounts of the carrier, however, should be sufficiently small so that undesirable physiological, pharmacological, or toxicological effects are not produced. Also, because the carrier is chemically identical to the radionuclide, the amount of carrier should be limited to avoid competitive interference with the desired chemical reactions and overall radiochemical yield.

The term "carrier free" refers only to radioactive preparations in which other isotopes of the radionuclide are absent (i.e., free from the presence of carrier). In practice, a true carrier-free state may be difficult or impossible to achieve because of the ubiquity of certain elements or molecules. Hence, the term "no carrier added" may more appropriately describe a preparation that may contain a trivial amount of carrier but for which additional carrier has not been purposefully added. Radionuclides produced by neutron activation reactions generally contain substantial amounts of nonradioactive isotope remaining from unreacted target material and thus cannot be considered carrier free. However, there are select cases in which this is not the case, such as (*n,p*) reactions.

The radioactivity per unit volume of a medium or vehicle containing a radionuclide is referred to as the "radioactivity concentration", "specific concentration" or "strength" and is expressed in units such as Bq/mL or Ci/mL. The radioactivity of a radionuclide per unit mass is referred to as "specific activity" and is expressed in units such as Bq/g, Ci/g, or Bq/mol. The maximum specific activity of a radioactive preparation exists when it is in a carrier-free state; the addition of a carrier results in lowered specific activity.

3.13 Radiochemical Purity

The radiochemical purity of a radiopharmaceutical preparation refers to the fraction of the stated radionuclide present in the stated chemical form. Radiochemical purity is important for radiopharmaceuticals because radiochemical impurities may affect the biodistribution and interfere with image interpretation (diagnostic accuracy). In addition, radiochemical impurities may alter radiation absorbed doses to various organs. When using therapeutic radiopharmaceuticals, radiochemical purity is very important because altered biodistribution associated with radiochemical impurities may result in insufficient irradiation of the target tissue (suboptimal treatment response) or excessive irradiation of other tissues (undesired radiation damage).

Radiochemical impurities in radiopharmaceuticals may result from by-products of the preparative method or from decomposition. Radiation causes decomposition of water, a main component of aqueous radiopharmaceutical preparations, leading to the production of reactive hydrogen atoms and hydroxyl radicals, hydrated electrons, hydrogen, hydrogen ions, and hydrogen peroxide. Hydrogen peroxide is formed in the presence of oxygen radicals, originating from the radiolytic decomposition of dissolved oxygen. Many radiopharmaceuticals show improved stability if oxygen is excluded or restricted. Radiation may also affect the radiopharmaceutical itself, giving rise to ions, radicals, and excited states. These species may combine with one another and/or with the active species formed from water. Radiation decomposition may be minimized by the use of chemical agents that act as electron or radical scavengers.

Radiochemical purity must meet compendial standards throughout the time of use until the stated expiration of the radiopharmaceutical.

Determination of radiochemical purity is typically a two-stage process: 1) the different chemical species are separated by paper, thin-layer, or column chromatography or other suitable analytical separation technique; and 2) the radioactivity content in each of the separated chemical species is measured with a suitable radiation detector and counting device. The ultimate confirmation of acceptable radiochemical purity of a radiopharmaceutical is its intended biodistribution after administration.

3.14 Radionuclidic Purity

The radionuclidic purity of a radiopharmaceutical preparation refers to the fraction of radioactivity attributable to the desired radionuclide in the total radioactivity measured. Hence, a radionuclidic impurity is the presence of an unwanted radionuclide. Radionuclidic purity is important for radiopharmaceuticals, because unwanted radionuclides may cause several undesired consequences.

- Radionuclidic impurities may cause the radioactive assay of the radiopharmaceutical to deviate from the prescribed amount.
- Radionuclidic impurities may deliver higher-than-desired, radiation-absorbed doses to various organs and tissues.

- In some situations, radionuclidic impurities may interfere with image interpretation (diagnostic accuracy). It should be remembered that radionuclidic purity will change with time and is generally specified as a percentage of the desired radionuclide's activity at the time of calibration or at the time of administration (e.g., molybdenum-99 in technetium-99m).

The radionuclidic purity must meet compendial standards throughout the useful life of the radiopharmaceutical. In addition, the impurity(ies) themselves will decay. Consideration must be given to the acceptable minimum and maximum allowable times between expiration of the product and analysis for impurities.

Radionuclidic impurities commonly arise during radionuclide production relating to impurities in target materials, differences in the values of various competing production cross-sections, and different excitation functions of competing reactions at the energy of the bombarding particles. In the case of generator-produced radionuclides, some generator breakthrough of parent radionuclide typically occurs and represents a radionuclide impurity in the eluate of the daughter radionuclide.

Determination of radionuclidic purity is typically based on evaluation of radioactive emissions, the principal analysis of the gamma spectrum obtained from a sample of the product. For short-lived isotopes, the half-life measurement could be an appropriate approach to assess radionuclidic purity. In cases involving radionuclidic impurities that have long half-lives relative to the desired radionuclide, measurement of the radionuclidic impurities can be performed after a sufficient time delay to allow the desired radionuclide to fully decay. In cases involving radionuclidic impurities that have substantially higher energy gamma emissions relative to the desired radionuclide, measurement of the radionuclidic impurities can be performed after placing the product inside a properly calibrated radiation shield that affords differential attenuation of the gamma rays emitted from the desired radionuclide versus those emitted from the radionuclidic impurities. Positron-emitting radionuclidic impurities typically cannot be differentiated, because their emitted energy (511 keV) is the same for each radionuclide. In any case, the appropriate instrument should be chosen to detect potential impurities and should be properly calibrated to accurately quantify any identified impurities.

3.15 Chemical Purity

The chemical purity refers to the fraction of the total chemical species present in the product as the specified chemical component(s). Hence, a chemical impurity is the presence of an unwanted nonradioactive chemical. Chemical purity is important for radiopharmaceuticals, because chemical impurities may cause undesirable consequences such as chemical interactions (e.g., precipitation) and toxic biologic effects.

Chemical impurities are typically associated with production procedures and may include contaminants from raw materials, synthetic by-products, solvents, excipients, equipment, preparative or purification columns, and containers. For certain radiopharmaceuticals, chemical impurities may also be associated with generator breakthrough of resin material from the generator column (for example, alumina) in the eluate solution.

Determination of chemical purity is generally not performed and reported as a single attribute. Rather, determinations of individual chemical impurities are performed and compared to specifications (limits) for the respective individual chemical impurities. Such determinations of chemical impurities use analytical techniques as appropriate and described in the individual radiopharmaceutical monograph.

3.16 Labeling

Individual radiopharmaceutical monographs indicate that the labeling is to include the date and time of calibration, the amount of radioactivity associated with the radiopharmaceutical expressed as total MBq (μCi or mCi) and concentration as MBq (μCi or mCi)/mL at the time of calibration, the expiration date (and time, if appropriate), and the statement, "Caution—Radioactive Material". The labeling indicates that in making dosage calculations, a correction is to be made for radioactive decay and also indicates the radioactive half-life of the radionuclide. Other labeling requirements may apply to biologics or articles intended for injection. Beyond-use dates of compounded preparations should be included as appropriate.

3.17 Naming Conventions for Isotopes

Various naming conventions exist for isotopes that are associated with radiopharmaceuticals and radioactive devices. For example, the name of an isotope may or may not use a superscripted value for the mass number. Superscripted values should precede the elemental symbol for the isotope, and non-superscripted values should follow the elemental symbol, preferably with a hyphen between the symbol and the mass number. Examples include ^{68}Ga and O-18, respectively. Square brackets should be used to denote a specific isotope when necessary within a chemical name, for example, 2- ^{18}F fluoro-2-deoxyglucose. Individual radiopharmaceutical monographs use non-proprietary names assigned by the USAN Council, which use the elemental symbol followed by the mass number separated by a space, for example, Thallous Chloride Tl 201 Injection. Although exceptions to these conventions undoubtedly exist, efforts should be made to adopt standardized conventions for radiopharmaceuticals and radioactive devices that fall within the scope of this general chapter.

4. INSTRUMENTATION FOR DETECTION AND MEASUREMENT OF RADIOACTIVE EMISSIONS AND APPLICATIONS

4.1 Ionization Chambers

Radioactive materials are not readily detected by ordinary chemical or physical methods. Instead, detection methods for radioactive materials rely on the ionization of matter that results from the emitted radiation. The charge separation created during this process forms the basis of radiation detection systems, which may be based on the ionization properties of gaseous, liquid, and solid materials.

An ionization chamber is an instrument that directly measures ions produced in a gas as the result of the interaction of radiation with the gas. The most common usage in nuclear medicine applications is as the detector used in a dose calibrator. The dose calibrator is an instrument used to measure the quantity of radioactivity in a radiopharmaceutical. The key component of a dose calibrator is an argon-filled chamber with an applied electrical potential that allows the detection of ions produced by the passage of gamma rays through the chamber. Calibration of the system may involve one or more radionuclides with gamma energies and quantities that span the range of typical analyses. The calibration of the ionization chamber should be performed, when possible, with suitable NMI-traceable radionuclide standards. Routine system suitability testing should include checks for these parameters. Frequency of testing should

occur as appropriate. Please refer to (821) for additional details on typical instrument requirements.

The position of the radioactive sample in the dose calibrator is ideal when it simulates 4 π geometry. The geometric goal is placement of the sample at a point in the center of the cylindrical detector. Reproducibility of placement within the chamber is critical, because the response typically drops off at the top and bottom of the cylinder because of a combination of geometry and electronic effects. The value of the ionization current per unit of radioactivity, known as the "calibration factor", is characteristic of each gamma-ray-emitting radionuclide. The current produced in a dose calibrator is related to the mean energy of the emitted radiation and is proportional to the intensity of the radiation. The calibration of the dose calibrator for a specific radionuclide is ideally performed with a radioactive calibration source of the same radionuclide. Alternatively, it may be performed by measuring radioactive calibration sources with gamma energies above and below the gamma energy for the radionuclide to be measured and interpolating these values, also correcting for differences in gamma abundance, to establish the calibration factor for that radionuclide.

The upper limit of the dose calibrator is normally specified by the manufacturer. If not, testing is required to ascertain this upper limit. With a deep re-entrant well-type chamber, reproducibility within approximately 5% or less can be readily obtained in a few seconds for quantities of radioactivity in the MBq (mCi) range and within about 30 s for quantities in the kBq (μ Ci) range.

The calibration of a dose calibrator should be maintained by relating the measured response of a standard to that of a long-lived reference standard, such as radium-226 in equilibrium with its daughters, cesium-137 in equilibrium with its daughters, barium-133, cobalt-60, or cobalt-57. The instrument should be checked on each day of use with the reference standard source to ascertain the stability over a long period of time. This check should include reference standard readings at all radionuclide settings used. Any necessary corrections for radioactive decay of the reference standard source should first be applied. It is also recommended that the reproducibility and/or stability of multi-range instruments be checked with the use of standards with appropriate activities for all ranges.

The size, shape, and location of a radioactive sample within the well will affect the response of a dose calibrator. This is usually referred to as "geometry". The shape, composition, and dimensions of the container holding the radioactive material can affect the result. Effects relating to container properties are generally more pronounced with radionuclides that emit beta particles (because of differences in Bremsstrahlung production) or emit low energy gamma or X-rays (because of differences in photon attenuation). It is important that geometric correction factors, if needed, be determined for each combination of radionuclide and configuration (i.e., size, shape, location with the well chamber, volume within the container, and container properties). The manufacturer's calibration factor for each radionuclide is determined using a specific geometry and container, which may not match the geometry or container used operationally.

4.2 Liquid Scintillation Counters

The liquid scintillation counter (LSC) detection method uses liquid scintillation cocktails to transform emitted radiation into detectable light photons. Alpha- and beta-emitting radionuclides may be assayed with the use of a liquid-scintillation detector system. In the liquid

scintillator, the emitted radiation is converted into light quanta that are usually detected by two multiplier phototubes arranged to detect only coincidence radiation. The liquid scintillator is a solution consisting of a solvent, primary and secondary solutes, and additives. As the emitted particle dissipates energy in the solvent, a fraction of this energy is converted into fluorescent light by the primary solute. The function of the secondary solute is to absorb the primary fluorescence and re-emit the light at a longer wavelength that is more efficiently detected by the multiplier phototubes. Traditionally used solvents (cocktails) are toluene and *p*-xylene; primary solutes are 2,5-diphenyloxazole (PPO) and 2-(4'-*tert*-butylphenyl)-5-(4-biphenyl)-1,3,4-oxadiazole (butyl-PBD); and secondary solutes are 2,2'-*p*-phenylenebis[4-methyl-5-phenyloxazole] (dimethyl-POPOP) and *p*-bis(*o*-methylstyryl)benzene (bis-MSB). Many aqueous scintillating solution cocktails that are less hazardous are available. Aqueous solutions tend to have a shorter shelf-life; therefore, it is important to ensure that they have not expired before use. As a means of attaining compatibility and miscibility with aqueous samples to be assayed, additives, such as surfactants and solubilizing agents, are also incorporated into the scintillator. For an accurate determination of radioactivity of the sample, care should be exercised to prepare a sample that is truly homogeneous. Quenching is a major concern for liquid scintillation and refers to any mechanism that causes a reduction of emitted light by the source. Quenching can result from multiple factors, including oxygen and dilution effects; therefore, it is critical to perform quenching corrections by counting comparative measurements of standard samples using the same conditions of volume, additives, and solvent to accurately account for these effects.

Alternatively, an external source, typically barium-133 or europium-152, is placed in close proximity to the sample vial to release Compton electrons. The shape of the resulting spectrum is analyzed to compute a quench-indication parameter. This parameter can then be related to the counting efficiency by measuring sources of known radioactivity at a determined level of quenching agent. The resulting quench curve allows the determination of the radioactivity of an unknown sample knowing the count rate and value of the quenching parameter. The scintillation fluid may require special handling for disposal, in addition to any residual radioactivity. Static electricity on the vials may also cause spurious counts in the system, especially in the case where low-energy beta emitters are being assayed. This problem is often greater in a low-humidity environment.

The disintegration rate of a beta-emitting source may be determined by a procedure in which the integral count rate of the sample is measured as a function of the pulse-height discriminator bias, and the emission rate is then obtained by extrapolation to zero bias. Energetic alpha-emitters may be similarly measured by this method.

4.3 Nuclear Spectroscopy Systems

GAMMA RAY SPECTROMETRY

Each gamma-emitting radionuclide has a unique spectrum of mono-energetic photons emitted that allows the identification and quantification of radioactive materials in a sample by comparing the energy(ies) of the photon(s) detected and the intensity at each energy. This gamma spectrum allows for both the quantitative determination of purity as well as identity of the radionuclide. Gamma-spectrum analysis can be performed by using either a scintillation crystal, typically sodium iodide activated with thallium [NaI(Tl)], or by using a semiconductor detector consisting of a germanium-lithium crystal, often referred to as a high-purity germanium detector (HPGe). Semiconductor detectors have a much higher energy resolution than NaI(Tl) detectors, with the ability to resolve gamma rays differing in energy by only a few

keV, as opposed to the 20–80 keV required for a NaI(Tl) detector. Because of their increased resolution, semiconductor detectors are the preferred analytical method for gamma spectral analysis. A lanthanum–bromide detector is also available that has a significantly better resolution (10–12 keV) than the NaI(Tl) detector, without the necessary requirement of liquid nitrogen cooling for a HPGe detector. The use of spectroscopy software to automate the analysis is acceptable; however, the operator should have an understanding of the parameters chosen to ensure that the performance of the system is adequate to meet test requirements. When all or part of the energy of beta or gamma radiation is dissipated within scintillators, photons of an intensity proportional to the amount of dissipated energy are produced. These pulses are detected by an electron multiplier phototube and converted to electrical pulses, which are subsequently analyzed with a pulse-height analyzer to yield a pulse-height spectrum related to the energy spectrum of the incident radiation. In general, a beta-particle, scintillation pulse-height spectrum approximates the true beta-energy spectrum, provided that the beta-particle source is prepared in such a manner that self-absorption is minimized. Beta-particle energy spectra may be obtained by using calcium fluoride or anthracene as the scintillator, whereas gamma-ray spectra are usually obtained with NaI(Tl) crystals, a HPGe semiconductor detector, or a lanthanum–bromide detector. The spectra of charged particles may also be obtained using silicon semiconductor detectors and/or gas proportional counters. Semiconductor detectors are, in essence, solid-state ionization chambers, but the energy required to create an electron-hole pair or to promote an electron from the valence band to the conduction band in the semiconductor is about one-tenth the energy required for creation of an ion-pair in a gas-filled ionization chamber or proportional counter. This energy threshold is also far less than the energy needed to produce a photon in a NaI(Tl) scintillation crystal. The energy resolution is a measure of the ability to distinguish the presence of two gamma rays closely spaced in energy and is defined by convention as the full width of the photopeak at its half maximum (FWHM), expressed as a percentage of the photopeak energy. For example, with 1.33 MeV gamma rays from cobalt-60, a HPGe detector has an energy resolution of about 0.3% FWHM, whereas a 3- × 3-in NaI(Tl) crystal has a value of about 6% .

Gamma-ray spectra exhibit one or more sharp, characteristic photopeaks, or full-energy peaks, as a result of total absorption in the detector of the full energy of incident gamma radiations. These photopeaks are useful for identification purposes. Other secondary peaks are observed as a consequence of backscatter, annihilation radiation, coincidence summing, fluorescent X-rays, and other factors, accompanied by a broad band known as the Compton continuum, which arises from the scattering of photons in the detector and surrounding materials. Because the photopeak response varies with gamma-ray energy, calibration of the gamma-ray spectrometer should be achieved with radionuclide standards having well-known gamma-ray energies and emission rates from an NMI. The shape of the gamma-ray spectrum is dependent upon the shape and size of the detector, the types of shielding materials used, and the electronic processing characteristics of the instrument.

One of the most useful applications of gamma-ray spectrometry is the identification of radionuclides and the determination of radionuclidic impurities. When confirming the identity of a radionuclide by gamma-ray spectrometry and/or quantifying the radioactivity, it is necessary to ensure that the detector has been accurately calibrated using a known source, as described above, and in the same geometry as the unknown sample. Where the radionuclides emit coincident gamma or X-radiations, the character of the pulse-height distribution often changes quite dramatically because of the summing effect of these coincident radiations in the detector as the efficiency of detection is increased, e.g., by bringing the source closer to the detector; this is referred to as "cascade summing". Such an effect is particularly evident in the case of

iodine-125. Most commercially available software packages include an ability to correct this source of error.

When identification of a radionuclide by means of a calibrated spectrometry system is not possible, the identity of the radionuclide may instead be established by measuring two or more of the following nuclear decay scheme parameters: 1) half-life; 2) energy of each gamma- or X-ray emitted; 3) the abundance of each emission; and (4) E_{max} , the maximum energy of emitted beta particles, for those radionuclides that decay with beta-particle emissions. Such measurements should be performed as directed in (821). Agreement of two or more of the measured parameters within 10% of the corresponding published nuclear decay scheme data confirms the identity of the radionuclide.

As with other types of detectors, the background should be determined and subtracted from the measurement. In addition, the background should be stable, especially in situations where long counting times are required. This can be achieved by running a background spectrum before analysis and comparing it to a previously obtained background spectrum. Generation of a background spectrum will also allow the calculation of a minimum detectable activity for each possible impurity.

BETA PARTICLE COUNTING SYSTEMS

Beta (β) particles are emitted with a distribution of energies ranging from zero to a definite maximum value. The maximum energy of the electrons is characteristic of a particular radionuclide and is normally the E_{max} shown in nuclear data tables. The determination of the maximum beta energy may aid in the identification of the beta-emitting radioisotope, and careful measurements can routinely quantify activities. Emitted beta particles rarely possess the maximum energy. On average, emitted beta particles possess one-third of the maximum energy. Beta particles can be difficult to detect because they only penetrate small thicknesses of solid materials. [Note—Radioisotopes that emit gamma radiation in addition to beta radiation are more easily quantified and identified by using gamma ray spectroscopy. In some cases, gamma ray detection is the preferred method for measuring these radioisotopes and is usually the best means of identification of a beta/gamma-emitting radionuclide.]

Several detectors can be used for the detection and measurement of beta particles. These can be ionization chambers, proportional counters, and scintillation counters with their associated electronics. Self-absorption and back scattering can be an issue in beta-particle analysis and can result in a lower or higher number. Ionization chambers and proportional counters can be used for the quantitation of beta particles but are less suited for identification, because they cannot measure the maximum beta energy. Scintillation counters can be used for both the quantitation and identification of beta particles.

The penetration power of beta particles is significantly larger than for alpha particles; a few mm of aluminum will stop beta particles. Care should be taken for the "Bremsstrahlung" X-rays that are created during the deceleration of the beta particles, because they may influence the measurement and can be a radiation safety concern.

Beta emitters can be quantitatively measured with ionization chambers and proportional counters that measure electrical current generated by the ionization of a select gas in a high-voltage field. Depending on the energy of the beta particle, the composition of the sample and container, and the design of the detector, the measurement may be based on Bremsstrahlung. For a radionuclide in solution, most of the beta energy is absorbed by the solvent, leaving only Bremsstrahlung exiting the sample. In the case of ionization chambers (e.g., dose calibrators), the walls housing the ionizable gas effectively convert all beta energy to secondary photons.

As is the case for all radiation measurements, quantitative determinations with an ion chamber or a proportional counter depend on rigorous calibration and standardization of the sample type and geometry.

Depending on the detection setup, alpha particles can interfere with measurement of the beta particles. This can be easily prevented by positioning an absorber for alpha particles between the source and the measuring equipment. However, because low-energy beta particles (<200 keV) may also be absorbed, the count rate should be corrected for the absorption of these low-energy beta particles.

An LSC can also be used for the quantification of beta particles and aid in radionuclide detection. Because of the high efficiency of the method, LSC is particularly useful in measuring very low levels of radioactivity and is commonly used for complex biological samples. The sample is normally dissolved in a solution containing a phosphor that converts the beta emission to light pulses, which are detected by a very sensitive system of photomultiplier tubes. At energies greater than ~100 keV, the energy conversion and therefore the counting efficiency, is essentially 100%. The method is somewhat compromised by quenching effects, but these can be easily overcome with careful calibration.

When high energy (>800 keV) beta particles are measured, it is possible to count without scintillation cocktails, because the beta particles create Cherenkov radiation, which can be directly detected with a photomultiplier. [Note—Although alpha particles can interfere with beta counting, this problem can be corrected for by use of thin absorbers or by instrumental energy discrimination.]

The identification of pure beta-emitting radioisotopes without accompanying gammas is best done by a combined measurement of the half-life of the radioisotope and the maximum energy of the beta radiation emitted by the radioisotope.

The approximate maximum energy of a beta particle can be determined by two procedures: 1) by measuring the radioactivity as a function of absorber thickness; and 2) by plotting the logarithm of the count rate versus the thickness of the absorber in mg/m^2 ; then, an absorption curve can be made. The absorption curve can be compared with standardized absorption curves, which aids in the identification of the radioisotope.

Using LSC, by measuring the pulse height over a calibrated energy range, a beta-energy spectrum can be generated from which the maximum energy can be estimated. LSC instruments typically automate the calibration factor, but care should be taken in correcting for quenching effects.

ALPHA PARTICLE COUNTING SYSTEMS

Several detectors can be used for the detection and measurement of alpha particles. These can be ionization chambers, proportional counters, silicon semiconductor detectors, and scintillation counters with their associated electronics. For the identification and quantification of alpha particles, ionization chamber and proportional counters are not suitable.

Special precautions should be taken in the measurements of alpha particles because of their high energy but limited penetration power (about 40 μm in human skin).

For the identification and assay of alpha-particle emitters, spectrometry using liquid scintillation is mostly used. For the identification and determination of radionuclidic purity of alpha-particle emitters, spectrometry using a silicon-diode semiconductor detector can be used.

In a scintillation counter, the energy of the alpha particle is transformed to a light pulse, which can be detected by a photomultiplier tube. The intensity of the pulse is a measure of the energy of the detected alpha particle. Solid scintillation counters using ZnS or phosphor

detectors can be used as well as liquid scintillation.

When solid-state detectors are used, the sample is usually electroplated on a planchet disc, and the detector is brought close to or immediately on the sample. Depending on the type of detector used, the maximum counting efficiency is about 50%. In liquid scintillation counting, when the sample is dissolved in the appropriate medium, the efficiency can be almost 100%. Each method of counting has its own advantages and disadvantages. For solid detectors, advantages are lower background noise and a better differentiation between alpha and beta particles. Disadvantages are that no volatile samples can be measured, and self-absorption by the sample material (related to thickness of the sample layer) can lower the detected count rate, giving a falsely low outcome of the assay.

For liquid scintillation, advantages are the ease of sample preparation and no self-absorption, because the sample is mixed with the scintillation fluid. Disadvantages are higher background noise levels and poor separation between alpha and beta particles.

4.4 Detector Systems for Chromatographic Applications

Chromatographic applications, wherein the radioactive components of a mixture are separated based on their distribution between a stationary phase and a mobile phase, represent a unique usage of radiation detection systems. The most common chromatography applications include thin-layer chromatography (TLC), gas chromatography (GC), and liquid chromatography (high-pressure liquid chromatography and high-performance liquid chromatography, typically denoted as HPLC). Depending on the chromatographic application and the type of emitted radiation, various detector systems may be used in the analysis of separated radioactive components. Gamma-ray detector systems can be used to dynamically measure separated radioactive components in GC and HPLC applications. In these applications, the eluate from the chromatography column is directed over or through the scintillating detector. Typically, these detector systems are not used for radionuclide identification; therefore, NaI(Tl) crystals tend to be the detector of choice in these applications. Depending on the required sensitivity of the technique, the geometry of detector may consist of a well that surrounds the eluate tubing, or a flow cell that passes the eluate across the surface of the detector. In either case, the design of the system should provide a reproducible geometric relationship between the tubing and the detector. In addition, the detector should be shielded sufficiently to prevent spurious peaks or baseline drift due to background radiation. For this application, the output pulses of the photomultiplier tube may be converted into an analog signal whose voltage is proportional to the number of pulses (i.e., the amount of radioactivity). In this manner, the resulting electric signal is used by a data acquisition and chromatography system to provide a chromatogram in a similar fashion as more traditional chromatography detection systems. The flow rate of the eluate and the amount of radioactivity in the eluate should be controlled to provide a count rate that is within the linear range of the detector system.

LSC methods can also be used in HPLC separations of beta-emitting components. Several techniques may be used in this application. In the first, the eluate from the chromatographic column is collected in discrete fractions. Each fraction is then mixed with the liquid scintillation cocktail before analysis in the LSC. Additional processing steps may be necessary before the addition of the cocktail to minimize quenching. In the second technique, the scintillation cocktail may be mixed with the eluate from the column before passage of the resulting mixture through an online flow cell surrounded by the photomultiplier tubes. Finally, inline solid scintillators may be used with in situ mixing of the eluate with a liquid scintillation cocktail. Beta-particle detector systems can be used to measure separated radioactive components in

TLC applications. In this application, windowless gas ionization detectors are most commonly used, and the detector is automatically scanned over the TLC plate, yielding a two-dimensional plot of the radioactivity. Because of the nature of the sample, self-adsorption is negligible, and the beta radiation is efficiently counted. If all of the components on the TLC plate contain the same beta emitter, the output signal is proportional to the fraction of radioactivity in the separated components. If the separated species contain different radionuclides, the detector should be calibrated with each radionuclide to correct for different signal responses.

Alternatively, if such a detector is not available, the TLC plate can be cut into multiple strips and counted by an appropriate detector. The individual strips should be counted using the same geometry. For the highest sensitivity, the strips may be extracted with solvent and then counted by LSC.

5. GLOSSARY

Alpha particles (α): Positively charged particles emitted from nuclei during radioactive decay. Alpha particles are essentially helium-4 nuclei, consisting of two protons and two neutrons but no electrons.

Beta particle (β^-): Negatively charged particles that are emitted from nuclei during radioactive decay. Beta particles are essentially electrons.

Beyond-use date: Date (and time, if appropriate) that establishes a limit for the use of a compounded preparation. The acceptable use period (i.e., the period of time between the date and time of compounding and the beyond-use date and time) is based on a knowledge of the radioactive properties of the preparation, the results of stability studies on the preparation, and, as appropriate, the assurance of sterility of the compounded sterile preparation.

Bremsstrahlung: Electromagnetic radiation produced by the deceleration of a charged particle through interaction with another charged particle, typically an electron and an atomic nucleus, respectively. The moving particle (e.g., beta particle) loses kinetic energy, which is converted into photons (X-rays). This electromagnetic radiation exhibits a continuous spectrum, with peak intensity as a function of the energy of the incident particle.

Calibration factor: The coefficient used to convert the measured ionization chamber current to a nominal radioactivity. This term is often referred to as the "calibration coefficient".

Calibration time: An arbitrary time at which the specified amount of radioactivity is present on a specific date.

Carrier free: A preparation free from stable isotopes of the same element as the radionuclide.

Counting assembly: An instrument that consists of a sensing unit and an electronic scaling device. The sensing unit may be a Geiger-Müller tube, a proportional counter, a scintillation detector in which a photomultiplier tube is used in conjunction with a scintillator, or a solid-state semi-conductor.

Dose calibrator: A well-type ionization chamber commonly used to assay radiopharmaceuticals. Display units are typically in Curies (μCi or mCi or Ci) or Becquerels (kBq or MBq or GBq).

Expiration date: The date (and time, if appropriate) that establishes a limit for the use of the manufactured product that is based on the knowledge of the radioactive properties of the product and the results of stability studies on the finished dosage form.

Gamma rays (γ rays): Electromagnetic radiation emitted from nuclei during radioactive decay. Gamma rays have a wide range of energies. The gamma rays emitted from a given radionuclide are always at the same energy(ies), providing a unique signature that enables the identification

of a gamma-emitting radionuclide.

Geiger-Müller counter: Often referred to as a G-M counter or Geiger counter. An instrument in which a high-voltage potential is applied across a volume of inert gas for the purpose of collecting ions produced by a radiation field. The negative electrons are internally multiplied to produce a readily detectable current pulse. Display units are typically counts per min (cpm) or milliroentgen per h (mR/h).

Geometry: The characteristics of a radioactive source (i.e., container type, container wall thickness, volume and position of the container in the well chamber) that along with the physical characteristics of the ionization chamber affect the magnitude of the calibration coefficient for a specific radionuclide. The principal geometry considerations that may affect the accuracy of a source measurement in a dose calibrator are container configuration, source volume, position of the source in the chamber well and the radionuclide itself. [Note—It is customary to compare a standardized preparation and radiopharmaceutical drug or preparation using identical geometry conditions for assay, identification and other parameters. The validity of the result is critically dependent upon the reproducibility of the spatial relationships of the source to the detector and its surroundings and upon the accuracy of the standardized preparation.]

Ionization chamber: An instrument in which an electric field is applied across a volume of inert gas for the purpose of collecting ions produced by a radiation field. The positive ions and negative electrons drift along the lines of force of the electric field and are collected on electrodes, producing an ionization current. The most commonly used form of ionization chambers for measurement of the activities of radiopharmaceuticals is a well-type ionization chamber known as a dose calibrator.

Isobars: Nuclides with the same mass number (protons + neutrons).

Isomers: Atoms with the same number of protons and neutrons, but a different nuclear energy configuration. Short-lived radioactive isomers are generally referred to as metastable. Different isomers are different nuclides based on their nuclear energy configurations.

Isotones: Nuclides with the same number of neutrons and a different number of protons. Isotones are different elements with different atomic masses.

Isotopes: Nuclides with the same number of protons and a different number of neutrons. Isotopes are the same element with a different atomic mass.

Isotopic carrier: A stable isotope of the element concerned either present in or added to the radioactive preparation in the same chemical form of the radionuclide.

Liquid scintillation counter (LSC): An instrument that detects scintillation light from the absorption of radiation energy in a scintillation liquid. This instrument is used primarily for beta-emitting radionuclides that do not also emit gamma photons. For best results, the radioactive sample must be able to be dissolved in the scintillation liquid.

Minimum detectable activity: The smallest quantity of radioactivity that can be detected above the background with a specified level of confidence.

National Metrology Institute (also known as NMI): A measurement standards body that is a laboratory of metrology that establishes standards for a country or organization. e.g., National Institute of Standards and Technology (NIST) is the NMI for the United States.

No carrier added: A preparation where no stable isotopes of the same element as the radionuclide being tested are intentionally added in the stated chemical form or at the position of the radionuclide in the molecule being tested.

Nuclide: An atom with a specific number of protons and neutrons in a given nuclear energy state.

Positrons (β^+): Positively charged particles emitted from a nucleus during radioactive decay.

Positrons are anti-electrons.

Radioactivity: 1) The spontaneous transformation of nuclei by radioactive decay. Radioactivity is typically described as atoms undergoing radioactive decay per unit time (or disintegrations per unit time). 2) The quantity of radioactive material, as measured in units of Curies (US units) or Becquerels (SI units). The quantity of radioactive material may also be referred to as activity.

Radiochemical identity: The molecular structure of the intended active radioactive drug ingredient that is present in the radiopharmaceutical preparation.

Radiochemical purity: The ratio, expressed as a percentage, of the radioactivity of the intended active radiopharmaceutical ingredient to the total radioactivity of all radioactive ingredients present in the radiopharmaceutical preparation.

Radioisotope: A radioactive atom, generally used in the context of an isotope of an element.

Radionuclide: An unstable nuclide that undergoes radioactive decay; a radioactive nucleus. The terms radionuclide and radioisotope are commonly used interchangeably.

Radionuclidic identity: The intended radionuclide in the radiopharmaceutical preparation.

Radionuclidic purity: The ratio, expressed as a percentage, of the radioactivity of the intended radionuclide to the total radioactivity of all radionuclides in the radiopharmaceutical preparation.

Radiopharmaceutical (radiopharmaceutical preparation/radioactive drug): A finished dosage form that contains a radioactive substance in association with one or more other ingredients and that is intended to diagnose, stage a disease, monitor treatment, or provide therapy. A radiopharmaceutical includes any nonradioactive reagent kit or radionuclide generator that is intended to be used in the preparation of any such substance. The terms radiopharmaceutical and radioactive drug are commonly used interchangeably.

Scintillation crystal counter: An instrument consisting of a crystal scintillator, such as NaI(Tl), with an attached photomultiplier tube and associated electronics. Scintillation light produced from the absorption of gamma and X-rays in the crystal is converted to electrons and amplified in the photomultiplier tube. The resultant current pulse may be further analyzed with regard to photon energy. A commonly used form of this instrument that has a hole in the crystal of sufficient size to allow placement of a test tube or similar container is known as a well counter.

Semiconductor detector: An instrument consisting of a semiconductor material, such as silicon or germanium crystals, that detects ionizing radiation through generation of charge carriers (passage of electrons through holes). The current pulse produced by migration of these charge carriers, under the influence of a voltage potential across the material, can be further amplified and analyzed to determine the quantity and energy of the incident radiation.

Solid-state detector: A crystal-based detector, in contrast to a gas-based detector; often is used as a synonym for a semiconductor detector.

Specific activity: The radioactivity of a radionuclide per unit mass of the element or compound. The unit of specific activity is radioactivity per mass expressed on a gram or mole basis [e.g., mCi/ μ g (MBq/ μ g); Ci/mmol (GBq/mmol)].

Strength: The radioactivity concentration of the radiopharmaceutical at the calibration time. The unit of strength is the amount of radioactivity on a volume basis (e.g., mCi/mL or MBq/mL).

Total radioactivity: The radioactivity of the radionuclide, expressed per unit (e.g., vial, capsule, ampule, generator, and others) at the calibration time.

Validation: Establishment of documented evidence that a method, process, or system meets its intended requirements.

Verification: Confirmation that an established method, process, or system meets

predetermined acceptance criteria.

X-rays: A type of electromagnetic radiation emitted from the electron orbitals. Although they do not arise from the nucleus, they are often present immediately after a decay event if there are interactions between the emitted radiation and the orbital electrons.

BRIEFING

⟨1823⟩ **Positron Emission Tomography Drugs—Information.** Until 2011, USP had two general chapters related to positron emission tomography (PET) drugs. The first was *Automated Radiochemical Synthesis Apparatus* ⟨1015⟩. This chapter described a quality assurance (QA) program for equipment, reagents, documentation, and software used in the production of PET drugs. The second was the *Positron Emission Tomography for Compounding, Investigational, and Research Uses* ⟨823⟩. This chapter provided an extensive QA program for compounding PET drugs. Since the introduction of standards for PET drugs in 1989, technological, marketplace, and regulatory changes necessitated revision of the standards. In addition, in 2009 the Food and Drug Administration (FDA) issued a guidance document on PET drug manufacturing in which the standards in ⟨823⟩ in USP 32 were recognized as an alternative for current good manufacturing practice (cGMP) for investigational and research PET drugs. In 2011, ⟨823⟩ was revised in its entirety to align with these changes and to represent current compendial thinking about the preparation of PET drugs. During the revision of ⟨823⟩, the need for a new chapter to provide additional information on concepts, technologies, and procedures related to PET drug manufacturing and controls to supplement ⟨823⟩ was recognized by the USP General Chapters—Physical Analysis Expert Committee (GCPA-EC). The proposed *Positron Emission Tomography Drugs—Information* ⟨1823⟩ includes relevant information regarding PET radionuclides, definitions of common terminology, along with information on production and quality assurance of PET drugs. The GCPA-EC hopes that this proposed chapter will serve the needs of patients, research subjects, medical institutions, clinical researchers, and all members of the PET community. This proposed ⟨1823⟩, when adopted into USP, eliminates the need for ⟨1015⟩, which is proposed for omission in this *PF* issue.

10. GLOSSARY

1. INTRODUCTION

Positron emission tomography (PET) drugs contain radionuclides that undergo nuclear transformation, or radioactive decay, predominantly by the emission of a positron. Positrons undergo annihilation upon interaction with electrons to produce two photons that are emitted in nearly opposite directions to each other. Each photon possesses an energy of 511 keV, which lies in the gamma ray portion of the electromagnetic spectrum. These photons are used in a wide range of PET imaging studies, including research, investigational, and clinical applications. The radionuclides used in PET imaging studies typically possess short physical half-lives (denoted as $T_{1/2}$). Some common examples of PET radionuclides and their associated half-lives are included in *Table 1*. Note that *Table 1* includes radionuclides currently in predominant use and is not intended to illustrate all positron-emitting radionuclides used in PET.

Table 1

PET Radionuclide	Half-Life, $T_{1/2}$
Fluorine-18	109.8 min
Carbon-11	20.4 min
Nitrogen-13	10.0 min
Oxygen-15	2.0 min
Copper-64	12.7 h
Gallium-68	68 min
Rubidium-82	75 s

Because these radionuclides have the same chemical and physical properties as their stable counterparts found in biological systems, PET offers a unique platform for in vivo imaging studies of complex biochemical pathways. As a result, PET radionuclides have found widespread use in cardiology, oncology, and neurology applications. PET drugs have also attracted interest as potential tools to accelerate and reduce the cost of therapeutic drug discovery efforts. Most PET radionuclides are produced at the point of use by a particle accelerator (e.g., a cyclotron) or a radionuclide generator. A cyclotron accelerates charged particles such as protons or deuterons to velocities sufficient to induce a nuclear transformation of the target nucleus into a different element. High-energy particles and/or radiation are emitted from the target nucleus during the transformation process. An example of a transformation is the

bombardment of stable Oxygen-18 nuclei with accelerated protons to produce Fluorine-18 nuclei along with the concomitant emission of a neutron. This process may be summarized according to the following shorthand notation:

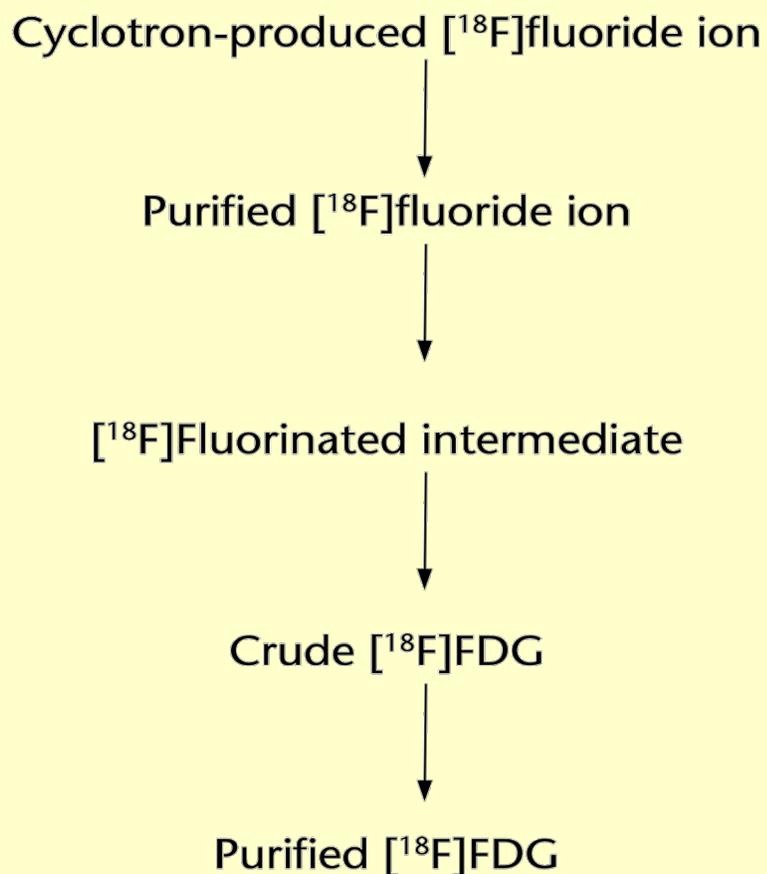

The chemical form and physical state of the bombarded nuclei vary, depending on the target and the subsequent usage of the PET radionuclide. This allows the production of PET radionuclides in gaseous, solid, and solution phases.

Radionuclide generators offer an alternative method for point-of-use access to some PET radionuclides. A radionuclide generator contains an immobilized parent radionuclide that undergoes radioactive decay to a daughter radionuclide, which may be eluted from the generator. An example of a PET radionuclide generator is the Germanium-68/Gallium-68 generator. The parent Germanium-68 ($T_{1/2} = 271$ days) is adsorbed onto the column packing material. The Germanium-68 undergoes radioactive decay by electron capture into Gallium-68, which is not adsorbed onto the column packing material and may be eluted from the generator. Regardless of the production method, other radionuclides may be present in addition to the desired PET radionuclide. In the case of cyclotron-produced PET radionuclides, other radionuclides may result from the bombardment of the target holder and/or other nuclei present in the target material. For generator-produced PET radionuclides, break-through of the parent radionuclide may occur. Safeguards are readily available to avoid unnecessary contamination with radionuclidic impurities of the final PET drug.

Once the PET radionuclide has been produced, it should be processed into a suitable form of a PET drug. The simplest form of processing involves the purification and/or formulation of the PET radionuclide. An example is the purification of the fluoride ^{18}F ion. After production of the fluoride ^{18}F ion by cyclotron bombardment, ion exchange procedures may be used to remove impurities and yield a formulation suitable for PET imaging studies. Another example is the purification of gaseous Oxygen-15 through various solid supports before administration of the finished PET drug by inhalation.

Simple forms of processing are rare, because PET drug products are typically synthesized from the appropriate radionuclide through multiple synthetic processing steps. The exact process depends on the desired PET drug. The synthesis of 2-[F-18]Fluoro-2-deoxyglucose (FDG F18) provides an illustration. The first step in this synthesis is the preparation of the anhydrous Fluoride-F18 ion from cyclotron-produced Fluorine-18. The Fluoride-F18 ion is activated with a phase transfer catalyst such as tetraethylammonium or [2.2.2]-cryptand to enhance its reactivity toward nucleophilic substitution. The resulting complex reacts with mannose triflate to yield a fluorinated ^{18}F intermediate, which is deprotected and purified to yield FDG-F18. This process is summarized in the following set of equations:

In addition to the chemical processing and/or purification steps used to generate the desired radiochemical of interest, other steps are typically required to formulate the PET drug product. For injectable PET drug products, formulation steps may include dilution, addition of a stabilizer, pH adjustment, and other steps. The overall process should take place in a manner that minimizes the presence of bacterial endotoxins and bioburden. Finally, the product should be sterilized, e.g., by passage through a membrane sterilizing filter, to provide a solution suitable for intravenous administration. In the above example, Fludeoxyglucose F-18 becomes the drug product Fludeoxyglucose F 18 Injection.

Before use, the finished PET drug product should be tested to ensure that the product meets suitable standards of identity, strength, and purity. Because of the short half-life of PET radionuclides, testing should be completed in a timely fashion; however, it is not possible to complete certain quality control (QC) tests within a suitable timeframe. In some cases, it may be necessary to adopt a "sub-batch" approach for QC testing, wherein a sub-batch of the PET drug product is prepared solely for purposes of QC testing. Examples of PET drug products with such short half-lives include water-¹⁵O and ammonia-¹³N.

Ultimately, the short half-lives of PET radionuclides create unique constraints for the production and testing of PET drug products and define how these products are used in research, investigational, and clinical settings. PET drugs are a unique class of products defined by the following characteristics:

- The mass of the radioactive ingredient in a PET drug product usually ranges from nanogram to microgram quantities. This affects pharmacological and toxicological considerations for PET drugs, usually by creating large safety margins due to low mass of the active ingredient in the administered dose.
- An entire batch of a PET drug product may be contained in a single vial. Samples withdrawn for QC testing are representative of the entire batch. PET drug products produced in this fashion undergo 100% QC testing.
- PET drug products are produced and handled in environments with overlapping areas of regulatory authority. For example, radiation protection regulations require a negative pressure environment to minimize personnel radiation exposure, but drug regulations for sterile products require a positive pressure environment.
- PET drug products are generally produced at or near their point of use in small-scale facilities with limited personnel and resources. This requires:
 - Allowance for multiple operations in one area with adequate controls
 - Allowance for making and testing multiple PET drug products using shared equipment with appropriate cleaning between batches
 - Appropriate requirements for aseptic operations
 - Appropriate requirements for system suitability and other day-of-use activities
 - Appropriate QC requirements for components, materials, and supplies
 - Self-verification of significant steps in radionuclide production, PET drug production, compounding, and testing
 - Single-person oversight of production or compounding, testing, review of batch records, and release authorization
- PET drug products do not enter a traditional distribution chain. Instead, PET drug products require just-in-time deliveries typically performed by dedicated carriers with experience in handling radioactive materials.
- It is not possible to complete sterility testing for PET drug products before their use. Therefore, considerations are made to provide for the assurance of sterility for injectable PET drugs intended for human use.
- Procedures should be in place to notify the responsible individuals in a timely manner if a PET drug product is found to be in noncompliance after release for human use.

2. TECHNIQUES FOR PRODUCTION AND QUALITY CONTROL

The unique characteristics of PET drug products play a large role in the choice of instrumentation and techniques used in production and QC testing. Production techniques and analytical methods should be efficient and rapid. The selection of techniques and methods is also strongly influenced by the development stage of the PET drug. For example, early development efforts focus on radiolabeling, purification, QC methods development, and others. These efforts are designed to support the usage of the PET drug for *in vitro* studies, animal studies, and may even include first-in-human studies. At this stage, relatively small quantities of the PET drug are required at a limited number of institutions or geographic areas. Manual production techniques or semi-automated equipment may provide sufficient quantities to meet this demand. Analytical methods should also be suitable for the usage of the PET drug at the early stages of development. Typically, method development efforts focus on accuracy, precision, and linearity. Before the use of injectable PET drugs in human studies, provisions are made to ensure that bacterial endotoxins are controlled at suitable levels and that the product

is sterile.

In later development stages, larger quantities of the PET drug may be required in more geographic areas. At this point, the synthesis, purification, and testing of the PET drug product should be well defined to support clinical trials. Development efforts at this stage typically focus on optimization and reliability of the production process. Manual production techniques are rarely used. Instead, semi-automated or fully-automated techniques are typically required to provide sufficient quantities of the PET drug at multiple geographic locations. This approach simultaneously assures consistent quality attributes of the PET drug at multiple production facilities and minimizes radiation exposure of operators. Method development activities at this stage focus on specificity, ruggedness, robustness, and other characteristics required to support QC testing of the PET drug at multiple geographic locations.

Finally, at the commercial stage of production, semi-automated or fully-automated techniques and equipment may be required to provide sufficient quantities of the PET drug in numerous geographic areas. Production techniques and analytical methods for commercial PET drug products should be well defined and adequately described in the appropriate marketing authorization.

Not all PET drugs are intended to advance through the various development stages from *in vitro* studies, to animal studies, to clinical trials, to commercial production. For example, a PET drug product may be produced at several institutions for research purposes without the intention of commercialization. In other instances, a PET drug product may be FDA approved but is only available in a single geographic area. These factors often result in different strategies for production techniques, analytical methodologies, and the underlying studies and documentation to support these strategies.

3. QUALITY ASSURANCE

The goal of quality assurance (QA) is to ensure that the techniques and equipment used in production and testing result in a product that meets established standards for that specific PET drug product. The QA program should be sufficient to establish the reliability and suitability of the techniques and equipment as appropriate to the development stage of the PET drug product. The following topics should be considered in a QA program.

3.1 Reagents and Materials

Reagents and materials used in the synthesis and testing of a PET drug product should conform to established acceptance criteria. Procedures for procuring, receiving, testing, storage, and use of reagents and materials should also be considered. An audit trail may be established for the traceability of specific lots of reagents and materials to specific batches of product. These acceptance criteria, procedures, and the audit trail should be appropriate for the development stage of the PET drug product.

3.2 Change Control

Changes in the synthesis and test methods should be evaluated for their potential for altering the product quality and be approved in advance through established procedures. If the resultant PET drug product does not meet the criteria appropriate to the development stage, the process change is unacceptable. Acceptable changes should be appropriately documented.

3.3 Validation

Production and analytical test methods should be validated at a level that is appropriate for the development stage of the PET drug product. Validation of the production process should result in a process that is reliable and consistent. Analytical method validation demonstrates that a method can quantitatively measure a PET drug product reliably and reproducibly. It is not necessary to validate analytical methods that are described in USP compendia. The emphasis on validation typically increases as the PET drug product moves through the development stages toward commercialization. Validation of the computer software used to control automated production equipment should also be considered as appropriate.

QUALIFICATION

Equipment used in the synthesis and testing of PET drug products should be qualified as appropriate for the development stage of the PET drug product. This may include qualification procedures (installation, operational, and performance), as well as procedures for periodic maintenance and equipment calibration. For commercially available equipment, the equipment vendor may be able to support qualification requirements.

STABILITY STUDIES

Stability studies should be performed on PET drug products to establish suitable storage conditions and the expiration time and date. Quality attributes such as radiochemical purity, appearance, pH, stabilizer, preservative effectiveness, and chemical purity should be evaluated. The frequency and extent of these studies should be appropriate for the development stage of the PET drug product. Significant process changes require stability studies to be repeated.

4. PRODUCTION

4.1 Equipment for Manual Synthesis

Equipment intended for the manual synthesis of PET drug products may be based on apparatus found in a typical chemistry laboratory such as glass reaction vessels, heating blocks, tubing, and other items. These items should be suitable for their intended use and selected according to the needs of the process. Items that are reused and come into contact with the reactants and/or final drug product of the synthesis should be cleaned and depyrogenated as appropriate for the use of the final product.

Written procedures for the manual syntheses of PET drug products should contain sufficiently detailed steps to ensure that a reproducible process is followed for each batch by the operator. Observations of critical process parameters should be documented as appropriate in the batch record.

4.2 Equipment for Automated Synthesis

Preparation of Fludeoxyglucose F 18 Injection and other common PET drug products can be adapted readily to automated synthesis. The use of programmable controllers and/or computers with switches, solenoids, and sensors allows the operator to control the sequence of steps in

an automated fashion. Thus, an automated synthesis requires minimal operator intervention, and batch-to-batch consistency is maintained with each step executed in a reproducible manner. Software may provide feedback to the operator such as alarm conditions, status reports, or an end-of-synthesis report. Modules for automated synthesis may be commercially available. These modules may use individual reagents or cassettes required for the appropriate PET drug product synthesis. The cassettes provide pre-assembled collections of reagents, reaction vessels, tubing, filters, and other items necessary to produce a batch of a PET drug product.

Laboratory robots may be appropriate in situations where complex manipulations are required for the procedure, such as the physical movement of a reaction vessel from one station to another, or the dispensing of doses from a vial into individual syringes. Customized equipment may also be fabricated to perform a specific function in the PET drug product synthesis.

5. QUALITY CONTROL

Quality control (QC) tests should be designed and executed in a manner that is appropriate for PET drugs. The short half-life of PET radionuclides significantly limits the timeframe for the performance of QC tests, and it may not be possible to complete all QC tests before the use of the PET drug product.

5.1 Quality Control Sampling

In most cases, the entire batch of a PET drug is contained within a single vial. The relatively small batch volume of PET drugs limits the amount of material available for QC testing. This is different from traditional manufacturing practices, where a batch may consist of numerous vials and not all vials are sampled for purposes of QC testing. QC sampling of PET drug products use a larger proportion of the drug volume, and thereby offers a greater degree of assurance that quality-related problems will be identified in the QC testing process.

5.2 Reference Standards

Reference standards are necessary to identify the API and impurities in the PET drug product. Reference standards may be commercially available or prepared in-house. Commercial reference standards should include documentation from the supplier to ensure they are properly characterized. The characterization and qualification of reference standards should be appropriate for the development stage of the PET drug product.

5.3 Conditional Release

When a required QC test for a PET drug product cannot be completed because of a malfunction of test equipment, it may be appropriate to conditionally release the batch. It is not appropriate in the absence of critical QC tests to conditionally release batches (e.g., radiochemical identity and purity). Procedures should be developed to describe the conditional release process, including the role of historical data, other QC test results, sample retention, and other procedures.

5.4 Out-of-Specification Results

When the results of a QC test do not meet product specifications, an investigation should be conducted to determine if the result is due to an analytical error (false positive) or if the result is due to a product failure. Because of the short half-life of PET radionuclides, it may not be possible to conduct investigations in the same manner as in traditional drug testing laboratories.

6. ANALYTICAL METHODOLOGIES

Various analytical methodologies and chromatographic techniques may be used for the testing of PET drug products. The most commonly used methodologies are discussed in this section for purposes of illustration. Similar principles should apply to other methodologies not included in this section.

6.1 Thin-Layer Chromatography

Thin-layer chromatography (TLC) involves separation, identification, and quantification of analytes using a stationary phase on a support or plate and a developing solvent that may also be known as mobile phase. The stationary phase may be silica or alumina spread in a uniform layer onto a plate of glass, metal, or plastic. A small sample of the PET drug product is applied (spotted) onto the stationary phase, and the plate is developed in a chromatographic tank. The mobile phase moves through the stationary phase by capillary action, and the analytes are separated based on partition, ion exchange, and/or adsorption. The retardation factor (R_f) and radiochemical purity of the PET drug on the developed plate can be determined by either counting the developed plate on a radio-TLC scanner, or cutting the plate into pieces and counting each piece in a radiation detector. The R_f of an analyte, under specific TLC conditions, is considered an identifying characteristic of the analyte.

6.2 Gas Chromatography

Gas chromatography (GC) involves separation, identification, and quantification of volatile analytes using a stationary phase and a gaseous mobile phase. A small sample of the solution is introduced into the GC instrument, which vaporizes the sample for passage over the stationary phase that is immobilized within a GC column. As the gaseous mobile phase passes over the stationary phase, the analytes are separated based on their partition between the gas and stationary phases. A detector located at the exit of the column provides an electronic signal to produce the gas chromatogram.

A GC instrument consists of a gas source, injection port, column, detector, and a data collection device. The injection port, column, and detector are temperature controlled and may be varied as part of the analysis. The gas source depends on the column and detector in use. The type of detector depends on the nature of the compounds analyzed. Typical detectors include flame ionization and thermal conductivity. In addition, radiation detectors may be used in GC analysis. Detector output is recorded over time, and the instrument response, measured as peak area or peak height, is a function of the amount present. The retention time of an analyte under specific GC conditions is considered an identifying characteristic. GC analysis is most typically used to quantify residual solvents in PET drug products but may also be used to determine radiochemical and chemical purity of the PET drug product formulation.

6.3 High-Performance Liquid Chromatography

High-performance liquid chromatography (HPLC) is an analytical technique used to separate, identify, and quantify the components of a solution. HPLC separations are based on the interaction of the analytes between the stationary and mobile phases, which in turn leads to the retention of the analytes. The mechanism of interaction between the analytes and stationary phase may be partition, size exclusion, adsorption, and/or ion exchange chromatography. The retention time of an analyte under specific HPLC conditions is considered an identifying characteristic.

HPLC instruments consist of a reservoir containing the mobile phase, a pump to force the mobile phase through the system at high pressure, an injector to introduce the sample into the mobile phase, a chromatographic column, a detector, and a data collection device. The type of detector used depends on the nature of the compounds analyzed. In addition to mass detectors such as refractive index, ultraviolet, and conductivity, radiation detectors are also used in HPLC analysis. An HPLC system with a radiation and mass detector allows the simultaneous determination of radiochemical and chemical purity, retention time, and the subsequent identity of the PET drug product. This configuration also allows the determination of specific activity. Elution methods include gradient or isocratic methods with aqueous and/or organic buffers.

The calibration of a GC or HPLC instrument may be achieved by different means. One approach involves the creation of a calibration curve from a range of standards with known concentrations. The calibration curve may be used over a specified period of time for product testing. A second approach for calibration involves the creation of a single-point calibration at the beginning of each testing cycle. The results may be averaged and used to provide a calibration factor for product testing. Regardless of the approach for calibration, the tailing factor and chromatographic resolution (or column efficiency as appropriate) should be determined routinely as a part of system suitability. Routine system suitability testing should include checks for these parameters.

6.4 Radiation Detectors used in Chromatographic Techniques

Radiation detectors used in TLC, GC, and HPLC should be calibrated when possible with suitable NMI-traceable radionuclide standards at appropriate frequency. Routine system suitability testing should be performed on the radiation detection system to ensure proper operation. Because of the nature of TLC, system suitability for a radio-TLC scanner should address uniformity, positional accuracy, detector linearity, and resolution. The calibration of radiation detectors should be repeated as appropriate.

6.5 Multichannel Analyzer

A multichannel analyzer (MCA) is an instrument used to obtain a spectrum of gamma rays emitted by a PET radionuclide. The key component of a MCA is an energy-sensitive detector. On the basis of the gamma spectrum of a sample, radionuclides present in the sample may be identified and quantified. Calibration of the system is typically performed with certified standards and may involve one or more radionuclides with gamma energies and quantities that span the range of typical analyses at appropriate frequency.

6.6 Ionization Chamber

An ionization chamber, often referred to as a dose calibrator, is an instrument used to measure the quantity of radioactivity in a PET drug product. The key component of an ionization chamber is an argon-filled chamber with an applied electrical potential that allows the detection of ions produced by the passage of gamma rays through the chamber. Calibration of the system is typically performed with certified standards at appropriate frequencies and may involve one or more radionuclides with gamma energies and quantities that span the range of typical analyses.

7. QUALITY ATTRIBUTES

Quality attributes should be defined and assessed for each PET drug. These attributes should be suitable for the intended use of the PET drug and should also reflect the dosage form. Because most PET drug products are administered by intravenous injection, this section focuses on quality attributes associated with injectable PET drug products. Different attributes may be appropriate for other dosage forms. In addition, the definition and assessment of quality attributes may vary with the development phase of the PET drug product in comparison to the final drug phase.

7.1 Appearance

Injectable PET drug products should be free of particulate matter. Because of the radioactive nature of PET drug products, the test for appearance should be a visual inspection that meets radiation safety requirements. The use of a visual standard should be considered to ensure the accuracy of appearance determinations.

7.2 pH

Injectable PET drug products should be in the pH range suitable for intravenous administration. Because of the limited volume of a PET drug product, pH measurement is typically performed using narrow-range paper strips. The use of pH standards should be considered to ensure the accuracy of pH determinations.

7.3 Total Radioactivity and Strength

The total radioactivity of a PET drug product may be determined by an ionization chamber and should be stated at a given date and time. From the total radioactivity and the volume of the PET drug product, the strength may be determined. The strength of the PET drug product should be stated, along with the date and time of the determination of total radioactivity.

7.4 Radionuclidic Identity

Half-life (also referred to as approximate half-life) is a characteristic of the radionuclide that may be used for its identification. To adequately confirm the identity of a PET radionuclide, the half-life should be measured in a suitable counting device over a period of time appropriate to the half-life of the radionuclide.

7.5 Radionuclidic Purity

By definition, all positron-emitting radionuclides emit 511 keV gamma rays but may also emit gamma rays with different energies. Therefore, it is generally not possible to determine the radionuclidic purity of PET drug products with a MCA. A suitable solution to this problem is the use of validation studies to ensure the removal and/or decay of radionuclidic impurities during the production process. In addition, periodic analysis of decayed samples in routine production with a MCA may be used to quantify radionuclidic impurities developed.

7.6 Radiochemical Identity and Purity

Depending on the physical and chemical properties of the PET drug product, the radiochemical identity and purity may be determined by TLC, HPLC, or GC. The identity of the active pharmaceutical ingredient (API), and possibly other analytes, should be based on the known retention time of the analyte. The simultaneous use of reference standards during sample analysis should be considered for purposes of radiochemical identification. The radiochemical purity of the PET drug product should be determined based on the sum of all chemical forms of the radionuclide of interest. As appropriate, it should be established during validation that all radiochemical analytes are eluting from the chromatographic system and that the radioactive detector is operating within its linear range.

7.7 Chemical Purity

The chemical purity of the PET drug product should be assessed for the presence of volatile impurities, residual reagents and/or precursors, stabilizers, excipients, and by-products. For example, residual solvents, such as acetonitrile and ethyl alcohol, may be assessed by GC. [2.2.2]-Cryptand, a common reagent used in the preparation of PET drug products, may be assessed by colorimetric techniques.

7.8 Total Mass of the Active Pharmaceutical Ingredient and Specific Activity

Potential toxicity issues and pharmacological effects may be associated with the API in a PET drug product (e.g., the mass-dependent localization of neurotransmitters or other more generalized forms of toxicity). In these instances, the total mass of the API should be determined before use of the PET drug product. The total mass of the API contained in a patient dose should be defined for each PET drug product, which may be determined by HPLC or GC. On the basis of the mass of the API, the specific activity may be calculated. To determine the appropriate quality of the injected drug product in the patient dose, any two of three measured parameters (total mass, total activity, or specific activity) are sufficient. Specific activity should be stated along with the date and time of determination.

7.9 Bacterial Endotoxin

The quantity of bacterial endotoxin in an injectable PET drug product should comply with USP standards (<175 USP Endotoxin Units/patient dose). The test for bacterial endotoxin uses a solution of limulus amoebocyte lysate (LAL). Various methods exist for this test, including gel-clot, chromogenic, and others. Test samples should be obtained and handled in a manner that minimizes contamination before testing. In addition, control measures should be used to ensure accurate test results without interferences from the test solution, such as certain formulations

that enhance or inhibit the interaction of LAL with bacterial endotoxin. This effect may be corrected by dilution of the PET drug product before testing. The necessity of dilution in this test is determined in the validation of the specific formulation of the PET drug product.

7.10 Sterility

Injectable PET drug products should be sterile. For reasons described in the *Introduction*, it is not possible to complete the sterility test before the use of PET drug products. The test for sterility should consist of inoculating a test sample into media capable of supporting the growth of aerobic and anaerobic microbes, which may be established with an appropriate certificate of analysis. The test samples should be obtained and handled in a manner that minimizes contamination before testing. To reduce radiation exposure to operators, the test samples may be allowed to decay before inoculation. The inoculation should use techniques that minimize the potential for false positives during the sterility test. In addition, control measures should be used to ensure accurate test results without interferences from the test solution. After inoculation, the sterility test samples should be incubated for the appropriate period of time at the prescribed temperature. If visible growth is detected during the incubation period, the investigator or physician should be informed in a timely manner, and an investigation should be initiated to determine whether the growth was due to accidental contamination during the sample handling process or to a true product failure. The investigation should include identification of the microbe(s) in the sterility test sample to determine the source of the contamination. This aspect of the investigation may be limited if production and sterility test sampling occur in the same laboratory.

8. STERILITY ASSURANCE

A suitable sterility assurance program should be established for PET drug products that are intended for intravenous injection. This section describes appropriate measures that assure the routine production of a sterile product suitable for injection.

8.1 Sterile Membrane Filtration

Injectable PET drug products are typically sterilized by passage of the solution through a sterile membrane filter into a pre-sterilized vial. To provide the greatest assurance of sterility, the PET drug product should pass through an appropriate sterilizing filter into a pre-sterilized vial that has been assembled using aseptic techniques.

8.2 Aseptic Techniques

Critical steps that affect the sterility of the PET drug product should be identified and, where appropriate, aseptic techniques should be used to complete these steps. Aseptic techniques should include the use of a suitable gowning, proper handling of components, environmental controls, and others. Aseptic techniques should be described in written procedures.

8.3 Pre-Sterilized Components

PET drug products are typically produced in a container-closure that is commercially available

as a pre-sterilized vial. Before use, the vial and other pre-sterilized components are assembled using aseptic techniques in a suitably controlled aseptic environment.

8.4 Environmental Controls

The environment where aseptic techniques are executed should be controlled to ensure appropriate aseptic conditions. These controls include temperature and humidity, ventilation and air filtration, cleaning and disinfection, equipment maintenance, proper garb, and microbiological monitoring. Air filtration standards should conform to local and/or national standards relevant to environmental standards, e.g., ISO standards.

8.5 Media Fills

A media fill, also known as a "process simulation", is the performance of an aseptic procedure using a sterile microbiological growth medium in place of the PET drug product. The goal of a media fill is to test whether the aseptic procedure is adequate to prevent microbiological contamination during the actual process. Media fills may be used to evaluate aseptic techniques used in the assembly of pre-sterilized components and to qualify operators for aseptic techniques. A media fill should be designed to ensure that the simulation is representative of the aseptic manipulations performed during the actual process, including personnel, components, gowning, locations, batch size, number of replicates, and other factors. After completing the media fill, components filled with media should be incubated appropriately to permit the growth of microbes. The use of negative controls should be considered during the media fill procedure.

8.6 Suitability of Media

Sterility test media should be tested before use to ensure that the media adequately support the growth of microbes. These tests are typically referred to as growth-promotion tests and may be conducted in-house, by the supplier, or by a contract laboratory. Media should be used within the manufacturer's expiration date and within 3 months of completing the growth-promotion test.

8.7 Suitability of the Sterility Test Method

The sterility test should be tested to ensure that the PET drug product is not bacteriostatic or fungistatic. The suitability of the sterility test may be conducted in-house or by a contract laboratory.

8.8 Membrane Filter Integrity Test

To ensure the proper sterilization of the PET drug product by passage through a membrane sterilization filter, the bubble point of the filter should be determined after completing the filtration process. The bubble point of the filter, measured in pounds per square inch (psi), is the pressure required to force air through the pores of the wetted membrane in the device. Other suitably validated procedures may be used.

8.9 Operator Training and Qualification

Operators involved in aseptic techniques should be trained in proper gowning, environmental controls, handling sterile components, and other techniques. Operators should be qualified through successful completion of media fills. Media fills should be periodically repeated to ensure ongoing competency of the technique.

9. LABELING

The labeling associated with PET drug products may evolve as the drug progresses through the various development stages. For example, the labeling for PET drug products used for *in vitro* and animal studies may be very simple and designed to avoid mix-ups in the routine use of the PET drug product. In later development stages, the labeling may include information required for the investigational use of the PET drug product in humans. Finally, at the commercial stage of production, the labeling should include ingredients, warnings, approved indications, and other elements required by the appropriate regulatory agencies (e.g., FDA, Nuclear Regulatory Commission, and others).

10. GLOSSARY

The following definitions apply to words and phrases as they are used in this chapter:

Accuracy: The closeness of test results obtained by that method to the true value established across the range of the method.

Active pharmaceutical ingredient (API): A radioactive substance that exhibits spontaneous disintegration of unstable nuclei by the emission of positrons and is incorporated into a PET drug product to furnish a direct effect in the diagnosis or monitoring of a disease or a manifestation of a disease in humans, or monitoring treatment of disease or therapeutic procedures (e.g., tumor therapy). Both radioactive and nonradioactive forms of the PET drug are included in the API.

Batch: A quantity of PET drug product that is intended to have uniform character and quality, within specified limits, and that is made in a single, defined operational cycle.

Chemical purity: The purity of a PET drug product based on the nonradioactive components of the formulation, e.g., residual solvents and/or volatile impurities, reagents, and or precursors used in the synthesis and purification, stabilizers, excipients, or by-products produced in the synthesis.

Compounding: The process of synthesis or formulation of a PET drug for use under the practice of pharmacy and medicine.

Conditional final release: A final release for patient administration before completion of a required test because of a breakdown of analytical equipment.

Limit of detection: The lowest amount of analyte in a sample that can be detected but not necessarily quantified under the stated method conditions.

Linearity: The ability to elicit test results that are, directly or by a well-defined mathematical transformation, proportional to the concentration of analyte in samples within a given range.

Lot: A quantity of materials (e.g., reagents, solvents, gases, purification columns, and other auxiliary materials) that have uniform character and quality within specified limits and are used to make a PET drug product.

Lower limit of quantification: The lowest amount of an analyte in a sample that can be determined with acceptable precision and accuracy under the stated method conditions.

National Metrology Institute (NMI): A measurement standards body that is a laboratory of metrology that establishes standards for a country or organization. The National Institute of Standards and Technology (NIST) is the NMI for the United States.

PET drug: A radioactive substance (active pharmaceutical ingredient) that exhibits spontaneous disintegration of unstable nuclei by the emission of positrons and is incorporated into a PET drug product to furnish direct effect in the diagnosis or monitoring of a disease or a manifestation of a disease in humans, or monitoring treatment of disease or therapeutic procedures (e.g., tumor therapy).

PET drug product: A finished dosage form that contains a PET drug, whether or not in association with one or more other ingredients.

Precision (as repeatability): The degree of agreement among individual test results when the method is applied repeatedly to multiple samplings of a homogenous sample within a lab over a short period of time using the same analyst with the same equipment.

Quality assurance (QA): A planned and systematic program to ensure that a PET drug product possesses the quality required for its intended purpose.

Quality control (QC): A system for testing the quality of components, materials, supplies, and PET drug products by procedures, tests, analytical methods, and acceptance criteria.

Radiochemical identity: The molecular structure of the intended active radiopharmaceutical ingredient that is present in the radiopharmaceutical preparation.

Radiochemical purity: The ratio, expressed as a percentage, of the radioactivity of the intended active radiopharmaceutical ingredient to the total radioactivity of all radioactive ingredients present in the radiopharmaceutical preparation.

Radionuclidic identity: The intended radionuclide in the radiopharmaceutical preparation.

Radionuclidic purity: The ratio, expressed as a percentage, of the radioactivity of the intended radionuclide to the total radioactivity of all radionuclides in the radiopharmaceutical preparation.

Range: The interval between the upper and lower levels of a quality attribute that can be determined with a suitable level of precision and accuracy.

Reagents and materials: A reagent is a chemical used in the synthesis and/or testing of a PET drug, whereas a material is an ancillary object, such as tubing, glassware, vials, and others.

Retardation factor (TLC): The ratio of the distance the analyte moved from the origin line divided by the distance the solvent moved from the origin line denoted by the variable R_f .

Retention time (HPLC or GC): The time required, after the injection, for the analyte to move through the column and reach the detector.

Robustness: The measure of the capacity of an analytical method to remain unaffected by small variations in method parameters.

Ruggedness (as reproducibility): The degree of reproducibility of test results obtained by the analysis of the same samples under a variety of conditions, such as different labs, different analysts, different instruments, different lots of reagents, different assays, and different days.

Specific activity: The radioactivity of a radionuclide per unit mass of the element or compound. The unit of specific activity is the amount of radioactivity on a mass basis [e.g., mCi/ μ g (MBq/ μ g) or Ci/mmol (GBq/mmol)].

Specificity: The ability to assess unequivocally the analyte in the presence of components that may be expected to be present such as impurities, degradation products, and matrix components.

Strength: The radioactivity concentration of the active pharmaceutical ingredient in a PET drug product at a given date and time. The unit of strength is the amount of radioactivity on a

volume basis [e.g., mCi/mL (MBq/mL)].

Sub-batch: A quantity of PET drug product having uniform character and quality, within specified limits, that is produced during one succession of multiple irradiations using a given synthesis or purification operation. A group of sub-batches collectively forms a batch that is intended to have uniform character and quality, within specified limits. Sub-batches may be required for PET drug products with very short-lived radionuclides (e.g., ^{13}N and ^{15}O), because QC tests cannot be completed before use.

System suitability: Requirements used to verify that the system performs according to established criteria.

Tailing factor (symmetry factor): A measure indicating the non-ideality of a chromatographic peak resulting from the distribution and the migration of the analyte through the chromatographic column.

Validation: Establishment of documented evidence that a method, process, or system meets its intended requirements.

Verification: Confirmation that an established method, process, or system meets predetermined acceptance criteria. ■2S (USP39)

BRIEFING

(2040) **Disintegration and Dissolution of Dietary Supplements**, *USP 38* page 1774 and *PF 40(6)* [Nov.–Dec. 2014]. It is proposed to make the following changes in this chapter:

1. Clarify the end point in the *Procedure* in the *Rupture Test for Soft Shell Capsules*.
2. Delete the information about flow-through cell (*USP Apparatus 4*), since there is no official procedure using this apparatus in *USP* for dietary supplements. *USP* has received no proposal to use this apparatus.
3. Revise the current *Test 2* dissolution procedure using *USP Apparatus 3* under the sections *Dissolution Conditions for Folic Acid* and *Dissolution Conditions for Index Water-Soluble Vitamins and Index Minerals*.
4. Introduce *Test 3*, a new dissolution procedure for folic acid and index water-soluble vitamins and index minerals, suitable for soft shell capsules using *USP Apparatus 2* with stationary basket.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

Comment deadline: November 30, 2015

(2040) DISINTEGRATION AND DISSOLUTION OF DIETARY SUPPLEMENTS

INTRODUCTION

This general chapter is provided to determine compliance with the disintegration and dissolution standards for dietary supplements where stated in the individual monographs.

For the purposes of this chapter, dietary supplement dosage forms have been divided into three categories: *Vitamin–Mineral Dosage Forms*, *Botanical Dosage Forms*, and *Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms*. *Vitamin–Mineral Dosage Forms* include articles prepared with vitamins, minerals, or combinations of these dietary ingredients, as described in *Table 1*. *Botanical Dosage Forms* comprise formulations containing ingredients of botanical origin, including plant materials and extracts. *Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms* encompass dietary supplements formulated with lawfully recognized dietary ingredients that are different from those pertaining to the two foregoing categories (e.g., amino acids, chondroitin, and glucosamine).

Where a dietary supplement represents a combination of the categories mentioned above, and there is a difference between the requirements for the individual categories, the more stringent requirement applies. [Note—“More stringent requirement” means stricter acceptance criteria and/or milder operational conditions.]

Disintegration and dissolution tests as described in this chapter are quality-control tools to assess performance characteristics of dietary supplement finished dosage forms. These performance standards are intended to detect problems that may arise due to use or misuse, or changes in coatings, lubricants, disintegrants, and other components. These performance tests are also intended to detect manufacturing process issues, such as overcompression and overdrying, that would affect the release characteristics of the final dosage forms. These tests are not intended to be used as a demonstration or as a surrogate for in vivo absorption, bioavailability, or effectiveness, unless an in vitro–in vivo correlation (IVIVC) has been established.

DISINTEGRATION

This test is provided to determine whether dietary supplement capsules or tablets disintegrate within the prescribed time when placed in a liquid medium at the experimental conditions presented below. Compliance with the limits on *Disintegration* stated in the individual monographs for dietary supplements is required, except where the label states that the products are intended for use as troches, are to be chewed, or are designed as extended-release dosage forms. Dietary supplements claiming to be extended-release dosage forms must comply with standards other than disintegration to verify that the release of the dietary ingredients from the dosage form is for a defined period of time. Dietary supplements claiming to be extended-release dosage forms must not be labeled as in compliance with USP unless a *USP* monograph exists for such product. Determine the type of dosage form under test from the labeling and from observation, and apply the appropriate procedure to 6 or more units. For purposes of this test, disintegration does not imply complete solution of the unit or even of its active constituent. Complete disintegration is defined as that state in which any residue of the unit, except fragments of insoluble coating or capsule shell, remaining on the screen of the test apparatus or adhering to the lower surface of the disk (if used) is a soft mass having no palpably firm core.

Apparatus

Apparatus A: Use the *Apparatus* described in *Disintegration* (701) for capsules or tablets that are NMT 18 mm long. For larger capsules or tablets, use *Apparatus B*.

Apparatus B: The apparatus consists of a basket-rack assembly, a 1000-mL low-form beaker for the immersion fluid, a thermostatic arrangement for heating the fluid between 35° and 39°,

and a device for raising and lowering the basket in the immersion fluid at a constant frequency rate between 29 and 32 cycles/min through a distance of 53–57 mm. The volume of the fluid in the vessel is such that at the highest point of the upward stroke, the wire mesh remains at least 15 mm below the surface of the fluid and descends to NLT 25 mm from the bottom of the vessel on the downward stroke. At no time should the top of the basket-rack assembly become submerged. The time required for the upward stroke is equal to the time required for the downward stroke, and the change in stroke direction is a smooth transition rather than an abrupt reversal of motion. The basket-rack assembly moves vertically along its axis. There is no appreciable horizontal motion or movement of the axis from the vertical.

Basket-rack assembly: The basket-rack assembly (see *Figure 1*) consists of three open-ended transparent tubes, each 77.5 ± 2.5 mm long and having an inside diameter of 32.0–34.6 mm and a wall 2.0–3.0 mm in thickness; the tubes are held in a vertical position by two plastic plates, each 97 ± 2 mm in diameter and 7.5–10.5 mm in thickness, with three holes, 36.0–40.6 mm in diameter, equidistant from the center of the plate and equally spaced from one another. Attached to the undersurface of the lower plate is 10-mesh No. 23 (0.025-inch) W- and M-gauge woven stainless-steel wire cloth having a plain square weave. The parts of the apparatus are assembled and rigidly held by means of three bolts passing through the two plastic plates. A suitable means is provided to suspend the basket-rack assembly from the raising and lowering device, using a point on its axis. The design of the basket-rack assembly may be varied somewhat, provided that the specifications for the glass tubes and the screen mesh size are maintained.

Beaker: Low form, 1000 mL; the difference between the diameter of the plastic plates, which hold the tubes in a vertical position, and the inside diameter of the beaker should be NMT 6 mm.¹

Disks: Each tube is provided with a perforated cylindrical disk 15.3 ± 0.15 mm in thickness and 31.4 ± 0.13 mm in diameter. The disk is made of a suitable, transparent plastic material having a specific gravity of between 1.18 and 1.20. Seven holes 3.15 ± 0.1 mm in diameter extend between the ends of the cylinder, one of the holes being in the center and the other six parallel to it and spaced equally tangent to a circle with a radius of 4.2 mm from the center of the disk. All surfaces of the disk are smooth.²

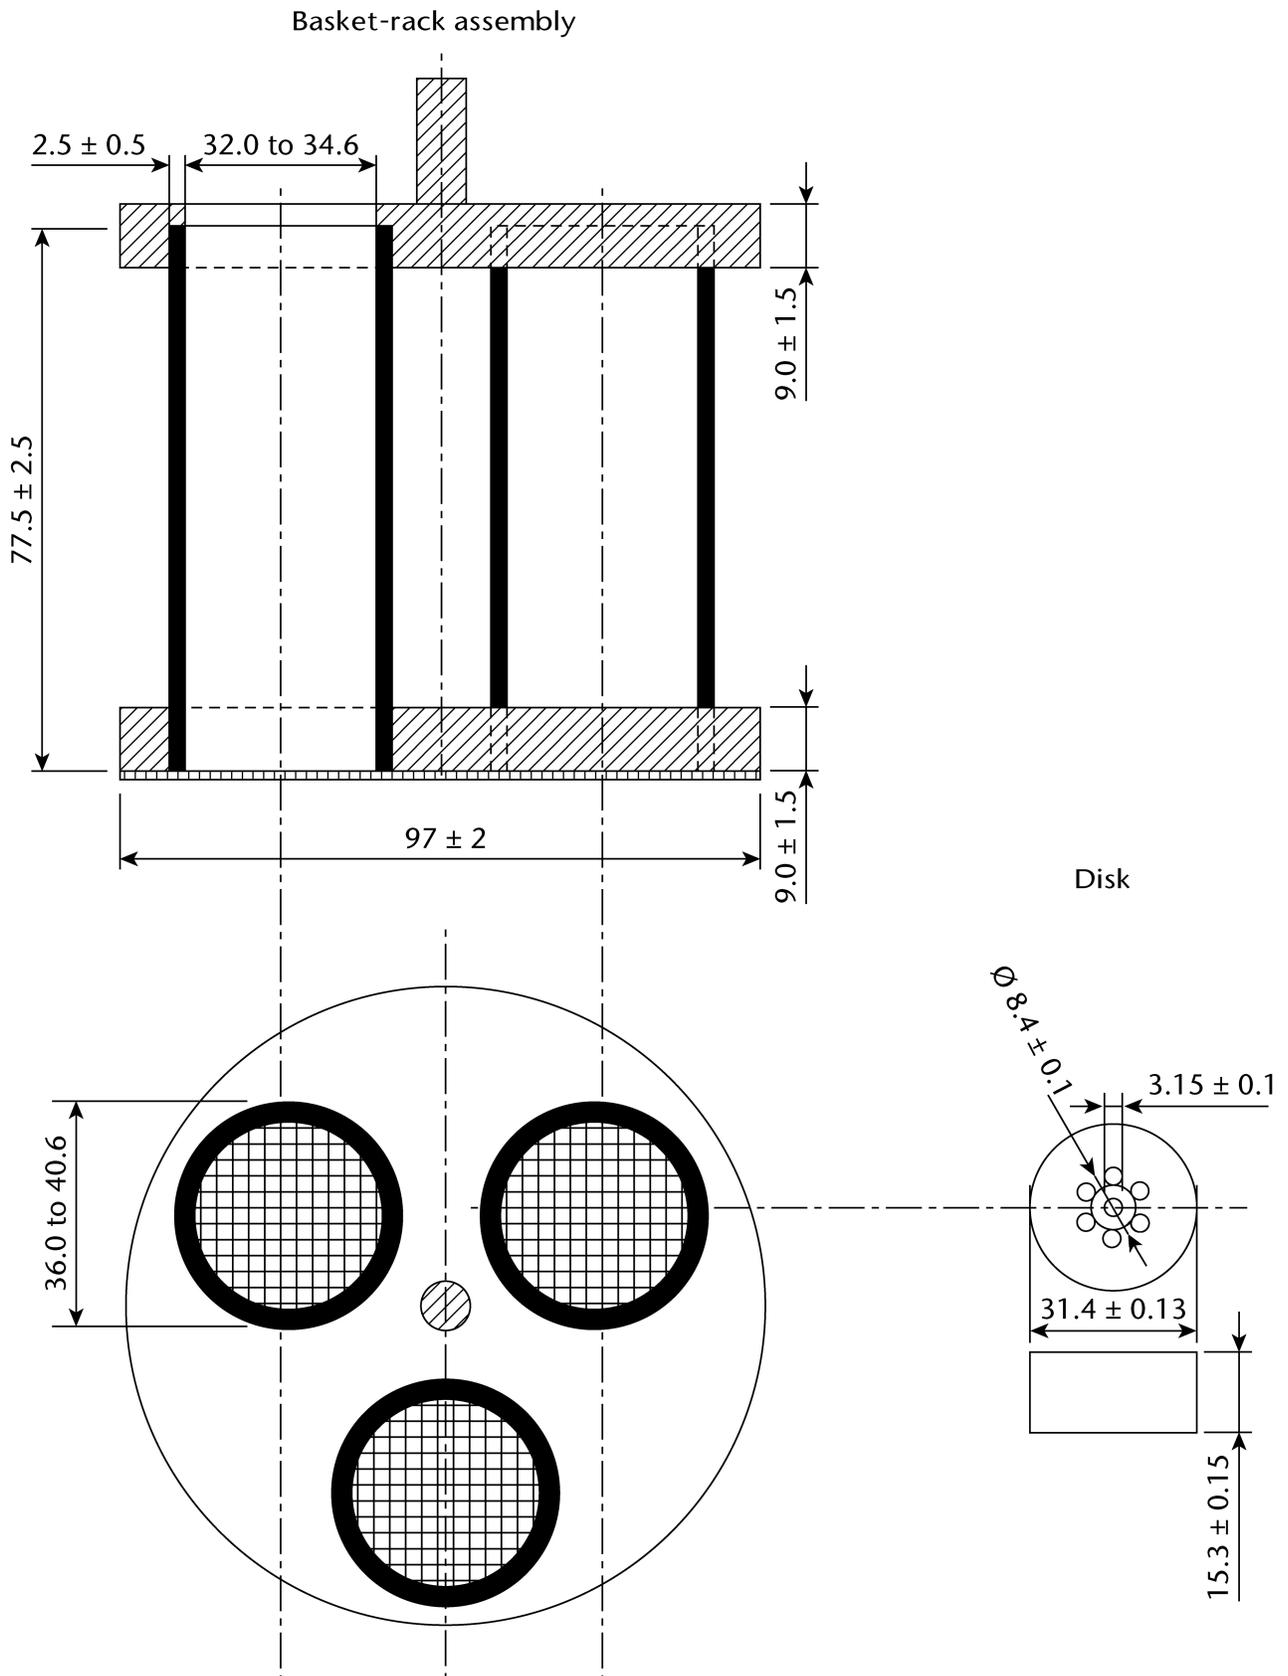

Figure 1. Basket-rack assembly, *Disintegration, Apparatus B* (dimensions in mm).

Procedure

Test 6 dosage units as described below for each type of dosage form. [Note—Two basket arrangements for a total of six tubes are necessary for *Apparatus B*.] If 1 or 2 dosage units fail to disintegrate completely, repeat the test on 12 additional dosage units.

Uncoated tablets: Place 1 tablet in each of the tubes of the basket and, if prescribed, add a disk to each tube. Operate the apparatus, using water or the specified medium as the immersion fluid, maintained at $37 \pm 2^\circ$. At the end of 30 min, lift the basket from the fluid and observe the tablets.

Plain coated tablets: Place 1 tablet in each of the tubes of the basket and, if the tablet has a soluble external sugar coating, immerse the basket in water at room temperature for 5 min. Then, if prescribed, add a disk to each tube and operate the apparatus, using water or the specified medium as the immersion fluid, maintained at $37 \pm 2^\circ$. At the end of 30 min, lift the basket from the fluid and observe the tablets.

Delayed-release (enteric-coated) tablets: Omit the use of a disk. Place 1 tablet in each of the six tubes of the basket, and if the tablet has a soluble external sugar coating, immerse the basket in water at room temperature for 5 min. Then operate the apparatus using simulated gastric fluid TS, maintained at $37 \pm 2^\circ$, as the immersion fluid. After 1 h of operation in simulated gastric fluid TS, lift the basket from the fluid and observe the tablets: the tablets show no evidence of disintegration, cracking, or softening. Operate the apparatus using simulated intestinal fluid TS, maintained at $37 \pm 2^\circ$, as the immersion fluid for the time specified in the monograph. Lift the basket from the fluid and observe the tablets.

Delayed-release (enteric-coated) soft shell capsules: Place 1 softgel capsule in each of the six tubes of the basket. Omit the use of a disk. Operate the apparatus using simulated gastric fluid TS, maintained at $37 \pm 2^\circ$, as the immersion fluid. After 1 h of operation in simulated gastric fluid TS, lift the basket from the fluid and observe the softgels: the softgels show no evidence of disintegration or rupture that would permit the escape of the contents. Operate the apparatus with disks using simulated intestinal fluid TS, maintained at $37 \pm 2^\circ$, as the immersion fluid for NMT 60 min. Lift the basket from the fluid and observe the capsules.

Hard shell capsules: Apply the test for *Uncoated tablets* using as the immersion fluid, maintained at $37 \pm 2^\circ$, a 0.05 M acetate buffer prepared by mixing 2.99 g of sodium acetate trihydrate and 1.66 mL of glacial acetic acid with water to obtain a 1000-mL solution with a pH of 4.50 ± 0.05 . Attach a removable wire cloth, as described in *Basket-rack assembly*, to the surface of the upper plate of the basket-rack assembly. At the end of 30 min, lift the basket from the fluid and observe the capsules.

Soft shell capsules: Proceed as directed in the *Rupture Test for Soft Shell Capsules*.

Use of Disks

Vitamin–mineral dosage forms: Add a disk to each tube unless otherwise specified in the *Procedure* above or in the individual monograph.

Botanical dosage forms: Omit the use of disks unless otherwise specified in the *Procedure* above or in the individual monograph.

Dietary supplements other than vitamin–mineral and botanical dosage forms: Omit the use of disks unless otherwise specified above or in the individual monograph.

Tolerances

All of the 6 dosage units initially tested or NLT 16 of a total of 18 dosage units tested disintegrate completely.

Change to read:

RUPTURE TEST FOR SOFT SHELL CAPSULES

Medium: Water; 500 mL

Apparatus: Use *Apparatus 2* as described in *Dissolution* (711), operating at 50 rpm.

Time: 15 min

Procedure: Place 1 capsule in each vessel, and allow the capsule to sink to the bottom of the vessel before starting rotation of the blade. Use sinkers if the capsules float. ~~Observe the capsules, and record the time taken for each capsule shell to rupture.~~

■ Observe the capsules throughout the test and at the end of the test. The capsule shell is considered ruptured if breached, exposing or allowing to escape the fill contents. ■2S (USP39)

Tolerances: The requirements are met if all of the capsules tested rupture in NMT 15 min. If 1 or 2 of the capsules rupture in >15 min but NMT 30 min, repeat the test on 12 additional capsules: NMT 2 of the total of 18 capsules tested rupture in >15 min but NMT 30 min. ▲ For soft gelatin capsules that do not conform to the above rupture test acceptance criteria, repeat the test with the addition of papain to the *Medium* in the amount that results in an activity of NMT 550,000 Units/L of *Medium* or with the addition of bromelain in the amount that results in an activity of NMT 30 gelatin-digesting units (GDU)/L of *Medium*. [Note—Determine papain activity using the *Assay* test in the monograph for *Papain* and bromelain activity using the procedure in *bromelain*, in the *Reagent Specifications* section.] ▲USP39

Change to read:

DISSOLUTION

This test is provided to determine compliance with the *Dissolution* requirements where stated in the individual monographs for dietary supplements. ▲▲USP39 The operative assumption inherent in this test is that if the index vitamin or mineral or marker compound(s) for a botanical is dissolved within the time frame and under conditions specified, the dosage form does not suffer from formulation- or manufacturing-related problems affecting the adequate release of the active ingredients.

▲

For Dosage Forms Containing or Coated with Gelatin

For hard or soft gelatin capsules and gelatin-coated tablets that do not conform to the dissolution specification because of the presence of cross-linking, the dissolution procedure should be repeated with the addition of enzymes to the medium, as described below.

DISSOLUTION MEDIUM WITH PH \leq 4.0

Enzyme: Pepsin, activity determined by the procedure in *pepsin*, in the *Reagent Specifications* section

Amount: A quantity of pepsin that results in an activity of NMT 750,000 Units/L of dissolution medium

DISSOLUTION MEDIUM WITH PH $>$ 4.0 AND $<$ 6.8

Enzyme: Papain, activity determined by the *Assay* test in the monograph for *Papain*; or bromelain, activity determined by the procedure in *bromelain*, in the *Reagent Specifications* section

Amount: A quantity of papain that results in an activity of NMT 550,000 Units/L of dissolution medium, or a quantity of bromelain that results in an activity of NMT 30 GDU/L of dissolution medium

DISSOLUTION MEDIUM WITH PH \geq 6.8

Enzyme: Pancreatin, protease activity determined by the procedure in *Assay for protease activity (Casein digestive powder)* in the monograph for *Pancreatin*

Amount: A quantity of pancreatin that results in a protease activity of NMT 2,000 Units/L of dissolution medium

DISSOLUTION MEDIUM CONTAINING SURFACTANTS OR OTHER COMPONENTS KNOWN TO DENATURE THE ENZYME

If the dissolution medium contains surfactants or other components known to denature the enzyme to be used, a pretreatment step should be applied. The pretreatment step is performed under the same dissolution conditions (apparatus, rotation, and flow rate), except to use a medium with the corresponding amount of enzyme as directed in the preceding section and without the surfactant or component known to denature the enzyme. To achieve the final specified volume of medium, the pretreatment step may be conducted with a smaller volume of medium without the surfactant or component in such a manner that the final specified volume is achieved after the addition of the surfactant or component at the end of the pretreatment step. Perform the pretreatment step until capsule rupture, but for NMT one-half of the total dissolution time specified in the procedure. The pretreatment time is included in the total dissolution time specified in the procedure.

▲USP39

Apparatus

See <711> for a description of the apparatus used, *Apparatus Suitability Test*, and other related information.

■ Where the procedure specifies the use of a stationary basket, use the quadrangular basket of stainless steel wire gauze as shown in *Figure 2a* and *Figure 2b*.

The capsule is placed in a basket, soldered in one of its upper, narrow sides to the end of a steel rod (see *Figure 2a*). The capsule cover is placed in the horizontal diagonal of the basket. The rod assembly is inserted vertically through the cover of the dissolution vessel, and fixed by

means of two teflon nuts, 3.2 cm from the center of the vessel, or by any other appropriate means. The lower edge of the bottom of the basket is adjusted to about 1 cm above the top of the paddle blade (see *Figure 2b*).

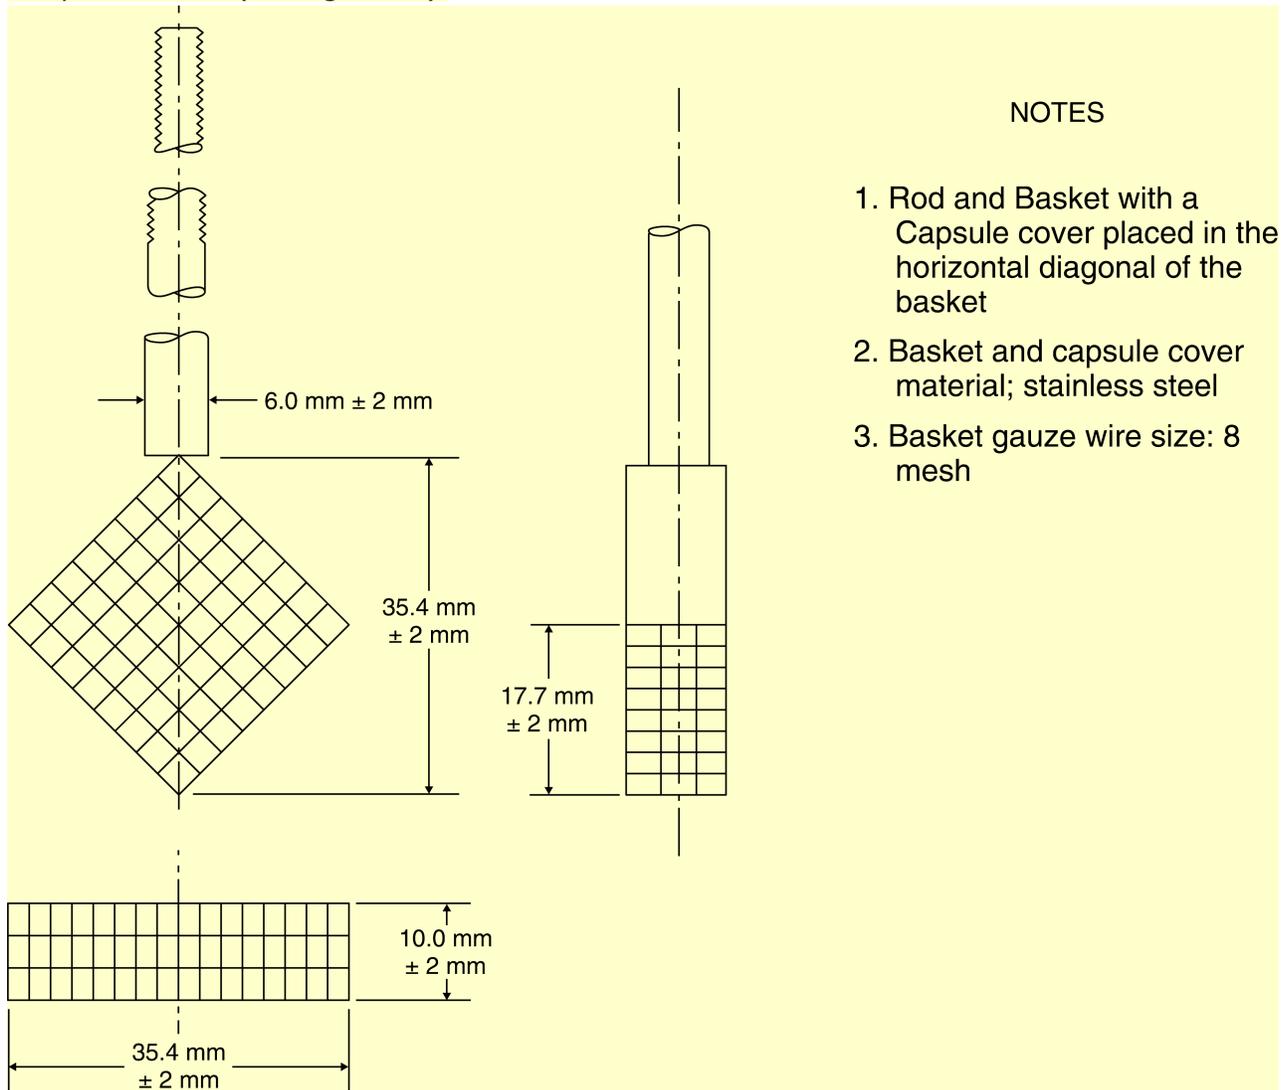

Figure 2a. Stationary Basket

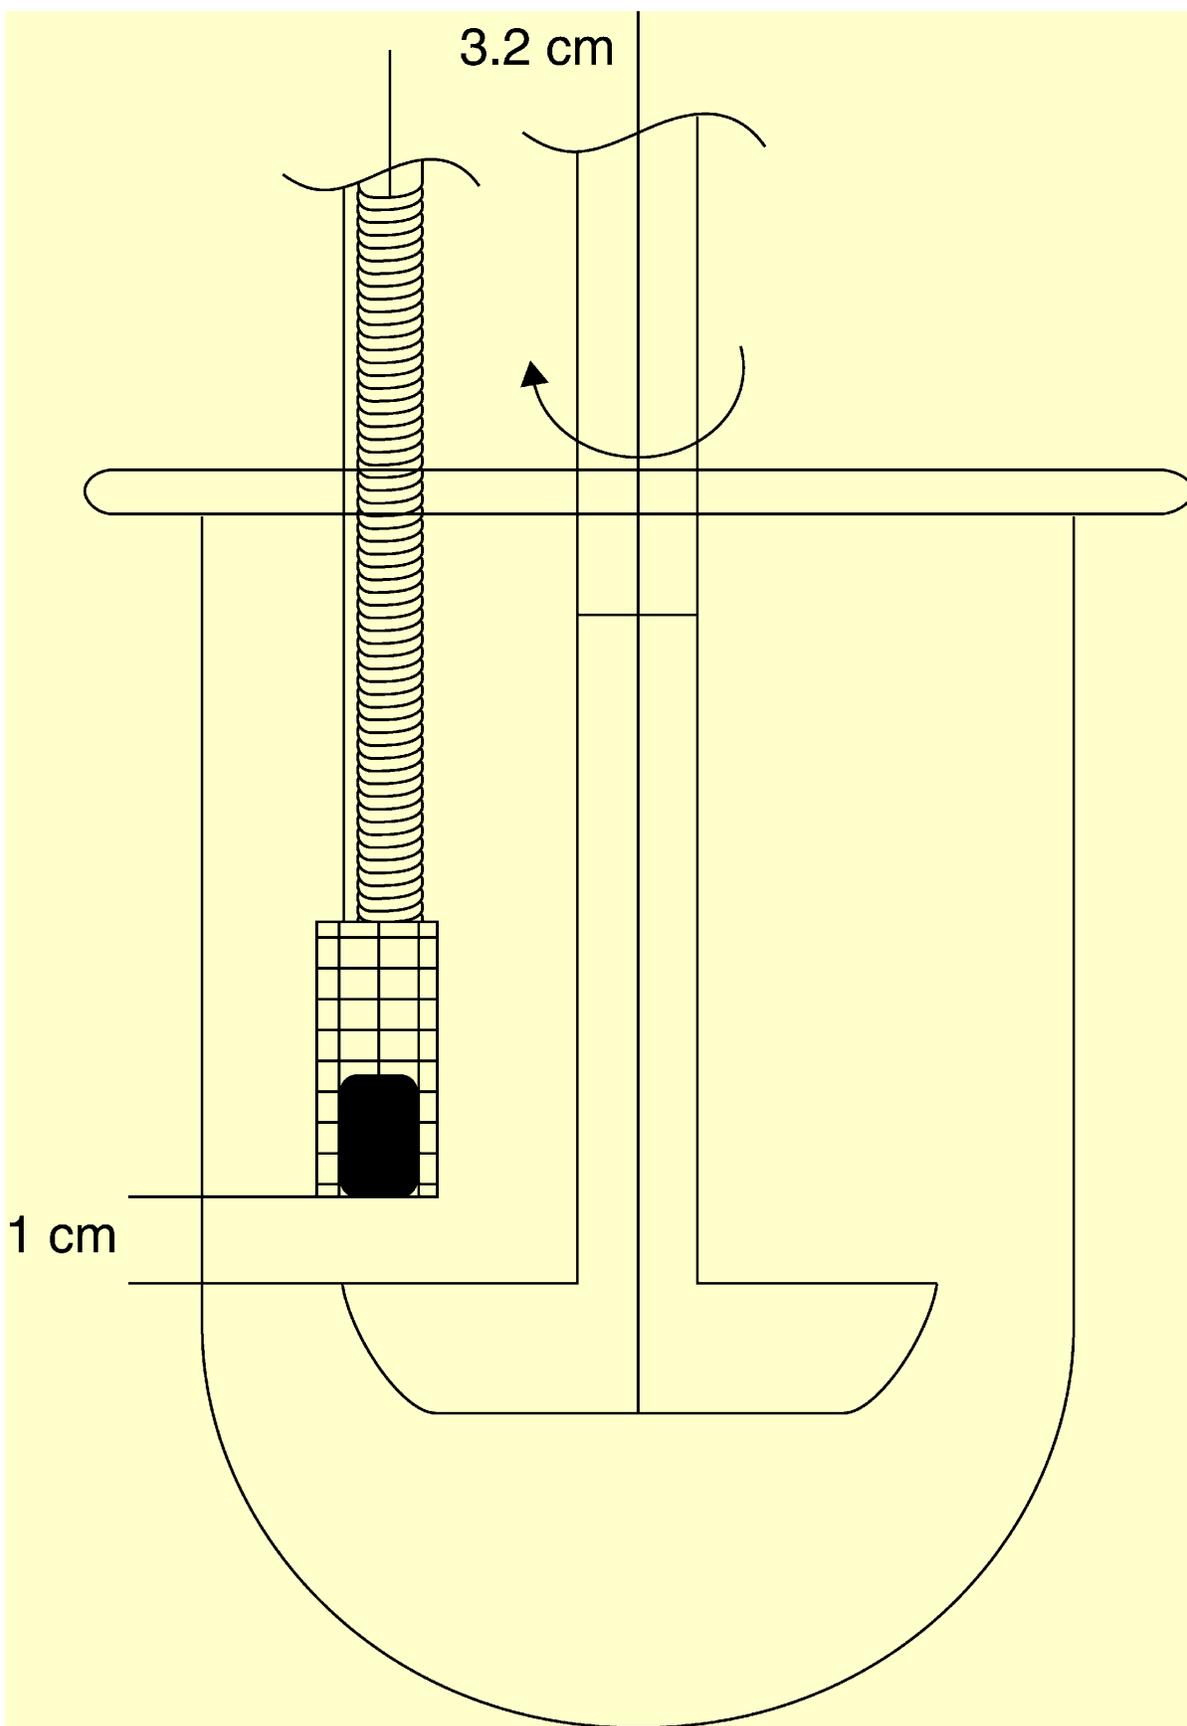

Figure 2b. Stationary Basket Configuration Diagram

~~Figure 2 shows the schematic view of a flow-through cell (USP Apparatus 4) specifically intended for dissolution of lipid-filled soft shell capsules. The lower part [Figure 2 (1)] is made up of two adjacent chambers connected to an overflow device. The dissolution medium passes through chamber A and is subjected to an upward flow. The flow in chamber B is directed downward to a small-size bore exit that leads upward to a filter assembly. The middle part [Figure 2 (2)] of the cell has a cavity designed to collect lipophilic excipients that float on the dissolution medium. A metal grid serves as a rough filter. The upper part [Figure 2 (3)] holds a filter unit for paper, glass fiber, or cellulose filters.~~

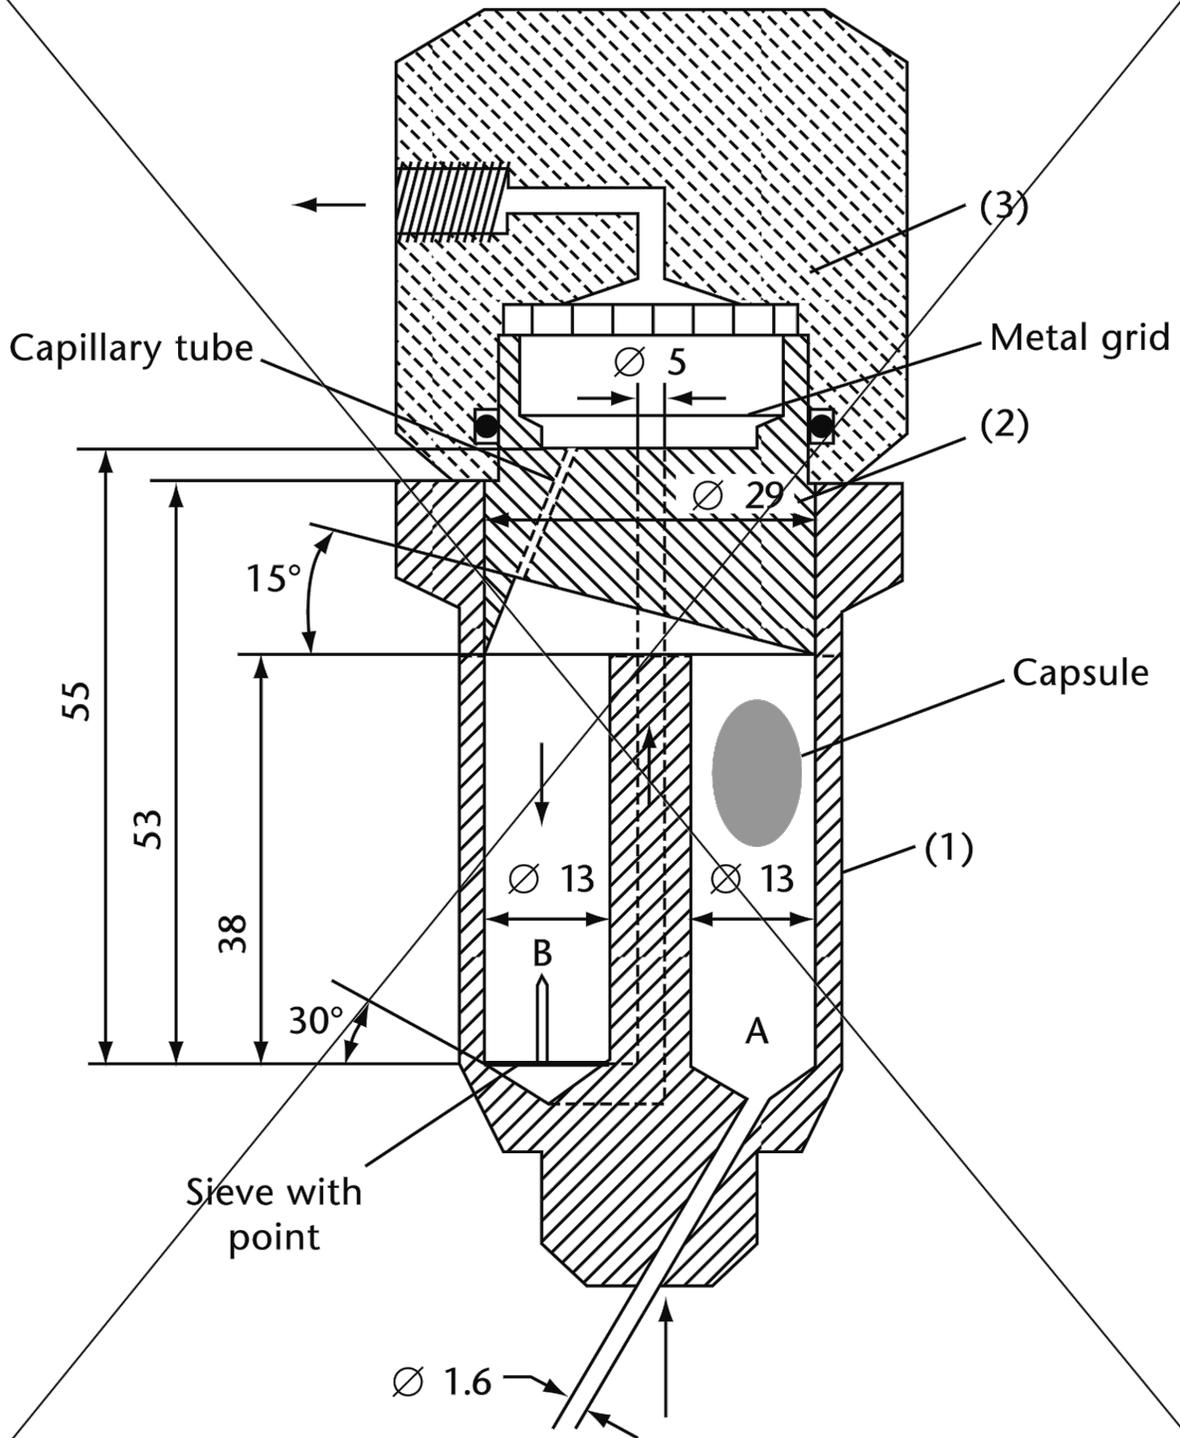

Figure 2. Flow-through cell designed for lipid-filled soft gelatin capsules (dimensions in mm).

■ 2S (USP39)

Of the types of apparatus described in (711), use the one specified in the individual monograph.

▲▲ USP39

Vitamin–Mineral Dosage Forms

All dietary supplement capsules or tablets containing folic acid are subject to the dissolution test and criteria for folic acid described in this chapter. This test is required because of the importance of the relationship between folate deficiency and the risk of neural tube defects. Dietary supplement capsules or tablets containing water-soluble vitamins, minerals, or their combination are subject to the dissolution test and criteria for index vitamins, index minerals, or both, described in this chapter. Dietary supplement tablet and hard shell capsule with solid contents dosage forms containing vitamin A are subject to the dissolution test and criteria for vitamin A described in this chapter. Dissolution standards were not established and therefore are not applicable to vitamin A in dietary supplement soft shell capsules filled with liquids. *Table 1* summarizes the dissolution requirements for the assigned USP classes of dietary supplements. Vitamin–mineral combinations that do not belong to any of the USP classes listed in *Table 1* are subject to the *Dissolution* test and criteria specified in the individual monographs.

Table 1. Dietary Supplements—Vitamin–Mineral Dosage Forms

USP Class	Ingredients	Dissolution Requirements for Tablets and Hard Shell Capsules with Solid Contents	Dissolution Requirements for Soft Shell Capsules Filled with Liquids
I	Oil-soluble vitamins	Vitamin A (if present)	Not applicable
II	Water-soluble vitamins	One index water-soluble vitamin and folic acid (if present)	One index water-soluble vitamin and folic acid (if present)
III	Water-soluble vitamins with minerals	One index water-soluble vitamin, one index element, and folic acid (if present)	One index water-soluble vitamin, one index element, and folic acid (if present)
IV	Oil- and water-soluble vitamins	Vitamin A (if present), one index water-soluble vitamin, and folic acid (if present)	One index water-soluble vitamin and folic acid (if present)
V	Oil- and water-soluble vitamins with minerals	Vitamin A (if present), one index water-soluble vitamin, one index element, and folic acid (if present)	One index water-soluble vitamin, one index element, and folic acid (if present)
VI	Minerals	One index element	One index element
VII	Oil-soluble vitamins with minerals	Vitamin A (if present) and one index element	One index element

SELECTION OF INDEX WATER-SOLUBLE VITAMINS AND INDEX ELEMENTS

Compliance with the dissolution requirements for dietary supplements representing combinations of water-soluble vitamins and combinations of oil- and water-soluble vitamins is determined by measuring the dissolution of a single index vitamin from the water-soluble vitamins present. Riboflavin is the index vitamin when present in the formulation. For formulations that do not contain riboflavin, pyridoxine is the index vitamin. If neither riboflavin nor pyridoxine is present in the formulation, the index vitamin is niacinamide (or niacin), and in the absence of niacinamide (or niacin), the index vitamin is thiamine. If none of these four water-soluble

vitamins are present in the formulation, the index vitamin is ascorbic acid.

Compliance with the dissolution requirements for dietary supplements representing combinations of minerals is determined by measuring the dissolution of only one index element. Iron is the index element when present in the formulation. For formulations that do not contain iron, the index element is calcium. If neither iron nor calcium is present, the index element is zinc. In the absence of all three of these elements, magnesium is the index element.

Compliance with the dissolution requirements for dietary supplements representing combinations of water-soluble vitamins and minerals and combinations of oil- and water-soluble vitamins and minerals is determined by measuring the dissolution of one index water-soluble vitamin and one index element, designated according to the respective hierarchies described above.

DISSOLUTION CONDITIONS FOR VITAMIN A

Note—Perform this test under light conditions that minimize photodegradation.

Medium: 1% (w/v) Sodium ascorbate and 1% (w/v) octoxynol 9 in 0.05 M phosphate buffer, pH 6.8; 900 mL

Apparatus 2: 75 rpm

Time: 45 min

DISSOLUTION CONDITIONS FOR FOLIC ACID

Note—Perform this test under light conditions that minimize photodegradation.

Test 1

Medium: Water; 900 mL. ~~If the units tested do not meet the requirements for dissolution in water, test six additional dosage units for dissolution in a medium of 900 mL of 0.05 M pH 6.0 citrate buffer solution, prepared by mixing 9.5 mL of 0.1 M citric acid monohydrate and 40.5 mL of 0.1 M sodium citrate dihydrate in a 100 mL volumetric flask, diluting with water to volume, mixing, and adjusting to a pH of 6.0 by using either 0.1 M hydrochloric acid or 0.1 M sodium hydroxide solution.~~

■ ■2S (USP39)

Apparatus 1: 100 rpm, for capsules

Apparatus 2: 75 rpm, for tablets

Time: 1 h

■ If the units tested do not meet the requirements for dissolution in water, use the following conditions:

Buffer: Mix 95 mL of 0.1 M citric acid monohydrate and 405 mL of 0.1 M sodium citrate dihydrate, dilute to 1000 mL with water, mix, and adjust to a pH of 6.0 by using either 0.1 M hydrochloric acid or 0.1 M sodium hydroxide solution.

Medium: Buffer; 900 mL

Apparatus 1: 100 rpm, for capsules

Apparatus 2: 75 rpm, for tablets

Time: 1 h ■2S (USP39)

Test 2

■ **(for lipid-filled soft shell capsules):** Proceed as directed for *Test 2* under *Dissolution Conditions for Index Water-Soluble Vitamins and Index Minerals*. ■_{2S} (USP39)

If the article complies with this test, the labeling indicates that it meets USP *Dissolution Test 2*.

~~Medium:~~ 45 mM citrate buffer, pH 6.0; 250 mL

~~Apparatus 3:~~ 30 rpm

~~Screen (top and bottom):~~ 56 mesh

~~Time:~~ 1 h

■

Test 3 (for lipid-filled soft shell capsules): Proceed as directed for *Test 3* under *Dissolution Conditions for Index Water-Soluble Vitamins and Index Minerals* If the article complies with this test, the labeling indicates that it meets USP *Dissolution Test 3*. ■_{2S} (USP39)

Note—Compliance with the dissolution requirements for folic acid does not exempt the article from compliance with the dissolution requirements of the pertinent index vitamin or the corresponding index mineral.

DISSOLUTION CONDITIONS FOR INDEX WATER-SOLUBLE VITAMINS AND INDEX MINERALS

Test 1

Medium: 0.1 N hydrochloric acid; 900 mL

Apparatus 1: 100 rpm, for capsules

Apparatus 2: 75 rpm, for tablets

Time: 1 h

For formulations containing 25 mg or more of the index vitamin, riboflavin, use the following conditions:

Medium: 0.1 N hydrochloric acid; 1800 mL

Apparatus 1: 100 rpm, for capsules

Apparatus 2: 75 rpm, for tablets

Time: 1 h

Test 2 (not suitable for minerals)

■ **(for lipid filled soft shell capsules):** ■_{2S} (USP39)

If the article complies with this test, the labeling indicates that it meets USP *Dissolution Test 2*.

~~Medium:~~ 45 mM citrate buffer, pH 6.0; 250 mL

■ 0.25% (w/v) Octoxynol 9, 0.02% (w/v) ascorbic acid, and 0.04% (w/v) simethicone in simulated gastric fluid TS ■_{2S} (USP39)

~~Apparatus 3:~~ 30 rpm

■ 15 rpm ■_{2S} (USP39)

Screen (top and bottom): 56-mesh

■ 20-mesh ■ 2S (USP39)

Time: 1 h

■ **Test 3 (for lipid-filled soft shell capsules):** If the article complies with this test, the labeling indicates that it meets USP *Dissolution Test 3*.

Medium: 0.25% (w/v) Octoxynol 9 and 0.02% (w/v) ascorbic acid in simulated gastric fluid TS; 500 mL

Apparatus 2: 125 rpm; dosage unit placed in stationary basket (*Figure 2a-b*)

Time: 1 h

■ 2S (USP39)

Note—Compliance with dissolution requirements for the pertinent index vitamin or index mineral does not exempt the article from compliance with the dissolution requirements for folic acid, if present.

PROCEDURES

In the following procedures, combine equal volumes of the filtered solutions of the six individual specimens withdrawn, and use the pooled sample as the test specimen. Determine the average amount of vitamin A, folic acid, or the index vitamin or element dissolved in the pooled sample. Make any necessary modifications, including concentration of the analyte in the volume of *Sample solution* taken. Use the *Medium* for preparation of the *Standard solution* and dilution, if necessary, of the *Sample solution*.

Vitamin A: Determine the percentage of retinyl acetate or retinyl palmitate dissolved by using the following procedure.

Standard solution: Dissolve a suitable amount of *USP Retinyl Acetate RS* or *USP Retinyl Palmitate RS* in isopropyl alcohol, and dilute with *Medium* to obtain a concentration similar to that expected in the *Sample solution*. [Note—The amount of isopropyl alcohol should be 5%–10%.]

Sample solution: Withdraw a portion of the solution under test, pass through a suitable filter of 0.45- μ m pore size, and use the pooled sample as the test specimen.

Solution A: Methanol and water (90:10)

Solution B: Methanol and isopropyl alcohol (55:45)

Mobile phase: See *Table 2*.

Table 2

Time (min)	Solution A (%)	Solution B (%)
0	100	0
8	0	100
13	0	100
13.1	100	0
15	100	0

Chromatographic system(See *Chromatography* (621), *System Suitability*.)**Mode:** LC**Detector:** UV 325 nm**Column:** 4.6-mm × 10-cm; 3-µm packing L1**Flow rate:** 1.0 mL/min**Injection volume:** 50 µL**System suitability****Sample:** *Standard solution***Suitability requirements****Tailing factor:** NMT 1.5 for retinyl acetate and NMT 2.0 for retinyl palmitate**Relative standard deviation:** NMT 2.0%**Analysis****Samples:** *Appropriate Standard solution and Sample solution*

$$\text{Result} = (r_U/r_S) \times (C_S \times V/L) \times 100$$

 r_U = peak area of the all-*trans*-retinyl ester from the *Sample solution* r_S = peak area of the all-*trans*-retinyl ester from the appropriate *Standard solution* C_S = concentration of retinol in the appropriate *Standard solution* (µg/mL) V = volume of *Medium*, 900 mL L = label claim of vitamin A, as retinol (µg/tablet)

Folic acid: Determine the amount of folic acid (C₁₉H₁₉N₇O₆) dissolved by using the procedure set forth in the assay for *Folic Acid* in the individual monograph. Make any necessary modifications.

Niacin or Niacinamide, Pyridoxine, Riboflavin, and Thiamine: Determine the amount of the designated index vitamin dissolved by using the procedure set forth in the *Assay for Niacin or Niacinamide, Pyridoxine Hydrochloride, Riboflavin, and Thiamine* in the individual monographs. Make any necessary modifications.

Ascorbic acid: Determine the amount of ascorbic acid ($C_6H_8O_6$) dissolved by using the procedure set forth in the *Assay for Ascorbic Acid* in the individual monograph. Make any necessary modifications.

Iron, Calcium, Magnesium, and Zinc: Determine the amount of the designated index element dissolved by using the procedure set forth in the appropriate assay in the individual monographs. Make any necessary modifications.

TOLERANCES

The requirements are met if NLT 75% of the labeled content of vitamin A, NLT 75% of the labeled content of folic acid, and NLT 75% of the labeled content of the index vitamin or the index element from the units tested is dissolved.

Botanical Dosage Forms

Compliance with dissolution requirements necessitates the testing of 6 dosage units individually, or testing 2 or more dosage units in each of the six vessels of the dissolution apparatus, and measuring the dissolution of one or more index/marker compound(s) or the extract specified in the individual monograph.

PROCEDURES

Combine equal volumes of the filtered solutions of the six or more individual specimens withdrawn, and use the pooled sample as the *Sample solution*. Determine the average amount of index or marker compound(s) or the extract dissolved in the pooled sample by the procedure specified in the individual monograph. Make any necessary modifications, including concentration of the analyte in the volume of the *Sample solution* taken. Use the *Medium* for preparation of the *Standard solution* and dilution, if necessary, of the *Sample solution*.

TOLERANCES

Unless otherwise specified in the individual monograph, the requirements are met if NLT 75% of the labeled content of the index or marker compound(s) or the extract from the units tested is dissolved in 1 h.

Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms

Unless otherwise stated in the individual monographs for dietary supplement dosage forms in this category, compliance requires the testing of 6 individual units, measuring the dissolution of the dietary ingredient as the average of the 6 units tested.

PROCEDURES

Combine equal volumes of the filtered solutions of the six specimens withdrawn, and use the pooled sample as the *Sample solution*. Determine the average amount of the dietary ingredient dissolved in the pooled sample by the procedure specified in the individual monograph. Make any necessary modifications, including concentration of the analyte in the volume of the *Sample solution* taken. Use the *Medium* for preparation of the *Standard solution* and for dilution, if necessary, of the *Sample solution*.

TOLERANCES

Because of the diversity of chemical characteristics and solubilities of dietary ingredients pertaining to this category, general tolerances cannot be established. See individual monographs for *Tolerances*.

~~USP Reference Standards (11)~~

~~USP Folic Acid RS~~

~~USP Retinyl Acetate RS~~

~~USP Retinyl Palmitate RS~~

■ ■ 2S (USP39)

¹ 1000-mL low-form beakers, designed in compliance with the current ASTM E 960 Type I or Type II or ISO 3819 specifications, meet the size requirements.

² The use of automatic detection using modified disks is permitted where the use of disks is specified or allowed. Such disks must comply with the requirements for density and dimensions given in this chapter.

BRIEFING

(2750) **Manufacturing Practices for Dietary Supplements**, *USP* 38 page 1789 and page 1319 of *PF* 35(5) [Sept.–Oct. 2009]. On the basis of comments received, the Food Ingredients Expert Committee proposes to revise this general chapter. The revisions are intended to align the text with current regulatory standards. Relevant sections in this chapter, particularly *Record Keeping* and *Testing and Approval or Rejection*, are revised.

Additionally, minor editorial changes have been made to update the chapter to current *USP* style.

(FI: C. Okunji.)

Correspondence Number—C160476

Comment deadline: November 30, 2015

(2750) MANUFACTURING PRACTICES FOR DIETARY SUPPLEMENTS**GENERAL PROVISIONS**

The principles included in this chapter contain recommended minimum current good manufacturing practices for the methods to be used in, and the facilities and controls to be used for, the manufacture, holding, packaging, labeling, and distribution of dietary ingredients and dietary supplements. These principles are set forth to ensure that such products meet the requirements of safety, have the identity and strength, and meet the quality and purity characteristics that they are represented to possess.

Excluded from this chapter are establishments engaged solely in the harvesting, storage, or distribution of one or more “raw agricultural commodities” as defined in Section 201(r) of the Federal Food, Drug, and Cosmetic Act [21 U.S.C. 321(r)], which are ordinarily cleaned, prepared, treated, or otherwise processed before being marketed to the consuming public.

The requirements pertaining to holding dietary ingredients and dietary supplements do not apply

to holding those dietary supplements at a retail establishment for the sole purpose of direct retail sale to individual consumers. A retail establishment does not include a warehouse or other storage facility for a retailer or a warehouse or other storage facility that sells directly to individual consumers.

A *Glossary* of terms used in this chapter is presented at the end.

ORGANIZATION AND PERSONNEL

Responsibilities of a Quality Control Unit

A quality control unit shall be established that has the responsibility and authority to approve or reject all raw materials, product containers, closures, in-process materials, packaging material, labeling, and finished dietary supplements, and the authority to review production records to ensure that no errors have occurred or, if errors have occurred, that they have been fully investigated. The quality control unit should be responsible for approving or rejecting products manufactured, processed, packed, or held under contract by another company. Adequate laboratory facilities for the testing and approval (or rejection) of raw materials, product containers, closures, packaging materials, in-process materials, dietary ingredients, and dietary supplements should be available to the quality control unit.

The quality control unit should have the responsibility for approving or rejecting all procedures or specifications that impact on the identity, strength, quality, and purity of the dietary supplement. All responsibilities and procedures applicable to the quality control unit shall be in writing.

The designated person within the Quality Control Unit who conducts a material review and makes the disposition decision must, at the time of performance, document the material review and disposition decision made.

Personnel Qualifications

Each person engaged in the manufacture of dietary ingredients and dietary supplements should have the proper education, training, and experience (or any combination thereof) needed to perform the assigned functions. Training should be in the particular operation(s) that the employee performs as they relate to the employee's functions. Each person responsible for supervising the manufacture of a dietary ingredient, a dietary supplement, or both should have the proper education, training, and experience (or any combination thereof) to perform assigned functions in such a manner as to provide assurance that the product has the safety, identity, strength, quality, and purity that it is represented to possess. Appropriate documentation of training shall be retained by the company.

An adequate number of qualified personnel to perform and supervise the manufacture of each dietary ingredient, dietary supplement, or both products should be provided.

Personnel Responsibilities

The company management shall take all reasonable measures and precautions to ensure the following:

- **Disease control:** Any person who, by medical examination or supervisory observation, is shown to have, or appears to have: an illness; open lesion, including boils, sores, or infected wounds; or any other abnormal source of microbial contamination by which

there is a reasonable possibility of an in-process or finished dietary ingredient or dietary supplement becoming adulterated; or processing equipment, utensils, or packaging materials becoming contaminated shall be excluded from any operations that may be expected to result in such adulteration or contamination until the condition is corrected. Personnel shall be instructed to report such health conditions to their supervisors.

- **Cleanliness:** All persons working in direct contact with raw materials, in-process or finished dietary ingredients and dietary supplements, processing equipment, utensils, or packaging materials shall conform to hygienic practices while on duty to the extent necessary to protect against adulteration or contamination of such materials. The methods for maintaining cleanliness include, but are not limited to, the following:
 - Wearing outer garments suitable to the operation in a manner that protects against the adulteration of raw materials or of in-process or finished dietary ingredients and dietary supplements, or contamination of processing equipment, utensils, or packaging materials;
 - Maintaining adequate personal cleanliness;
 - Removing cosmetics from parts of the body that may contact raw materials, in-process or finished dietary ingredients and dietary supplements, equipment, utensils, or containers;
 - Washing hands thoroughly (and sanitizing if necessary to protect against contamination with undesirable microorganisms) in an adequate hand-washing facility before starting work, after each absence from the work station, and at any other time when the hands may have become soiled or contaminated;
 - Removing all unsecured jewelry and other objects that might fall into raw materials, in-process or finished dietary ingredients and dietary supplements, equipment, or containers, and removing hand jewelry that cannot be adequately sanitized during periods in which in-process or finished product is manipulated by hand. If such hand jewelry and cosmetics cannot be removed, they may be covered by material that can be maintained in an intact, clean, and sanitary condition and that effectively protects against the adulteration of dietary ingredients and dietary supplements or contamination of processing equipment, utensils, or packaging materials;
 - Maintaining gloves, if they are used in raw materials or in in-process or finished product handling, in an intact, clean, and sanitary condition. The gloves should be of a material that adequately protects the product from contamination;
 - Wearing, where appropriate, in an effective manner, hair nets, caps, beard covers, or other effective hair restraints;
 - Storing clothing or other personal belongings in areas other than where in-process or finished product is exposed or where processing equipment or utensils are washed;
 - Confining the following actions to areas other than where in-process or finished product may be stored or exposed, or where processing equipment or utensils are washed: eating food, chewing gum, drinking beverages, or using tobacco; and
 - Taking any other necessary precautions to protect against adulteration of raw materials or of in-process or finished product; or contamination of processing equipment, utensils, or packaging materials with microorganisms or foreign substances, including but not limited to, perspiration, hair, cosmetics, tobacco, chemicals, and medicines applied to the skin.

GROUND, BUILDING, AND FACILITIES

Grounds

The grounds around a dietary ingredient manufacturing plant and a dietary supplement manufacturing plant under the control of the operator shall be kept in a condition that will protect against the adulteration of dietary ingredients and dietary supplements. The methods for adequate maintenance of grounds include, but are not limited to, the following:

- Properly storing equipment, removing litter and waste, and cutting weeds or grass within the immediate vicinity of the plant building or structures that may constitute an attractant, breeding place, or harborage for pests;
- Maintaining roads, yards, and parking lots so that they do not constitute a source of adulteration in areas where product is exposed;
- Adequately draining areas that may contribute to product adulteration by seepage, foot-borne filth, or providing a breeding place for pests; and
- Operating systems for waste treatment and disposal in an adequate manner so that they do not constitute a source of adulteration in areas where product is exposed. If the plant grounds are bordered by grounds not under the operator's control and not maintained in the manner described above, care shall be exercised in the plant by inspection, extermination, or other means to exclude pests, dirt, and filth that may be a source of product adulteration.

Building Design

Any building or buildings used in the manufacture of a dietary ingredient, a dietary supplement, or both should be of suitable size and shall be constructed in such a manner that floors, walls, and ceilings may be adequately cleaned and kept clean and in good repair; that drips or condensates from fixtures, ducts, and pipes do not adulterate raw materials or in-process or finished dietary ingredients and dietary supplements, or contaminate product containers, utensils, or packaging materials; and that aisles or working spaces are provided between equipment and walls and are adequately unobstructed and of adequate width to permit employees to perform their duties and to protect against adulterating in-process or finished product, or contaminating processing equipment with clothing or personal contact. Adequate screening or other protection against pests and insects should be installed, where necessary. The building should have adequate space for the orderly placement of equipment and materials to prevent mixups between different raw materials, product containers, closures, labeling, in-process materials, or finished products, and to prevent contamination. The flow of raw materials, product containers, closures, labeling, in-process materials, and products through the building or buildings should be designed to prevent contamination.

Operations should be performed within specifically defined areas of adequate size to prevent contamination or mixups or adulteration of in-process or finished dietary ingredients and dietary supplements, or contamination of processing equipment, utensils, or packaging materials with microorganisms, chemicals, filth, or other extraneous materials. The potential for mixups and product adulteration may be reduced by adequate product safety controls and operating practices or effective design, including the separation of operations in which contamination is likely to occur, by one or more of the following means: location, time, partition, airflow, enclosed systems, or other effective means. There should be separate or defined areas as

follows:

- An area for the receipt, identification, storage, and withholding from use of components, product containers, closures, and labeling, pending the appropriate sampling, testing, or examination by the quality control unit before release for manufacturing or packaging;
- An area for the storage of released components, product containers, closures, and labeling;
- An area for storage of in-process materials;
- An area for manufacturing and processing operations;
- An area for packaging and labeling operations; and
- An area for control and laboratory operations.

Any building used in the manufacture of a dietary ingredient or a dietary supplement shall permit the taking of proper precautions to protect dietary ingredients or dietary supplements in outdoor bulk fermentation vessels by any effective means, including the following:

- Using protective coverings,
- Controlling areas over and around the vessels to eliminate harborage for pests,
- Checking on a regular basis for pests and pest infestation, and
- Skimming the fermentation vessels, as necessary.

Lighting

Adequate lighting shall be provided in all areas and should not expose bulk or finished product to adulteration or contamination. Adequate lighting should be provided in hand-washing areas, dressing and locker rooms, and toilet rooms, and in all areas where product is examined, processed, or stored and where equipment or utensils are cleaned; and such lighting should provide safety-type light bulbs, fixtures, skylights, or other glass suspended over exposed product in any step of preparation or otherwise protect against product adulteration in case of glass breakage.

Ventilation, Air Filtration, Air Heating, and Cooling

Adequate ventilation shall be provided, as well as equipment for adequate control over microorganisms, dust, humidity, and temperature when used in the manufacture of a dietary ingredient and a dietary supplement to minimize odors and vapors (including steam and noxious fumes) in areas where they may adulterate dietary ingredients and dietary supplements; and to locate and operate fans and other air-blowing equipment in a manner that minimizes the potential for adulterating raw materials, in-process or finished dietary ingredients and dietary supplements, or contaminating processing equipment, utensils, or packaging materials.

Plumbing

The plumbing in the physical plant must be of an adequate size and design and be adequately installed and maintained to:

- Carry sufficient amounts of water to the required locations throughout the physical plant;
- Properly convey sewage and liquid disposable waste from the physical plant; and
- Avoid being a source of contamination to components, raw materials, dietary

ingredients, dietary supplements, water supplies, or any contact surface, or creating an unsanitary condition.

Potable water at a suitable temperature, and under pressure as needed, should be supplied in a plumbing system free of defects that could contribute contamination to any dietary ingredients and dietary supplements. Potable water should meet the standards prescribed in the Environmental Protection Agency's Primary Drinking Water Regulations (40 CFR Part 141) or any state or local drinking water requirements that are more stringent. Water not meeting such standards should not be permitted in the potable water system for *Purified Water*. If potable water is to be used as a raw material, it should be further purified to satisfy compendial requirements.

Drains should be of adequate size and, where connected directly to a sewer, should have an air break or other mechanical device to prevent back-siphonage.

Sewage and Refuse

Sewage, trash, and other refuse in and from the building and immediate premises shall be disposed of in a safe and sanitary manner.

Washing and Toilet Facilities

Adequate washing facilities shall be provided, including hot and cold water, soap or detergent, air driers or single-service towels, and clean toilet facilities easily accessible to working areas.

General Maintenance and Sanitation

Any building used in the manufacture of a dietary ingredient, a dietary supplement, or both should be maintained in a clean and sanitary condition and shall be kept in repair sufficient to prevent raw materials and in-process or finished dietary ingredients and dietary supplements from becoming adulterated. It shall be free of infestation by rodents, birds, insects, and other vermin. Trash and organic waste matter shall be held and disposed of in a timely and sanitary manner.

Cleaning compounds and sanitizing agents used in cleaning and sanitizing procedures shall be free from undesirable microorganisms and shall be safe and adequate under the conditions of use. Compliance with this requirement may be verified by any effective means, including purchase of these substances under a supplier's guarantee or certification, or examination of these substances for contamination. Only the following toxic materials may be used or stored in a plant where product is processed or exposed:

- Those required to maintain clean and sanitary conditions,
- Those necessary for use in laboratory testing procedures,
- Those necessary for plant and equipment maintenance and operation, and
- Those necessary for use in the plant's operations.

Written procedures assigning responsibility for sanitation and describing in sufficient detail the cleaning schedules, methods, equipment, and materials to be used in cleaning the building and facilities shall be required.

Toxic cleaning compounds, sanitizing agents, and pesticide chemicals shall be identified, used, held, and stored in a manner that protects against adulteration of raw materials or of in-

process or finished product, or contamination of processing equipment or packaging materials. All relevant regulations promulgated by other federal, state, and local government agencies for the application, use, or holding of these products should be followed.

No pests shall be allowed in any area of a dietary ingredient manufacturing plant and a dietary supplement manufacturing plant. Effective measures shall be taken to exclude pests from the processing areas and to protect against the adulteration by pests of product on the premises. The use of insecticides or rodenticides is permitted only under precautions and restrictions that will protect against the adulteration of raw materials, in-process or finished product, or contamination of processing equipment, utensils, or packaging materials.

Written procedures are also required for use of suitable rodenticides, insecticides, fungicides, fumigating agents, and cleaning and sanitizing agents. These procedures should be designed to prevent the contamination of equipment, raw materials, product containers, closures, packaging, labeling materials, or products. Rodenticides, insecticides, and fungicides should be registered and used in accordance with the Federal Insecticide, Fungicide, and Rodenticide Act. Sanitation procedures shall apply to work performed by contractors or temporary employees as well as work performed by full-time employees during the ordinary course of operations.

EQUIPMENT AND UTENSILS

Equipment and utensils used in the manufacture of dietary ingredients and dietary supplements shall be of appropriate design or selection, adequate size, and suitably located to facilitate operations for its intended use and for its cleaning and maintenance and to ensure that the specifications of dietary ingredients and dietary supplements are correct and are met.

Equipment and utensils include, but are not limited to, the following:

- Equipment used to hold or convey;
- Equipment used to measure;
- Equipment using compressed air or gas;
- Equipment used to carry out processes in closed pipes and vessels; and
- Equipment used in automatic, mechanical, or electronic systems.

Construction

All equipment and utensils shall be:

- Constructed so that surfaces that contact raw materials, in-process materials, or finished products are not reactive, additive, or absorptive so as to alter the safety, identity, strength, quality, or purity of the product beyond the established requirements;
- Made of nontoxic materials;
- Designed and constructed to withstand the environment in which they are used; the action of raw materials, in-process materials, dietary ingredients, or dietary supplements; and, if applicable, cleaning compounds and sanitizing agents; and
- Maintained to protect raw materials, in-process materials, dietary ingredients, and dietary supplements from being contaminated by any source.

Equipment and utensils must have seams that are smoothly bonded or maintained to minimize the accumulation of dirt, filth, organic material, particles of raw materials, in-process materials, dietary ingredients, or dietary supplements, or any other extraneous materials or contaminants,

to minimize the opportunity for growth of microorganisms.

Each freezer, refrigerator, and cold storage compartment used to hold raw materials, in-process materials, dietary ingredients, or dietary supplements:

- Must be fitted with an indicating thermometer, temperature-measuring device, or temperature-recording device that shows, indicates, and records, or allows for recording by hand, the temperature accurately within the compartment; and
- Must have an automated device for regulating temperature or an automated alarm system to indicate a significant temperature change in a manual operation.

The design, construction, and use of equipment and utensils shall preclude the adulteration of raw materials, packaging materials, in-process materials, or finished product with any substances required for operation, such as:

- Lubricants,
- Fuel,
- Coolants,
- Metal or glass fragments,
- Filth or any other extraneous material,
- Contaminated water, or
- Any other contaminants.

Instruments or controls used in the manufacturing, packaging, labeling, or holding of a dietary ingredient, a dietary supplement, or both; and instruments or controls that are used to measure, regulate, or record temperatures, hydrogen-ion concentration (pH), water activity, or other conditions, and to control or prevent the growth of microorganisms or other contamination must be:

- Accurate and precise,
- Adequately maintained, and
- Adequate in number for their designated uses.

For any automated, mechanical, or electronic equipment that is used to manufacture, package, label, or hold a dietary ingredient, a dietary supplement, or both:

- The suitability of the equipment must be determined by ensuring that the equipment is capable of operating satisfactorily within the operating limits required by the process;
- The equipment must be routinely calibrated, inspected, or checked to ensure proper performance. The quality control unit must approve these calibrations, inspections, or checks;
- The appropriate controls for automated, mechanical, and electronic equipment (including software for a computer-controlled process) must be established and used to ensure that any changes to the manufacturing, packaging, labeling, holding, or other operations are approved by the quality control unit and instituted only by authorized personnel; and
- The appropriate controls must be established and used to ensure that the equipment functions in accordance with its intended use. These controls must be approved by the quality control unit.

Compressed air or other gases introduced mechanically into or onto raw materials, in-process materials, dietary ingredients, dietary supplements, or contact surfaces, or that are used to clean any contact surface, must be treated in such a way that the raw material, in-process

material, dietary ingredient, dietary supplement, or contact surface is not contaminated.

Cleaning and Maintenance

Equipment and utensils shall be cleaned, maintained, and sanitized at adequate intervals, between the manufacture of different batches of the same product and between the manufacture of different products, to prevent malfunctions or contamination that would alter the safety, identity, strength, quality, or purity of the product beyond the established requirements.

In wet processing during manufacturing, all contact surfaces must be cleaned and sanitized, as necessary, to protect against the introduction of microorganisms into components, dietary ingredients, or dietary supplements. When cleaning and sanitizing are necessary, all contact surfaces must be cleaned and sanitized before use and after any interruption during which the contact surface may have become contaminated.

In a continuous production operation or in back-to-back consecutive operations, which involve different batches of the same dietary ingredient or dietary supplement, the contact surfaces must be adequately cleaned and sanitized.

The surfaces that do not come into direct contact with raw materials, in-process materials, dietary ingredients, or dietary supplements must be cleaned as frequently as necessary to protect against contaminating raw materials, in-process materials, dietary ingredients, or dietary supplements.

Single-service articles (such as utensils intended for one-time use, paper cups, and paper towels) must be:

- Stored in appropriate containers; and
- Handled, dispensed, used, and disposed of in a manner that protects against contamination of raw materials, in-process materials, dietary ingredients, dietary supplements, or any contact surface.

Cleaning compounds and sanitizing agents must be adequate for their intended use and safe under their conditions of use.

The portable equipment and utensils that have contact surfaces must be cleaned, sanitized, and then stored in a location and manner that protects them from contamination.

Written procedures for cleaning and maintaining equipment, including utensils, used in the manufacture of a product should be established and followed. These procedures should include, but are not necessarily limited to, the following:

- Assignment of responsibility for cleaning and maintaining equipment;
- Maintenance and cleaning schedules, including, where adequate, sanitizing schedules;
- A description in sufficient detail of the methods, equipment, and materials used in cleaning and maintenance operations, and the methods of disassembling and reassembling equipment, as necessary, to ensure proper cleaning and maintenance;
- Removal or obliteration of previous batch identification;
- Identification and protection of clean equipment from contamination before use;
- Inspection of equipment for cleanliness immediately before use;
- Regular calibration and inspection of equipment, or checking machines, to ensure proper performance and function must be conducted:
 - Before first use, and
 - At a frequency specified in writing by supporting references.
- Instruments or controls that cannot be adjusted to agree with the reference standard

must be repaired or replaced.

A written record of calibration, inspection, maintenance of equipment, and major equipment cleaning and use shall be maintained in individual equipment logs that show the date, product, and lot number of each batch processed. The persons performing the cleaning shall record in the log that the work was performed. Entries in the log should be in chronological order.

The following is specified to keep records related to automated or electric equipment:

- There must be backup file(s) of current software programs (and of outdated software that is necessary to retrieve records that are required to be retained, in accordance with the section *Records and Reports* in this chapter, when current software is not able to retrieve such records) and of data entered into computer systems used to manufacture, package, label, or hold dietary supplements.
 - A backup file (e.g., a hard copy of data entered, diskettes, tapes, microfilm, or compact disks) must be an exact and complete record of the data entered.
 - Backup software programs and data must be kept secure from alterations, inadvertent erasures, or loss.

Change to read:

RAW MATERIALS, PRODUCT CONTAINERS, AND CLOSURES

Written procedures describing in sufficient detail the receipt, identification, storage, handling, sampling, testing, and approval or rejection of raw materials, product containers, and closures should be provided.

Raw materials, product containers, and closures at all times should be handled and stored in a manner to prevent contamination.

Raw agricultural materials that contain soil or other contaminants shall be washed or cleaned as necessary. Water used for washing, rinsing, or conveying raw agricultural materials shall be safe and of adequate sanitary quality. Notwithstanding the general requirement for potable water, water may be reused for washing, rinsing, or conveying raw agricultural materials if it does not increase the level of contamination of such materials.

Bagged or boxed raw materials of product containers or closures should be stored off the floor and suitably spaced to permit cleaning and inspection.

Each lot should be appropriately identified as to its status (i.e., quarantined, approved, or rejected).

Receipt and Storage of Untested Raw Materials, Product Containers, and Closures

Written procedures shall be established and followed describing the receipt, identification, examination, handling, and sampling of raw materials. Upon receipt and before acceptance, each container or grouping of containers of raw materials, product containers, and closures should be examined visually for appropriate labeling as to contents, container damage, or broken seals, and for contamination. They are then stored under quarantine until they have been tested or examined, as appropriate, and released.

Raw materials shall be held in bulk, or in containers designed and constructed so as to protect against adulteration, and shall be held at such temperature and relative humidity and in such a

manner as to prevent a dietary ingredient or dietary supplement from becoming adulterated. Frozen raw materials and other ingredients shall be kept frozen. If thawing is required before use, it shall be done in a manner that prevents the raw materials and other ingredients from becoming adulterated within the meaning of the Act.

Testing and Approval or Rejection

Each lot of raw materials, product containers, and closures should be sampled, tested, or examined, as appropriate, and released for use by the quality control unit. On the basis of adequate process verification, in-process controls, and statistical confidence, a skip-lot testing plan is an alternative to fully testing every batch provided that at least one identity test is conducted. An appropriate amount of each lot of raw materials should be reserved for ~~3 years~~

■ 1 year ■ 2S (USP39)

beyond the shelf life appearing on the label of finished dietary supplements in which the raw materials were used. If adverse event reports are received (see the subsection *Adverse Event Reports*), the reserved raw materials should be kept for 6 years (serious events) or 3 years (nonserious events) from the date the first report is received.

Representative samples should be collected for testing or examination. Sampling of botanicals should be in compliance with the provisions set in *Articles of Botanical Origin* (561). The number of containers sampled, and the amount of material taken from each container, should be based upon appropriate criteria such as statistical criteria for raw material variability, confidence levels, and degree of precision desired, the past quality history of the supplier, and the quantity needed for analysis and reserve where required. The following procedures should be used to collect the samples:

- The containers of raw materials selected should be cleaned, where necessary, by adequate means.
- The containers should be opened, sampled, and resealed in a manner designed to prevent contamination of their contents and contamination of other raw materials, product containers, or closures.
- These containers should be identified so that the following information can be determined: name of the material sampled, the lot number, the container from which the sample was taken, the date on which the sample was taken, and the name of the person who collected the sample.

Use the following procedure to examine and test the samples:

- At least one test should be conducted to verify the identity of each raw material of a product even in cases where skip-lot testing is used. Such tests may include any appropriate test with established sufficient specificity to determine identity, including chemical and laboratory tests, gross organoleptic analysis, microscopic identification, or analysis of constituent markers.
- Each raw material should be tested for conformity with all appropriate written specifications for purity, strength, and quality. However, a report of analysis may be accepted from the supplier of a raw material, provided that the manufacturer establishes the reliability of the supplier's analyses and provided that at least one identity test is conducted on such raw material by the manufacturer.
- Containers and closures should be tested for conformance with all appropriate written procedures. However, a certificate of testing may be accepted from the supplier, provided that at least a visual identification is conducted on such containers or closures

by the manufacturer.

- Each lot of a raw material, rework, product container, or closure that is liable to contamination with filth, insect infestation, or other extraneous adulterant should be examined against established specifications for such contamination and shall comply with any applicable Food and Drug Administration regulations and guidelines. Skip-lot examination should not apply in such cases.
- Each lot of a raw material that is liable to microbiological contamination that is objectionable in view of its intended use shall be subjected to microbiological tests before use. Raw materials either shall not contain levels of microorganisms that may produce food poisoning or other disease in humans, or shall be otherwise treated during manufacturing operations so that they no longer contain levels that would cause the product to be adulterated within the meaning of the Act. In lieu of such testing by the manufacturer, a guarantee or certification of analysis may be accepted from the supplier of a component provided that the manufacturer establishes the reliability of the supplier's analysis.
- Raw materials and other ingredients susceptible to adulteration with aflatoxin, other natural toxins, pesticides, or heavy metals shall comply with current Food and Drug Administration regulations, guidelines, and action levels for poisonous or deleterious substances and the requirements in (561), or in each monograph, before these materials or ingredients are incorporated into a finished dietary ingredient or dietary supplement. Compliance with this requirement may be accomplished by analyzing these materials and ingredients for aflatoxins and other natural toxins; or, in lieu of such testing by the manufacturer, a guarantee or certification of analysis may be accepted from the supplier of a raw material provided that the manufacturer establishes the reliability of the supplier's analysis.
- Any lot of raw material, product container, or closure that meets the appropriate written specifications of identity, strength, quality, and purity and related tests may be approved and released for use. Any lot of such material that does not meet such specifications should be rejected.

Use of Approved Raw Materials, Product Containers, and Closures

Raw materials, product containers, and closures approved for use should be rotated so that the oldest approved stock is used first. Deviation from the requirement is permitted if such deviation is temporary and adequate.

Retesting of Approved Raw Materials, Product Containers, and Closures

Raw materials, product containers, and closures should be retested or reexamined, as appropriate, for identity, strength, quality, and purity and approved or rejected by the quality control unit after a specified time in storage or as necessary, e.g., after exposure to air, heat, or other conditions that might adversely affect the raw material, product container, or closure or after storage of active and inactive ingredients and in-process materials for long periods of time.

Rejected Raw Materials, Product Containers, and Closures

Rejected raw materials, product containers, and closures should be identified and controlled

under a quarantine system that prevents their use in manufacturing or processing operations for which they are unsuitable.

PRODUCTION AND PROCESS CONTROLS

Written Procedures

Written procedures should be provided for production and process controls designed to ensure that the dietary ingredients and dietary supplements have the identity, strength, quality, and purity that they are represented to possess. These procedures should be drafted, reviewed, and approved by the appropriate organizational units and reviewed and approved by the quality control unit. These production and process control procedures should be followed in the execution of the various production and process control functions and should be documented at the time of performance. Any deviation from the written procedures should be recorded and justified.

- All operations in the receiving, inspecting, transporting, segregating, preparing, manufacturing, packaging, and storing of dietary ingredients and dietary supplements shall be conducted in accordance with adequate sanitation principles.
- All reasonable precautions shall be taken to ensure that production procedures do not contribute adulteration from any source. Chemical, microbial, or extraneous-material testing procedures shall be used where necessary to identify sanitation failures or possible product adulteration.
- All product that has become contaminated to the extent that it is adulterated within the meaning of the Act shall be rejected, or if permissible, treated or processed to eliminate the contamination.
- All product manufacturing, including packaging and storage, shall be conducted under such conditions and controls as are necessary to minimize the potential for the growth of microorganisms, or for the adulteration of raw materials, in-process materials, and finished product.
- Measures taken to destroy microorganisms, reduce the microbial load, or prevent the growth of undesirable microorganisms, particularly those of public health significance, shall be adequate under the conditions of manufacture, handling, and distribution to prevent dietary supplements and ingredients from being adulterated within the meaning of the Act. These measures shall also comply with current regulations affecting dietary supplement products and ingredients.
- Work-in-process shall be handled in a manner that protects against adulteration.
- In-process material must be held under appropriate conditions of temperature, humidity, and light.
- Effective measures shall be taken to protect finished dietary ingredients and dietary supplements from adulteration by raw materials, in-process materials, or refuse. When raw materials, in-process materials, or refuse are unprotected, they shall not be handled simultaneously in a receiving, loading, or shipping area if that handling could result in adulterated dietary ingredients and dietary supplements. Dietary ingredients and dietary supplements transported by conveyor shall be protected against adulteration as necessary.
- Effective measures shall be taken as necessary to protect against the inclusion of metal or other extraneous material in product. Compliance with this requirement may be

accomplished by using sieves, traps, magnets, electronic metal detectors, or other suitable effective means.

- Mechanical manufacturing steps such as cutting, sorting, inspecting, shredding, drying, grinding, blending, and sifting shall be performed so as to protect dietary ingredients and dietary supplements against adulteration. Compliance with this requirement may be accomplished by providing adequate physical protection of dietary ingredients and dietary supplements from contact with adulterants. Protection may be provided by adequate cleaning and sanitizing of all processing equipment between each manufacturing step.
- Heat blanching, when required in the preparation of a dietary ingredient or a dietary supplement, should be effected by heating the product to the required temperature, holding it at this temperature for the required time, and then either rapidly cooling the material or passing it to subsequent manufacturing without delay. Thermophilic growth and contamination in blanchers should be minimized by the use of adequate operating temperatures and by periodic cleaning. Where the blanched product is washed before filling, potable water shall be used.
- Intermediate of dehydrated dietary ingredients and dietary supplements that rely on the control of water (a_w) for preventing the growth of undesirable microorganisms shall be processed to and maintained at a safe moisture level. Compliance with this requirement may be accomplished by any effective means, including employment of one or more of the following practices:
 - Monitoring the water activity (a_w) of the material;
 - Controlling the soluble solids–water ratio in finished product; and
 - Protecting finished product from moisture pickup, by use of a moisture barrier or by other means, so that the water activity (a_w) of the product does not increase to an unsafe level.
- Dietary ingredients and dietary supplements that rely principally on the control of pH for preventing the growth of undesirable microorganisms shall be monitored and maintained at an appropriate pH. Compliance with this requirement may be accomplished by any effective means, including employment of one or more of the following practices:
 - Monitoring the pH and water activity, if appropriate, of raw materials, in-process material, and finished product; and
 - Controlling the amount of acid added to the product.
- When ice is used in contact with dietary ingredients and dietary supplements, it shall be made from potable water, and shall be used only if it has been manufactured in accordance with current good manufacturing practice in manufacturing, packing, or holding human food as outlined in 21 CFR Part 110.

Charge-In of Raw Materials

Written production and control procedures should include the following, which are designed to ensure that the dietary supplements have the identity, strength, quality, and purity that they are represented to possess:

- The batch should be formulated with the intent to provide NLT 100% of the labeled or established amount of dietary ingredient.
- Raw materials for product manufacturing should be weighed, measured, or subdivided as appropriate and the appropriate signatures recorded in the batch record.
- Actual yields and percentages of theoretical yield should be determined at appropriate

phases of processing.

Material scheduled for rework shall be identified as such.

Equipment Identification

All compounding and storage containers, processing lines, and major equipment used during the production of a batch of a product should be properly identified to indicate their contents and, when necessary, the phase of processing of the batch.

Sampling and Testing of In-Process Materials, Dietary Ingredients, and Dietary Supplements

To ensure batch uniformity and integrity of dietary supplements, written procedures should be established and followed that describe the in-process controls and tests or examinations to be conducted on appropriate samples of in-process materials. On the basis of process verification, in-process controls, and statistical confidence, a skip-lot testing plan is an alternative to testing every batch of finished products provided that at least one representative measure is performed. Control procedures should be established to monitor the output of those manufacturing processes that may be responsible for causing variability in the characteristics of in-process material and the finished product. Such control procedures may include, but are not limited to, the following, where appropriate:

- Friability
- Weight variation
- Disintegration time
- Dissolution time
- Clarity, completeness, or pH of solutions
- Blend uniformity

In-process specifications for such characteristics should be consistent with finished product specifications. Examination and testing of samples should ensure that the in-process material and dietary supplement conform to the established specifications.

In-process materials should be tested for identity, strength, quality, and purity as adequate, and approved or rejected by the quality control unit during the production process, e.g., at commencement or completion of significant phases or after storage for long periods.

Rejected or adulterated in-process materials should be identified and controlled under a quarantine system designed to prevent their use in manufacturing or processing operations for which they are unsuitable and to prevent the adulteration of other products.

LABELING AND PACKAGING

Materials Examination and Usage Criteria

Written procedures should be provided describing in sufficient detail the receipt, identification, storage, handling, sampling, examination, testing of labeling and packaging materials, or products received for packaging or labeling. Each immediate container or grouping of immediate containers in a shipment of product received for packaging or labeling, or of packaging and labeling materials, must be visually examined for appropriate content label, container damage,

or broken seals to determine whether the container condition may have resulted in contamination or deterioration of the received product. The supplier's invoice, guarantee, or certification in a shipment of the received product must be visually examined to ensure that the received product is consistent with the purchase order. Labeling and packaging materials or products received for packaging or labeling should be quarantined until:

- Representative samples of each unique shipment, and of each unique lot within each unique shipment, of received product for packaging or labeling, or of packaging and labeling materials, are collected;
- The quality control unit reviews and approves the documentation to determine whether the received product for packaging or labeling, or packaging and labeling materials, meets the specifications; and
- The quality control unit approves the received product for packaging or labeling, or packaging and labeling materials, and releases for use from quarantine.

Those that do not meet such specifications should be identified and rejected to prevent their use in operations for which they are unsuitable.

A record should be kept of each shipment received of each different labeling and packaging material, or each different received product for packaging or labeling, indicating receipt, date of examination or testing, and whether accepted or rejected.

Each unique lot within each unique shipment of received product for packaging or labeling, or of packaging and labeling materials, must be identified in a manner that allows the recipient to trace the lot to the supplier, the date received, the name of the received product, the status of the received product (e.g., quarantined, approved, or rejected), and to the product that was packaged or labeled and distributed.

This unique identifier must be used whenever the disposition of each unique lot within each unique shipment of the received product for packaging or labeling, or of packaging and labeling materials, is recorded.

Labels and other labeling materials for each different product, strength, product type, or quantity of contents should be stored separately under conditions that will protect against contamination and deterioration and avoid mixups. Only authorized personnel should have access to the storage area.

Packaging and labels must be held under appropriate conditions so that the packaging and labels are not adversely affected (e.g., contamination or deterioration).

Gang printing of labeling to be used for different products or different strengths of the same product (or labeling of the same size and identical or similar format or color schemes) should be minimized. If gang printing is employed, packaging and labeling operations should provide for special control procedures, taking into consideration sheet layout, stacking, cutting, and handling during and after printing.

Printing devices on, or associated with, manufacturing lines used to imprint labeling upon the product unit label or case should be monitored to ensure that all imprinting conforms to the print specified in the batch production record.

Obsolete and outdated labels, labeling, other packaging materials, and products received for packaging or labeling should be destroyed and documented.

Labeling Issuance

Strict control should be exercised over labeling issued for use in product labeling operations. The control procedures employed should be in writing with sufficient detail.

Labeling materials issued for a batch should be carefully examined for identity and conformity to the labeling specified in the master and batch production records.

Procedures should be used to reconcile the quantities of labeling issued, used, and returned, and should require evaluation of discrepancies found. If discrepancies are found between the quantity of product finished and the quantity of labeling issued and are outside preset limits based on historical operating data, such discrepancies should be investigated.

Returned labeling should be maintained and sorted in a manner to prevent mixups and provide proper identification.

All excess labeling bearing lot or control numbers should be destroyed and documented.

Operations

Written procedures designed to ensure that correct labels, labeling, and packaging materials are used for dietary supplements should incorporate the following features:

- Prevention of mixups and cross-contamination by physical or spatial separation from operations on other products;
- Identification of the product with a lot or control number;
- Examination of packaging and labeling materials for suitability and correctness before packaging operations, and documentation of such examination in the batch production record; and
- Inspection of the packaging and labeling facilities immediately before use to ensure that all products have been removed from previous operations. Inspection should also be made to ensure that packaging and labeling materials not suitable for subsequent operations have been removed. Results of the inspection should be documented in the batch production records.

Relabeling and Repackaging

- Dietary ingredients and dietary supplements may be repackaged or relabeled only after the quality control unit has approved such repackaging or relabeling.
- A representative sample of each batch of repackaged or relabeled dietary ingredients and dietary supplements must be examined to determine whether the repackaged or relabeled dietary ingredients and dietary supplements meet all established specifications.
- The quality control unit must approve or reject each batch of repackaged or relabeled dietary ingredients and dietary supplements before its release for distribution.

Tamper-Resistant Packaging

REQUIREMENTS

Each manufacturer and packer who packages a dietary supplement for retail sale shall package the product in a tamper-resistant package, if this product is accessible to the public while held for sale. A tamper-resistant package is one having an indicator or barrier to entry which, if breached or missing, can reasonably be expected to provide visible evidence to consumers that tampering has occurred. To reduce the likelihood of substitution of a tamper-resistant feature after tampering, the indicator or barrier to entry is required to be distinctive by design or by the use of an identifying characteristic (e.g., a pattern, name, registered trademark, logo, or picture). For purposes of this section, the term "distinctive by design" means that the packaging cannot be duplicated with commonly available materials or through commonly

available processes. A tamper-resistant package may involve an immediate-container and closure system, or secondary-container or carton system, or any combination of systems intended to provide a visual indication of package integrity. The tamper-resistant feature should be designed to remain intact when handled in a reasonable manner during manufacture, distribution, and retail display.

LABELING

Each retail package of a dietary supplement covered by this section shall bear a statement that is prominently placed so that consumers are alerted to the specific tamper-resistant feature of the package. The labeling statement should be so placed that it will be unaffected if the tamper-resistant feature of the packaging is breached or missing. If the tamper-resistant feature chosen to meet the requirement above is one that uses an identifying characteristic, that characteristic should be referred to in the labeling statement. For example, the labeling statement on a bottle with a shrink band could say "For your protection, this bottle has an imprinted seal around the neck."

Dietary Supplement Examination

Packaged and labeled products should be examined during finishing operations to ensure that containers and packages in the lot have the correct label. A representative sample of units should be collected at the completion of finishing operations and visually examined for correct labeling. Results of these examinations should be recorded in the batch production or control records.

Contact Information

The manufacturer, packer, or distributor of dietary supplements is required to comply with the current labeling requirements in the law that also include a domestic address or phone number through which an adverse event report for a dietary supplement may be received.

Shelf Life

Dietary supplements should bear a date indicative of their shelf life, determined by appropriate testing, to ensure that they meet applicable standards of identity, strength, quality, and purity at or before the labeled shelf-life date.

Shelf life should be related to any storage conditions stated on the labeling.

HOLDING AND DISTRIBUTION

Warehousing Procedures

Storage and transportation of the finished product shall be under conditions that will protect the product against physical, chemical, and microbial adulteration as well as against deterioration of the product and the container.

Written procedures describing the warehousing of dietary supplements should be established and followed and should include the following:

- Quarantine of finished products before disposition by the quality control unit; and

- Storage of finished products under appropriate conditions of temperature, humidity, and light so that the identity, strength, quality, and purity of the products are not affected.

Distribution Procedures

Written procedures describing the distribution of dietary supplements shall be established and followed and should include the following:

- A procedure whereby the oldest approved stock of a product is distributed first. (Deviation from this requirement is permitted if such deviation is temporary and adequate.)
- A system by which the distribution of each lot of product can be readily determined to facilitate its recall if necessary.

QUALITY CONTROL OPERATIONS

The establishment of any specifications, standards, sampling plans, test procedures, or other laboratory control mechanisms required by this chapter, including any change in such specifications, standards, sampling plans, test procedures, or other laboratory control mechanisms, shall be drafted by the appropriate organizational unit and reviewed and approved by the quality control unit. The requirements in this section should be followed and documented at the time of performance. Any deviation from the written specifications, standards, sampling plans, test procedures, or other laboratory control mechanisms shall be recorded and justified. Quality control operations include the establishment of scientifically sound and appropriate specifications, standards, sampling plans, and test procedures designed to ensure that raw materials, product containers, closures, in-process materials, labeling, products received for labeling and packaging operations as dietary supplements, and finished products conform to adequate standards of identity, strength, quality, and purity. These controls include the following:

- Determination of conformance to appropriate written specifications for the acceptance of each lot within each shipment of raw materials, product containers, closures, and labeling used in the manufacture of dietary ingredients and dietary supplements, and of products received for labeling and packaging operations as dietary supplements. (The specifications include a description of the sampling and testing procedures used. Samples should be representative and adequately identified. Such procedures also require appropriate retesting of any raw material, product container, or closure that is subject to deterioration.) On the basis of adequate process verification, in-process controls, and statistical confidence, a skip-lot testing plan is an alternative to testing every batch, excluding raw materials, which require 100% identity testing.
- Determination of conformance to written specifications and a description of sampling and testing procedures for in-process materials. (Such samples should be representative and properly identified.)
- Determination of conformance to written descriptions of sampling procedures and appropriate specifications for finished products. (Such samples should be representative and properly identified.)
- The calibration of instruments, at suitable intervals, in accordance with an established written program containing specific directions, schedules, limits for accuracy and precision, and provisions for remedial action in the event that accuracy and/or precision

limits are not met. Instruments not meeting established specifications shall not be used until repaired.

Testing and Release for Distribution

There should be appropriate laboratory determination of satisfactory conformance to specifications for the finished product, including the identity and strength before release. On the basis of adequate process verification, in-process controls, or statistical confidence, a skip-lot or composite testing plan is an alternative to testing every batch.

There should be appropriate laboratory testing, as necessary, of each batch of dietary supplement required to be free of objectionable microorganisms. The accuracy, linearity, sensitivity, specificity, and precision of test methods employed by the firm, when they differ from compendial methods, should be established and documented.

Written procedures should describe any sampling and testing plans, which should include the method of sampling and the number of units per batch to be tested.

Products failing to meet established standards or specifications and any other relevant quality control criteria should be rejected. Rejected or adulterated dietary ingredients and dietary supplements shall be identified, stored, and disposed of in a manner that protects against the adulteration of the other products. Reprocessing may be performed. Before acceptance and use, reprocessed material must meet established standards, specifications, and any other relevant criteria. Written procedures shall be established and followed prescribing the method for reprocessing batches or operations start-up materials that do not conform to finished goods standards or specifications. Finished goods manufactured using such materials shall meet all established purity, composition, and quality standards.

Stability Testing

There should be a written protocol designed to assess the stability characteristics of dietary supplements. The results of such testing should be used in determining appropriate storage conditions and shelf life. This protocol should include the following:

- Sample size and test intervals based on statistical criteria for each attribute should be examined to ensure valid estimates of stability;
- Storage conditions for samples retained for testing;
- Reliable, meaningful, and specific test methods should be used; and
- The dietary supplement should be tested in the same type of container-closure system as that in which the dietary supplement is marketed.

An adequate number of batches of each dietary supplement should be tested to determine an adequate shelf life, and a record of these data should be maintained. Accelerated studies combined with basic stability information on the raw materials, dietary supplements, and container-closure systems may be used to support tentative shelf life if full shelf-life studies are not available. Simplified stability testing procedures may be used where data from similar product formulations are available to support a shelf-life estimation of a new product. Where data from accelerated studies are used to project a tentative shelf-life date that is beyond a date supported by actual shelf-life studies, stability studies should be conducted, including dietary supplement testing at appropriate intervals, until the tentative shelf life is verified or the adequate shelf life is determined.

Reserve Samples

An appropriately identified reserve sample that is representative of each lot or batch of dietary supplement should be retained and stored under conditions consistent with product labeling until at least 3 years after the shelf life of the product. The reserve sample should be stored in the same immediate container–closure system in which the finished product is marketed or in one that has essentially the same characteristics. The reserve sample consists of at least twice the quantity necessary to perform all of the required tests. If an adverse event report is received, the reserve samples of dietary supplements and dietary ingredients from the same lot or batch must be analyzed by an appropriate procedure to confirm their identity and determine any adulteration or contamination. The recovered samples associated with adverse event reports from consumers, distributors, or both should also be analyzed, following the same method used for the reserved samples, if available. The results should be reported with other required information to the federal authority, using the required form. The reserve samples from a particular lot or batch associated with an adverse event report should be held for 6 years (serious events) or 3 years (nonserious events) from the date when the first adverse event report is received by the manufacturer, packer, or distributor.

Change to read:

RECORDS AND REPORTS

Any record for production, control, quality control operations, or distribution that is required to be maintained and is specifically associated with a batch of a product should be retained for at least 3 years after the shelf life of the batch.

Records should be maintained for all raw materials, product containers, closures, and labeling for at least 3 years after the shelf life of the last lot of product incorporating the raw material or using the container, closure, or labeling.

Master Production and Control Records

To ensure uniformity from batch to batch, master production and control records for each product should be prepared, dated, and signed by one person and independently checked, dated, and signed by a second person from the quality control unit.

Master production and control records should include the following:

- The name and strength of the product;
- The name and weight or measure of each dietary ingredient per unit or portion or per unit of weight or measure of the product, and a statement of the total weight or measure of any dosage unit;
- A complete list of raw materials designated by names or codes sufficiently specific to indicate any special quality characteristic;
- An accurate statement of the weight or measure of each raw material, using the same weight system (metric, avoirdupois, or apothecary) for each raw material;
- A statement concerning any calculated excess of raw material;
- A statement of theoretical weight or measure at appropriate phases of processing;
- A statement of theoretical yield, including the maximum and minimum percentages of theoretical yield beyond which investigation is required;

- A description of the product containers, closures, and packaging materials, including a specimen or copy of each label and all other labeling signed and dated by the person or persons responsible for approval of such labeling or, in lieu of specimens or copies of each label or other labeling, a positive identification of all labeling used; and
- Complete manufacturing and control instructions, testing procedures, acceptance limits, special notations, and precautions to be followed.
- Specific actions necessary to perform and verify points, steps, or stages in the manufacturing process where control is necessary to ensure the quality of dietary ingredients and dietary supplements, and to ensure that dietary ingredients and dietary supplements are packaged and labeled as specified in the master production record.
 - Such specific actions must include verifying the weight or measure of any component and verifying the addition of any component; and
 - For manual operations, such specific actions must include:
 - One person weighing or measuring a component and another person verifying the weight or measure; and
 - One person adding the component and another person verifying the addition.
- Corrective action plans for use when a specification is not met.

Batch Production and Control Records

Batch production and control records should be prepared for each batch of product produced and should include complete information relating to the production and control of each batch. These records should be reviewed and signed by a second person from the quality control unit. These records should include accurate reproduction of the appropriate master production or control record and documentation that each significant step in the manufacture, processing, packing, or holding of the batch was accomplished, including the following:

- Dates;
- Identity of individual major equipment and lines used;
- Specific identification of each batch of raw material or in-process material used;
- Weights and measures of raw materials used in the course of processing;
- In-process and laboratory control results;
- Inspection of the packaging and labeling areas before and after use;
- A statement of the actual yield and a statement of the percentage of theoretical yield at appropriate phases of processing;
- Description of product containers and closures used;
- Complete labeling control records, including:
 - The unique identifier assigned to packaging and labels used, the quantity of the packaging and labels used, and, when label reconciliation is required, reconciliation of any discrepancies between issuance and use of labels; and
 - An actual or representative label, or a cross-reference to the physical location of the actual or representative label specified in the master manufacturing record;
- Any sampling performed;
- Identification of the persons performing and directly supervising or checking any step in the operation;
- Any investigation made;
- The results of any tests or examinations conducted on packaged and labeled dietary

- supplements (including repackaged or relabeled dietary supplements), or a cross-reference to the physical location of such results;
- Documentation at the time of performance that quality control unit:
 - Reviewed the batch production record, including:
 - Review of any required monitoring operation, and
 - Review of the results of any tests and examinations, including tests and examinations conducted on components, in-process materials, finished batches of dietary supplements, and packaged and labeled dietary ingredients and dietary supplements;
 - Approved or rejected any reprocessing or repackaging;
 - Approved and released, or rejected, the batch for distribution, including any reprocessed batch; and
 - Approved and released, or rejected, the packaged and labeled dietary supplement, including any repackaged or relabeled dietary supplement;
 - Documentation at the time of performance of any required material review and disposition decision; and
 - Documentation at the time of performance of any reprocessing.

Records for Raw Materials, Packaging, and Labels and for Product Received for Packaging or Labeling as a Dietary Supplement

The following records must be made and retained:

- Written procedures for fulfilling the requirements for raw materials, packaging, and labels and for product received for packaging or labeling;
- Receiving records (including records such as certificates of analysis, suppliers' invoices, and suppliers' guarantees) for components, packaging, and labels and for products received for packaging or labeling; and
- Documentation that the requirements of *Raw Materials, Product Containers, and Closures* were met:
 - The person who performs the required operation must document, at the time of performance, that the required operation was performed; and
 - The documentation must include:
 - The date of receipt of the raw materials, packaging, labels, or products received for packaging or labeling as a dietary supplement;
 - The initials of the person performing the required operation;
 - The results of any tests or examinations conducted on raw materials, packaging, or labels, and of any visual examination of product received for packaging or labeling as a dietary supplement; and
 - Any material review and disposition decision conducted on raw materials, packaging, labels, or products received for packaging or labeling as a dietary supplement.

Laboratory Records

Laboratory records should include complete data derived from all tests necessary to ensure compliance with established specifications and standards, including examinations and assays, as follows:

- A description of the sample received for testing with identification of source (that is,

location from where sample was obtained), quantity, lot number or other distinctive code, and date sample was taken.

- A statement of each method used in the testing of the sample.
- A statement of the weight or measure of sample used for each test, where appropriate.
- A complete record of all data secured in the course of each test, including all graphs, charts, and spectra from laboratory instrumentation, properly identified to show the specific raw material, product container, closure, in-process material, or finished product, and lot tested.
- A record of all calculations performed in connection with the test, including units of measure, conversion factors, and equivalency factors.
- A statement of the results of tests and how the results compare with established standards of identity, strength, quality, and purity for the raw material, product container, closure, in-process material, or finished product tested.
- The initials or signature of the person who performs each test and the date(s) the tests were performed.

Complete records should be maintained of any modification of an established method employed in testing. Such records should include the reason for the modification and data to verify that the modification produced results that are at least as accurate and reliable for the material being tested as the established method.

Complete records should be maintained of any testing and standardization of laboratory reference standards, reagents, and standard solutions, the periodic calibration of laboratory instruments, and all stability testing should be performed. Any deviation should be reviewed and signed by the management of the quality control unit.

Quality Control Operation Records

The following records must be made and retained:

- Written procedures for the responsibilities of the quality control operations, including written procedures for conducting a material review and making a disposition decision and written procedures for approving or rejecting any reprocessing;
- Written documentation, at the time of performance, that quality control unit performed the review, approval, or rejection requirements, by recording the following:
 - Date on which the review, approval, or rejection was performed; and
 - Signature of the person performing the review, approval, or rejection; and
- Documentation of any material review and disposition decision and follow-up. Such documentation must be included in the appropriate batch production record and must include:
 - Description of the investigation into the cause of the deviation from the specification or the unanticipated occurrence;
 - Evaluation of whether the deviation or unanticipated occurrence has resulted in, or could lead to, a failure to ensure the quality of the dietary supplement or a failure to package and label the dietary supplement as specified in the master manufacturing record;
 - Identification of the action(s) taken to correct, and prevent a recurrence of, the deviation or the unanticipated occurrence;
 - Explanation of the actions taken with the raw material, dietary supplement, packaging, or label;

- A scientifically valid reason for any reprocessing of a dietary supplement that is rejected or any treatment or in-process adjustment of a component that is rejected; and
- The signatures of 1) the individual(s) designated to perform the quality control operation, who have conducted the material review and made the disposition decision; and in addition, 2) each qualified individual who has provided information relevant to that material review and disposition decision.

Distribution Records

Distribution records should contain the name and strength of the product, name and address of the consignee, date and quantity shipped, and lot or control number of the finished product.

Record Keeping

The manufacturer, packer, or distributor of dietary supplements must keep all required records, as shown in this chapter, for ~~3 years~~

■ 1 year ■ 2S (USP39)

beyond the shelf life of dietary supplements associated with those records. If adverse event reports are received, those records must be kept for additional 6 years

■ (serious events) or for 3 year (nonserious events) ■ 2S (USP39)

from the date when the first report is received. All records must be accessible by the regulatory authority when requested.

Records must be kept as original records, as true copies (such as photocopies, microfilm, microfiche, or other accurate reproductions of the original records), or as electronic records. All electronic records must comply with part 11 of Code of Federal Regulations Title 21 (21 CFR Part 11).

If reduction techniques are used, such as microfilming, suitable reader and photocopying equipment must be readily available to auditors and inspectors.

Complaint Files

Written procedures describing the handling of all written and oral complaints regarding a dietary supplement shall be established and followed. These procedures should include provisions for review by the quality control unit of any complaint involving the possible failure of a product to meet any of its specifications and a determination as to the need for an investigation. Each complaint should be recorded in a file designed especially for dietary supplement complaints. Written records should be maintained until at least 3 years after the shelf life of the product, or 3 years after the date when the complaint was received, whichever is longer. The written record should include the following information, where known: the name and strength of the product, lot number, name of complainant, nature of complaint, and reply to complainant.

If an investigation is necessary, the written record should include the findings of the investigation and follow-up.

The review and investigation of the product complaint by a qualified person, the review by quality control unit about whether to investigate a product complaint, and the findings and follow-up action of any investigation performed must extend to all relevant batches and records.

Adverse Event Reports

Adverse event reports include reports on any health-related adverse event associated with the use of a dietary supplement that is adverse. It includes both nonserious and serious adverse event reports.

The manufacturer, packer, or distributor of a dietary supplement (called the "responsible person") whose name appears on the label shall be responsible for keeping reports of all nonserious adverse events along with any related records (e.g., records of communications with the person who reported the nonserious event). All such records of nonserious adverse events should be kept for 6 years.

The responsible person whose name appears on the label shall also be responsible for reporting any serious adverse event reported to it, and associated with a dietary supplement that is marketed and used in the same country, to the regulatory authority as soon as appropriate, but NLT 15 business days after receipt of the report, using the appropriate form as defined by the regulation

(<http://www.fda.gov/food/dietarysupplements/reportadverseevent/ucm111110.htm>). A serious adverse event is an event that results in any of following:

- Death,
- A life-threatening experience,
- Inpatient hospitalization,
- A persistent or significant disability or inability,
- A congenital anomaly or birth defect, or
- A condition that requires, according to reasonable medical judgment, a medical or surgical intervention to prevent one of the five outcomes listed above.

A retailer whose name appears on the label as a distributor may, by agreement, authorize the manufacturer or packer to submit the required reports to the regulatory authority, as long as the retailer directs all received adverse event reports to the manufacturer or packer. Each serious adverse event report should include a copy of the product's label, the information described in the preceding section *Complaint Files*, and if possible, the contact information of the complainant; daily intake; alcohol consumption and amount; use of prescription medicine and OTC medicine, including a daily dose; and other medical information. The information associated with personal identification and medical records should be obtained only for the reports and kept safe from disclosure. Any new medical information that is related to an already submitted serious adverse event report that is received within 1 year of the initial report shall be submitted to the regulatory authority as soon as appropriate, but NLT 15 business days after receipt of the information. The records related to each report of a serious adverse event received by the manufacturer, packer, or retailer should be maintained for 6 years. The authorized person who is designated by the regulatory authority should be permitted access to those records.

RETURNED AND SALVAGED PRODUCTS

Returned Dietary Supplements

Returned products should be identified as such and held. If the conditions under which returned dietary ingredients and dietary supplements have been held, stored, or shipped before or during

their return, or if the condition of the product, its container, carton, or labeling, as a result of storage or shipping, casts doubt on the safety, identity, strength, quality, or purity of the product, the returned product should be destroyed unless examination, testing, or other investigations prove the product meets appropriate standards of safety, identity, strength, quality, or purity. The returned products associated with adverse events must be destroyed after a sufficient sample of products is stored for the purpose of further investigation only. The products related to the adverse event that have been returned should be kept for 6 years (serious events) or for 3 years (nonserious events) from the date when the first report is received. A product may be reprocessed provided that the subsequent product meets adequate standards, specifications, and characteristics. Records of returned products should be maintained and should include the name and label potency of the product, lot number (or control number or batch number), reason for the return, quantity returned, date of disposition, and ultimate disposition of the returned product. If the reason for a product being returned implicates associated batches, an appropriate investigation is necessary.

Dietary Supplement Salvaging

Products that have been involved in adverse events or subjected to improper storage conditions, including extremes in temperature or humidity, smoke, fumes, pressure, age, or radiation due to natural disasters, fires, accidents, or equipment failures should not be salvaged and returned to the marketplace. Whenever there is a question whether products have been subjected to such conditions, salvaging operations may be conducted only if there is *a*) evidence from laboratory tests and assays that the products meet all applicable standards of identity, strength, quality, and purity; and *b*) evidence that the products and their associated packaging were not subjected to improper storage conditions as a result of the disaster or accident. Organoleptic examinations should be accepted only as supplemental evidence that the dietary supplement meets appropriate standards of identity, strength, quality, and purity. Records including name, lot number, and disposition should be maintained for salvaged products. If the products are involved in adverse events, the instructions described in the preceding section *Records and Reports* should be followed.

Defect Action Levels

Some dietary ingredients and dietary supplements, even when produced under current good manufacturing practice, contain natural or unavoidable defects that at low levels are not hazardous to health. The Food and Drug Administration establishes maximum levels for these defects in dietary ingredients and dietary supplements produced under current good manufacturing practice and uses these levels in deciding whether to recommend regulatory action.

Defect action levels are established for dietary ingredients and dietary supplements whenever it is necessary and feasible to do so. These levels are subject to change upon the development of new technology or the availability of new information.

Compliance with defect action levels does not excuse violation of the requirement in section 402(a)(4) of the Act that dietary ingredients and dietary supplements shall not be prepared, packed, or held under unsanitary conditions or the requirements in this part that manufacturers, distributors, and holders of both dietary ingredients and dietary supplements shall observe current good manufacturing practice. Evidence indicating that such a violation exists causes a dietary ingredient and a dietary supplement to be adulterated within the

meaning of the Act, although the amounts of natural or unavoidable defects are lower than the currently established defect action levels. The manufacturer, distributor, and holder of a dietary ingredient or a dietary supplement shall, at all times, utilize quality control operations that reduce natural or unavoidable defects to the lowest level currently feasible.

The mixing of a dietary ingredient or dietary supplement containing defects above the current defect action level with another lot of dietary ingredient or dietary supplement is not permitted and renders the final product adulterated within the meaning of the Act, regardless of the defect level of the final product.

A compilation of the current defect action levels for natural or unavoidable defects in dietary ingredients and dietary supplements that present no health hazard may be obtained upon request from the Industry Activities Staff (HFS-565), Center for Food Safety and Applied Nutrition, U.S. Food and Drug Administration, 5100 Paint Branch Parkway, College Park, MD 20740-3835.

GLOSSARY

Acceptance criteria: The product specifications and acceptance or rejection criteria, such as acceptable quality level and unacceptable quality level, with an associated sampling plan, that are necessary for making a decision to accept or reject a lot or batch (or any other convenient subgroups of manufactured units).

Act: Federal Food, Drug and Cosmetic Act [United States Code (U.S.C.) Title 21, Chapter 9].

Adequate: That which is needed to accomplish the intended purpose in keeping with good public health practice.

Adverse event: Any health-related event that is adverse and that is associated with the use of a dietary supplement.

Adverse event report: A report of an adverse event (see definition above). (See also *Serious adverse event report*.)

Batch: A specific quantity of a finished product or other material that is intended to have uniform character and quality, within specified limits, and is produced according to a single manufacturing order during the same cycle of manufacture.

Blanching: A prepackaging heat treatment of a dietary ingredient and a dietary supplement for a sufficient time and at a sufficient temperature to partially or completely inactivate the naturally occurring enzymes and to effect other physical or biochemical changes in the product.

Composition: 1) The identity of a dietary ingredient or dietary supplement, and 2) the concentration of a dietary ingredient (e.g., weight or other unit of use/weight or volume), or the potency or activity of one or more dietary ingredients, as indicated by appropriate procedures.

Dietary ingredient: An ingredient intended for use or used in a dietary supplement that is:

- A vitamin;
- A mineral;
- An herb or other botanical;
- An amino acid;
- A dietary substance for use by humans to supplement the diet by increasing the total dietary intake, or a concentrate, metabolite, constituent, extract; or
- A combination of any of the foregoing ingredients.

Dietary supplement: A product (other than tobacco) that is intended to supplement the diet

and that bears or contains one or more of the following dietary ingredients: a vitamin, a mineral, an herb or other botanical, an amino acid, a dietary substance for use by humans to supplement the diet by increasing the total daily intake, or a concentrate, metabolite, constituent, extract or combination of these ingredients, that is intended for ingestion in a pill, capsule, tablet or liquid form, that is not represented for use as a conventional food or as the sole item of a meal or diet, and that is labeled as a dietary supplement, and includes products such as a new drug, certified antibiotic, or licensed biologic that was marketed as a dietary supplement or food before approval, certification, or license unless a sanitary authority waives this provision.

Inactive ingredient: Any raw material other than a dietary ingredient.

In-process material: Any material fabricated, compounded, blended, ground, extracted, sifted, sterilized, or processed in any other way that is produced for, and used in, the preparation of the dietary supplement.

Lot: A batch, or a specific identified portion of a batch, having uniform character and quality within specified limits.

Lot number, control number, or batch number: Any distinctive combination of letters, numbers, or symbols, or any combination of them from which the complete history of the manufacture, processing, packing, holding, and distribution of a batch or lot of finished dietary ingredient, dietary supplement, or other material can be determined.

Manufacture or manufacturing: Includes all operations associated with the production of dietary ingredients and dietary supplements, including packaging and labeling operations, testing, and quality control of a dietary ingredient or dietary supplement.

Microorganisms: Yeast, molds, bacteria, and viruses and includes, but is not limited to, species having public health significance. The term "undesirable microorganisms" includes those microorganisms that are of public health significance, that subject a dietary ingredient or a dietary supplement to decomposition, that indicate that a dietary ingredient or dietary supplement is contaminated with filth, or that otherwise may cause a dietary ingredient or a dietary supplement to be adulterated within the meaning of the Act. Occasionally in these regulations, the adjective "microbial" is used instead of an adjectival phrase containing the word "microorganism".

Pest: Any objectionable animals or insects including, but not limited to, bird, rodents, flies, and larvae.

Plant: The building or facility or parts thereof, used for or in connection with the manufacturing, packaging, labeling, or holding of a dietary ingredient and a dietary supplement.

Process evaluation: A set of tests performed on a process intended to evaluate its capacity to consistently produce the results that it is intended for.

Quality control operation: A planned and systematic procedure for taking all actions necessary to prevent a dietary ingredient and a dietary supplement from being adulterated.

Quality control unit: Any person or organizational element designated by the firm to be responsible for the duties relating to quality control operations.

Raw material: Any ingredient intended for use in the manufacture of a dietary ingredient or dietary supplement, including those that may not appear in such finished product. (A dietary ingredient is a raw material when considering the manufacture of a dietary supplement.)

Representative sample: A sample that consists of a number of units that are drawn based on rational criteria, such as random sampling, and is intended to ensure that the sample accurately portrays the material being sampled.

Rework: A clean, unadulterated material that has been removed from processing for reasons other than unsanitary conditions or that has been successfully reconditioned by reprocessing

and that is suitable for use in the manufacture of a dietary ingredient or a dietary supplement.

Sanitizing: To adequately treat equipment, containers, or utensils by a process that is effective in destroying vegetative cells of microorganisms of public health significance and in substantially reducing other undesirable microorganisms but without affecting the product or its safety for the consumer.

Serious adverse event report: A report of an adverse event that is termed "serious" because it meets certain criteria (see the subsection *Adverse Event Reports*). The Dietary Supplement and Nonprescription Drug Consumer Protection Act requires manufacturers and distributors of dietary supplements and OTC drugs to report all serious adverse events to the Secretary of the Food and Drug Administration (FDA). This is an entirely new requirement for dietary supplements.

Shall: Used to state requirements that must be met under the provisions of this guideline.

Shelf life: The period of time after manufacturing in which the dietary supplement is ensured to meet applicable standards of identity, strength, quality, and purity.

Shelf-life (Use by) date: The date beyond which the dietary supplement is no longer ensured to meet applicable standards of identity, strength, quality, and purity.

Should: Used to state recommended or advisory procedures or identify recommended equipment.

Skip-lot testing (or sampling): A reduced level of testing (or sampling) for a particular specified parameter(s) based upon one or more of the following:

- Statistical analysis of an adequate quantity of historical test data;
- Statistical confidence in the capability of the manufacturing process as determined by suitable verification; or
- Ongoing monitoring of the process using recognized statistical process control (SPC) techniques.

Strength: The concentration of the active substance (weight/weight, weight/volume, or unit of use/volume or weight basis); and/or the potency, i.e., the activity of the product as indicated by appropriate laboratory tests.

Water activity (a_w): A measure of the free moisture in a dietary ingredient or dietary supplement and is the quotient of the water vapor pressure of the substance divided by the vapor pressure of pure water at the same temperature.

BRIEFING

2,2,2-Trichloroethanol. It is proposed to add this new reagent used in the test for content of *Chlorobutanol* in the revision made to *Antimicrobial Agents—Content* (341), published in *PF* 41(2).

(HDQ: M. Marques.)

Correspondence Number—C99464

Comment deadline: November 30, 2015

Add the following:

■ 2,2,2-Trichloroethanol (*Trichloroethyl Alcohol*), $C_2H_3OCl_3$ —**149.40** [115-20-8]—Use a suitable grade with a content of NLT 99%. ■2S (*USP39*)

BRIEFING

Acetonitrile, Chromatographic. It is proposed to add this new reagent.

(HDQ: M. Marques.)

Correspondence Number—C161640

Comment deadline: November 30, 2015

Add the following:

■ Acetonitrile, Chromatographic—Use ACS reagent grade, which meets the requirements for liquid chromatography suitability. ■ 2S (USP39)

BRIEFING

Ascorbic Acid. It is proposed to add this new reagent.

(HDQ: M. Marques.)

Correspondence Number—C161905

Comment deadline: November 30, 2015

Add the following:

■ Ascorbic Acid (Vitamin C), $C_6H_8O_6$ —**176.13** [50-81-7]—Use ACS reagent grade. ■ 2S (USP39)

BRIEFING

Citric Acid, *USP 38* page 1831. It is proposed to update the specification of this reagent.

Additionally, minor editorial changes have been made to update the reagent to current *USP* style.

(HDQ: M. Marques.)

Correspondence Number—C162133

Comment deadline: November 30, 2015

Change to read:

Citric Acid, Use *Citric Acid Monohydrate* (USP monograph):

■ $C_6H_8O_7 \cdot H_2O$ —**210.14**[5949-29-1]—Use ACS reagent grade. ■ 2S (USP39)

BRIEFING

Citric Acid, Anhydrous, *USP 38* page 1831. It is proposed to update the specification of this reagent.

Additionally, minor editorial changes have been made to update the reagent to current *USP* style.

(HDQ: M. Marques.)

Correspondence Number—C162217

Comment deadline: November 30, 2015

Change to read:

Citric Acid, Anhydrous,

■ $C_6H_8O_7$ —**192.13** ■ 2S (USP39)

[77-92-9]—Use ~~Anhydrous Citric Acid~~ (USP monograph).

- Use ACS reagent grade. ■ 2S (USP39)
-

BRIEFING

4-Cyanopyridine. It is proposed to add this new reagent used for peak identification/system suitability in the test for *Organic Impurities* in the monograph for *Isoniazid*.

(HDQ: M. Marques.)

Correspondence Number—C161526

Comment deadline: November 30, 2015

Add the following:

- 4-Cyanopyridine (*4-Pyridinecarbonitrile; Isonicotinic Acid Nitrile; Isonicotinonitrile*), $C_6H_4N_2$ —**104.11** [100-48-1]—Use a suitable grade with a content of NLT 98%. ■ 2S (USP39)
-

BRIEFING

2-Isoniazid. It is proposed to add this new reagent used for peak identification/system suitability in the test for *Organic Impurities* in the monograph for *Isoniazid*.

(HDQ: M. Marques.)

Correspondence Number—C161524

Comment deadline: November 30, 2015

Add the following:

- 2-Isoniazid (*2-Pyridinecarboxylic acid hydrazide; Picolinic acid hydrazide; 2-Picolinyl hydrazide*), $C_6H_7N_3O$ —**137.14** [1452-63-7]—Use a suitable grade with a content of NLT 98.0%. [Note—A suitable grade is available as catalog number P0426 from www.tcichemicals.com.] ■ 2S (USP39)
-

BRIEFING

Isonicotinamide. It is proposed to add this new reagent used for peak identification/system suitability in the test for *Organic Impurities* in the monograph for *Isoniazid*.

(HDQ: M. Marques.)

Correspondence Number—C161525

Comment deadline: November 30, 2015

Add the following:

- Isonicotinamide (*Pyridine-4-carboxylic Acid Amide*), $C_6H_6N_2O$ —**122.12** [1453-82-3]—Use a suitable grade with a content of NLT 99%. ■ 2S (USP39)
-

BRIEFING

Methanol, Chromatographic. It is proposed to add this new reagent.

(HDQ: M. Marques.)

Correspondence Number—C161641

Comment deadline: November 30, 2015

Add the following:

■ Methanol, Chromatographic—Use ACS reagent grade, which meets the requirements for liquid chromatography suitability. ■2S (USP39)

BRIEFING

L-Phenylalanine. It is proposed to add this new reagent.

(HDQ: M. Marques.)

Correspondence Number—C162310

Comment deadline: November 30, 2015

Add the following:

■ L-Phenylalanine ((*S*)-2-Amino-3-phenylpropionic acid), C₉H₁₁NO₂—**165.19** [63-91-2]—Use a suitable grade with a content of NLT 98%. ■2S (USP39)

BRIEFING

Polyethylene Glycol Standards with Molecular Weights of 1000, 2000, 3000, 4000, and 6000 Daltons (g/mol). It is proposed to add this new reagent used in the monograph for *Polyethylene Glycol 3350*, published in PF 41(4) [July–Aug. 2015].

(HDQ: M. Marques.)

Correspondence Number—C161035

Comment deadline: November 30, 2015

Add the following:

■ Polyethylene Glycol Standards with Molecular Weights of 1000, 2000, 3000, 4000, and 6000 Daltons (g/mol) (*Poly(oxy-1,2-ethanediyl), α-hydroxy-Ω-hydroxy-; 1,2-Ethandiol, homopolymer*), H(OCH₂CH₂)_nOH, in which the average values of *n* are 22, 45, 69, 92, and 149—average molecular weight (*M_w*), 1020, 2010, 3060, 4080, and 6550 [25332-68-3]—Use molecular weight standard grades. [Note—Suitable grades are available from www.polymer.de.] ■2S (USP39)

BRIEFING

Silver Sulfate. It is proposed to add this new reagent.

(HDQ: M. Marques.)

Correspondence Number—C162122

Comment deadline: November 30, 2015

Add the following:

■ Silver Sulfate, Ag₂SO₄—**311.80** [10294-26-5]—Use ACS reagent grade. ■2S (USP39)

BRIEFING

10% Ascorbic Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161906

Add the following:

■ **10% Ascorbic Acid TS**—Transfer 10 g of *ascorbic acid* to a 100-mL volumetric flask. Dissolve in and dilute with water to volume. ■ 2S (USP39)

BRIEFING

0.001 N Hydrochloric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161847

Add the following:

■ **0.001 N Hydrochloric Acid TS**—Transfer 1.0 mL of *1 N hydrochloric acid VS* to a 1000-mL volumetric flask and dilute with water to volume. ■ 2S (USP39)

BRIEFING

0.06 N Hydrochloric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C162048

Add the following:

■ **0.06 N Hydrochloric Acid TS**—Transfer 20.0 mL of *3 N hydrochloric acid TS* to a 1000-mL volumetric flask. Dilute with water to volume. ■ 2S (USP39)

BRIEFING

0.36 N Hydrochloric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C162068

Add the following:

■ **0.36 N Hydrochloric Acid TS**—Transfer 120 mL of *3 N hydrochloric acid TS* to a 1000-mL volumetric flask. Dilute with water to volume. ■ 2S (USP39)

BRIEFING

2 N Hydrochloric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161902

Add the following:

■ **2 N Hydrochloric Acid TS**—Transfer 17.0 mL of *hydrochloric acid* to a 100-mL volumetric flask containing about 50 mL of water. Cool and dilute with water to volume. ■ 2S (USP39)

BRIEFING

3 N Hydrochloric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C162040

Add the following:

■ **3 N Hydrochloric Acid TS**—Transfer 246 mL of *hydrochloric acid* to a 1000-mL volumetric

flask containing about 500 mL of water. Cool and dilute with water to volume. ■ 2S (USP39)

BRIEFING

6 N Hydrochloric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161647

Add the following:

■ **6 N Hydrochloric Acid TS**—Slowly transfer 49.8 mL of *hydrochloric acid* to a 100-mL volumetric flask containing about 45 mL of water. Cool and dilute with water to volume.

■ 2S (USP39)

BRIEFING

0.01 N Nitric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161904

Add the following:

■ **0.01 N Nitric Acid TS**—Transfer 10.0 mL of *1 N nitric acid TS* to a 1000-mL volumetric flask. Dilute with water to volume. ■ 2S (USP39)

BRIEFING

0.2 N Nitric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C162121

Add the following:

■ **0.2 N Nitric Acid TS**—Slowly transfer 12.7 mL of *nitric acid* to a 1000-mL volumetric flask containing about 250 mL of water. Cool and dilute with water to volume. ■ 2S (USP39)

BRIEFING

1 N Nitric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161903

Add the following:

■ **1 N Nitric Acid TS**—Transfer 63.7 mL of *nitric acid* to a 1000-mL volumetric flask containing about 250 mL of water. Cool and dilute with water to volume. ■ 2S (USP39)

BRIEFING

2 N Nitric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161659

Add the following:

■ **2 N Nitric Acid TS**—Transfer 12.74 mL of *nitric acid* slowly to a 100-mL volumetric flask containing about 40 mL of water. Cool and dilute with water to volume. ■ 2S (USP39)

BRIEFING

10% Phosphoric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161846

Add the following:

■ **10% Phosphoric Acid TS**—Transfer 7 mL of *phosphoric acid* to a 100-mL volumetric flask containing about 50 mL of water. Cool and dilute with water to volume. ■2S (USP39)

BRIEFING

2 N Potassium Hydroxide TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161593

Add the following:

■ **2 N Potassium Hydroxide TS**—Dissolve 112.2 g of *potassium hydroxide* in about 800 mL of water. Cool and dilute with water to 1000 mL. ■2S (USP39)

BRIEFING

20% Potassium Iodide TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161907

Add the following:

■ **20% Potassium Iodide TS**—Transfer 20 g of *potassium iodide* to a 100-mL volumetric flask. Dissolve in and dilute with water to volume. ■2S (USP39)

BRIEFING

0.2 N Sodium Hydroxide TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161850

Add the following:

■ **0.2 N Sodium Hydroxide TS**—Transfer 10.0 mL of *2 N sodium hydroxide TS* to a 100-mL volumetric flask and dilute with water to volume. ■2S (USP39)

BRIEFING

5 N Sodium Hydroxide TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161804

Add the following:

■ **5 N Sodium Hydroxide TS**—Transfer 20 g of *sodium hydroxide* to a 100-mL volumetric flask. Dissolve in about 80 mL of water. Cool and dilute with water to volume. ■2S (USP39)

BRIEFING

0.02 N Sulfuric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161934

Add the following:

■ **0.02 N Sulfuric Acid TS**—Transfer 2.9 mL of 7 N sulfuric acid TS to a 1000-mL volumetric flask and dilute with water to volume. ■2S (USP39)

BRIEFING

6 N Sulfuric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161909

Add the following:

■ **6 N Sulfuric Acid TS**—Slowly transfer 168.5 mL of sulfuric acid to a 1000-mL volumetric flask containing about 500 mL of water. Cool and dilute with water to volume. ■2S (USP39)

BRIEFING

7 N Sulfuric Acid TS. It is proposed to add this new test solution.

(HDQ: M. Marques.)

Correspondence Number—C161910

Add the following:

■ **7 N Sulfuric Acid TS**—Slowly transfer 196.5 mL of sulfuric acid to a 1000-mL volumetric flask containing about 500 mL of water. Cool and dilute with water to volume. ■2S (USP39)

BRIEFING

0.07 N Ferrous Ammonium Sulfate VS. It is proposed to add this new volumetric solution.

(HDQ: M. Marques.)

Correspondence Number—C162130

Comment deadline: November 30, 2015

Add the following:

■ **0.07 N Ferrous Ammonium Sulfate VS**

$\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$, **392.14**

27.5 g in 1000 mL

In a 100-mL volumetric flask, dissolve 27.5 g of ferrous ammonium sulfate in 500 mL of water. Add 20 mL of sulfuric acid. Cool and dilute with water to volume.

Standardize this solution on the day of use as follows. Dilute 25 mL of 0.025 N potassium dichromate VS with water to 100 mL. Add 30 mL of sulfuric acid and cool to room temperature. Add 3 drops of ferroin TS and titrate with 0.07 N ferrous ammonium sulfate VS. The color change is sharp, going from blue-green to reddish brown.

$$N = \frac{\text{mL K}_2\text{Cr}_2\text{O}_7 \times N\text{K}_2\text{Cr}_2\text{O}_7}{\text{mL Fe}(\text{NH}_4)_2\text{SO}_4)_2}$$

■ 2S (USP39)

BRIEFING

0.1 N Hydrochloric Acid VS. It is proposed to add this new volumetric solution.

(HDQ: M. Marques.)

Correspondence Number—C161529

Comment deadline: November 30, 2015

Add the following:

■ **0.1 N Hydrochloric Acid VS**

HCl, **36.46**

3.646 g in 1000 mL

Dilute 8.5 mL of *hydrochloric acid* with water to 1000 mL.

Standardize the solution as follows.

Accurately weigh about 2.5 g of *tromethamine*, dried according to the label instructions or, if this information is not available, dried at 105° for 3 h. Dissolve in 50 mL of water, and add 2 drops of *bromocresol green TS*. Titrate with 0.1 N hydrochloric acid to a pale yellow endpoint. Each 12.114 mg of *tromethamine* is equivalent to 1 mL of 0.1 N hydrochloric acid.

[Note—If this volumetric solution is used in a qualitative application such as pH adjustment, dissolution medium, or diluent, its standardization is not required.]

$$N = \frac{\text{mg tromethamine}}{121.14 \times \text{mL HCl}}$$

■ 2S (USP39)

BRIEFING

0.025 N Potassium Dichromate VS. It is proposed to add this new volumetric solution.

(HDQ: M. Marques.)

Correspondence Number—C162123

Comment deadline: November 30, 2015

Add the following:

■ **0.025 N Potassium Dichromate VS**

$K_2Cr_2O_7$ **294.18**

1.2259 g in 1000 mL

Transfer 12.259 g of *potassium dichromate* primary standard, previously dried according to the label instructions or, if this information is not available, dried at 103° for 2 h, to a 1000-mL volumetric flask. Dissolve in and dilute with water to volume. Transfer 100.0 mL of this solution to a 1000-mL volumetric flask and dilute with water to volume. ■2S (USP39)

BRIEFING

L90. It is proposed to add this new column packing used in the test for *Enantiomeric Purity* in the monograph for *Frovatriptan Succinate*, published elsewhere in this issue of *PF*.

(HDQ: M. Marques.)

Correspondence Number—C154837

Comment deadline: November 30, 2015

Add the following:

■ L90—Amylose tris-[(S)- α -methylbenzyl]carbamate coated on porous, spherical silica particles, 3–10 μ m in diameter. ■2S (USP39)

BRIEFING

L91. It is proposed to add this new column used in the chromatographic procedure in the test for *Purity* in general chapters *Collagenase I* (89.1) and *Collagenase II* (89.2), published elsewhere in this issue of *PF*.

(HDQ: M. Marques.)

Correspondence Number—C153137

Comment deadline: November 30, 2015

Add the following:

■ L91—Strong anion-exchange resin consisting of monodisperse polystyrene/divinyl benzene beads coupled with quaternary amine. Bead size is 10 μ m. [Note—A suitable column is available as Mono Q 5/50 GL from <http://www.gelifesciences.com/webapp/wcs/stores/servlet/productById/en/GELifeSciences-us/17516601>.] ■2S (USP39)

CONTAINERS FOR DISPENSING CAPSULES AND TABLETS

BRIEFING

Container Specifications for Capsules and Tablets, page 7697 of the *Second Supplement to USP 38*.

(HDQ.)

Correspondence Number—C109140;

C130330;C130331;C133990;C136127;C137138;C137240;C143061;C143427;C151124;C153117;C16

The following table is provided as a reminder for the pharmacist engaged in the typical

dispensing situation who already is acquainted with the *Packaging and Storage* requirements set forth in the individual monographs. It lists the capsules and tablets that are official in the *United States Pharmacopeia* and indicates the relevant tight (T), well-closed (W), and light-resistant (LR) specifications applicable to containers in which the drug that is repackaged should be dispensed.

This table is not intended to replace, nor should it be interpreted as replacing, the definitive requirements stated in the individual monographs.

Container Specifications for Capsules and Tablets

Monograph Title	Container Specification
Change to read: Chlorothiazide Tablets	W, ■ LR _{2S} (USP39)
Change to read: Codeine Sulfate Tablets	W, ■ LR _{2S} (USP39)
Delete the following: ■ Doxasetron Mesylate Tablets	W, LR_{2S} (USP39)
Add the following: ■ Eleuthero Root and Rhizome Dry Extract Capsules	W, LR _{2S} (USP39)
Add the following: ■ Eleuthero Root and Rhizome Dry Extract Tablets	W, LR _{2S} (USP39)
Add the following: ■ Frovatriptan Tablets	T _{2S} (USP39)
Add the following: ■ Imipramine Pamoate Capsules	T, LR _{2S} (USP39)
Add the following: ■ Metronidazole Extended-Release Tablets	W _{2S} (USP39)
Add the following: ■ Nebivolol Tablets	T, LR _{2S} (USP39)
Add the following: ■ Quetiapine Extended-Release Tablets	W _{2S} (USP39)
Add the following: ■ Ropinirole Extended-Release Tablets	W _{2S} (USP39)
Add the following: ■ Ziprasidone Capsules	W _{2S} (USP39)

BRIEFING

Description and Relative Solubility of USP and NF Articles, page 7708 of the *Second Supplement to USP 38*.

(HDQ.)

C162763;C155480;C154837;C125865;C162939;C161670;C151320;C161930;C162489

Add the following:

■ **Acamprosate Calcium:** A white or almost-white powder. Freely soluble in water; practically insoluble in alcohol and in methylene chloride. ■ 2S (USP39)

Change to read:

Desoxycholic Acid:

■ [(Title for this monograph is not to change until December 1, 2021.) Prior to December 1, 2021, the current practice of labeling the article of commerce with the name Desoxycholic Acid may be continued. Use of the name Deoxycholic Acid will be permitted as of December 1, 2016; however, the use of this name will not be mandatory until December 1, 2021. The 60-month extension will provide the time needed by manufacturers and users to make necessary changes.] **Deoxycholic Acid:** ■ 2S (NF34)

Occurs as a white, crystalline powder. Freely soluble in alcohol; soluble in acetone and in solutions of alkali hydroxides and carbonates; slightly soluble in chloroform and in ether; practically insoluble in water. *NF category:* Emulsifying agent.

Change to read:

Estradiol: White or creamy white, small crystals or crystalline powder. Is odorless, and is stable in air. Is hygroscopic. Soluble in alcohol, in acetone, in dioxane, ~~in chloroform,~~

■ ■ 2S (USP39)

and in solutions of fixed alkali hydroxides;

■ slightly soluble in chloroform; ■ 2S (USP39)

sparingly soluble in vegetable oils; practically insoluble in water.

Add the following:

■ **Frovatriptan Succinate:** A white to off-white powder. Soluble in water; very slightly soluble in methanol. ■ 2S (USP39)

Add the following:

■ **Methylnaltrexone Bromide:** White to almost-white crystalline powder. Freely soluble in dimethylsulfoxide; soluble in dimethylformamide and in water; slightly soluble in methanol; very slightly soluble in ethanol; practically insoluble in toluene. ■ 2S (USP39)

Change to read:

Naphazoline Hydrochloride: White, crystalline powder. ~~Is odorless and has a bitter taste. Melts at a temperature of about 255°, with decomposition. Freely soluble in water and in alcohol; very slightly soluble in chloroform; practically insoluble in ether.~~

■ Freely soluble in water; soluble in alcohol. ■ 2S (USP39)

Add the following:

■ **Nebivolol Hydrochloride:** White to off-white powder. Soluble in dimethyl sulfoxide; practically insoluble in acetone, in purified water, and in 0.1 N hydrochloric acid. ■ 2S (USP39)

Add the following:

■ **Sodium Succinate:** White crystals or white powder. Freely soluble in water. *NF category:* Flavors and fragrance. ■2S (NF34)

Add the following:

■ **Solifenacin Succinate:** White to pale, yellowish-white crystal or crystalline powder. Freely soluble in water and in methanol. ■2S (USP39)

Change to read:

Thalidomide: White to off-white powder. Very soluble in ~~dimethylformamide, in dioxane, and in pyridine~~

■ dimethyl sulfoxide; ■2S (USP39)

sparingly soluble in ~~acetone, in butyl acetate, in ethanol, in ethyl acetate, in glacial acetic acid, in methanol, and in water; practically insoluble in benzene, in chloroform, and in ether~~

■ in ethanol, and in water. ■2S (USP39)

BRIEFING**Excipients, USP and NF Excipients, Listed by Functional Category, USP 38 page 6493.**

It is proposed to change the *Emulsifying Agent* category for *Desoxycholic Acid* to complement the proposed title change to the *Desoxycholic Acid* monograph, which also appears in this issue of *PF*. It is also proposed to add Sodium Succinate to the *Flavors and Fragrance* category to complement the proposed *Sodium Succinate* monograph, which also appears in this issue of *PF*.

(HDQ: G. Holloway, H. Wang.)

Correspondence Number—C151320; C162763

In the following reference table, the grouping of excipients by functional category is intended to summarize commonly identified purposes that these excipients serve in drug product formulations. The association of a functional category with a particular dosage form in this table is not absolute and does not limit the use of an excipient to a single type of dosage form or delivery system.

Change to read:**Emulsifying Agent**

BRIEFING

Acamprosate Calcium. Because there is no existing *USP* monograph for this drug substance, a new monograph, based on validated methods of analysis, is proposed.

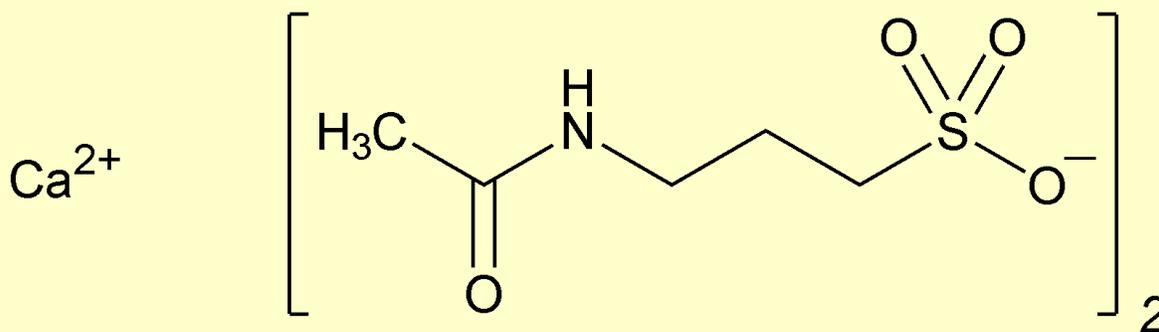

1. The liquid chromatographic procedures used in the proposed *Assay* and the test for *Organic Impurities* are based on analyses performed with the Cosmosil C18-PAQ brand of L1 column manufactured by Nacalai. The retention time for acamprosate is about 9.5 min.
2. The liquid chromatographic procedure within the proposed *Limit of Acamprosate Related Compound A* test is based on analyses conducted using the Hypersil ODS brand of L1 column manufactured by Thermo Fisher with a 5- μ m particle size. The retention time for acamprosate related compound A is about 10 min. A Discovery HS C18 brand of L1 column manufactured by Supelco may also be suitable.

All interested parties are encouraged to submit their FDA-approved specifications to USP if they are wider than those proposed.

(CHM4: H. Joyce.)

Correspondence Number—C142092

Comment deadline: November 30, 2015

Add the following:**■ Acamprosate Calcium**

$C_{10}H_{20}CaN_2O_8S_2$ 400.48

1-Propanesulfonic acid, 3-(acetylamino)-, calcium salt (2:1);
Calcium 3-(acetylamino)propane-1-sulfonate [77337-73-6].

DEFINITION

Acamprosate Calcium contains NLT 98.0% and NMT 102.0% of acamprosate calcium ($C_{10}H_{20}CaN_2O_8S_2$), calculated on the dried basis.

IDENTIFICATION

- **A. Infrared Absorption** (197K)
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.
- **C. Identification Tests—General** (191), *Calcium*: Meets the requirements for the oxalate precipitation test

ASSAY

• Procedure

Mobile phase: Add 5.0 mL of *triethylamine* per 1 L of water and adjust with *phosphoric acid* to a pH of 4.0.

System suitability solution: 10 mg/mL of USP Acamprosate Calcium RS and 0.005 mg/mL each of USP Acamprosate Related Compound B RS and *glacial acetic acid* in water. Sonication may be used to aid in dissolution.

Standard solution: 0.3 mg/mL of USP Acamprosate Calcium RS in water. Sonication may be used to aid in dissolution.

Sample solution: 0.3 mg/mL of Acamprosate Calcium in water. Sonication may be used to aid in dissolution.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 210 nm

Column: 4.6-mm × 25-cm; 5- μ m packing L1

Flow rate: 0.7 mL/min

Injection volume: 20 μ L

Run time: NLT 2 times the retention time of the acamprosate peak

System suitability

Samples: *System suitability solution* and *Standard solution*

[Note—See *Table 1* for relative retention times.]

Suitability requirements

Resolution: NLT 1.5 between acetic acid and acamprosate related compound B; NLT 1.3 between acamprosate related compound B and acamprosate, *System suitability solution*

Tailing factor: NMT 2.0, *Standard solution*

Relative standard deviation: NMT 1.0%, *Standard solution*

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of acamprosate calcium ($C_{10}H_{20}CaN_2O_8S_2$) in the portion of Acamprosate Calcium taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*

r_S = peak response from the *Standard solution*

C_S = concentration of USP Acamprosate Calcium RS in the *Standard solution* (mg/mL)

C_U = concentration of Acamprosate Calcium in the *Sample solution* (mg/mL)

Acceptance criteria: 98.0%–102.0% on the dried basis

IMPURITIES

• Limit of Acamprosate Related Compound A

Solution A: 5 g/L of *fluorescamine* in acetonitrile. Use within 24 h of preparation.

Buffer: 13.8 g/L of *monobasic sodium phosphate* prepared as follows. Transfer a suitable amount of *monobasic sodium phosphate* to a volumetric flask. Dissolve in 90% of the final flask volume of water. Adjust with 10 M *sodium hydroxide* or *phosphoric acid* to a pH of 6.5. Dilute with water to volume.

Mobile phase: *Acetonitrile*, *methanol*, and *Buffer* (10:10:80)

Diluent: 24.6 g/L of *boric acid* prepared as follows. Transfer a suitable amount of *boric acid* to an appropriate volumetric flask. Dissolve in 90% of the final flask volume of water. Adjust with 10 M *sodium hydroxide* to a pH of 10.4. Dilute with water to volume.

Standard stock solution A: 250 µg/mL of USP Acamprosate Related Compound A RS in water

Standard stock solution B: 1 µg/mL of USP Acamprosate Related Compound A RS from *Standard stock solution A* in *Diluent*

Standard solution: Transfer 3.0 mL of *Standard stock solution B* to an appropriate container. Add 0.15 mL of *Solution A* and shake vigorously for 30 s. Heat in a water bath at 50° for 30 min. Cool under a stream of cold water, centrifuge, and pass the supernatant through a suitable membrane filter.

Sample stock solution A: 20 mg/mL of Acamprosate Calcium in water

Sample stock solution B: 2 mg/mL of Acamprosate Calcium from *Sample stock solution A* in *Diluent*

Sample solution: Transfer 3.0 mL of *Sample stock solution B* to an appropriate container. Add 0.15 mL of *Solution A* and shake for 30 s. Heat in a water bath at 50° for 30 min. Cool under a stream of cold water, centrifuge, and pass the supernatant through a suitable membrane filter.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 261 nm

Column: 4.6-mm × 15-cm; 3-µm or 5-µm packing L1

Flow rate: 1 mL/min

Injection volume: 20 μ L

Run time: NLT 2 times the retention time of acamprosate related compound A

System suitability

Sample: *Standard solution*

[Note—The relative retention times for fluorecamine and acamprosate related compound A are about 0.5 and 1.0, respectively. Acamprosate calcium is not detected by this chromatographic system.]

Suitability requirements

Resolution: NLT 2.0 between fluorecamine and acamprosate related compound A

Relative standard deviation: NMT 5.0% for acamprosate related compound A

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of acamprosate related compound A in the portion of Acamprosate Calcium taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*

r_S = peak response from the *Standard solution*

C_S = concentration of USP Acamprosate Calcium Related Compound A RS in the *Standard solution* (mg/mL)

C_U = concentration of Acamprosate Calcium in the *Sample solution* (mg/mL)

Acceptance criteria: NMT 0.05%

• Organic Impurities

Mobile phase: Add 5.0 mL of *triethylamine* per 1 L of water and adjust with *phosphoric acid* to a pH of 4.0.

System suitability solution: 10 mg/mL of USP Acamprosate Calcium RS and 0.005 mg/mL each of USP Acamprosate Related Compound B RS and *glacial acetic acid* in water. Sonication may be used to aid in dissolution.

Standard solution: 0.005 mg/mL of USP Acamprosate Calcium RS in water. Sonication may be used to aid in dissolution.

Sample solution: 10 mg/mL of Acamprosate Calcium in water. Sonication may be used to aid in dissolution.

Chromatographic system

(See *Chromatography* <621>, *System Suitability*.)

Mode: LC

Detector: UV 210 nm

Column: 4.6-mm \times 25-cm; 5- μ m packing L1

Flow rate: 0.7 mL/min

Injection volume: 20 μ L

Run time: NLT 6 times the retention time of the acamprosate peak

System suitability

Samples: *System suitability solution* and *Standard solution*

[Note—See *Table 1* for relative retention times.]

Suitability requirements

Resolution: NLT 1.5 between acetic acid and acamprosate related compound B; NLT 1.3 between acamprosate related compound B and acamprosate, *System suitability solution*

Tailing factor: NMT 1.5 for acamprosate, *Standard solution*

Relative standard deviation: NMT 15.0% for acetic acid, *System suitability solution*; NMT 5% for acamprosate, *Standard solution*

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of each impurity in the portion of Acamprosate Calcium taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response for each impurity from the *Sample solution*

r_S = peak response of acamprosate from the *Standard solution*

C_S = concentration of USP Acamprosate Calcium RS in the *Standard solution* (mg/mL)

C_U = concentration of Acamprosate Calcium in the *Sample solution* (mg/mL)

Acceptance criteria: See *Table 1*. Disregard peaks less than 0.05%.

Table 1

Name	Relative Retention Time	Acceptance Criteria, NMT (%)
Calcium ^a	0.4	—
Acetic acid	0.7	0.10
Acamprosate related compound B	0.8	0.05
Acamprosate	1.0	—
<i>N</i> -Methyl acamprosate ^b	1.9	0.05
Any individual, unspecified impurity	—	0.10
Total impurities ^c	—	0.30

^a Included for identification only. This peak is due to the calcium counterion and hence is not an impurity.

^b 3-(*N*-Methylacetamido)propane-1-sulfonate.

^c The sum of acamprosate related compound A from the *Limit of Acamprosate Related Compound A* test and all impurities from the test for *Organic Impurities*; do not include acetic acid in the total impurities.

SPECIFIC TESTS

- **pH** (791)

Sample solution: 0.05 g/mL of Acamprosate Calcium in *carbon dioxide-free water*

Acceptance criteria: 5.5–7.0

- **Loss on Drying** (731)

Analysis: Dry at 105° for 3h.

Acceptance criteria: NMT 0.4%

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Store in tight containers.

- **USP Reference Standards** (11)

USP Acamprosate Calcium RS

USP Acamprosate Related Compound A RS

3-Aminopropane-1-sulfonic acid.

C₃H₉NO₃S 139.17

■ 2S (USP39)

BRIEFING

Acetaminophen Suppositories, *USP 38* page 2008. As part of the USP monograph modernization initiative, the following revisions are proposed:

1. A new HPLC procedure for monitoring 4-aminophenol, based on *4-Aminophenol in Acetaminophen-Containing Drug Products* (227), is proposed. This liquid chromatographic procedure is based on analyses performed with the Dionex Acclaim Mixed Mode WCX-1 brand of L85 column. The proposed limit for 4-aminophenol is 0.15%.
2. USP 4-Aminophenol RS is added to the *USP Reference Standards* section to support the proposed revision.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

(CHM6: C. Anthony.)

Correspondence Number—C128008

Comment deadline: November 30, 2015

Acetaminophen Suppositories

DEFINITION

Acetaminophen Suppositories contain NLT 90.0% and NMT 110.0% of the labeled amount of acetaminophen (C₈H₉NO₂).

IDENTIFICATION

- **A.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*.
- **B. Thin-Layer Chromatographic Identification Test** (201)

Sample solution: Transfer the equivalent of 20 mg of acetaminophen from a portion of Suppositories to a beaker. Add 20 mL of methanol and heat on a steam bath until melted. Remove the beaker from the steam bath, allow to cool with occasional stirring, and filter. Use the clear filtrate.

Chromatographic system

Developing solvent system: Methylene chloride and methanol (4:1)

Acceptance criteria: Meet the requirements

ASSAY**Change to read:**

- **Procedure**

Mobile phase: Methanol and water (1:3)

Standard solution: 0.01 mg/mL of USP Acetaminophen RS in *Mobile phase*

Sample stock solution: Nominally 0.5 mg/mL of acetaminophen prepared as follows. Tare a small dish and a glass rod, place NLT 5 Suppositories in the dish, heat gently on a steam bath until melted, stir, cool while stirring, and weigh. Transfer a weighed portion of the mass, equivalent to 100 mg of acetaminophen, to a separator, •add 30 mL of solvent hexane, •(ERR 1-Jun-2014) and dissolve. Add 30 mL of water, shake gently, and allow the phases to separate. If an emulsion forms, allow sufficient time for it to separate. Transfer the aqueous layer to a 200-mL volumetric flask, •wash the solvent hexane •(ERR 1-Jun-2014) in the separator with three 30-mL portions of water, adding the washings to the volumetric flask. Dilute with *Mobile phase* to volume.

Sample solution: Nominally 0.01 mg/mL of acetaminophen in *Mobile phase* from the *Sample stock solution*. Pass a portion of this solution through a filter of 0.5- μ m or finer pore size, discarding the first 10 mL of the filtrate. Use the clear filtrate.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 243 nm

Column: 3.9-mm \times 30-cm; packing L1

Flow rate: 1.5 mL/min

Injection volume: 10 μ L

System suitability

Sample: *Standard solution*

Suitability requirements

Column efficiency: NLT 1000 theoretical plates

■ **2S (USP39)**

Tailing factor: NMT 2

Relative standard deviation: NMT 2.0%

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of acetaminophen ($C_8H_9NO_2$) in the portion of Suppositories taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response from the *Sample solution*

r_S = peak response from the *Standard solution*

C_S = concentration of USP Acetaminophen RS in the *Standard solution* (mg/mL)

C_U = nominal concentration of acetaminophen in the *Sample solution* (mg/mL)

Acceptance criteria: 90.0%–110.0%

IMPURITIES

Add the following:

■ ● **4-Aminophenol in Acetaminophen-Containing Drug Products** <227>

Buffer: 4.0 g/L of sodium citrate dihydrate and 1.5 g/L of anhydrous citric acid, in water

Diluent: *Buffer* and acetonitrile (9:1)

Sample stock solution: Approximately 12–13 mg/mL of acetaminophen prepared as follows. Transfer an appropriate number of whole Suppositories to a suitable volumetric flask. Add *Diluent* until the flask is about half filled and sonicate for 1 h with frequent swirling. Allow to cool and then dilute with *Diluent* to volume.

Sample solution: Approximately 4.8–5.2 mg/mL of acetaminophen in *Diluent* from the *Sample stock solution* prepared as follows. Pipet 20.0 mL of the *Sample stock solution* into a 50-mL volumetric flask and dilute with *Diluent* to volume.

Acceptance criteria: Meet the requirements ■ **2S (USP39)**

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in tight containers, and store at controlled room temperature or in a cool place.

- **USP Reference Standards** <11>

USP Acetaminophen RS

■ **USP 4-Aminophenol RS**

■ **2S (USP39)**

BRIEFING

Albuterol Tablets, *USP 38* page 2072. As a part of USP monograph modernization efforts,

the following revisions are proposed:

1. Replace the TLC procedure in *Identification* test *A* with a retention time agreement from the liquid chromatographic procedure in the *Assay*.
2. Delete the identification test for *Sulfate* because the counter ion is controlled in the drug substance.
3. Add *Identification* test *B* based on a diode-array spectra agreement from the chromatographic procedures in the *Assay*.
4. Add the use of a diode-array detector in the *Assay* to support the proposed *Identification* test *B*.
5. Specify the particle size of the columns used in the *Assay* and *Dissolution* tests.
6. Remove *Column efficiency* from the system suitability requirements in the *Assay* and *Dissolution* tests. The remaining criteria are adequate to evaluate system suitability.
7. Add an equation to the *Dissolution* test for consistency with current *USP* style.
8. Replace the TLC procedure in the test for *Organic Impurities* with a stability-indicating liquid chromatographic procedure. The LC procedure is based on validated analyses performed with the Waters Acquity UPLC BEH C18 brand of L1 column. The typical retention time for albuterol is about 2.7 min.
9. Add the new Reference Standards to the *USP Reference Standards* section to support the proposed test for *Organic Impurities*.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Interested parties are encouraged to submit validated dissolution procedures, which test individual units, along with supporting data to further improve the monograph.

Albuterol Tablets

DEFINITION

Albuterol Tablets contain an amount of albuterol sulfate $[(C_{13}H_{21}NO_3)_2 \cdot H_2SO_4]$ equivalent to NLT 90.0% and NMT 110.0% of the labeled amount of albuterol ($C_{13}H_{21}NO_3$).

IDENTIFICATION

Change to read:

- **A.** ~~The R_f value of the principal spot of the *Sample solution* corresponds to that of *Standard solution A*, obtained as directed in the *Procedure for Organic Impurities*.~~
 - The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ■2S (*USP39*)

Delete the following:

■ ● **B. Identification Tests—General, Sulfate** (191)

Sample solution: Shake a quantity of powdered Tablets equivalent to 4 mg of albuterol with 10 mL of water, and filter. Use the filtrate.

Acceptance criteria: Meet the requirements ■ 2S (USP39)

Add the following:

- ● **B.** The UV spectrum of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ■ 2S (USP39)

ASSAY

Change to read:

● **Procedure**

Solution A: 10 mL/L of *glacial acetic acid* in water

Solution B: 1.13 g of *sodium 1-hexanesulfonate* in 1200 mL of water. Add 12 mL of *glacial acetic acid*.

Diluent: *Methanol* and water (40:60)

Mobile phase: *Methanol* and *Solution B* (40:60)

Standard stock solution: 0.12 mg/mL of USP Albuterol Sulfate RS, prepared as follows.

Transfer USP Albuterol Sulfate RS to a suitable volumetric flask and add 60% of the final flask volume of *Solution A*. Sonicate for 5 min and dilute with *methanol* to volume.

Standard solution: 0.03 mg/mL of USP Albuterol Sulfate RS from the *Standard stock solution* in *Diluent*

Sample solution: Nominally 0.025 mg/mL of albuterol, prepared as follows. Transfer a number of whole Tablets, equivalent to 50 mg of albuterol, to a suitable volumetric flask. Add 60% of the final flask volume of *Solution A*, shake by mechanical means for 45 min, sonicate for 10 min, allow to cool to room temperature, and dilute with *methanol* to volume. Pass through a suitable filter of 0.45- μ m or finer pore size.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 276 nm.

- For *Identification* test B, use a diode-array detector in the range of 200–400 nm.

■ **2S (USP39)**

Tailing factor: NMT 2.5

Relative standard deviation: NMT 2.0%

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of albuterol ($C_{13}H_{21}NO_3$) dissolved:

■

$$\text{Result} = (r_U/r_S) \times C_S \times V \times M \times (M_{r1}/M_{r2}) \times (1/L) \times 100$$

r_U = peak response from the *Sample solution*

r_S = peak response from the *Standard solution*

C_S = concentration of USP Albuterol Sulfate RS in the *Standard solution* (mg/mL)

V = volume of *Medium*, 500 mL

M = number of moles of albuterol per mole of albuterol sulfate, 2

M_{r1} = molecular weight of albuterol, 239.31

M_{r2} = molecular weight of albuterol sulfate, 576.70

L = label claim (mg/Tablet) ■ **2S (USP39)**

Acceptance criteria: NLT 80% (Q) of the labeled amount of albuterol ($C_{13}H_{21}NO_3$) is dissolved.

- **Uniformity of Dosage Units** (905): Meet the requirements

IMPURITIES

Change to read:

- **Organic Impurities**

Standard solution A: ~~0.580 mg/mL of USP Albuterol Sulfate RS in water, equivalent to 0.483 mg/mL of albuterol~~

Standard solution B: ~~0.218 mg/mL of USP Albuterol Sulfate RS in water, equivalent to 0.183 mg/mL of albuterol~~

Standard solution C: ~~0.073 mg/mL of USP Albuterol Sulfate RS in water, equivalent to 0.061 mg/mL of albuterol~~

Sample solution: ~~Place a quantity of finely powdered Tablets, equivalent to 48 mg of albuterol, into a suitable container. Add 60 mL of diluted alcohol (1 in 2), and shake by mechanical means for 30 min. Filter the mixture, and wash the filter with small portions of~~

alcohol, combining this with the filtrate. Evaporate the filtrate to dryness under reduced pressure below 40°. Dissolve the residue as completely as possible in 2 mL of water.

Chromatographic system

(See *Chromatography* (621), *Thin-Layer Chromatography*.)

Mode: TLC

Adsorbent: 0.25-mm layer of chromatographic silica gel

Application volume: 10 µL. Apply two successive 5-µL aliquots, allowing the solvent to evaporate between applications.

Developing solvent system: Methyl isobutyl ketone, isopropyl alcohol, ethyl acetate, ammonium hydroxide, and water (50:45:35:3:18)

Spray reagent A: 3-Methyl-2-benzothiazolinone hydrazone hydrochloride TS

Spray reagent B: Ammoniacal potassium ferricyanide TS

Analysis

Samples: *Standard solution A*, *Standard solution B*, *Standard solution C*, and *Sample solution*

Air-dry the plate. Develop the chromatograms until the solvent front has moved about 17 cm. Spray the plate first with *Spray reagent A*, and then *Spray reagent B*, and finally again with *Spray reagent A*. Examine the plate and estimate the responses of any secondary spots observed in the lane of the *Sample solution* by comparison with those of *Standard solutions A*, *B*, and *C*.

Acceptance criteria

1. 2.0%; no major secondary spot is greater in size or intensity than the principal spot produced by *Standard solution A*.
2. 0.75%; no other secondary spot is greater in size or intensity than the principal spot produced by *Standard solution B*.
3. 0.25%; no more than two other secondary spots are equal in size or intensity to the principal spot produced by *Standard solution C*.
4. The sum of the intensities of all secondary spots obtained from the *Sample solution* corresponds to NMT 3.5%.

■ **Solution A:** 9.5 g/L of sodium borate in water; adjusted with a sodium hydroxide solution to a pH of 10.1

Solution B: Acetonitrile

Mobile phase: See Table 1.

Table 1

Time (min)	Solution A (%)	Solution B (%)
0	95	5
1	95	5
9	47	53
9.5	47	53
9.6	95	5
11	95	5

[Note—The gradient was established on an LC system with a dwell volume of 350–400 μL .]

System suitability solution: 2 $\mu\text{g}/\text{mL}$ each of USP Albuterol Related Compound A RS, USP Albuterol Related Compound C RS, USP Levalbuterol Related Compound C RS, and USP Levalbuterol Related Compound E RS in water

Standard solution: 0.0025 mg/mL of USP Albuterol Sulfate RS, 0.003 mg/mL of USP Albuterol Related Compound E RS, 0.0015 mg/mL of USP Levalbuterol Related Compound C RS, and 0.001 mg/mL of USP Levalbuterol Related Compound D RS in water

Sample solution: Nominally 1.0 mg/mL of albuterol from NLT 20 Tablets in water prepared as follows. Transfer a suitable amount of the Tablets to an appropriate volumetric flask. Add 80% of the final flask volume of water and sonicate for 15 min. Dilute with water to volume. Pass through a suitable filter of 0.2- μm pore size.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 231 nm

Column: 2.1-mm \times 10-cm; 1.7- μm packing L1

BRIEFING

Aminohippurate Sodium Injection, USP 38 page 2184. In preparation for the omission of the flame tests from *Identification Tests—General* (191), proposed in PF 41(2) [Mar.–Apr. 2015], it is proposed to delete the reference to (191) in *Identification* test C and include a complete description of the flame test in the monograph. Manufacturers are encouraged to submit a replacement wet chemistry or an instrumental procedure for consideration by the Expert Committee.

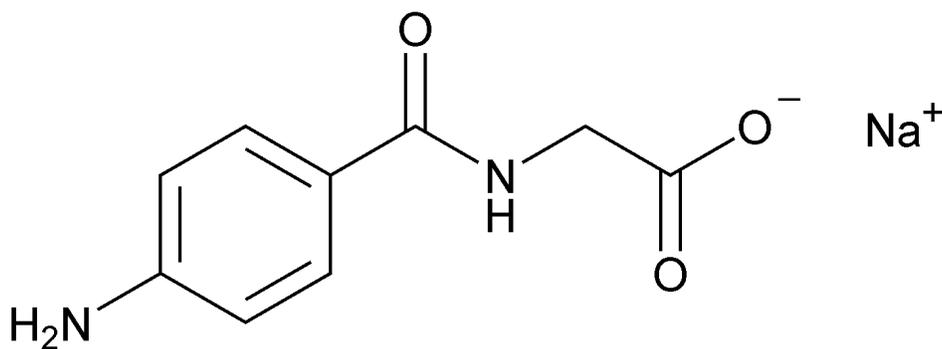

Additionally, minor editorial changes have been made to update the monograph to current USP style.

(BIO2: M. Metta.)

Correspondence Number—C160573

Comment deadline: November 30, 2015

Aminohippurate Sodium Injection

$C_9H_9N_2NaO_3$ 216.17

Glycine, *N*-(4-aminobenzoyl)-, monosodium salt;
 Monosodium *p*-aminohippurate [94-16-6].

DEFINITION

Aminohippurate Sodium Injection is a sterile solution of Aminohippuric Acid in Water for Injection prepared with the aid of Sodium Hydroxide. It contains NLT 95.0% and NMT 105.0% of the labeled amount of aminohippurate sodium ($C_9H_9N_2NaO_3$).

IDENTIFICATION

• A.

Sample solution: A volume of Injection equivalent to 100 mg of aminohippuric acid

Analysis: Dilute the *Sample solution* with water to 50 mL. To 5 mL of this solution add 0.5 mL of 3 N *hydrochloric acid*, 0.5 mL of *sodium nitrite* solution (1 in 10), and a solution of 0.20 g of *2-naphthol* in 10 mL of 6 N *ammonium hydroxide*.

Acceptance criteria: A red color is produced.

• B.

Sample solution: A volume of Injection equivalent to about 200 mg of aminohippurate sodium

Analysis: In the order named, add to the *Sample solution* 2 mL of *potassium iodide TS*, 10 mL of water, and 5 mL of *sodium hypochlorite TS*.

Acceptance criteria: A red color is produced.

Delete the following:

- • ~~C. Identification Tests—General, Sodium (191): Meets the requirements of the flame test~~
 ■ 2S (USP39)

Add the following:

- • C. A sample imparts an intense yellow color to a nonluminous flame. ■ 2S (USP39)

ASSAY

• Procedure

Sample solution: A volume of Injection equivalent to 1 g of aminohippurate sodium

Analysis: Transfer the *Sample solution* to a 200-mL volumetric flask, and dilute with water to volume. Transfer 50.0 mL of the solution to a suitable container, and add 5 mL of *hydrochloric acid*. Proceed as directed in *Nitrite Titration* (451), beginning with "cool to about 15°". Each mL of 0.1 M *sodium nitrite* is equivalent to 21.62 mg of aminohippurate sodium ($C_9H_9N_2NaO_3$).

Acceptance criteria: 95.0%–105.0%

SPECIFIC TESTS

- pH (791): 6.7–7.6
- **Bacterial Endotoxins Test** (85): NMT 0.04 USP Endotoxin Units/mg of aminohippurate sodium
- **Other Requirements:** Meets the requirements in *Injections* (1)

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in single-dose or multiple-dose containers, preferably of

Type 1 glass.

- **USP Reference Standards** (11)
USP Endotoxin RS

BRIEFING

Antithrombin III Human, *USP 38* page 2271. On the basis of comments received, the following stage one revisions are proposed:

1. The CAS number for this substance is added in the chemical information section.
2. Revise the *Definition* to remove aspects of processing and references to the USP Antithrombin Unit.
3. Revise the *Assay* to use the International Unit.
4. Revise the *Assay* in agreement with validated methods of analysis.
5. Revise the *Assay* acceptance criteria in agreement with validated methods of analysis.
6. Revise the test for *Organic Impurities, Procedure: Heparin Content* in agreement with validated methods of analysis.
7. Revise the test for *Molecular Weight Distribution* in agreement with validated methods of analysis.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Antithrombin III Human

Add the following:

[■ 9000-94-6]. ■ 2S (*USP39*)

DEFINITION

Change to read:

Antithrombin III Human is a glycoprotein, which is the major inhibitor of thrombin and other activated clotting factors, including factors IX, X, XI, and XII. ~~and the cofactor through which heparin exerts its effect~~

■ ■ 2S (*USP39*)

It is obtained from human plasma of healthy donors who ~~must, as far as can be ascertained,~~

■ have been tested and shown to ■ 2S (*USP39*)

be free from detectable agents of infection transmissible by transfusion of blood or blood derivatives. The ~~method of manufacturing includes steps that have been~~

■ manufacturing steps are ■ 2S (*USP39*)

shown to remove or inactivate known agents of infection. If substances are used for inactivation of viruses during production, the subsequent purification procedure must be validated to demonstrate that the concentration of these substances is reduced to an acceptable level and that any residues are such as not to compromise the safety of the preparation for patients.

~~The antithrombin III concentrate is passed through a bacteria-retentive filter, filled aseptically into its final, sterile containers, and immediately frozen. It is then freeze-dried, and the containers are closed under vacuum. No antimicrobial preservative is added at any stage of production. Antithrombin III Human complies with the requirements for *Biologics* (1041):~~

■ **2S (USP39)**

When reconstituted in the recommended volume of diluent, the potency is NLT 25 USP Antithrombin III Units

■ **International Units (IU)** ■ **2S (USP39)**

/mL.

■ **It contains 80%–120% of the potency stated on the label.** ■ **2S (USP39)**

~~[Note—One USP Antithrombin III Unit is the amount of antithrombin III that forms a complex with one unit of thrombin at 25° in the presence of heparin at a pH of 8.4.]~~

■ **2S (USP39)**

IDENTIFICATION

- Meets the requirements of the Assay

ASSAY

Change to read:

- **Procedure**

Solution A: Dissolve Tris(hydroxymethyl)aminomethane, edetic acid, and sodium chloride in water containing ~~0.1% polyethylene glycol 6000~~

■ **2S (USP39)**

to obtain a solution having concentrations of 0.050, 0.0075, and 0.175 M, respectively. Adjust with hydrochloric acid or sodium hydroxide solution to a pH of 8.4.

Solution B: 0.05% (w/v) of albumin human in *Solution A*

Solution C: 10 mg/mL of polybrene in *Solution B*

Solution D: ~~15 USP Heparin Units/mL of USP Heparin Sodium for Assays RS in *Solution B*~~

■ **Reconstitute thrombin bovine (factor IIa), and dilute with *Solution B* to obtain a solution having a concentration of 4 Thrombin IU/mL.** ■ **2S (USP39)**

Solution E: ~~Reconstitute thrombin bovine, and dilute with *Solution B* to obtain a solution having a concentration of 2.0 Thrombin Units/mL.~~

■ **Prepare a solution of chromogenic substrate for amidolytic test (see *Reagents, Indicators, and Solutions—Reagent Specifications*) for thrombin (factor IIa) in *Solution C* to obtain a solution having a concentration of about 40.0 mM.** ■ **2S (USP39)**

Solution F: ~~Prepare a solution of chromogenic substrate for amidolytic test (see *Reagents, Indicators, and Solutions—Reagent Specifications*) for factor II_a in water to obtain a solution having a concentration of about 5.0 mM, and dilute the solution further with *Solution C* to 1.0 mM.~~

■ **Resuspend USP Heparin Sodium for Assays RS according to the Certificate and dilute to 3 USP Heparin Units/mL in *Solution A*.** ■ **2S (USP39)**

Stopping solution: ~~20% (v/v) of acetic acid in water~~

Standard solution A: ~~USP Antithrombin III Human RS in *Solution D* to obtain a solution containing 1.0 USP Antithrombin III Unit~~

■ **Standard solutions:** Prepare seven dilutions from USP Antithrombin III Human RS within the linear range of the assay in *Solution F* (for example, 1.7, 1.5, 1.2, 1.0, 0.8, 0.6, and 0.4 IU/mL.) ■ 2S (USP39)

~~**Standard solutions B, C, D, and E:** Dilute *Standard solution A* with *Solution D* 60-, 120-, 180-, and 300-fold.~~

~~**Sample solution A:** Dissolve a quantity of Antithrombin III Human in *Solution D* to obtain a solution having the same concentration as *Standard solution A*.~~

■ **Sample solutions:** Prepare three or more dilutions in *Solution F* within the linear range of the assay.

Blank: *Solution A* ■ 2S (USP39)

~~**Sample solutions B, C, D, and E:** Dilute *Sample solution A* with *Solution D* 60-, 120-, 180-, and 300-fold.~~

■ 2S (USP39)

Analysis:

■ [Note—The procedure also can be performed using alternative platforms.] ■ 2S (USP39)
Pipet 400 μL each of *Standard solutions B, C, D, and E* and *Sample solutions B, C, D, and E* into suitable tubes placed in a water bath set at 37°. Add 200 μL of *Solution E*, prewarmed at 37° to each tube, mix, and incubate for 1 min. Add 200 μL of *Solution F* prewarmed at 37° to each tube, mix, and incubate for 60 s. Stop the reaction by adding 200 μL *Stopping solution*. To prepare a blank, add the reagents in reverse order, starting with 200 μL of *Stopping solution*, followed by the addition of 200 μL of *Solution F*, then adding 200 μL of *Solution E*, and ending with 400 μL of *Solution D*. Record the absorbance at 405 nm against the blank.

For *Standard solutions* and *Sample solutions*, calculate the regression of the absorbance against log concentrations, and calculate the activity of Antithrombin III Human in USP Antithrombin III Units, using a suitable statistical method for parallel line assays. The four independent relative activity estimates are then combined to obtain the final mean, and the confidence limits are calculated.

■ For each dilution of the *Standard solution* and *Sample solution*, at least duplicates should be tested. Label a suitable number of tubes depending on the number of replicates that will be tested. For example, if five blanks will be used: B1, B2, B3, B4, and B5 for the blanks; T1, T2, and T3 each at least in duplicate for the dilutions of the *Sample solutions*; and S1, S2, S3, S4, S5, S6, and S7 each at least in duplicate for the dilutions of the *Standard solutions*. Distribute the blanks over the series in such a way that they accurately represent the behavior of the reagents during the experiments. [Note—Treat the tubes in the order B1, S1, S2, S3, S4, S5, S6, S7, B2, T1, T2, T3, B3, T1, T2, T3, B4, S1, S2, S3, S4, S5, S6, S7, B5.]

Prewarm *Solution D* and *Solution E* at 37°. Pipet 50 μL each of the *Standard solutions*, *Sample solutions*, and *Blank* into suitable tubes placed in a water bath set at 37°. Add 350 μL of prewarmed *Solution D* to each tube, mix, and incubate for 1 min. Add 100 μL of prewarmed *Solution E* to each tube in the same order and mix. Follow the change in absorbance for each solution over 1 min at 405 nm using a suitable spectrophotometer

(see *Ultraviolet-Visible Spectroscopy* (857)). Calculate the change in absorbance/min. Plot standard concentrations against resulting absorbance values and determine potency by interpolating from the standard curve using mean sample absorbances.

System suitability

Samples: *Standard solutions and Sample solutions*

The R^2 value of the standard curve is NLT 0.99. The initial and final blanks differ by NMT 10%. The absorbances of the three dilutions of the *Sample solution* must fall within the range of absorbances of the standard curve. The three dilutions of the *Sample solution* give potency estimates that differ by NMT 10%.

■ 2S (USP39)

Acceptance criteria: 80%–120% of the potency stated on the label. The specific activity is NLT 6.0 USP Antithrombin III Units/mg of total protein. The confidence interval ($P = 0.95$) is between 90% and 110% of the estimated potency.

■ 2S (USP39)

IMPURITIES

Change to read:

Organic Impurities

● Procedure: Heparin Content

Solution A: Dissolve Tris(hydroxymethyl)aminomethane, edetic acid, and sodium chloride in water containing 0.1% polyethylene glycol 6000 to obtain a solution having concentrations of 0.050 M, 0.0075 M, and 0.175 M, respectively. Adjust with hydrochloric acid or sodium hydroxide solution to a pH of 8.4.

Solution B: Solution of chromogenic substrate for amidolytic test for factor X_a in water to obtain a solution of concentration of 2.5 mM

Solution C: Dissolve Factor X_a in *Solution A* to obtain a solution containing 20 nanokatalytic units (nkats).

Solution D: 20% (v/v) of acetic acid in water

Standard solution: Dissolve USP Antithrombin III Human RS in *Solution A* to obtain a solution containing 1.0 USP Antithrombin III Unit.

Sample solution: Dissolve Antithrombin III Human in *Solution A* to obtain a solution containing 1.0 USP Antithrombin III Unit.

Analysis: Pipet 250 μ L each of *Solution A*, the *Standard solution*, and the *Sample solution* to suitable tubes placed in a water bath set at 37°. Add 250 μ L of *Solution C* prewarmed at 37° to each tube, and incubate for 2 min. Add 250 μ L of *Solution B* prewarmed at 37° to each tube, mix, and incubate for 120 s. Stop the reaction by adding 250 μ L of *Solution D*. Record the absorbance at 405 nm, using *Solution A* as the blank.

Calculate the USP Heparin Unit per USP Antithrombin III Unit:

$$\text{Result} = P_R (A_F - A_U) / (A_F - A_S)$$

P_R = heparin content of USP Antithrombin III Human RS in USP Heparin Unit per USP Antithrombin III Unit

A_f = absorbance value from *Solution A*

A_y = absorbance value from the *Sample solution*

A_S = absorbance value from the *Standard solution*

Acceptance criteria: NMT 0.1 USP Heparin Unit per USP Antithrombin III Unit

■ • Heparin Content

Solution A: 9 g/L of sodium chloride

Sheep plasma substrate: Use sheep plasma suitable for the test procedure. If frozen, thaw at 37°.

APTT reagent: Use a suitable Activated Partial Thromboplastin Time (APTT) reagent containing phospholipid and a contact activator at a dilution giving a suitable blank recalcification time not exceeding 60 s.

Calcium chloride solution: 3.7 g/L of calcium chloride

System suitability solution: 5 IU/mL of heparin sodium for assays in USP Antithrombin III Human RS

Standard solutions: Make three or more dilutions of USP Heparin Sodium for Assays RS to known concentrations in USP Heparin Units/mL that are in the expected range of the sample (for example, 0.5–1.5 USP Heparin Units/mL)

Sample solutions: Make three or more dilutions of Antithrombin III Human in the range of the *Standard solution* dilutions.

Blank: *Solution A*

Analysis: [Note—The procedure also can be performed using alternative platforms.] For each *System suitability solution*, *Standard solution*, and *Sample solution*, at least duplicates should be tested. Label a suitable number of tubes depending on the number of replicates that will be tested. For example, if five blanks will be used: B1, B2, B3, B4, and B5 for the blanks; T1, T2, and T3 each at least in duplicate for the dilutions of the *Sample solutions*; and S1, S2, and S3 each at least in duplicate for the dilutions of the *Standard solutions* and SS for the *System suitability solution*. Distribute the blanks over the series in such a way that they accurately represent the behavior of the reagents during the experiments. [Note—Treat the tubes in the order B1, S1, S2, S3, B2, SS, T1, T2, T3, B3, T1, T2, T3, SS, B4, S1, S2, S3, B5.] In the following order add 1.0 mL of thawed *Sheep plasma substrate* to 1.0 mL of the *Standard solution* dilutions or the *Sample solution* dilutions or the *System suitability solution*. After each addition, mix but do not allow bubbles to form. Transfer each tube to a water bath at 37°, allow to equilibrate at 37° for about 15 min, and add to each tube 1 mL of *APTT reagent* previously heated to 37°. After an appropriate time for the *APTT reagent* used, usually 2–5 min, add 1 mL of *Calcium chloride solution* previously heated to 37° and determine the clotting time. Plot standard concentrations against resulting clotting times and determine heparin content by interpolating from the standard curve using mean sample clotting times. For samples with clotting times longer than the lowest standard dilution, report the result as NMT the lowest *Standard solution* concentration.

System suitability

Samples: *Standard solutions* and *Sample solutions*

The R^2 value of the standard curve is NLT 0.99. The three dilutions of the *Sample solution* give heparin content estimates that differ by NMT 10%. The heparin content in the *System suitability solution* is in the range of 4.0–7.5 IU/mL.

Acceptance criteria: NMT 0.1 USP Heparin Unit/Antithrombin III IU

■ 2S (USP39)

SPECIFIC TESTS

- **Sterility Tests** (71), *Test for Sterility of the Product to Be Examined, Direct Inoculation of the Culture Medium*: Meets the requirements
- **Water Determination** (921), *Method I*: NMT 3.0%
- **Pyrogen Test** (151): Inject 50 USP Antithrombin III Units per kg of the rabbit's weight, calculated from the activity stated on the label: meets the requirements.
- **General Safety**: Meets the requirements for biologics as set forth under *Biological Reactivity Tests, In Vivo* (88), *Safety Tests—Biologicals*
- **Osmolality and Osmolarity** (785), *Osmolality*: Reconstitute with the diluent according to the manufacturer's instruction: NLT 240 mOsm/kg for the solution.
- **pH** (791): Reconstitute with the diluent according to the manufacturer's instruction: 6.0–7.5.

Change to read:

Analysis

Samples: *Solution A* and *Sample solution*

Acceptance criteria: Note the retention times of the major peak in the *Solution A* chromatogram. The relative peak area of the high-molecular weight peak eluting at about the same retention time as the major peak in the *Solution A* chromatogram, or earlier, is NMT 13%.

• Total Protein Content

Solution A: 1000 mg/mL of trichloroacetic acid in water

Sample solution: 7.5 mg/mL of Antithrombin III Human in 0.15 M sodium chloride solution

Blank: 0.15 M solution of sodium chloride

Analysis: To each of 2.0 mL of the *Sample solution* and the *Blank* in suitable centrifuge tubes, add 1.5 mL of *Solution A*. Mix, allow to stand for at least 10 min, centrifuge for 5 min, and decant the supernatant. Resuspend the precipitates in 1.5 mL of *Solution A*, centrifuge for 5 min, decant the supernatant, and hold the tubes inverted on a filter paper to drain. Quantitatively transfer the residues with a minimum quantity of water to a micro-Kjeldahl flask, and determine the nitrogen content using *Method II* (see *Nitrogen Determination* (461)). Multiply the result, corrected for the *Blank*, by 6.25 to calculate the quantity of protein.

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Use a Type I glass container with an appropriate stopper and seal. Store protected from light between 2° and 8°, excursions permitted up to 25°.
- **Labeling:** The labeling should state the content of antithrombin III in USP Antithrombin III Units. The diluent and the volume to be used to reconstitute the preparation are indicated.

USP Antithrombin III Human RS

BRIEFING

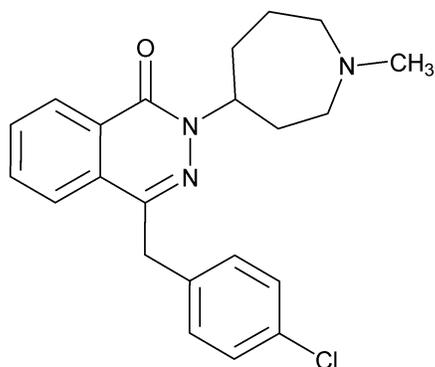

Azelastine Hydrochloride, *USP 38* page 2338. On the basis of comments and supporting data received, it is proposed to revise the relative response factor of chlorophenylacetylbenzoic acid from 1.0 to 0.45.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

(CHM5: D. A. Porter.)

Correspondence Number—C157907

Comment deadline: November 30, 2015

Azelastine Hydrochloride

$C_{22}H_{24}ClN_3O \cdot HCl$ 418.36

1(2*H*)-Phthalazinone, 4-[(4-chlorophenyl)methyl]-2-(hexahydro-1-methyl-1*H*-azepin-4-yl), monohydrochloride;

4-(*p*-Chlorobenzyl)-2-(hexahydro-1-methyl-1*H*-azepin-4-yl)-1(2*H*)-phthalazinone monohydrochloride [79307-93-0].

DEFINITION

Azelastine Hydrochloride contains NLT 99.0% and NMT 101.0% of azelastine hydrochloride ($C_{22}H_{24}ClN_3O \cdot HCl$), calculated on the dried basis.

IDENTIFICATION

- **A. Infrared Absorption** (197K)
- **B.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Identification solution*, as obtained in the test for *Organic Impurities*.
- **C. Identification Tests—General** (191), *Chloride*: Meets the requirements

ASSAY

- **Procedure**

Sample: 300 mg

Blank: 5 mL of anhydrous formic acid and 30 mL of acetic anhydride

Titrimetric system

(See *Titrimetry* (541).)

Mode: Direct titration

Titrant: 0.1 N perchloric acid VS

Endpoint detection: Potentiometric

Analysis: In order to avoid overheating in the reaction medium, mix thoroughly throughout and stop the titration immediately after the endpoint has been reached.

Dissolve the *Sample* in 5 mL of anhydrous formic acid, and add 30 mL of acetic anhydride. Titrate with *Titrant*.

Calculate the percentage of azelastine hydrochloride ($C_{22}H_{24}ClN_3O \cdot HCl$) in the portion of Azelastine Hydrochloride taken:

$$\text{Result} = \{[(V_S - V_B) \times N \times F] / W\} \times 100$$

V_S = *Titrant* volume consumed by the *Sample* (mL)

V_B = *Titrant* volume consumed by the *Blank* (mL)

N = actual normality of the *Titrant* (mEq/mL)

F = equivalency factor, 41.84 mg/mEq

W = weight of the *Sample* (mg)

Acceptance criteria: 99.0%–101.0% on the dried basis

BRIEFING

Betamethasone Valerate Cream, *USP 38* page 2423. As part of the USP monograph modernization initiative, it is proposed to make the following changes:

1. Replace the TLC procedure in *Identification* test A with a test based on the retention time agreement in the proposed *Assay*.
2. Add *Identification* test B based on the UV spectrum agreement of the major peak in the chromatogram of the sample and standard in the proposed *Assay*.
3. Replace the HPLC procedure in the *Assay*, which uses an internal standard, with a new HPLC procedure similar to the one in the proposed *Organic Impurities* test. The chromatographic procedure is based on analyses performed with the Agilent Zorbax SB-C18 brand of L1 column. The typical retention time for betamethasone valerate is about 16 min.
4. Add the test for *Organic Impurities*. The proposed procedure uses the same chromatographic system as in the proposed *Assay* to be operationally efficient.
5. Add proposed acceptance criteria for specified and unspecified degradation products to the *Organic Impurities* section.
6. Add USP Betamethasone RS and USP Betamethasone Valerate Related Compound A RS to the *USP Reference Standards* section to support the proposed revision. Remove USP Beclomethasone Dipropionate RS, which is no longer needed as an internal standard in the proposed procedures, from the *USP Reference Standards* section.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

(CHM5: G. Hsu.)

Correspondence Number—C143025

Comment deadline: November 30, 2015

Betamethasone Valerate Cream

DEFINITION

Betamethasone Valerate Cream contains an amount of betamethasone valerate ($\text{C}_{27}\text{H}_{37}\text{FO}_6$) equivalent to NLT 90.0% and NMT 110.0% of the labeled amount of betamethasone ($\text{C}_{22}\text{H}_{29}\text{FO}_5$), in a suitable cream base.

IDENTIFICATION

Delete the following:

- ~~**A. Thin-Layer Chromatographic Identification Test** (201)~~

~~**Standard solution:** 1 mg/mL of USP Betamethasone Valerate RS in alcohol~~

~~**Sample solution:** Transfer an amount of Cream, equivalent to 2 mg of betamethasone, to a separator, add 20 mL of water and 2 mL of dilute hydrochloric acid (1 in 120), and mix. Extract with four 50 mL portions of chloroform, and combine the extracts. Filter through a~~

~~cotton pledget, previously layered over with anhydrous sodium sulfate. Evaporate the filtrates on a steam bath under a stream of dry nitrogen to dryness. Dissolve the residue in alcohol to obtain a solution containing about 1 mg/mL.~~

Developing solvent system: Toluene and ethyl acetate (1:1)

Application volume: 10 μ L

Analysis

Samples: *Sample solution* and *Standard solution*

~~Proceed as directed in the chapter. Spray the plate with a mixture of sulfuric acid, methanol, and nitric acid (10:10:1), and heat at 105° for 15 min.~~

■ 2S (USP39)

Add the following:

- ● **A.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ■ 2S (USP39)

Add the following:

- ● **B.** The UV spectrum of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ■ 2S (USP39)

ASSAY

BRIEFING

Betamethasone Valerate Lotion, USP 38 page 2424. As part of the USP monograph modernization initiative, it is proposed to make the following changes:

1. Replace the TLC procedure in *Identification* test A with a test based on the retention time agreement in the proposed *Assay*.
2. Add *Identification* test B based on the UV spectrum agreement in the proposed *Assay*.
3. Replace the LC procedure in the *Assay*, which uses an internal standard in chloroform, with a new LC procedure that uses the same chromatographic system as the *Organic Impurities* test to be operationally efficient.
4. Add the test for *Organic Impurities*. The proposed procedure is based on analyses

performed with the Agilent Zorbax SB-C18 brand of L1 column. The typical retention time for betamethasone valerate is about 16 min.

5. Add proposed acceptance criteria for specified and unspecified impurities to the monograph. Manufacturers are encouraged to submit their approved specifications to USP if they are different from those proposed in this revision.
6. Add USP Betamethasone RS and USP Betamethasone Valerate Related Compound A RS to the *USP Reference Standards* section to support the proposed revision.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Betamethasone Valerate Lotion

DEFINITION

Betamethasone Valerate Lotion contains an amount of Betamethasone Valerate ($C_{27}H_{37}FO_6$) equivalent to NLT 95.0% and NMT 115.0% of the labeled amount of betamethasone ($C_{22}H_{29}FO_5$).

IDENTIFICATION

Delete the following:

■ ● ~~A. Thin-Layer Chromatography~~

~~**Standard solution:** 0.6 mg/mL of USP Betamethasone Valerate RS in a mixture of methanol and chloroform (2:1)~~

~~**Sample solution:** Equivalent to 0.5 mg/mL of betamethasone from Lotion, in a mixture of methanol and chloroform (2:1)~~

~~**Chromatographic system** (See *Chromatography* (621) *Thin-Layer Chromatography*.)~~

~~**Adsorbent:** 0.25-mm layer of chromatographic silica gel mixture~~

~~**Application volume:** 20 μ L~~

~~**Developing solvent system:** Chloroform and ethyl acetate (1:1)~~

~~Analysis~~

~~**Samples:** *Standard solution* and *Sample solution*~~

~~Allow the spots to dry, and develop the chromatogram in a solvent system, until the solvent front has moved three-fourths of the length of the plate. Remove the plate from the developing chamber, mark the solvent front, and allow the solvent to evaporate. View the spots under UV light.~~

~~**Acceptance criteria:** The R_f value of the principal spot from the *Sample solution* corresponds to that from the *Standard solution*. ■ 2S (USP39)~~

Add the following:

- **A.** The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ■ 2S (USP39)

Add the following:

- **B.** The UV spectrum of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the *Assay*. ■ 2S (USP39)

BRIEFING

Betamethasone Valerate Ointment, USP 38 page 2424. As part of the USP monograph modernization initiative, it is proposed to make the following changes:

1. Replace the TLC procedure in *Identification* test A with a test based on the retention time agreement in the proposed *Assay*.
2. Add *Identification* test B based on the UV spectrum agreement in the proposed *Assay*.
3. Replace the LC procedure in the *Assay*, which uses an internal standard, with a new LC procedure which uses the same chromatographic system as the *Organic Impurities* test to be operationally efficient.
4. Add the test for *Organic Impurities*. The proposed procedure is based on analyses performed with the Agilent Zorbax SB-C18 brand of L1 column. The typical retention time for betamethasone valerate is about 16 min.
5. Add proposed acceptance criteria for specified and unspecified impurities to the monograph. Manufacturers are encouraged to submit their approved specifications to

USP if they are different from those proposed in this revision.

6. Add USP Betamethasone RS and USP Betamethasone Valerate Related Compound A RS to the *USP Reference Standards* section to support the proposed revision.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Betamethasone Valerate Ointment

DEFINITION

Betamethasone Valerate Ointment contains an amount of Betamethasone Valerate ($C_{27}H_{37}FO_6$) equivalent to NLT 90.0% and NMT 110.0% of the labeled amount of betamethasone ($C_{22}H_{29}FO_5$), in a suitable ointment base.

IDENTIFICATION

Delete the following:

- **A. Thin-Layer Chromatographic Identification Test** ~~(201)~~

Standard solution: 1 mg/mL of USP Betamethasone Valerate RS in alcohol

Sample solution: Transfer the equivalent to 2 mg of betamethasone from the Ointment to a separator. Add 20 mL of water and 2 mL of dilute hydrochloric acid (1 in 120). Extract with four 50 mL portions of chloroform, and combine the extracts. Filter through a cotton pledget, previously layered over with anhydrous sodium sulfate. Evaporate the filtrates on a steam bath under a stream of dry nitrogen to dryness. Dissolve the residue in alcohol to obtain a solution containing 1 mg/mL.

Chromatographic system (See *Chromatography* ~~(621)~~ *Thin-Layer Chromatography*.)

Adsorbent: 0.25-mm layer of chromatographic silica gel mixture

Application volume: 10 μ L

Developing solvent system: *Toluene and ethyl acetate (1:1)*

Spray reagent: *A mixture of sulfuric acid, methanol, and nitric acid (10:10:1)*

Analysis

Samples: *Sample solution and Standard solution*

When the solvent front has moved three-fourths of the length of the plate, remove the plate from the chamber, mark the solvent front, and allow to air-dry. Locate the spots on the plate by spraying lightly with *Spray Reagent*, and dry at 105° for 15 min.

Acceptance criteria: The R_f value of the principal spot of the *Sample solution* corresponds to that of the *Standard solution*. ■ 2S (USP39)

Add the following:

- **A.** The retention time of the major peak of the *Sample solution* corresponds to that of the

Standard solution, as obtained in the Assay. ■2S (USP39)

Add the following:

- ● **B.** The UV spectrum of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the Assay. ■2S (USP39)

Standard solution: 25 µg/mL of USP Betamethasone Valerate RS in *Diluent B*. Sonicate to dissolve if necessary.

Sample solution: Nominally 20 µg/mL of betamethasone, prepared as follows. Transfer 1.0 mg of betamethasone from a portion of Ointment to a suitable glass centrifuge tube. Add 15.0 mL of *Diluent A* and mix with a vortex mixer to disperse the sample thoroughly. Add 35.0 mL of *Diluent B* and sonicate for 10 min with intermittent shaking. Centrifuge to obtain a clear supernatant and use the clear supernatant.

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 240 nm. For *Identification* test B, use a diode-array detector in the range of 200–400 nm.

Column: 4.6-mm × 15-cm; 3.5-μm packing L1

Flow rate: 1 mL/min

Injection volume: 100 μL

Autosampler temperature: 4°

System suitability

Samples: *System suitability solution* and *Standard solution*

[Note—See *Table 2* for relative retention times.]

Suitability requirements

Resolution: NLT 2.0 between betamethasone valerate and betamethasone valerate related compound A, *System suitability solution*

Tailing factor: NMT 2.0, *Standard solution*

Relative standard deviation: NMT 1.0%, *Standard solution*

Analysis

Samples: *Standard solution* and *Sample solution*

Calculate the percentage of the labeled amount of betamethasone (C₂₂H₂₉FO₅) in the portion of Ointment taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

r_U = peak response from the *Sample solution*

r_S = peak response from the *Standard solution*

C_S = concentration of USP Betamethasone Valerate RS in the *Standard solution* (μg/mL)

C_U = nominal concentration of betamethasone in the *Sample solution* (μg/mL)

M_{r1} = molecular weight of betamethasone, 392.46

M_{r2} = molecular weight of betamethasone valerate, 476.58

■ 2S (USP39)

Acceptance criteria: 90.0%–110.0%

IMPURITIES

Add the following:

■ ● Organic Impurities

Solution A, Solution B, Mobile phase, Diluent A, Diluent B, System suitability solution, Sample solution, and Chromatographic system: Proceed as directed in the *Assay*.

Standard solution: 0.25 μg/mL each of USP Betamethasone RS, USP Betamethasone Valerate RS, and USP Betamethasone Valerate Related Compound A RS in *Diluent B*.

Sonicate to dissolve if necessary.

System suitability

Samples: *System suitability solution* and *Standard solution*

[Note—See *Table 2* for relative retention times.]

Suitability requirements

Resolution: NLT 2.0 between betamethasone valerate and betamethasone valerate related compound A, *System suitability solution*

Tailing factor: NMT 2.0, *Standard solution*

Relative standard deviation: NMT 5.0%, *Standard solution*

Analysis

Samples: *Sample solution* and *Standard solution*

Calculate the percentage of each specified degradation product in the portion of Ointment taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times 100$$

r_U = peak response of each specified degradation product from the *Sample solution*

r_S = peak response of the corresponding USP Reference Standard from the *Standard solution*

C_S = concentration of the corresponding USP Reference Standard in the *Standard solution* ($\mu\text{g/mL}$)

C_U = nominal concentration of betamethasone in the *Sample solution* ($\mu\text{g/mL}$)

Calculate the percentage of each unspecified degradation product in the portion of Ointment taken:

$$\text{Result} = (r_U/r_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

r_U = peak response of each unspecified degradation product from the *Sample solution*

r_S = peak response of betamethasone valerate from the *Standard solution*

C_S = concentration of USP Betamethasone Valerate RS in the *Standard solution* ($\mu\text{g/mL}$)

C_U = nominal concentration of betamethasone in the *Sample solution* ($\mu\text{g/mL}$)

M_{r1} = molecular weight of betamethasone, 392.46

M_{r2} = molecular weight of betamethasone valerate, 476.58

Acceptance criteria: See *Table 2*. Disregard any impurity peak less than 0.1%.

Table 2

Name	Relative Retention Time	Acceptance Criteria, NMT (%)
Betamethasone	0.30	1.0
Betamethasone valerate	1.00	—
Betamethasone valerate related compound A	1.04	1.0
Any individual unspecified degradation product	—	1.0
Total degradation products	—	2.0

BRIEFING

Bismuth Subsalicylate Oral Suspension, USP 38 page 2455. On the basis of comments received, it is proposed to revise the monograph as follows:

1. Clarify requirements for *Identification* test *B* based on the supporting data.
2. Widen the upper pH limit from 5.0 to 5.5 to accommodate products with different formulations.

Additionally, minor editorial changes have been made to update the monograph to current *USP* style.

Correspondence Number—C141882; C137544

Comment deadline: November 30, 2015

Bismuth Subsalicylate Oral Suspension

DEFINITION

Bismuth Subsalicylate Oral Suspension contains NLT 90.0% and NMT 110.0% of the labeled amount of bismuth subsalicylate ($C_7H_5BiO_4$). It may contain one or more suitable buffers, coloring agents, flavors, preservatives, stabilizers, sweeteners, and suspending agents.

IDENTIFICATION

- **A. Identification Tests—General** (191), *Bismuth*: Meets the requirements

Change to read:

- **B. Identification Tests—General** (191), *Salicylate*: ~~Meets the requirements after acidifying with nitric acid~~
 - Meets the requirements for the response to *ferric chloride TS* after acidifying with *nitric acid* ■ 2S (USP39)

ASSAY

- **Procedure**

Standard stock solution: 2.5 mg/mL of *bismuth* in *nitric acid*. Prepare by dissolving in 6% of the flask volume of *nitric acid* and diluting with 0.01 N nitric acid to volume.

Standard solution: 0.05 mg/mL of *bismuth* in 1 N nitric acid from the *Standard stock solution*

Sample solution: Transfer 10 g of Oral Suspension, previously well shaken in its original container to ensure homogeneity, to a 200-mL volumetric flask. Add about 100 mL of 1 N nitric acid, and dilute with 1 N nitric acid to volume. Mix well without shaking, transfer 10.0 mL of this mixture to a 100-mL volumetric flask, and dilute with 1 N nitric acid to volume. Centrifuge about 20 mL at 4500 rpm for at least 10 min.

Instrumental conditions

(See *Spectrophotometry and Light-Scattering* (851).)

Mode: UV-Vis

Analytical wavelength: 463 nm

Cell: 1 cm

Blank: 1 N nitric acid

Analysis

Samples: *Standard solution*, *Sample solution*, and *Blank*

Transfer a measured volume of the *Sample solution* that contains 0.9 mg of bismuth subsalicylate and 10 mL of the *Standard solution* to separate 50-mL volumetric flasks. Add 10.0 mL of 10% ascorbic acid solution and 25.0 mL of 20% potassium iodide solution to each volumetric flask, and dilute with water to volume. Concomitantly determine the absorbances of both solutions, using the *Blank* to set the spectrophotometer. Calculate the percentage of the labeled amount of bismuth subsalicylate ($C_7H_5BiO_4$) in the portion of Oral Suspension taken:

$$\text{Result} = (A_U/A_S) \times (C_S/C_U) \times (M_{r1}/M_{r2}) \times 100$$

A_U = absorbance of the *Sample solution*

A_S = absorbance of the *Standard solution*

C_S = concentration of bismuth in the *Standard solution* (mg/mL)

C_U = nominal concentration of bismuth subsalicylate in the *Sample solution* (mg/mL)

M_{r1} = molecular weight of bismuth subsalicylate, 362.09

M_{r2} = molecular weight of bismuth, 208.98

Acceptance criteria: 90.0%–110.0%

SPECIFIC TESTS

- **Microbial Enumeration Tests** (61) and **Tests for Specified Microorganisms** (62): The total aerobic microbial count is NMT 10^2 cfu/g, and the total combined molds and yeasts count is NMT 5×10^1 cfu/g. It meets the requirements of the tests for the absence of *Escherichia coli*.

Change to read:

- **pH** (791): 3.0–5.0
 - 5.5 (USP39)

ADDITIONAL REQUIREMENTS

- **Packaging and Storage:** Preserve in tight containers. Protect from freezing. Avoid excessive heat (over 40°).

BRIEFING

Bivalirudin. Because there is no existing *USP* monograph for this drug substance, a new monograph based on validated methods of analyses is being proposed. The liquid chromatographic procedure in the *Assay* is based on analyses performed with the Vydac C18 brand of *L1* column. The typical retention time for bivalirudin in the *Assay* is about 24 min. The liquid chromatographic procedures in the *Product Related Substances and Impurities* are based on analyses performed with the Vydac C18 brand of *L1* column and Waters Xbridge HILIC brand of *L3* column. The typical retention times for bivalirudin in the tests for *Product-Related Substances and Impurities* are about 24 min and between 9.4 and 14.7 min, respectively.

Comment deadline: November 30, 2015

Add the following:

- **Bivalirudin**

DFPRPGGGGNG DFEEIPEEYL

$C_{98}H_{138}N_{24}O_{33}$ 2180.29 (free base)

L-Leucine, D-phenylalanyl-L-prolyl-L-arginyl-L-prolylglycylglycylglycylglycyl-L-asparaginyglycyl-L- α -aspartyl-L-phenylalanyl-L- α -glutamyl-L- α -glutamyl-L-isoleucyl-L-prolyl-L- α -glutamyl-L- α -glutamyl-L-tyrosyl-;

D-Phenylalanyl-L-prolyl-L-arginyl-L-prolylglycylglycylglycylglycyl-L-asparaginyglycyl-L- α -aspartyl-L-phenylalanyl-L- α -glutamyl-L- α -glutamyl-L-isoleucyl-L-prolyl-L- α -glutamyl-L- α -glutamyl-L-tyrosyl-L-leucine [128270-60-0].

DEFINITION

Bivalirudin is a synthetic 20 amino acid peptide, which is a specific and reversible direct thrombin inhibitor. Bivalirudin is indicated for use as an anticoagulant in patients with unstable angina undergoing percutaneous transluminal coronary angioplasty (PTCA). Bivalirudin is intended for use with aspirin and has been studied only in patients receiving concomitant aspirin. It contains NLT 96.0% and NMT 103.0% of bivalirudin ($C_{98}H_{138}N_{24}O_{33}$), calculated on the anhydrous, counter ion-free basis. Bivalirudin is a white to off-white powder. [Note—Bivalirudin is very hygroscopic. Protect from exposure to moisture.]

IDENTIFICATION

• A

Standard solution and Sample solution: Proceed as directed in the Assay.

Identity sample solution: 0.75 mg/mL each of USP Bivalirudin RS and Bivalirudin in water

Acceptance criteria: The retention time of the major peak of the *Sample solution* corresponds to that of the *Standard solution*, as obtained in the Assay. The major peaks of the *Identity sample solution* co-elute.

• **B.** The monoisotopic mass by *Mass Spectrometry* (736) is 2179.0 ± 1.0 mass units.

• C. Amino Acid Content

For further discussion of the theory and applications, see *Biotechnology-Derived Articles—Amino Acid Analysis* (1052), which may be a helpful, but not mandatory, resource.

Standard solution: Standardize the instrument with a mixture containing equal molar per volume amounts (except for L-cystine, which is half the molar amount) of glycine and the L-form of the following amino acids: lysine, threonine, alanine, leucine, histidine, serine, valine, tyrosine, arginine, glutamic acid, methionine, phenylalanine, aspartic acid, proline, isoleucine, tryptophan, and cystine.

Sample solution: Accurately weigh out 1.0 mg of bivalirudin in glass ampuls. Add a minimum of 1.0 mL of *Hydrolysis Solution* containing 4% phenol, freeze the sample ampul, and flame seal under vacuum. Hydrolyze at 110° for about 18 h. After hydrolysis, dry the test sample under vacuum to remove any residual acid. To the ampul add 2 mL of a buffer solution that is suitable for the amino acid analyzer, and pass through a filter of 0.45- μ m pore size.

Analysis

Samples: *Standard solution and Sample solution*

First record and measure the responses for each amino acid peak in the *Standard solution*.

Express the content of each amino acid in moles.

Calculate the mean nmol of the amino acids in the *Sample solution*:

Result = (nmol found in the *Sample solution* for Asx, Glx, Gly, Leu, Phe, Ile, Arg, Pro, Tyr)/20

Divide the nmol of each amino acid by the *Result* to determine the amino acid ratios that must meet the *Acceptance criteria*.

Acceptance criteria: See *Table 1*.

Table 1

Name	Acceptance Criteria
Glycine	Between 4.5 and 5.5
Aspartic acid	Between 1.8 and 2.2
Glutamic acid	Between 3.6 and 4.4
Proline	Between 2.7 and 3.3
Leucine, isoleucine, arginine, and tyrosine	Between 0.9 and 1.1
Phenylalanine	Between 1.8 and 2.2

• D. Bioidentity

Thrombin inhibition activity

Buffer solution: 50 mM tris-HCl and 120 mM sodium chloride in water. Adjust to a pH of 7.40 ± 0.04 . Add bovine serum albumin (BSA) to obtain a 100-mg/mL concentration and pass through a filter of 0.45- μ m pore size.

Human thrombin solution: 10 μ g/mL of human thrombin¹ in *Buffer solution*

Diluted human thrombin solution: Dilute *Human thrombin solution* in *Buffer solution* to obtain a 0.5- μ g/mL solution. Thrombin from alternate sources must be standardized in the substrate reaction. Prepare six replicates by adding 910 μ L of *Buffer solution* to each sample tube followed by 30 μ L of *Chromogenic substrate solution*. Add 60 μ L of *Diluted human thrombin solution*, vortex, and begin the 20-min incubation as described below. Determine the absorbance at 405 nm for each replicate.

Calculate the standardized volume (E_C) of *Diluted human thrombin solution* from the mean absorbance as follows:

$$E_C = (0.45 \times 60 \mu\text{L}) / \text{mean absorbance}$$

Chromogenic substrate solution: 5 mM solution of H-d-cyclohexylalanyl-Ala-Arg-p-Nitroanilide diacetate salt in water. Dilute with water to obtain a 50- μ M solution.

Standard solution: Prepare a 0.6-mg/mL solution of USP Bivalirudin RS in water. Dilute with *Buffer solution* to obtain a 5- μ g/mL solution.

Sample solution: Prepare a 0.6-mg/mL solution of Bivalirudin in water. Measure the absorbance of the 0.6-mg/mL solution at 275 nm (A_{275}), using the *Blank* to auto-zero. Calculate the concentration of bivalirudin ($C_{98}H_{138}N_{24}O_{33}$) in the portion of Bivalirudin taken:

$$C_{\text{bivalirudin}} (\text{mg/mL}) = A_{275} / 0.62$$

From this concentration, dilute with *Buffer solution* to obtain a 5- μ g/mL solution. Prepare triplicate dilutions of the *Sample solution*.

Blank: Water

Stop solution: Glacial acetic acid

Preparation of Control assay solution, Sample assay solution, and Standard assay solution: In each sample tube, add the *Buffer solution* (1000 μL – E_C – S_C) first, then 30 μL of *Chromogenic substrate solution* (S_C), then the Bivalirudin (if using). Vortex and incubate at 37° for 10 min in a water bath. Add the appropriate volume of *Diluted human thrombin solution* to give a final concentration of 0.095 NIH Units/mL (E_C) and immediately after activate the chronometer. Vortex for a few s and heat to 37° for 20 min \pm 15 s in a water bath. Stop the reaction by adding 100 μL of *Stop solution*. Measure the absorbance of the six solutions at 405 nm using the *Blank* to auto-zero. Prepare the solutions for the analysis as indicated in *Table 2*.

Table 2

	Blank	Control Assay Solution	Sample Assay Solution	Standard Assay Solution
Number of replicate	1	3	3	3
Total number of UV readings	1	3	9	3
Chromogenic substrate solution	30 μL	30 μL	30 μL	30 μL
Bivalirudin	100 μL (<i>Standard solution</i>)	0	100 μL (<i>Sample solution</i>)	100 μL (<i>Standard solution</i>)
Thrombin	0	E_C	E_C	E_C
Buffer solution	1000 μL –30 μL –100 μL	1000 μL –30 μL – E_C	1000 μL –30 μL –100 μL – E_C	1000 μL –30 μL –100 μL – E_C

System suitability

Samples: *Control assay solution* and *Standard assay solution*

Suitability requirements

Mean absorbance: Between 0.428 and 0.473, *Control assay solution*

Relative standard deviation: NMT 5% for six replicates, *Control assay solution*

Percent average inhibition: 44%–50% for the three readings, *Standard assay solution*

Analysis

Samples: *Standard assay solution* and *Sample assay solutions*. Prepare three independent preparations of the *Sample assay solution* to obtain a 0.6-mg/mL concentration.

Calculations: Determine the %thrombin inhibition for each of the nine sample readings of the sample tested. The final inhibition %result is given by the average of these nine values.

$$\% \text{ Inhibition} = [1 - (r_U/r_S)] \times 100$$

r_U = absorbance response of the *Sample assay solution*

r_S = average absorbance response of the six readings of the *Control assay solution*
