

## BRIEFING

**⟨1382⟩ Assessment of Elastomeric Component Functional Suitability in Parenteral Product Packaging/Delivery Systems, PF 43(3)** [May–June 2017]. The previous proposal for this chapter, published in *PF 43(3)* under a different title, *Assessment of Elastomeric Closure Functionality in Injectable Pharmaceutical Packaging/Delivery Systems* was canceled and an updated version is being proposed. This new general chapter contains information and guidance to assist users in the functional suitability assessment of elastomeric components as part of packaging/delivery systems intended for parenteral dosage forms described in *Elastomeric Component Functional Suitability in Parenteral Product Packaging/Delivery Systems* (382). Such components include primary packaging/delivery system components that are partially or completely made of elastomeric material. The proper selection and design of functional suitability assessment studies is based on sound scientific principles that are consistent with:

1. The packaging/delivery system design and mechanics
2. The nature of the pharmaceutical dosage form contained and delivered by the packaging/delivery system
3. The physical environment to which the finished drug product will be exposed during the product life cycle
4. The clinical setting and the manner in which the product dosage form is to be administered
5. The safety risks assessed to those using and/or exposed to the contents of the packaging/delivery system during patient administration.

Alternative testing strategies for functional suitability assessment may be appropriate in certain circumstances with proper justification. In all cases, when reporting functional suitability assessment findings, the drug product applicant is advised to offer justification for the testing program chosen.

(GCPD: D. Hunt.)

18 **1. INTRODUCTION**

19 This chapter contains information and guidance to assist in the functional  
20 suitability assessment of elastomeric components as part of  
21 packaging/delivery systems intended for parenteral dosage forms contained  
22 in *Elastomeric Component Functional Suitability in Parenteral Product  
23 Packaging/Delivery Systems* (382). Such components include primary  
24 packaging/delivery system components that are partially or completely  
25 made of elastomeric material. The proper selection and design of functional  
26 suitability assessment studies is based on sound and justifiable scientific  
27 principles provided in (382), *1. Introduction*.

28 **2. EARLY PACKAGING/DELIVERY SYSTEM SELECTION AND DEVELOPMENT: FUNCTIONAL SUITABILITY ASSESSMENT  
29 CONSIDERATIONS**

30 Early in the packaging/delivery system selection and development process,  
31 the final packaging/delivery system and its components may not be fully  
32 defined and functional suitability requirements may not be established. This  
33 is especially true if the packaging/delivery system or the drug product is  
34 novel to the drug product applicant. At this phase of the product life cycle,  
35 functional suitability assessments are performed to better understand  
36 packaging/delivery system performance and/or to screen potential  
37 elastomeric component and container candidates. To that end, [Table 1](#) lists  
38 elastomeric component functional suitability tests in standards published by  
39 the International Organization for Standardization (ISO). The list should not  
40 be considered all-inclusive. The most recent standards should be referenced.

41 The terms "standards" and "recognized standards" used throughout this  
42 chapter and (382) refer to those published by ISO.

43 Although not mandated, testing components and/or closure  
44 packaging/delivery systems according to such standards may provide useful  
45 information, especially during early product packaging/delivery system

46 development. Other relevant internationally recognized standards deemed  
47 scientifically appropriate may be used instead of, or in addition to, those  
48 listed in [Table 1](#). Standard test data may be made available by elastomeric  
49 component or packaging/delivery system suppliers.

50 **Table 1. ISO Standards: Functional Suitability Tests for Elastomeric**  
51 **Components**

<b>ISO Standard (listed in numeric order)</b>	<b>Functional Suitability Tests</b>
Sterile hypodermic syringes for single use	<b>7886-1 Syringes for manual use</b> <ul style="list-style-type: none"><li>• Freedom from air and liquid leakage past plunger stopper</li><li>• Force to operate the piston</li><li>• Fit of plunger stopper/plunger in barrel</li></ul>

---

53 **3. FINAL PRODUCT PACKAGING/DELIVERY SYSTEM FITNESS-FOR-INTENDED-USE SUITABILITY ASSESSMENT**

54 Evidence of the elastomeric component's ability to satisfactorily function as  
55 part of the final packaging/delivery system according to its intended product  
56 use is required to support commercial market approval of a finished drug  
57 product. Internationally recognized standards, such as those listed in [Table](#)  
58 [1](#), can provide a useful benchmark when designing appropriate elastomeric  
59 component functional suitability assessment studies. However, the drug  
60 product applicant is advised to exercise caution before prescriptively  
61 adopting standardized tests. Such tests may not provide a complete or  
62 adequate assessment of the elastomeric component's ability to meet the  
63 final packaging/delivery system's product-specific functional demands.  
64 Standardized tests may not be adequate or appropriate in specific situations  
65 for many reasons, for example:

- 66 •The final packaging/delivery system components may differ in design  
67 or dimension from the description in the standard.
- 68 •The manner in which the final packaging/delivery system's  
69 components are processed, reprocessed, and/or assembled may  
70 differ from the description in the standard.
- 71 •The manner in which a liquid, such as a diluent, must be added to the  
72 packaging/delivery system for final dosage form preparation (such  
73 as for lyophilized product reconstitution, powdered product  
74 constitution, product dilution, or admixture) may differ from the  
75 description in the standard.
- 76 •The manner in which the packaged product is to be accessed at the  
77 time of use may differ from the description in the standard.  
78 Differences may include needle or spike design, material, or  
79 lubricity; needle puncture speed; and the number of penetrations  
80 per closure.

- 81 •The standard's test procedure or analysis method may provide an  
82 inadequate measure of packaging/delivery system functional  
83 suitability given the specific rigorous demands placed on the final  
84 packaging system. For instance, bench test conditions may not  
85 sufficiently mirror the rigors imposed on the marketed product  
86 during actual storage, distribution, and usage conditions.
- 87 •The test method may lack sufficient sensitivity or precision to provide  
88 an adequate measure of packaging/delivery system functional  
89 suitability. For example, a container-closure seal integrity test that  
90 relies on dye ingress observation may be too insensitive to provide  
91 an accurate picture of a lyophilized dosage form package's ability to  
92 meet the maximum allowable leakage limit demanded by the  
93 finished product packaging/delivery system.
- 94 •The standard test's acceptance criterion may not reflect the functional  
95 performance demanded of the final packaging/delivery system. For  
96 example, the maximum allowable needle penetration force for a  
97 closure dictated by a standard may result in damage to the  
98 penetration needle supplied with the intended delivery device.

99 Therefore, the drug product applicant is tasked with developing a body of  
100 elastomeric component functional suitability assessment tests that logically  
101 and most appropriately assess the final packaging/delivery system.  
102 Challenges placed on the final product's packaging/delivery system during  
103 testing should mimic challenges the product is likely to encounter through  
104 storage/distribution, product expiry, and final use. These testing challenges  
105 should provide clear and definitive measures of packaging/delivery system  
106 performance.

107 **4. GENERAL CHAPTER (382) BACKGROUND AND GUIDANCE**

108 Chapter (382) offers drug product packaging/delivery system fitness-for-  
109 intended-use functional suitability assessment procedures and acceptance  
110 criteria that are reflective of current best practices. These best practices take  
111 into consideration all the recognized ISO standards in [Table 1](#) as well as USP  
112 tests and guidances. Specific sources for the various tests are detailed in the  
113 following sections. These tests are not intended to be exhaustive. The drug  
114 product applicant may require additional tests to adequately assess the  
115 component's functional suitability as part of a particular packaging/delivery  
116 system.

117 Re-evaluation of functional suitability may be required when changes occur  
118 in components, processes, or even the commercialized product itself during  
119 its life cycle. The functional suitability of a drug product packaging/delivery  
120 system is the responsibility of the drug product applicant.

121 The following sections contain guidance and background information  
122 relevant to tests in (382).

123

#### 4.1 Test Samples

124 The following relates to [Elastomeric Component Functional Suitability in](#)  
125 [Parenteral Product Packaging/Delivery Systems \(382\), 3. General Test](#)  
126 [Requirements, 3.1 Test Samples](#). Functional suitability of elastomeric  
127 components cannot be tested for in isolation from the intended  
128 packaging/delivery system. Furthermore, a component's functional  
129 performance assessment outcome can be affected by the design, processing,  
130 and assembly of that packaging/delivery system. For example, closure  
131 processing parameters and vial package sealing forces directly impact  
132 parenteral vial packaging integrity results. Plunger break loose and glide  
133 forces are directly related to the design, material of construction, and  
134 lubricity of the syringe barrel.

135 Test samples employed for each functional suitability test are to mirror the  
136 components and packaging/delivery system of the intended product as  
137 closely as possible, because component functionality is connected to the  
138 packaging/delivery system. Components are to be prepared, processed, and  
139 assembled as defined for the final product packaging/delivery system,  
140 especially if such steps are believed to have a potential impact on  
141 component functionality.

142 The following examples are offered as illustration:

- 143 •Components are to be washed, lubricated, and sterilized according to  
144 intended product protocol.
- 145 •Components are to be laminated or coated according to the  
146 requirements of the intended product packaging/delivery system.
- 147 •Vial and bottle closures are to be optimally capped onto vials in a  
148 manner reflective of the intended finished product  
149 packaging/delivery system.
- 150 •Syringe/cartridge barrels are to be prepared and lubricated according  
151 to the requirements of the intended pharmaceutical product.
- 152 •Syringe/cartridge plungers are to be inserted into syringe barrels  
153 according to production practices (e.g., by use of a vent tube or  
154 vacuum insertion).

155 Some tests, such as [Elastomeric Component Functional Suitability in](#)  
156 [Parenteral Product Packaging/Delivery Systems \(382\), 5. Needle and Spike](#)  
157 [Access Functional Suitability Tests, 5.1 Fragmentation](#), state that the test  
158 sample areas are to be filled with water. However, in cases where package  
159 contents can influence test outcome, such as (382), [6. Plunger Functional](#)

160 *Suitability Tests, 6.1 Plunger Break-Loose and Glide Forces* tests, it is  
161 recommended that test samples be filled with product or a product proxy so  
162 that the test outcome better reflects packaging/delivery system intended  
163 use. Alternatively, content material that brackets the characteristics of  
164 multiple products may be chosen.

165 Some flexibility in test sample preparation and content is permitted if the  
166 variation is judged to have little or no impact on test outcome. With  
167 appropriate justification, test samples may bracket relevant parameters of  
168 packaging/delivery system design and dimension, component processing,  
169 package assembly, and product contents. Bracketing may be employed to  
170 allow a functional suitability assessment program that addresses a wider  
171 spectrum of packaging/delivery systems and/or products.

172 The selection, design, preparation, assembly, and contents of test samples  
173 should follow sound scientific principles so that the final product  
174 packaging/delivery system can be comprehensively evaluated for functional  
175 suitability.

#### 176 4.2 Test Sample Population Size

177 As described in [Elastomeric Component Functional Suitability in Parenteral](#)  
178 [Product Packaging/Delivery Systems \(382\) 3. General Test Requirements,](#)  
179 [3.2 Test Sample Population Size](#), test sample quantity should provide a  
180 reasonable measure of confidence of the packaging/delivery system  
181 elastomeric component functionality. Current recognized standards inform  
182 the test sample population sizes specified in chapter tests. For this reason,  
183 sample sizes vary across test categories and even among package types  
184 within a test category. For example, (382), *5. Needle and Spike Access*  
185 *Functional Suitability Tests, 5.1 Fragmentation* vial system tests require 12  
186 test samples (as per ISO 8362-2, 8362-5, and 8871-5), whereas bottle  
187 system tests require 10 test samples (as per ISO 8536-2 and -6). In the  
188 case of fragmentation tests, it was deemed important to respect the  
189 historical particulate findings generated using these varied sample  
190 population sizes. On the other hand, (382), *5. Needle and Spike Access*  
191 *Functional Suitability Tests, 5.3 Needle Self-Sealing Capacity* tests require  
192 30 test samples regardless of the packaging/delivery system to ensure more  
193 meaningful leakage findings even though recognized standards require fewer  
194 samples.

195 Test sample population sizes cited in chapter test methods represent  
196 minimal test sample population size requirements. Sample population sizes  
197 that are larger than those specified in test procedures are encouraged to  
198 provide greater assurance of packaging/delivery system performance and to  
199 minimize the risk of product failure during commercial use.

200

#### 4.3 Packaging/Delivery System Integrity Tests

201 The verification of packaging/delivery system integrity is required  
202 according to *Elastomeric Component Functional Suitability in Parenteral*  
203 *Product Packaging/Delivery Systems* (382), 4. *Packaging/Delivery System*  
204 *Integrity Tests*. All components that are intended to seal or affect container  
205 closure must adequately protect and contain the packaging/delivery system  
206 contents. In this context, all such components are termed closures. All  
207 closures are required to ensure adequate system integrity; therefore, all  
208 packaging/delivery systems within the scope of the chapter are required to  
209 meet an appropriate system integrity functional suitability assessment. This  
210 section does not apply to closures after they have been breached by a  
211 needle, spike, or other access device.

212 Packaging/delivery system integrity refers to the ability of a  
213 packaging/delivery system to keep product contents in, and to keep  
214 detrimental environmental contaminants out. All packaging/delivery systems  
215 for parenteral products closed with elastomeric components are required to  
216 demonstrate integrity, as defined by the level of protection necessary for  
217 product quality maintenance. All systems with elastomeric closures  
218 mechanically fitted to the container demonstrate some gaseous leakage past  
219 the seal interface, even when optimally assembled. Leaks of concern for  
220 sterile product packaging/delivery systems are those that pose an  
221 unacceptable level of risk to relevant product physicochemical and  
222 microbiological quality attributes.

223 Specifically, all parenteral product packaging/delivery systems must: 1)  
224 prevent microbiological ingress to ensure that product sterility is met; and 2)  
225 prevent product escape or entry of external liquid or solid matter to ensure  
226 that relevant product physicochemical quality attributes are met. In addition,  
227 some products require the maintenance of package headspace content in a  
228 manner that ensures relevant product physicochemical quality attributes are  
229 met and/or allows for ease of product access by the end user. As some  
230 packaging/delivery systems employ more than one closure, and each closure  
231 may provide a different level of product protection, different integrity tests  
232 may be required to effectively evaluate the inherent integrity of the various  
233 closure types.

234 See *Package Integrity Evaluation—Sterile Products* (1207), as well as its  
235 subchapters, for further guidance on the concepts of inherent package  
236 integrity and maximum allowable leakage limit, and for guidance on the  
237 proper selection, development, validation, and utilization of appropriate leak  
238 test methods.

239

#### 4.4 Needle and Spike Access Functionality Tests

240 Information in *Elastomeric Component Functional Suitability in Parenteral*  
241 *Product Packaging/Delivery Systems* (382), 5. *Needle and Spike Access*  
242 *Functional Suitability Tests* applies to packaging/delivery system closures  
243 that allow for drug product access by hypodermic needle, spike, or other  
244 closure penetration device. Packaging/delivery systems intended for  
245 parenteral products that permit dosage form access by insertion of a closure  
246 piercing device are required to allow for safe and effective product access,  
247 without damaging the packaging/delivery system or the drug product and  
248 without risking harm to either the patient receiving the medication or the  
249 individual accessing and/or administering the product.

250 Traditionally, needle and spike access functionality tests have not  
251 accounted for the possibility of an additional closure penetration commonly  
252 performed to introduce liquids into the product packaging/delivery system  
253 for lyophilized product reconstitution, powdered product constitution,  
254 product admixture, or product dilution. Closure penetration practices for  
255 dosage form preparation vary widely. The piercing device employed for  
256 dosage form preparation may be very different in size or design from the  
257 needle or spike used for subsequent product access and withdrawal. There is  
258 little published information on the impact of such initial closure penetrations  
259 on closure performance or product quality. To address this gap, needle and  
260 spike access functional suitability tests have been expanded to incorporate a  
261 first closure piercing for products requiring final dosage form preparation in  
262 addition to the closure piercing(s) for product access and withdrawal.

263 Tests dictate that all piercings be performed using the dosage form  
264 preparation piercing device(s) and/or the product access piercing device(s)  
265 intended or recommended by the drug product applicant. For example, if the  
266 intent is to provide or to specify a needle or other piercing device with the  
267 marketed product for a given purpose, then this same item or a facsimile is  
268 to be used. If a piercing device will neither be specified nor provided (i.e.,  
269 not designated), the procedures cite dosage form preparation and drug  
270 product access devices to be used for the tests. Drug product access  
271 needles/spikes cited align with current reference standards. Dosage form  
272 preparation needles cited in the procedures are unique to USP.

273 The following tests are included in this functional suitability assessment  
274 category.

#### 275 FRAGMENTATION

276 See *Elastomeric Component Functional Suitability in Parenteral Product*  
277 *Packaging/Delivery Systems* (382), 5. *Needle and Spike Access Functional*  
278 *Suitability Tests, 5.1 Fragmentation*. Also called coring, fragmentation is a  
279 measure of the packaging/delivery system's tendency to fragment or core  
280 when penetrated by a dosage form preparation piercing device (if applicable)

281 and by a product access piercing device. If injected, such closure fragments  
282 may pose a health risk to the patient.

283 The penetration tests largely align with fragmentation tests in ISO  
284 standards in the piercing devices used and the number of piercings per test  
285 sample. Specifically, *Procedure A* in *Elastomeric Component Functional*  
286 *Suitability in Parenteral Product Packaging/Delivery Systems* (382), 5.  
287 *Needle and Spike Access Functional Suitability Tests, 5.1 Fragmentation, Vial*  
288 *and bottle systems* was informed by ISO 8362-5 and 8871-5. *Procedure*  
289 *B* was informed by ISO 8536-2 and -6. The (382), 5. *Needle and Spike*  
290 *Access Functional Suitability Tests, 5.1 Fragmentation, BFS systems* test  
291 method was informed by ISO 15759. *Procedure A* of (382), 5. *Needle and*  
292 *Spike Access Functional Suitability Tests, 5.1 Fragmentation, Cartridge*  
293 *systems* was informed by ISO 13926-3 and *Procedure B* was informed by ISO  
294 11608-3.

295 Unlike ISO tests, an extra initial piercing option representing a dosage  
296 form preparation piercing is included in the vial and bottle systems as well  
297 as the BFS systems test procedures.

298 Also unlike ISO tests, fragmentation count analysis is to be performed  
299 according to *Particulate Matter in Injections* (788), *Method 2 Microscopic*  
300 *Particle Count Test*, with noted modifications. Modifications include  
301 allowances for microscope magnification range adjustment and the use of  
302 the linear graticule for particle sizing. Test procedures require particle sizing  
303 based on the longest linear dimension of the particle.

304 Acceptance criteria are defined according to the quantity of detected  
305 particles  $\geq 150 \mu\text{m}$  in the longest linear dimension. Smaller particles are not  
306 reported. Recognized standards define fragmentation acceptance criteria  
307 according to the number of particles visibly detected, i.e., particles  $\geq 50 \mu\text{m}$   
308 (e.g., ISO 8871-5). *Elastomeric Component Functional Suitability in*  
309 *Parenteral Product Packaging/Delivery Systems* (382), 5. *Needle and Spike*  
310 *Access Functional Suitability Tests, 5.1 Fragmentation* has adopted the same  
311 particle quantity limits, as per the recognized standards, but counted  
312 particles are  $\geq 150 \mu\text{m}$ , sized microscopically, defined by the longest linear  
313 dimension. This change was based on more recent data suggesting visibly  
314 detected particles are closer to  $150 \mu\text{m}$  in size, as per *Visible Particulates in*  
315 *Injections* (790).

#### 316 PENETRATION FORCE

317 See *Elastomeric Component Functional Suitability in Parenteral Product*  
318 *Packaging/Delivery Systems* (382), 5. *Needle and Spike Access Functional*  
319 *Suitability Tests, 5.2 Penetration Force*. Also called penetrability, penetration  
320 force is the maximum force necessary to penetrate the closure using a  
321 dosage form preparation piercing device (if applicable) and a product access

322 piercing device. Penetration force tests also confirm the ability of the closure  
323 to remain in place without being forced into the container during piercing.

324 Test procedures and acceptance criteria were informed by current  
325 reference standards. In some cases details were modified so all  
326 packaging/delivery systems could be tested similarly. Details are included  
327 below.

328 *Procedure A and Procedure B of Elastomeric Component Functional*  
329 *Suitability in Parenteral Product Packaging/Delivery Systems (382), 5.*  
330 *Needle and Spike Access Functional Suitability Tests, 5.2 Penetration Force,*  
331 *Vial and bottle systems* evaluate the penetration force required for a dosage  
332 form preparation hypodermic needle and for a dosage form access  
333 hypodermic needle, respectively. *Procedure C* evaluates the penetration  
334 force required for spike access. ISO standard vial package closure  
335 penetration tests do not specify the needle insertion rate or the use of a  
336 mechanical testing machine (ISO 8362-2, 8362-5, 8871-5). Standard bottle  
337 spike penetration force tests specify use of a mechanical testing machine,  
338 operated at an insertion rate of 200 mm/min with a load cell accuracy of  $\pm 2$   
339 Newtons (N) (ISO 8536-2 and -6). For consistency among chapter tests, the  
340 vial and bottle systems tests specify use of a mechanical testing machine  
341 operated at the penetration rate of 200 mm/min for both vials and bottles  
342 penetrated by either needles or spikes.

343 *Procedure A and Procedure B*, which use a needle for penetration, require  
344 a load cell accuracy of  $\pm 0.25$  N in anticipation of results less than 10  
345 N. *Procedure C*, which uses a spike, anticipates higher penetration forces,  
346 therefore, a load cell accuracy of  $\pm 2$  N is specified, similar to the  
347 corresponding ISO standards.

348 There exists no published data or ISO standard for dosage form  
349 preparation penetration force for vial and bottle systems;  
350 therefore *Procedure A* does not include quantitative acceptance limits. The  
351 end user is responsible for establishing a limit appropriate for the system  
352 and its intended use.

353 The penetration force acceptance limit for BFS systems is also not  
354 specified. The penetration force limit in ISO 15759 only evaluates the  
355 penetration force through the closure, not the force required to penetrate  
356 the closure combined with the underlying plastic layer in a fully assembled  
357 BFS system. For this reason, the end user is responsible for establishing a  
358 limit that is appropriate for the system and its intended use.

359 The penetration force acceptance limit for plastic systems of no more than  
360 200 N is the highest for all package types. This high value is informed by  
361 ISO 15747 and includes the friction force between the spike and the access  
362 port tube.

NEEDLE SELF-SEALING CAPACITY

See *Elastomeric Component Functional Suitability in Parenteral Product Packaging/Delivery Systems (382), 5. Needle and Spike Access Functional Suitability Tests, 5.3 Needle Self-Sealing Capacity*. Also called reseal capacity, injection port tightness, or in-use leakage tests, this term applies to product packaging/delivery system closures required to ensure adequate package integrity during in-use conditions of multiple breaches by a needle(s). Such systems include multiple-dose product packaging/delivery systems, as well as systems with closures that must be penetrated more than once to permit dosage form preparation followed by penetration(s) for product access and administration.

Test samples are challenged prior to packaging/delivery system in-use integrity verification by exposing the closures to worst case (i.e., the most challenging) piercing conditions anticipated for the intended product. In cases where the largest gauge piercing device(s) and/or the maximum penetration quantity conditions are undefined, (382) lists challenge conditions to be employed, similar to self-sealing test requirements corresponding to recognized standards.

The (382) test requires a minimum of 30 test samples for all packaging/delivery system types. This quantity is greater than the specification in ISO's standards for resealability tests. However, the requirement for 30 test samples does align with the requirements of (382), *4. Packaging/Delivery System Integrity Tests*. A smaller quantity was viewed to be less likely to yield meaningful leakage information.

No leak test procedure is mandated for self-sealing capacity. Tests described in corresponding recognized standards may be consulted. However, such tests may not accurately or appropriately measure the integrity of the compromised closure for the intended product and its use. Therefore, the reader is referred to *Package Integrity Evaluation—Sterile Products (1207)* and its subchapters for guidance in test method selection, development, validation, and utilization.

SPIKE RETENTION AND SEALABILITY CAPACITY

See *Elastomeric Component Functional Suitability in Parenteral Product Packaging/Delivery Systems (382), 5. Needle and Spike Access Functional Suitability Tests, 5.4 Spike Retention and Sealability Capacity*. This test is a measure of a closure system's ability to be fully penetrated by a spike (without pushing the closure into the container); to block visible evidence of liquid product leakage between the spike and the closure during the product-dosing time period; and to retain the spike during this time period.

Test samples are to be challenged by exposing the closures to worst case (i.e., the most challenging) piercing conditions anticipated for the intended

404 product. In cases where the spike piercing device is undefined, utilize the  
405 device described in the corresponding ISO standards. Note that  
406 the (382) test sample size and test conditions are similarly based on  
407 recognized standard procedures for the respective packaging/delivery  
408 system categories.

#### 409 4.5 Plunger Functional Suitability Tests

410 Information in *Elastomeric Component Functional Suitability in Parenteral*  
411 *Product Packaging/Delivery Systems (382)*, 6. *Plunger Functional Suitability*  
412 *Tests* applies to packaging/delivery systems that incorporate a plunger (also  
413 called a piston), namely cartridge systems and syringe systems. This section  
414 include tests to evaluate plunger break-loose and glide forces as well as  
415 plunger seal integrity.

416 Packaging/delivery systems designed to allow for product elution via a  
417 plunger are required to allow for complete, safe, and effective product  
418 delivery without damaging the system and without risking harm to either the  
419 patient receiving the medication or the individual accessing and/or  
420 administering the product. The plunger is also required to ensure adequate  
421 product containment from the time the product is filled until product delivery  
422 to the patient is complete.

#### 423 PLUNGER BREAK LOOSE AND GLIDE FORCES

424 See *Elastomeric Component Functional Suitability in Parenteral Product*  
425 *Packaging/Delivery Systems (382)*, 6. *Plunger Functional Suitability Tests*,  
426 *6.1 Plunger Break-Loose and Glide Forces*. This test evaluates plunger  
427 break-loose force (also known as the initiating force), which is the force  
428 required to initiate the movement of the plunger. It also evaluates plunger  
429 glide force (also known as the sustaining force), which is the force required  
430 to sustain the movement of the plunger to expel the content of the syringe  
431 or cartridge. This test allows an analysis of the ease with which product  
432 delivery may be performed.

433 Many variables can affect these forces. For example, product  
434 characteristics of viscosity and density can directly impact break-loose and  
435 glide forces. These forces are also influenced by the interference fit between  
436 the plunger and the barrel, the lubrication of the plunger and the inner  
437 surface of the barrel, and the fit of the plunger rod into the threaded  
438 plunger. The use of connecting devices with the test sample can influence  
439 the findings.

440 Furthermore, it is noteworthy that break-loose force can increase over  
441 time to an unacceptable level at which point it is difficult to initiate plunger  
442 movement by hand. If the plunger is operated by a spring, the break-loose  
443 force required may be greater than the capability of the spring. The drug  
444 product applicant is advised to consider this possibility when designing drug

445 product shelf-life stability assessment studies. Finally, component processing  
446 can also impact plunger function. For example, an irregular glide force, or  
447 one that rises significantly towards the syringe nozzle, can indicate non-  
448 homogeneous lubrication of the barrel.

449 The performance requirements of the packaging/delivery system should  
450 consider the intended use of the syringe or cartridge. For example, if the  
451 product is to be manually delivered, break-loose and glide forces should  
452 accommodate the skill set of the population responsible for product  
453 administration. If the product is to be delivered using an automatic pen  
454 injector, forces must be appropriate for the delivery system hardware.

455 In conclusion, a wide number of variables can impact break-loose and  
456 glide force results. The many combinations of products, packaging/delivery  
457 systems, and intended uses influence acceptable functional performance  
458 criteria. Therefore, a single test method cannot be defined, nor can  
459 acceptance criteria be specified, for all relevant packaging/delivery systems,  
460 products, and intended-use applications. The user is responsible for following  
461 the generic test method outlined in <382> and for establishing meaningful  
462 quantitative acceptance criteria that best represent the demands of the  
463 specific product packaging/delivery system.

#### 464 PLUNGER SEAL INTEGRITY

465 See *Elastomeric Component Functional Suitability in Parenteral Product*  
466 *Packaging/Delivery Systems <382>, 6. Plunger Functional Suitability Tests,*  
467 *6.2 Plunger Seal Integrity.* This test is designed to apply a fixed force to the  
468 plunger of a sealed syringe or cartridge containing liquid product in order to  
469 detect leakage past the plunger. *Procedure A* applies to manually operated  
470 prefilled and single-use syringe systems. This procedure and acceptance  
471 criteria were informed by ISO 7886-1. *Procedure B* applies to non-manually  
472 operated prefilled syringe systems that function as part of an auto-injector  
473 system such as a spring-driven or power-driven delivery device. This  
474 procedure and acceptance criteria were informed by ISO 11040-8. *Procedure*  
475 *C* is specifically for cartridge systems used for dental local anesthesia  
476 products and was informed by ISO 11040-2 and -3. *Procedure D* is for all  
477 cartridge systems, excluding those for dental local anesthesia products. The  
478 procedure and acceptance criteria were informed by ISO 13926-2 and -3.  
479 For all procedures, satisfactory plunger seal tightness will not permit visible  
480 leakage of liquid product past the rear rib or final seal of the plunger when  
481 forces simulating product delivery are applied. For cartridge containers that  
482 are also closed with a stopper or septum (without a needle), acceptance  
483 criteria also require the absence of visible leakage past this closure.

484

#### 4.6 Tip Cap and Needle Shield Functional Suitability Tests

485 *Elastomeric Component Functional Suitability in Parenteral Product*  
486 *Packaging/Delivery Systems* (382), 7. *Tip Cap and Needle Shield Functional*  
487 *Suitability* tests examine the functional suitability of tip caps and needle  
488 shields. These components are intended to protect the needle or nozzle  
489 (Luer end) of the syringe, allow for nozzle/needle sterilization, and maintain  
490 the sterility of the contents of the syringe container. The functional  
491 suitability tests examine the forces required to remove the tip cap or needle  
492 shield prior to dose administration. *Procedure A* measures the axial force  
493 used to pull off needle shields and tip caps. *Procedure B* is a torque test that  
494 measures the force use to unscrew and remove the Luer lock rigid tip caps.  
495 A packaging/delivery system is satisfactory if the force needed to remove  
496 the component allows for the manual removal of the tip cap or needle shield  
497 with relative ease but prevents the accidental loss of these components  
498 during storage or transit.

499 When selecting acceptance criteria, the user should consider the various  
500 factors that can influence removal forces. For example, processes applied to  
501 the components pre- and post- assembly, such as lubrication and  
502 sterilization, can impact test results. Other factors include elastomeric  
503 component age, age of the assembled system, and possibly finished product  
504 storage conditions.

505 The procedures and acceptance criteria in *Elastomeric Component*  
506 *Functional Suitability in Parenteral Product Packaging/Delivery*  
507 *Systems* (382), 7. *Tip Cap and Needle Shield Functional Suitability* were  
508 influenced by ISO 11040-4 and -8.

#### 509 5. CONCLUSION

510 In summary, the functional performance of elastomeric components is to  
511 be evaluated in a manner that ensures the final packaging/delivery system is  
512 fit for its intended use of safely and effectively providing the patient with the  
513 highest quality parenteral medication. Although this chapter's scope does not  
514 include functional suitability tests relevant to other components of the  
515 packaging/delivery system, or to all aspects of the system itself, such tests  
516 are nevertheless important. Consideration should be given to the full scope  
517 of packaging/delivery system functional demands inherent in the  
518 manufacture, safety, use, and marketability of the intended product. To this  
519 end, the applicant may seek direction in other relevant packaging/delivery  
520 system guidances and standards. This process requires that the applicant  
521 employ a science- and risk-based approach to accomplish a thorough and  
522 complete functional suitability assessment verifying the entire  
523 packaging/delivery system's fitness for intended use.▲ (USP 1-Dec-2020)
